#### **DISCLAIMER**

Care has been taken to confirm the accuracy of the information present and to describe generally accepted practices. However, the authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. Application of this information in a particular situation remains the professional responsibility of the practitioner; the clinical treatments described and recommended may not be considered absolute and universal recommendations.

The authors, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with the current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.

Some drugs and medical devices presented in this publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of the health care providers to ascertain the FDA status of each drug or device planned for use in their clinical practice.

To purchase additional copies of this book, call our customer service department at (800) 638-3030 or fax orders to (301) 223-2320. International customers should call (301) 223-2300.

# FOREWORD

---

This book is a valuable resource for registered dietitians, dietetic interns and students, and other health care professionals involved or interested in medical nutrition therapy. Given the increasing time demands confronting health care professionals, efficient time management is essential for delivering high-quality patient care. The ever-changing health care environment necessitates that registered dietitians efficiently and effectively maintain their high level of practice skills. Thus, this book remains a key resource for prioritizing patient care and appropriately planning nutrition therapy. The guidance provided by *Nutrition and Diagnosis-Related Care* is of immense value in charting the clinical course for each patient, especially for clinical conditions that the practitioner does not routinely treat. This book continues to present an

extensive, succinct compilation of nutrition information. The most impressive attribute is that the germane information required by dietitians is presented in a single resource. This greatly simplifies the development of nutrition care plans. Thus, this book provides dietetic practitioners with superb guidance they can use to maintain outstanding practice skills. This book is a resource that can help achieve excellence in dietetic practice.

Penny Kris-Etherton, PhD, RD

Karen Kubena, PhD, RD  
Texas A & M University

# PREFACE

Health care professionals must identify all elements of patient care capable of affecting nutritional status and outcomes. The registered dietitian must provide nutritional care in a practical, efficient, timely, and effective manner regardless of setting. Various environments provide unique and special considerations. The astute dietitian is sensitive to the patient/client's current status in the continuum of care, meticulously adapting the nutritional care plan. Communication between staff of different facilities will save time for screenings and assessments and will promote the implementation of strategic interventions. With electronic health records, data and summary reports can be shared from one practitioner to the next while maintaining confidentiality.

*Nutrition and Diagnosis-Related Care* has evolved since 1985 to supplement other texts and references and to quickly assimilate and implement medical nutrition therapy (MNT.) This guide can be used to help write protocols, to establish priorities in nutrition care, to demonstrate cost-effective therapies, and to categorize disorders in which nutrition interventions can decrease complications, further morbidity, mortality, or lengthy hospital stays. Adequate nutritional intervention often results in financial savings for the patient, the family, and the health care system. Indeed, current knowledge solidifies the role of nutrition as therapy, and not just adjunctive support.

The seventh edition updates guidance in MNT, adding commentary about nutritional genetics and nutrition care process concepts for each condition. The format of the book continues to promote easy navigation for quick retrieval of information. Appendix A summarizes the nutrients and their major food sources and functions. Appendix B promotes use of the Nutrition Care Process approved for the profession of dietetics. Sample forms are included, including language related to the critical thinking involved with A-D-I (assessment, nutrition diagnosis, interventions) and M-E (monitoring and evaluation) as follow-up documentation. The Nutritional Acuity Level Ranking for dietitian services is found in Appendix C. Content previously in appendices D and E has been moved into the text.

Using evidence-based practice guides from the American Dietetic Association, and use of this manual can improve nutrition therapy in any setting. The profession of dietetics continues to evolve and develop a deeper understanding of the prominence of nutrition in health promotion and disease management.

## ASSUMPTIONS ABOUT THE READER

For this text, the following assumptions have been made:

1. The reader has an adequate background in nutrition sciences, physiology, pathophysiology, medical terminology, biochemistry, basic pharmacotherapy, and interpretation of biochemical data to understand the abbreviations, objectives, and interventions in this book.
2. An individualized drug history review is essential, as only a few medications are listed in this manual.
3. Herbs, botanicals, and dietary supplements are included because they are often used without prior consultation with a dietitian or a physician; they have side effects as well as perceived or real benefits.
4. For patient education, the reader must provide appropriate handouts, printed materials and teaching tools to prepare the patient for independent functioning. The nutrition counselor must share relevant information, as deemed appropriate, with the patient and significant other(s). The educator must identify teachable moments and share what is needed at the time. Follow-up interventions are highly recommended to assess successful behavioral changes by the patient/client.
5. Providers must prioritize key nutritional diagnoses that can be managed within the given time frame. With roles in ambulatory centers, extended care facilities, subacute or rehabilitative centers, private practices, grocery stores, Web-based practices, rehabilitation facilities, and home care, the "seamless" continuum affords registered dietitians the possibility of lifelong patient relationships, a reality that promotes more effective monitoring, follow-up, and evaluation.
6. The Clinical Indicators section for each condition lists tests, disease markers, and common biochemical evaluations reviewed by physicians or dietitians for that condition. Because few laboratory tests are available in nonhospital settings for monitoring nutritional status, appetite and weight changes are the most viable screening factors. Physical changes and signs of malnutrition are important for assessment and should be identified.
7. A current diet manual and MNT text should be used to acquire diet modification lists; comprehensive lists are not included with this book.
8. Use of evidence-based guides from American Dietetic Association must be used to provide predictable types of interventions over multiple visits, especially for reimbursement. Use the [www.eatright.org](http://www.eatright.org) Web site to select current guidelines for practice.
9. Except where specifically noted for children, nutrition therapy plans are for individuals over the age of 18.
10. Vitamin and mineral supplements are needed in cases of a documented or likely deficiency. However, in large doses, they may cause food-drug interactions. Plan meals and nourishments carefully to avoid the need for individual supplements.
11. Use of a general multivitamin-mineral supplement may be beneficial for many adults; monitor intakes judiciously from all food and supplemental sources. Athletes, women, elderly individuals, and vegetarians tend to take vitamin and mineral supplements more often than other individuals and may be at risk for overdoses if not carefully monitored.

12. Most evidence points to the benefits of whole foods to acquire phytochemicals and yet unknown substances. Healthy persons should obtain nutrients from a balanced diet as much as possible. The use of functional food ingredients, such as antioxidant foods, is highly recommended. A well-balanced, varied diet uses the US Department of Agriculture (USDA) MyPyramid Food Guidance System and various ethnic, vegetarian, pediatric, geriatric, or diabetes food guides for menu planning and design.
13. Ethics, cultural sensitivity, and a concern for patient rights should be considered and practiced at all times. When available, the wishes and advanced directives of the patient are to be followed. This may preclude aggressive use of artificial nutrition.
14. Interesting and varied Web sites have been included for the reader for additional insights into various diseases, conditions, and nutritional interventions.

# ACKNOWLEDGMENTS

---

Thanks to all reviewers who made valuable suggestions for changes.

I wish to thank John Larkin, Samir Roy and Shelley Opremcak, RD, LDN and other colleagues for their valuable suggestions, insights, and edits. This book is dedicated to my family and to my students, interns and colleagues.

Sylvia Escott-Stump, MA, RD, LDN

# COMMON ABBREVIATIONS

AA	amino acid	DV	daily value
abd	abdomen, abdominal	Dx	diagnosis
ABW	average body weight	D5W	5% dextrose solution in water
ACE	angiotensin-converting enzyme	EAA	essential amino acid
ACTH	adrenocorticotrophic hormone	ECG, EKG	electrocardiogram
ADA	American Dietetic Association	EEG	electroencephalogram
Alb	albumin	EFA	essential fatty acids
Alk phos	alkaline phosphatase	Elec	electrolytes
ALT	alanine aminotransferase	EN	enteral nutrition
amts	amounts	ESRD	end-stage renal disease
ARF	acute renal failure	ETOH	ethanol/ethyl alcohol
ASHD	atherosclerotic heart disease	Fe <sup>++</sup>	iron
AST	aspartate aminotransferase	F & V	fruits and vegetables
ATP	adenosine triphosphate	FSH	follicle-stimulating hormone
BCAAs	branched-chain amino acids	FTT	failure to thrive
BEE	basal energy expenditure	FUO	fever of unknown origin
BF	breastfeeding	G, g	gram(s)
BMR	basal metabolic rate	GA	gestational age
BP	blood pressure	GBD	gallbladder disease
BS	blood sugar	GE	gastroenteritis
BSA	body surface area	gest	gestational
BUN	blood urea nitrogen	GFR	glomerular filtration rate
BW	body weight	GI	gastrointestinal
bx	biopsy	Gluc	glucose
C	cup(s)	GN	glomerular nephritis
C	coffee	GTT	glucose tolerance test
CA	cancer	H & H	hemoglobin and hematocrit
Ca <sup>++</sup>	calcium	HbA <sub>1c</sub>	hemoglobin A <sub>1c</sub> test (glucose)
CABG	coronary artery bypass grafting	HBV	high biological value
CBC	complete blood count	HBW	healthy body weight
CF	cystic fibrosis	HCl	hydrochloric acid
CHD	cardiac heart disease	Hct	hematocrit
CHF	congestive heart failure	HDL	high-density lipoprotein
CHI	creatinine-height index	HLP	hyperlipoproteinemia or hyperlipidemia
CHO	carbohydrate	HPN, HTN	hypertension
Chol	cholesterol	ht	height
Cl <sup>-</sup>	chloride	Hx	history
CNS	central nervous system	I	infant
CO <sub>2</sub>	carbon dioxide	I & O	intake and output
CPK	creatine phosphokinase	IBD	inflammatory bowel disease
CPR	cardiopulmonary resuscitation	IBS	irritable bowel syndrome
CrCl	creatinine clearance	IBW	ideal body weight
CRP	C-reactive protein	IEM	inborn error of metabolism
CT	computed tomography	INR	international normalized ratio
Cu	copper	IU	international units
CVA	cerebrovascular accident	IUD	intrauterine device
DAT	diet as tolerated	IV	intravenous
dec	decreased	K <sup>+</sup>	potassium
decaf	decaffeinated	kcal	food kilocalories
def	deficiency	kg	kilogram(s)
DJD	degenerative joint disease	L	liter(s)
dL	deciliter	lb	pound(s)
DM	diabetes mellitus	LBM	lean body mass
DNA	deoxyribonucleic acid	LBV	low biological value
DOB	date of birth	LBW	low birth weight
DRI	dietary reference intakes	LCT	long-chain triglycerides

LDH	lactate dehydrogenase	pO <sub>2</sub>	partial pressure of oxygen
LDL	low-density lipoproteins	prn	pro re nata (as needed)
LE	lupus erythematosus	Prot	protein
LGA	large for gestational age	PT	prothrombin time or physical therapy
LH	luteinizing hormone	PTH	parathormone
lytes	electrolytes	PUFA(s)	polyunsaturated fatty acid(s)
M	milk	PVD	peripheral vascular disease
MAC	midarm circumference	RAST	radioallergosorbent test
MAMC	midarm muscle circumference	RBC	red blood cell count
MAO	monoamine oxidase	RDA	recommended dietary allowance (specific)
MBF	meat-base formula	RDS	respiratory distress syndrome
MCH	mean cell hemoglobin	REE	resting energy expenditure
MCT	medium-chain triglycerides	RQ	respiratory quotient
MCV	mean cell volume	Rx	treatment
Mg <sup>++</sup>	magnesium	SFA	saturated fatty acids
mg	milligram(s)	SGA	small for gestational age
μg	micrograms	SI	small intestine
MI	myocardial infarction	SIADH	syndrome of inappropriate antidiuretic hormone
mm	millimeter(s)	SIDS	sudden infant death syndrome
MODS	multiple organ dysfunction syndrome	SOB	shortness of breath
MSG	monosodium glutamate	Sub	substitute
MUFA	monounsaturated fatty acids	Sx	symptoms
N&V	nausea and vomiting	t	teaspoon(s)
N	nitrogen	T	tablespoon
Na	sodium	TB	tuberculosis
NCEP	National Cholesterol Education Program	TF	tube feeding; tube fed
NCP	Nutrition Care Process	TG	triglycerides
NEC	necrotizing enterocolitis	TIBC	total iron-binding capacity
NG	nasogastric	TLC	total lymphocyte count
NPO	nil per os (nothing by mouth)	TPN	total parenteral nutrition
NSI	Nutrition Screening Initiative	TSF	triceps skinfold
O <sub>2</sub>	oxygen	UA	uric acid
OP	outpatient	UTI	urinary tract infection
OT	occupational therapist	UUN	urinary urea nitrogen
oz	ounce(s)	VMA	vanillylmandelic acid
P	phosphorus	VO <sub>2max</sub>	maximum oxygen intake
PCM	protein—calorie malnutrition	WBC	white blood cell count
pCO <sub>2</sub>	partial pressure of carbon dioxide	WNL	within normal limits
PG	pregnant, pregnancy	Zn	zinc
PKU	phenylketonuria		
PN	parenteral nutrition

10-10	Power of Food Scale	612
10-11	Medications That Cause Weight Gain	616
10-12	Medications Used for Weight Reduction in the United States	617
10-13	Portion Adjustments Using Everyday Objects	618
10-14	Physical Activity Equivalents	618
10-15	Weight Management for Sleep Apnea and Pickwickian Syndrome	619
10-16	Smoking Cessation and Weight Gain	619
10-17	Diet Program Comparisons	620
10-18	Strengthening Tips	623
10-19	Complicating Effects of Chronic Malnutrition on Body Systems	627
10-20	Indicators of Malnutrition	628
10-21	Malnutrition Universal Screening Tool (MUST)	629
10-22	Selected Biochemical Changes Observed in Severe Protein–Energy Malnutrition (PEM)	631
10-23	Poor Prognosis and Consequences of Not Feeding a Patient	632
10-24	Conditions with High Risk for Refeeding Syndrome	633

## SECTION 11

11-1	Autoimmune Rheumatic Disorders	638
11-2	Phytochemicals and Dietary Factors Affecting Rheumatic Disorders	640
11-3	Recommendations for Prevention of Osteoporosis	642
11-4	Acquired Causes of Hyperuricemia	645
11-5	Types of Muscular Dystrophy and Nutritional Implications	653
11-6	Medications Commonly Used for Osteoarthritis	660
11-7	Side Effects of Herbs Commonly Used for Arthritis	661
11-8	Nutrients and Bone Health	665
11-9	Risk Factors for Osteoporosis	667
11-10	Tips on Calcium Supplements	669
11-11	Medications Commonly Used for Management of Osteoporosis	670
11-12	Features of Rheumatic Arthritis	671

11-13	Variant Forms of Rheumatic Arthritis (RA)	677
11-14	Medications Used in Rheumatoid Arthritis	679

## SECTION 12

12-1	Nutritional Factors in Blood Formation	689
12-2	Definitions	689
12-3	Iron Tests	689
12-4	General Signs and Symptoms of Anemia	689
12-5	Signs and Symptoms of Aplastic or Fanconi's Anemias	696
12-6	Symptoms of Copper Insufficiency and Anemia	699
12-7	Food Sources of Copper	700
12-8	Conditions and Medications That Deplete Folic Acid	702
12-9	Folic Acid Sources	704
12-10	Types of Hemolytic Anemia	705
12-11	Stages of Iron Deficiency	707
12-12	Normal Iron Distribution in the Body	707
12-13	Factors That Modify Iron Absorption	707
12-14	Medications to Correct Iron-Deficiency Anemia	709
12-15	Micronutrient Deficiencies in Parasitic Anemias such as Malaria	712
12-16	Risks and Causes of Pernicious Anemia or Vitamin B <sub>12</sub> -Deficiency Anemia	713
12-17	Equation to Predict Energy Needs in Adolescents with Sickle Cell Disease	719
12-18	Blood Clotting Factors That Involve Nutrition	722
12-19	Food Sources of Vitamin K	723
12-20	Facts About Hemochromatosis	725

## SECTION 13

13-1	Cancer Definitions	732
13-2	Phytochemicals, Functional Food Ingredients, and Cancer	734
13-3	Cancer Risk Factors by Site	737
13-4	Use of Nutrition Support in Cancer Patients	738
13-5	Side Effects of Treatment and Common Problems of Cancer	739
13-6	Cancer Drugs and Chemotherapy Agents	744
13-7	Antineoplastic Agents: Generic and Brand Names	745
13-8	Herbs, Dietary Supplements, and Cancer	746
13-9	General Patient Education Tips	750
13-10	Neutropenic Diet Guidelines	754
13-11	Drugs Commonly Used in Bone Marrow or Stem-Cell Transplantation	755
13-12	Types of Brain Tumors	757
13-13	Risks and Protective Factors for Colorectal Cancer	760
13-14	Key Factors in Types of Head and Neck Cancer	764
13-15	Risks for Gastric Cancer	767
13-16	Risk Factors for Liver Cancer	770
13-17	Staging of Breast Cancer	783
13-18	Preventive Dietary Factors for Prostate Cancer	789
13-19	Antioxidant Color Link	790

13-20	Various Forms of Leukemia	793
13-21	Medications for Acute Leukemias	793
13-22	Medications for Chronic Leukemias	794

## SECTION 14

14-1	Postsurgical Phases in Nutrition	800
14-2	Time Required to Deplete Body Nutrient Reserves in Well-Nourished Individuals	801
14-3	Measuring Energy Expenditure in Critical Illness	802
14-4	The Small Intestine After Surgery	803
14-5	Managing Electrolyte Imbalances	806
14-6	Herbal Medications and Recommendations for Discontinued Use before Surgery	808
14-7	Percentage of Body Weight in Amputees	808
14-8	Surgeries, Level of Nutritional Acuity, and Nutritional Recommendations	809
14-9	Tips for Diet after Gastric Bypass	814

## SECTION 15

15-1	How the Immune System Works	820
15-2	Immunocompetence and Immunity Concerns	821
15-3	Nutritional and Host Factors in Immunity	823
15-4	Factors of Importance in Critical Care	824
15-5	Infections and Febrile Conditions and Nutritional Implications	825
15-6	Virulence Increased by Iron	829
15-7	WHO Clinical Staging of HIV/AIDS for Adults and Adolescents	830
15-8	Guidelines for Nutrition Therapy in HIV Management	831
15-9	Medications Used for HIV Infections and AIDS	834
15-10	Pharmacotherapy for Burns	841
15-11	Intestinal Parasites and Treatments	845
15-12	Stages of Sepsis	851
15-13	Glasgow Coma Scale (GCS)	855

## SECTION 16

16-1	Human Kidney Functions	860
16-2	Renal Abbreviations	861
16-3	Stages, Symptoms, and Preventive Measures for Chronic Kidney Disease (CKD)	865
16-4	Protein-Energy Malnutrition (PEM) in Renal Patients	867
16-5	Spices and Condiment Substitutes for Salt	869
16-6	Tips for Managing Potassium and Phosphorous in the Diet	870
16-7	Drugs Used in Chronic Kidney Disease (CKD) and Dialysis Patients	872
16-8	Tips for Managing Thirst and Fluid Restrictions	873
16-9	Nutrition Therapy for Dialysis Patients	877
16-10	Vitamin D <sub>3</sub> Repletion	878
16-11	Role of the Renal Dietitian in Dialysis Care	878
16-12	Causes of and Predisposition to Kidney Stones	882
16-13	Dietary Treatment of Specific Renal Stones	884

- 16-14 Complications After Renal Transplantation 891  
 16-15 Immunosuppressant Drugs Used After Renal Transplantation 893

## SECTION 17

- 17-1 ASPEN Definition of Terms Related to Nutrition Support 899  
 17-2 Ethics of Nutrition Support Therapy and End-of-Life Care 900  
 17-3 Consequence Statement: Not Feeding a Resident/Patient When Oral Intake Is Inadequate 904  
 17-4 Clinical Practice Guidelines for Nutrition Support 905  
 17-5 Sample Types of Formulas 906  
 17-6 Key Enteral Issues 908  
 17-7 Critical Control Point Checklist for Tube Feedings 910  
 17-8 Candidates for Central Parenteral Nutrition (CPN) in Adults 912  
 17-9 Sample Basic Adult Daily Requirements for CPN 914  
 17-10 Complications in Parenteral Nutrition (PN) 915

## APPENDIX A

- A-1 Carbohydrate and Fiber 920  
 A-2 Food Sources of Dietary Fiber 921  
 A-3 Fats and Lipids 922  
 A-4 Amino Acids 924  
 A-5 Biological Value of Proteins 926  
 A-6 Protein Sources 927  
 A-7 Dairy Sources of Calcium 928  
 A-8 Food Sources of Magnesium 929  
 A-9 Food Sources of Potassium 930  
 A-10 Food Sources of Iron 932  
 A-11 Food Sources of Vitamin A 935  
 A-12 Food Sources of Vitamin D 936  
 A-13 Food Sources of Vitamin E 938  
 A-14 Food Sources of Vitamin K 938  
 A-15 Food Sources of Folic Acid 942  
 A-16 Food Sources of Vitamin B<sub>12</sub> 942  
 A-17 Food Sources of Vitamin C 943

## APPENDIX B

- B-1 Sample Hospital Nutrition Department Scope of Services 948

- B-2 Dietary Intake Assessment and Nutrition History 951  
 B-3 Adult Nutrition History Questionnaire 952  
 B-4 Physical Assessment for Clinical Signs of Malnutrition 954  
 B-5 Calculation of Adult Energy Requirements 955  
 B-6 Calculations of Adult Protein Requirements 957  
 B-7 Pediatric Nutrition Assessment 957  
 B-8 Interpretation of Lab Values 958  
 B-9 Quick Reference: Food–Drug Interactions 970  
 B-10 Sample Worksheet for Using Standardized Nutrition Terminology 971  
 B-11 Clinical Case Review and Audit 973  
 B-12 Tips for Adult Education and Counseling 974  
 B-13 Health-Promotion Intervention Models 976  
 B-14 Sample Monitoring and Evaluation Audits for Patient Education 980

## APPENDIX C

- C-1 Nutrition Acuity and Medical Diagnosis–Related Survey Questions 983  
 C-2 Acuity for Dietitian Roles in Medical Diagnoses 983

## APPENDIX D

- Dietary Reference Intakes (DRIs): Recommended Intakes for Individuals, Vitamins 992  
 Dietary Reference Intakes (DRIs): Recommended Intakes for Individuals, Elements 993  
 Dietary Reference Intakes (DRIs): Tolerable Upper Intake Levels (UL), Vitamins 994  
 Dietary Reference Intakes (DRIs): Tolerable Upper Intake Levels (UL), Elements 995  
 Dietary Reference Intakes (DRIs): Estimated Energy Requirements (EER) for Men and Women 30 Years of Age 996  
 Dietary Reference Intakes (DRIs): Acceptable Macronutrient Distribution Ranges 996  
 Dietary Reference Intakes (DRIs): Recommended Intakes for Individuals, Macronutrients 997  
 Dietary Reference Intakes (DRIs): Additional Macronutrient Recommendations 997  
 Dietary Reference Intakes (DRIs): Estimated Average Requirements for Groups 998

# CONTENTS

Foreword	iii
Preface	iv
Acknowledgments	vi
Common Abbreviations	vii
List of Tables	ix
Alphabetical List of Topics	xviii

## SECTION 1

### NORMAL LIFE STAGES 1

<b>Pregnancy and Lactation</b>	<b>5</b>
Pregnancy	5
Lactation	12
<b>Infancy, Childhood, and Adolescence</b>	<b>19</b>
Infant, Normal (0–6 Months)	19
Infant, Normal (6–12 Months)	22
Childhood	27
Adolescence	33
<b>Physical Fitness and Stages of Adulthood</b>	<b>38</b>
Sports Nutrition	38
Adulthood	44
Nutrition in Aging	58

## SECTION 2

### NUTRITION PRACTICES, FOOD SAFETY, ALLERGIES, SKIN AND MISCELLANEOUS CONDITIONS 69

<b>Complementary or Integrative Nutrition</b>	<b>70</b>
Complementary or Integrative Nutrition	70
<b>Cultural Food Patterns, Vegetarianism, Religious Practices</b>	<b>84</b>
Cultural Food Patterns	84
Vegetarianism	88
Eastern Religious Dietary Practices	91
Western Religious Dietary Practices	93
Middle Eastern Religious Dietary Practices	95
<b>Orofacial Conditions</b>	<b>96</b>
Dental Difficulties and Oral Disorders	96
Periodontal Disease and Gingivitis	102
Temporomandibular Joint Dysfunction	104
<b>Self-Feeding Problems: Vision, Coordination, Chewing, Hearing Loss</b>	<b>106</b>
Self-Feeding Problems: Vision, Coordination, Chewing, Hearing Loss	106

<b>Skin Conditions, Pressure Ulcers, and Vitamin Deficiencies</b>	<b>110</b>
Skin Disorders	110
Pressure Ulcers	114
Vitamin Deficiencies	118
<b>Food Allergy and Ménière's Syndrome</b>	<b>122</b>
Food Allergy and Intolerances	122
Ménière's Syndrome (Autoimmune Inner-Ear Disease)	128
<b>Foodborne Illness</b>	<b>130</b>
Foodborne Illness	130

## SECTION 3

### PEDIATRICS: BIRTH DEFECTS AND GENETIC AND ACQUIRED DISORDERS 137

Abetalipoproteinemia	144
Attention-Deficit Disorders	145
Autism Spectrum Disorder	148
Biliary Atresia	150
Bronchopulmonary Dysplasia	152
Carbohydrate Metabolic Disorders	155
Cerebral Palsy	158
Cleft Lip and Palate (Orofacial Clefts)	161
Congenital Heart Disease	163
Cystinosis and Fanconi's Syndrome	165
Down Syndrome	167
Failure to Thrive	169
Fatty Acid Oxidation Disorders	172
Fetal Alcohol Syndrome	173
Hirschsprung's Disease (Congenital Megacolon)	175
HIV Infection, Pediatric	177
Homocystinuria	180
Large for Gestational Age Infant (Infant Macrosomia)	182
Leukodystrophies	184
Low Birth Weight or Prematurity	186
Maple Syrup Urine Disease	189
Necrotizing Enterocolitis	192
Neural Tube Defects: Spina Bifida and Melomeningocele	194
Obesity, Childhood	197
Otitis Media	202
Phenylketonuria	203
Prader-Willi Syndrome	206
Rickets	208
Small for Gestational Age Infant and Intrauterine Growth Retardation	210
Tyrosinemia	212
Urea Cycle Disorders	213
Wilson's Disease (Hepatolenticular Degeneration)	216

**SECTION 4****NEURO-PSYCHIATRIC CONDITIONS 219****Neurological Disorders 227**

- Alzheimer's Disease and Dementias 227
- Amyotrophic Lateral Sclerosis 232
- Brain Trauma 234
- Cerebral Aneurysm 236
- Coma or Persistent Vegetative State 238
- Epilepsy and Seizure Disorders 240
- Guillain-Barré Syndrome 242
- Huntington's Disease 244
- Migraine Headache 245
- Multiple Sclerosis 248
- Myasthenia Gravis and Neuromuscular Junction Disorders 251
- Parkinson's Disease 253
- Spinal Cord Injury 256
- Stroke (Cerebrovascular Accident) 259
- Tardive Dyskinesia 263
- Trigeminal Neuralgia 265

**Psychiatric Disorders-Eating Disorders 266**

- Anorexia Nervosa 266
- Binge Eating Disorder 269
- Bulimia Nervosa 270

**Mental Disorders-Other 273**

- Bipolar Disorder 273
- Depression 277
- Schizophrenia 281
- Sleep and Circadian Rhythm Disorders 285
- Substance Use Disorders and Addiction 287

**SECTION 5****PULMONARY DISORDERS 291**

- Asthma 293
- Bronchiectasis 297
- Bronchitis (Acute) 298
- Chronic Obstructive Pulmonary Disease 300
- Chylothorax 304
- Cor Pulmonale 305
- Cystic Fibrosis 307
- Interstitial Lung Disease 311
- Pneumonia 313
- Pulmonary Embolism 315
- Respiratory Distress Syndrome 317
- Respiratory Failure and Ventilator Dependency 319
- Sarcoidosis 322
- Sleep Apnea 324
- Thoracic Empyema 326
- Transplantation, Lung 327
- Tuberculosis 330

**SECTION 6****CARDIOVASCULAR DISORDERS 335**

- Angina Pectoris 343
- Arteritis 345

- Atherosclerosis, Coronary Artery Disease, Dyslipidemia 347
- Cardiac Cachexia 352
- Cardiomyopathies 354
- Heart Failure 357
- Heart Transplantation or Heart-Lung Transplantation 363
- Heart Valve Diseases 365
- Hypertension 367
- Myocardial Infarction 372
- Pericarditis and Cardiac Tamponade 375
- Peripheral Artery Disease 377
- Thrombophlebitis 379

**SECTION 7****GASTROINTESTINAL DISORDERS 383****Upper GI: Esophagus 386**

- Dysphagia 386
- Esophageal Stricture or Spasm, Achalasia, or Zenker's Diverticulum 390
- Esophageal Trauma 392
- Esophageal Varices 393
- Esophagitis, Gastroesophageal Reflux Disease and Hiatal Hernia 395

**Stomach 397**

- Dyspepsia/Indigestion or Bezoar Formation 397
- Gastrectomy and Vagotomy 399
- Gastritis and Gastroenteritis 401
- Gastroparesis and Gastric Retention 403
- Giant Hypertrophic Gastritis and Ménétrier's Disease 405
- Peptic Ulcer Disease 407
- Vomiting, Pernicious 410

**Lower GI: Intestinal Disorders 412**

- Carcinoid Syndrome 412
- Celiac Disease 414
- Constipation 418
- Diarrhea, Dysentery, and Traveler's Diarrhea 421
- Diverticular Diseases 425
- Fat Malabsorption Syndrome 427
- Inflammatory Bowel Disease: Crohn's Disease 430
- Inflammatory Bowel Disease: Ulcerative Colitis 434
- Intestinal Fistula 437
- Intestinal Lymphangiectasia 439
- Intestinal Transplantation 440
- Irritable Bowel Syndrome 443
- Lactose Maldigestion 445
- Megacolon 448
- Ostomy: Colostomy 450
- Ostomy: Ileostomy 452
- Peritonitis 454
- Short Bowel Syndrome 456
- Tropical Sprue 460
- Whipple's Disease (Intestinal Lipodystrophy) 461

**Rectal Disorders 463**

- Fecal Incontinence 463
- Hemorrhoids 466
- Proctitis 467

**SECTION 8****HEPATIC, PANCREATIC, AND BILIARY DISORDERS 471****Liver Disorders 474**

Alcoholic Liver Disease 474

Ascites and Chylous Ascites 477

Hepatitis 479

Hepatic Cirrhosis 483

Hepatic Failure, Encephalopathy, and Coma 487

Liver Transplantation 493

**Pancreatic Disorders 497**

Pancreatitis, Acute 497

Pancreatitis, Chronic 501

Pancreatic Insufficiency 507

Pancreatic Transplantation 509

Zollinger-Ellison Syndrome 511

**Biliary Disorders 512**

Biliary Cirrhosis 512

Cholestasis 514

Gallbladder Disease 516

**SECTION 9****ENDOCRINE DISORDERS 519****Diabetes Mellitus, Complications, and Related Conditions 528**

Type 1 Diabetes Mellitus 528

Islet Cell Transplantation 537

Metabolic Syndrome 539

Prediabetes 542

Type 2 Diabetes in Adults 544

Type 2 Diabetes in Children and Teens 549

Gestational Diabetes 552

Pre-Eclampsia and Pregnancy-Induced Hypertension 556

Diabetic Gastroparesis 558

Diabetic Ketoacidosis 560

Hyperosmolar Hyperglycemic State 563

Hypoglycemia 565

Hyperinsulinism and Spontaneous Hypoglycemia 567

**Pituitary Gland 571**

Hypopituitarism 571

**Pituitary Gland (Anterior) 573**

Acromegaly 573

**Pituitary Gland (Anterior) 575**

Cushing's Syndrome 575

**Pituitary Gland (Posterior) 577**

Diabetes Insipidus 577

**Pituitary Gland 579**

Syndrome of Inappropriate Antidiuretic Hormone (SIADH) 579

**Ovary 580**

Polycystic Ovarian Disease 580

**Adrenal Gland (Cortex) 582**

Adrenocortical Insufficiency and Addison's Disease 582

**Adrenal Gland (Cortex) 585**

Hyperaldosteronism 585

**Adrenal Gland (Medulla) 586**

Pheochromocytoma 586

**Thyroid Gland 589**

Hyperthyroidism 589

**Thyroid Gland 591**

Hypothyroidism 591

Parathyroid Glands 594

Hypoparathyroidism and Hypocalcemia 595

Hyperparathyroidism and Hypercalcemia 596

**SECTION 10****MALNUTRITION—OBESITY AND UNDERNUTRITION 601****Overnutrition 609**

Overweight and Obesity 609

**Underweight and Malnutrition 622**

Underweight and Unintentional Weight Loss 622

Undernutrition and Protein-Energy Malnutrition 626

Refeeding Syndrome 633

**SECTION 11****MUSCULO-SKELETAL AND COLLAGEN DISORDERS 637**

Ankylosing Spondylitis (Spinal Arthritis) 643

Gout 645

Immobilization 647

Lupus 649

Muscular Dystrophy 652

Myofascial Pain Syndromes: Fibromyalgia and Polymyalgia Rheumatica 656

Osteoarthritis and Degenerative Joint Disease 658

Osteomyelitis 662

Osteomalacia 664

Osteopenia and Osteoporosis 666

Paget's Disease (Osteitis Deformans) 672

Polyarteritis Nodosa 673

Rhabdomyolysis 675

Rheumatoid Arthritis 677

Ruptured Disc 683

Scleroderma (Systemic Sclerosis) 684

**SECTION 12****HEMATOLOGY: ANEMIAS AND BLOOD DISORDERS 687****Anemias 690**

Anemia of Chronic Disease 690

Anemias in Neonates 692

Anemia of Renal Diseases 694

Aplastic Anemia and Fanconi's Anemia 696

Copper Deficiency Anemia 698

Folic Acid Deficiency Anemia 701

Hemolytic Anemias 705

Iron-Deficiency Anemia 706

Malaria and Parasitic Anemias 710

## **Megaloblastic Anemias: Pernicious or Vitamin B<sub>12</sub> Deficiency 713**

Sideroblastic Anemia 715

## **Hemoglobinopathies 717**

Sickle Cell Anemia 717

Thalassemias 720

## **Other Blood Disorders 722**

Bleeding Disorders: Hemorrhage and Hemophilia 722

Hemochromatosis and Iron Overload 724

Polycythemia Vera 726

Thrombocytopenia 728

## **SECTION 13**

## **CANCER 731**

Cancer Prevention and Risk Reduction 733

## **Cancer Treatment and Tips for Long-Term Survival 738**

Cancer: Treatment Guidelines 738

Bone Cancer and Osteosarcoma 751

Bone Marrow or Hematopoietic Stem-Cell

Transplantation 753

Brain Tumor 756

Colorectal Cancer 759

Esophageal, Head and Neck, and Thyroid Cancers 763

Gastric Cancer 767

Liver Cancer 769

Kidney, Bladder, and Urinary Tract Cancers 772

Lung Cancer 774

Pancreatic Cancer 777

Skin Cancers 780

## **Hormonal Cancers 782**

Breast Cancer 782

Choriocarcinoma 786

Prostate Cancer 788

## **Hematological Cancers 791**

Leukemias 791

Lymphomas 795

Myeloma 797

## **SECTION 14**

## **SURGICAL DISORDERS 799**

### **General Surgical Guidelines 800**

Surgery 800

### **Gastrointestinal Surgeries 812**

Bariatric Surgery and Gastric Bypass 812

Bowel Surgery 816

## **SECTION 15**

## **AIDS AND IMMUNOLOGY, BURNS, SEPSIS AND TRAUMA 819**

AIDS and HIV Infection 829

Burns (Thermal Injury) 838

Fractures 842

Intestinal Parasite Infections 845

Multiple Organ Dysfunction Syndrome 847

Sepsis and Systemic Inflammatory Response Syndrome 850

Trauma 854

## **SECTION 16**

## **RENAL DISORDERS 859**

Collagen-IV Nephropathies: Alport Syndrome and Thin Glomerular Basement Membrane Nephropathy 862

Chronic Kidney Disease and Renal Failure 864

Dialysis 874

Glomerular and Autoimmune Kidney Diseases 879

Kidney Stones 882

Nephrotic Syndrome 885

Renal Metabolic Disorders: Hypophosphatemic Rickets and Hartnup Disorder 887

Polycystic Kidney Disease 889

Renal Transplantation 891

Urinary Tract Infections 894

## **SECTION 17**

## **ENTERAL AND PARENTERAL NUTRITION THERAPY 897**

Enteral Nutrition 902

Parenteral Nutrition 911

## **APPENDIX A**

### **Nutritional Review 919**

Recommended Dietary Allowances and Dietary Reference Intakes 919

Macronutrients 919

Micronutrients 923

Vitamins 935

## **APPENDIX B**

### **Dietetic Process, Forms, and Counseling Tips 945**

Introduction to the Practice of Dietetics 945

Nutrition Care Process, Forms, and Documentation Tools 948

## **APPENDIX C**

Acuity Ranking for Dietitian Services and Concept Map 983

## **APPENDIX D**

Dietary Reference Intakes 991

Index 999

# ALPHABETICAL LIST OF TOPICS

# Normal Life Stages

## CHIEF NUTRITION SCREENING AND ASSESSMENT FACTORS

Public health measures are established to promote wellness and reduce disease for all ages; Table 1-1.

- Priority Factors: Unintentional Weight Loss with Appetite Changes in Adults, Protein-Energy Deficiency, or Growth Retardation in Children
- Body Fat and Muscle Mass: Weight, Height, Body Mass Index (BMI), Percentage of Healthy Body Weight (HBW) for Height, Loss of Lean Body Mass (LBM), Previous Weight Percentile or Curve, Weight Changes, Waist Circumference, Skinfold Measurements, Visceral Proteins, Estimated Basal Energy Expenditure, Nitrogen Balance
- Illiteracy or Low Educational Level: Low Socioeconomic Status, Food Insecurity
- Hair or Nails: Changes, Rashes, Itching, Lesions, Turgor, Petechiae, Pallor
- Eyes: Glasses, Blurred Vision, Glaucoma, Cataracts, or Macular Degeneration
- Ears, Nose: Hearing Loss, Chronic Otitis Media, Altered Sense of Smell, Nasal Obstruction, Sinusitis
- Dental and Mouth: Ill-fitting Dentures, Loose or Missing Teeth, Caries, Bleeding Gums, Severe Gum Disease, Poor Oral Hygiene, Taste Alterations, Dysphagia
- Neurological: Headache, Seizures, Convulsions, Altered Speech, Paralysis, Altered Gait, Anxiety, Memory Loss, Altered Sleep Patterns, Depression, Substance Abuse, Low Motivation, Fatigue, Weakness, Fever or Chills, Excessive Sweating, Tremors
- Heart: Chest Pain, Dyspnea, Wheezing, Cough, Hemoptysis, Ventilator Support, Altered Blood Gas Levels, Abnormal Blood Pressure, Electrolyte Imbalance, Cyanosis, Edema, Ascites, Low Cardiac Output
- Blood: Anemias, Altered Heart Rate, Arrhythmias, Blood Loss
- Gastrointestinal (GI): Cachexia, Anorexia, Nausea, Diarrhea, Vomiting, Jaundice, Constipation, Indigestion, Ulcers, Hemorrhoids, Melena, Altered Stool Characteristics, Gluten Intolerance, Lactase Insufficiency
- Therapies: Radiation, Chemotherapy, Physical Therapy, Dialysis, Recent Surgery or Hospitalizations
  - Urinary and Renal: Hematuria, Fluid Requirements, Specific Gravity, Urinary Tract Infections, Renal Disease or Stones
  - Hormonal Balance: Altered Blood Glucose, Hyper or Hypothyroidism, Goiter, Glucose Intolerance or Metabolic Syndrome

- Immunity: Food Allergy or Intolerances, Sensitivities, Cellular Immunity, HIV or Other Chronic Infections, Inflammation
- Musculoskeletal System: Pain, Arthritis, Numbness, Amputations, Limited Range of Motion or Muscular Strength
- Phenotype or Genotype (see the adult nutrition content in this section)
- Nutrition: Any Special Diets or Nutrition Support, Dietary Pattern, Typical Intake of Food and Alcohol, Use of Vitamin/Minerals/Herbs/Botanicals/Supplements, Over-the-Counter and Prescribed Medications, Knowledge of Food and Nutrition

### Life Stage–Specific Assessments

- Pregnancy: Vegan or disordered eating pattern; presence of diabetes, hepatitis B, hypothyroidism, obesity, AIDS or HIV infection, phenylketonuria (PKU), sexually transmitted disorders; use of accutane, alcohol, anticoagulant, or antiepileptic medications; poor foliate intake; lack of rubella immunity; and smoking habits (March of Dimes, 2009)
- Lactating Women: Mother's Intake and Breastfeeding Practices; Extent to Which Infant Is Breastfeeding; Composition of Milk Variable with Use of Medications
- Infants: Breast Milk; Formula Intake; Mixed Feedings with Other Foods; Disordered Eating Patterns Including Supplemented with Nutrients or Foods
- Preschool Children: Variable Intakes; Food Jags; Anemia
- School Children: Limited Ability to Recall Foods Eaten; Limited Attention Span; Use of Any Medications or Special Therapies; Anemia; Exposure to Lead
- Adolescents: Intakes Altered by Growth Spurts; Meal Skipping; Dieting; Fasting; Disordered Eating; Abuse of Drugs, Alcohol, Diuretics, Prescription Drugs, Laxatives

**TABLE 1-1 Public Health: Ten Achievements and Ten Essential Services**

#### 10 Public Health Achievements in the 20th Century

- Development of vaccines
- Increased motor vehicle safety
- Safer workplaces
- Control of infectious diseases
- Decline in deaths from coronary artery disease and stroke
- Safer and healthier foods
- Healthier mothers and babies
- Better family planning
- Fluoridation of drinking water
- Recognition of tobacco as a health hazard

#### 10 Essential Public Health Services

- Monitor health status to identify community health problems.
- Diagnose and investigate health problems and hazards in the community.
- Inform, educate, and empower people about health issues.
- Mobilize community partnerships to identify and solve health problems.
- Develop policies and plans that support individual and community health efforts.
- Enforce laws and regulations that protect health and ensure safety.
- Link people to needed personal health services and assure the provision of health care when otherwise unavailable.
- Assure competent public health and personal health care workforce.
- Evaluate effectiveness, accessibility, and quality of personal and population-based health services.
- Research for new insights and innovative solutions to health problems.

Adapted from: Centers for Disease Control and Prevention, <http://www.cdc.gov/mmwr/preview/mmwrhtml/00056796.htm> and American Public Health Association, <http://www.health.gov/phfunctions/public.htm>; accessed January 11, 2009.

- Adults: Illiteracy; Biased or False Reporting; Failure to Report Use of Herbs, Alcohol, Supplements; Unusual Work Patterns such as Shift Work; Vegan or Disordered Eating Pattern
- Older Adults: Limited Dietary Recall; Limitations in Hearing or Sight; Chronic Illness that Affects Intake; Polypharmacy; Monotonous or Limited Intake

**TABLE 1-2 Dietary Guideline Systems**

The Food and Agriculture Organization (FAO) and the World Health Organization (WHO) have frequently brought together scientists and experts in agriculture to address nutrition and malnutrition. Dietary guidelines offer dietary advice for the population to promote overall nutritional wellbeing. As a result, many countries have established food-based dietary guidelines. Several principles and guidelines are included here.

Source: <http://www.fao.org/docrep/v7700t/v7700t02.htm>

#### *Energy*

- Nutritional guidelines should aim to prevent the consequences of either energy deficit or excess.
- Food-based dietary guidelines should promote appropriate energy intakes by encouraging adequate food choices from a balance of foods containing carbohydrates, fats, proteins, vitamins, and minerals.
- The role of physical activity in the energy balance equation should be addressed.

#### *Protein*

- For high-quality proteins, requirements for most people are met by providing 8–10% of total energy as protein.
- For predominantly vegetable-based, mixed diets, which are common in developing country settings, 10–12% is suggested to account for lower digestibility and increased incidence of diarrheal disease.
- In the case of the elderly, where energy intake is low, protein should represent 12–14% of total energy.

#### *Fat*

- In general, adults should obtain at least 15% of their energy intake from dietary fats and oils.
- Women of childbearing age should obtain at least 20% to better ensure an adequate intake of essential fatty acids needed for fetal and infant brain development.
- Active individuals who are not obese may consume up to 35% fat energy as long as saturated fatty acids do not exceed 10% of energy intake.
- Sedentary individuals should limit fat to not more than 30% of energy intake.
- Saturated fatty acids should be limited to less than 10% of intake.

#### *Carbohydrate*

- Carbohydrates are the main source of energy in the diet (>50%) for most people.
- Grain products, tubers, roots, and some fruits are rich in complex carbohydrates. Generally, they need to be cooked before they are fully digestible.
- Sugars usually increase the acceptability and energy density of the diet. Total sugar intake is often inversely related to total fat intake. Moderate intakes of sugar are compatible with a varied and nutritious diet, and no specific limit for sugar consumption is proposed in the report.

#### *Micronutrients*

- Vitamins and minerals include compounds with widely divergent metabolic activities and are essential for normal growth and development and optimal health.
- Micronutrients may help to prevent infectious and chronic diseases. Epidemiological, clinical, and experimental studies define the role of specific foods and nutrients in disease development and prevention.

#### *American Dietary Guidelines*

An evidence-based, scientific approach is used for updates to the Dietary Guidelines for Americans (Nicklas et al, 2005). The guidelines are updated every 5 years. In 2010, the guidelines were enhanced to describe the need for a Total Diet approach. There is no single “American” or “Western” diet. According to the National Health and Nutrition Examination Survey (NHANES), Americans eat too many calories and too much solid fats, added sugars, refined grains, and sodium. Americans also eat too little dietary fiber, vitamin D, calcium, potassium, and unsaturated fatty acids (specifically omega-3s), and other important nutrients that are mostly found in vegetables, fruits, whole grains, low-fat milk and milk products, and seafood. See the website at <http://www.cnpp.usda.gov/DGAs2010-DGACReport.htm> for the evidence-based recommendations.

#### Balance Nutrients With Calories

Eat a variety of nutrient-dense foods and beverages within and among the basic food groups.

Choose foods that limit the intake of saturated and trans fats, cholesterol, added sugars, salt, and alcohol.

Meet recommended intakes within energy needs by adopting a balanced eating pattern, such as the U.S. Department of Agriculture (USDA) Food Guide or the Dietary Approaches to Stop Hypertension (DASH) Eating Plan.

#### Manage Weight

To maintain body weight in a healthy range, balance calories from foods and beverages with calories expended.

To prevent gradual weight gain over time, make small decreases in food and beverage calories and increase physical activity.

#### Maintain Physical Activity

Engage in regular physical activity and reduce sedentary activities to promote health, psychological well-being, and a healthy body weight.

To reduce the risk of chronic disease in adulthood, engage in at least 30 minutes of moderate-intensity physical activity, above usual activity, at work or home on most days of the week. For most people, greater health benefits can be obtained by engaging in physical activity of more vigorous intensity or longer duration.

To help manage body weight and prevent gradual, unhealthy body weight gain in adulthood, engage in approximately 60 minutes of moderate- to vigorous-intensity activity on most days of the week, while not exceeding caloric intake requirements.

(continued)

**TABLE 1-2 Dietary Guideline Systems (continued)**

To sustain weight loss in adulthood, participate in at least 60–90 minutes of daily physical activity.

Achieve physical fitness by including cardiovascular conditioning, stretching exercises for flexibility, and resistance exercises or calisthenics for muscle strength and endurance.

#### Food Groups to Emphasize

Consume nine 1/2-cup servings of fruits and vegetables daily (2 cups of fruit and 2½ cups of vegetables for reference 2000-calorie intake).

Choose a variety of fruits and vegetables each day. In particular, select from all five vegetable subgroups (dark green, orange, legumes, starchy vegetables, and other vegetables) several times a week.

Consume ≥3-oz equivalents of whole-grain products per day, with the rest of the recommended grains coming from enriched or whole-grain products; half the grains should come from whole grains.

Consume 3 cups per day of fat-free or low-fat milk or equivalent milk products.

#### Eat the Right Fats

Aim for 20–35% of total calories from fats, mostly from polyunsaturated and monounsaturated sources, such as fish, nuts, and vegetable oils.

Consume less than 10% of calories from saturated fatty acids and less than 300 mg/d of cholesterol, and keep trans fatty acid consumption as low as possible.

When selecting and preparing meat, poultry, dry beans, and milk or milk products, make choices that are lean, low fat, or fat free.

#### Carbohydrates Do Matter

Choose fiber-rich fruits, vegetables, and whole grains.

Choose and prepare foods and beverages with little added sugars or caloric sweeteners, such as amounts suggested by the USDA Food Guide and the DASH Eating Plan.

Consuming sugar- and starch-containing foods and beverages less frequently for good oral hygiene.

#### Less Sodium and More Potassium

Consume less than 2300 mg (approximately 1 teaspoon of salt) of sodium per day. Choose and prepare foods with little salt. Eat more potassium-rich foods, such as fruits and vegetables.

#### Take It Easy on Alcoholic Beverages

Those who choose to drink alcoholic beverages should limit to one drink per day for women and up to two drinks per day for men.

Alcoholic beverages should not be consumed by individuals who cannot restrict their alcohol intake, women of childbearing age who could become pregnant, pregnant and lactating women, children and adolescents, individuals taking medications that can interact with alcohol, and those with specific medical conditions.

Alcoholic beverages should be avoided by individuals engaging in activities that require attention, skill, or coordination, such as driving or operating machinery.

#### Keep Food Safe

Wash hands, food contact surfaces, and fruits and vegetables. Meat and poultry should not be washed or rinsed.

Separate raw, cooked, and ready-to-eat foods while shopping, preparing, or storing foods.

Cook foods to a safe temperature to kill micro-organisms.

Chill (refrigerate) perishable food promptly and defrost foods properly.

Avoid raw (unpasteurized) milk or any products made from unpasteurized milk, raw or partially cooked eggs or foods containing raw eggs, raw or undercooked meat and poultry, unpasteurized juices, and raw sprouts.

#### *Canada's Food Guide to Healthy Eating*

- Provide energy consistent with the maintenance of body weight within the recommended range.
- Include essential nutrients in amounts specified in the Recommended Nutrient Intakes.
- Include no more than 30% of energy as fat (33 g/1000 kcal or 39 g/5000 kJ) and no more than 10% as saturated fat (11 g/1000 kcal or 13 g/5000 kJ).
- Provide 55% of energy as carbohydrate (138 g/1000 kcal or 165 g/5000 kJ) from a variety of sources.
- Reduce sodium content.
- Include no more than 5% of total energy as alcohol, or 2 drinks daily, whichever is less.
- Contain no more caffeine than the equivalent of 4 cups of regular coffee per day.
- Use community water supplies that are fluoridated.

Source: Health Canada, <http://www.hc-sc.gc.ca/fn-an/food-guide-aliment/index-eng.php>

#### *Chinese Nutrition Society—Balance Dietary Pagoda*

- Eat a variety of foods, with grains as the staple food.
- Eat more vegetables, fruits, and tubers.
- Eat milk and legumes, and their products, every day.
- Increase appropriately the consumption of fish, poultry, egg, and/or lean, meat, and decrease the consumption of fat meat and/or animal fat.
- Balance the amount of food consumed with physical activity to maintain a healthy body weight.
- Eat a diet with less fat/oil and salt.

(continued)

**TABLE 1-2 Dietary Guideline Systems (continued)**

- For those who consume alcohol, be moderate.
- Do not eat putrid and deteriorated foods.

Source: Chinese Nutrition Society, <http://www.cnsoc.org/asp-bin/EN/?page=8&class=92&id=144>

#### South African Dietary Guidelines

- Enjoy a variety of foods; this is difficult but necessary in developing countries.
- Be active.
- Make starchy foods the basis of most meals.
- Eat plenty of vegetables and fruits every day.
- Eat more legumes for better overall health.
- Foods from animals can be eaten every day.
- Eat fats sparingly—implications for health and disease.
- Eat salt sparingly—sprinkle, do not shake!
- Drink water—the neglected nutrient.
- If you drink alcohol, drink sensibly.

## PREGNANCY AND LACTATION

# PREGNANCY

### NUTRITIONAL ACUITY RANKING: LEVEL 1 (UNCOMPLICATED); LEVEL 3 (HIGH RISK)

#### DEFINITIONS AND BACKGROUND

Women who are interested in becoming pregnant need a “preconception risk assessment” (March of Dimes, 2009). They should be aware of their personal genetic biomarkers that could cause problems with infertility, pregnancy, childbirth, or chronic diseases.

Pregnancy is an anabolic state that affects maternal tissues using hormones synthesized to support successful pregnancy. Progesterone induces fat deposition to insulate the baby, supports energy reserves, and relaxes smooth muscle, which will cause a decrease in intestinal motility for greater nutrient absorption. Estrogen increases tremendously during pregnancy for growth promotion, uterine function, and water retention. Progesterone and estrogen secreted during pregnancy in combination also help prepare for successful lactation.

Adequate weight gain is needed to ensure optimal fetal outcome. Underweight is associated with small for gestational age (SGA) or preterm deliveries. Energy costs of pregnancy vary by the BMI of the mother (Butte et al, 2004). Tissue growth in pregnancy is approximately: breast, 0.5 kg; placenta, 0.6 kg; fetus, 3–3.5 kg; amniotic fluid, 1 kg; uterus, 1 kg; increase in blood volume, 1.5 kg; and extracellular fluid, 1.5 kg. Rapid weight losses or gains are not desirable during pregnancy.

Higher maternal weight before pregnancy increases the risk of late fetal death, although it protects against the delivery of an SGA infant. Obesity increases risk of first trimester

Reprinted with permission from: Weber J RN, EdD and Kelley J RN, PhD. *Health Assessment in Nursing*, 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

or recurrent miscarriages and the need for caesarean delivery; obesity should be corrected before pregnancy whenever possible (Rasmussen and Yaktine, 2009). Some obese women will seek bariatric surgery to enhance fertility. Women who have had bariatric surgery usually have a positive outcome (Maggard et al, 2008).

A short span between pregnancies or an early pregnancy within 2 years of menarche increases the risk for preterm or growth-retarded infants. Maternal nutrient depletion of energy and protein leads to poor nutritional status at conception and may alter pregnancy outcomes. Poor maternal iron and folate intakes have been associated with preterm births and intrauterine growth retardation, two outcomes for which women with early or closely spaced pregnancies are at high risk.

Brain development starts during pregnancy and continues into adulthood. Deficiency of various micronutrients has long-term implication for cognitive development (Benton, 2008). Major diseases including heart disease, hypertension, and type 2 diabetes may originate from impaired intrauterine growth and development as consequences of an insult at a critical, sensitive time. People who are small or disproportionate (thin or short) at birth may later have CHD, high BP, high cholesterol concentrations, and abnormal glucose–insulin metabolism, independent of length of gestation (Godfrey and Barker, 2000).

Nutritional deficits are serious during pregnancy. Living with marginal food security has been found to correlate with greater weight gain, more complications, and gestational diabetes (Laraia et al, 2010). Planned pregnancies usually have the most favorable outcomes. Continuous

dietary monitoring of pregnant women and pregnant teens is essential, especially for calcium, iron, folate, vitamins A, C, B<sub>6</sub>, and B<sub>12</sub> (ACOG, 2009). Other nutrients of importance include magnesium, fiber, zinc, vitamin D, and biotin (Zempleni et al, 2008). Table 1-3 lists risk assessments and indicators of potentially poor maternal or fetal outcomes.

Many cardiac defects may be prevented by maternal use of multivitamins during the periconceptual period. To prevent SGA births, a mother is encouraged not to smoke, to manage any cardiac disease or conditions such as elevated blood pressure (BP), and to gain sufficient weight. Women who are HIV positive may experience undesirable weight loss (Villamore, 2004). Bulimia nervosa during pregnancy can lead to miscarriage, inappropriate weight gain (excessive or inadequate), complicated delivery, low birth weight (LBW), prematurity, infant malformation, low Apgar scores, and other problems. Women with unmanaged PKU may also have poor reproductive outcomes. Prevention requires initiation of the low Phe diet before conception or early in pregnancy, with metabolic control and sufficient intake of energy and proteins.

For twin and multiple pregnancies, twice-monthly visits, sufficient energy intake, multimineral supplementation, and patient education may reduce complications such as LBW and neonatal morbidity (Luke et al, 2003). The American Dietetic Association suggests at least three visits for medical nutrition therapy in high-risk pregnancies. The individual may require more visits if there are complex or multiple risk factors, such as diabetes and celiac disease.

**TABLE 1-3 Prenatal Risk Assessments and Indicators of Potentially Poor Outcomes**

*Prepregnancy*

- Adolescence (poor eating habits, greater needs for growth of teen and fetus).
- History of three or more pregnancies in past 2 years, especially miscarriages.
- History of poor obstetrical/fetal performance.
- Overweight and obesity, which can cause a higher risk for gestational diabetes, preeclampsia, eclampsia, C-section, and/or delivery of infant with macrosomia.

*Prepregnancy or During Pregnancy*

- Economic deprivation.
- Food faddist; smoker; user of drugs/alcohol; practice of pica with related iron or zinc deficiencies; anorexia nervosa or bulimia.
- Modified diet for chronic systemic diseases, such as diabetes, celiac disease, PKU.
- Prepartum weight of less than 85% or more than 120% of desirable BMI for height and age; these may reflect inability to attain proper weight or poor dietary habits.
- Deficient Hgb (<11 g) or hematocrit (Hct) (<33%) with medical diagnosis of anemia.
- Weight loss during PG or gain <2 lb/month in the last two trimesters; dehydration; hyperemesis.
- Risk of toxemia (2-lb weight gain per week or more).
- Poorly managed vegetarian diet, especially vegan diet without supplementation.
- Poor nutrient or energy intakes over the duration of the pregnancy.
- Poor intake of magnesium, zinc, calcium, iron, folate, vitamins A and C, and other key nutrients.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Each individual has a unique genetic profile and phenotype. Because both parents contribute genes and chromosomes to the fetus, a genetic history may be beneficial. Epigenetics involves inherited changes in chromatin and DNA that affect human pathologies, including inflammatory disorders and cancers, and nutritional factors can have a profound effect on gene expression (Wilson, 2008).

Clinical/History		
Gravida (number of pregnancies)	Uterine or cervical abnormalities	Serum Fe
Para (number of births)	Diet history, including use of alcohol	Urea N
Abortus (number of abortions)	Smoking habits, herbs, botanicals, and drug use	Glucose (by 24–28 weeks)
Height	Exposure to accutane, diethylstilbestrol (DES), anticoagulants, anti-epilepsy drugs	Ca <sup>++</sup> , Mg <sup>++</sup>
Prepregnancy weight (% standard)	Nausea or vomiting (frequency, duration, impact on intake)	Albumin (Alb)
Weight grid or prenatal BMI (19.8–20.0)	Pica, harmful beliefs, or disordered eating patterns	Transferrin
Present weight for gestational age		Ceruloplasmin
Desired weight at term		T3, T4, TSH
BP		Blood urea nitrogen (BUN)
Multiple gestation?		Creatinine
Diabetes or other chronic disease?		Homocysteine
Hx of births with neural tube defects, preterm delivery, multiple births		Cholesterol (may be increased)
		Alkaline phosphatase (alk phos) (may be increased)
		Total iron-binding capacity (TIBC) (often increased in late pregnancy)
	<b>Lab Work</b>	
	Hemoglobin and hematocrit (H & H)	

## INTERVENTION

### OBJECTIVES

- Maintain adequate gestational duration; avoid preterm delivery.
- Provide adequate amount of weight gain during the pregnancy; prevent delivery of LBW infants. Underweight women (BMI <18.5) should gain 28–40 lb. Normal

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Protein Intake for Multiple Gestation

**Assessment Data:** Dietary recall indicating low use of protein-rich foods; labs such as albumin, BUN, and H & H; insufficient rate of weight gain on prenatal grid.

**Nutrition Diagnosis (PES):** Inadequate protein intake related to needs for twin pregnancy as evidenced by dietary intake records (60% of goal) and slow growth on prenatal growth grid.

**Intervention:** Education on protein and protein-sparing kilocalories during pregnancy for twins. Counseling for individual needs, snack habits, recipes, tips for reducing nausea, physical activity.

**Monitoring and Evaluation:** Changes in dietary intake, improved lab values, improved weight gain on prenatal growth grid, successful pregnancy outcomes.

#### Rapid Weight Gain in Pregnancy

**Assessment Data:** Dietary history reflects high-caloric food intake; patient statements reflect misinformation; weights and rate of weight gain exceed recommended rate.

**Nutrition Diagnosis (PES):** Excessive energy intake related to misinformation about nutrition needs during pregnancy as evidenced by dietary recall showing daily intake of high-calorie foods, 3-lb body weight gain per week during the second trimester, and 20-lb weight gain by the middle of the second trimester.

**Intervention:** Education on food and nutrient needs during pregnancy. Referral to Women-Infants-Children Program (WIC) if eligible financially and medically.

**Monitoring and Evaluation:** Monthly appointment; include diet history and rate/amount of weight gain.

weight women (BMI = 19–24.9) should gain 25–35 lb total. Overweight women (BMI = 25–29.9) should gain 15–25 lb. Obese women (BMI >30) should gain 11–20 lb, as obesity is a risk for undesirable consequences, including neural tube defects (Rasmussen and Yaktine, 2009; Scialli, 2006).

- Encourage proper rate of weight gain: 2–4 lb first trimester, 10–11 lb second trimester, and 12–13 lb third trimester. More weight should be gained if patient is below ideal weight range before pregnancy, especially in younger women. Adolescents are at high risk of gaining an excessive amount of weight during pregnancy and should be closely monitored.
- Provide additional nutrients and energy (net cost of pregnancy varies from 20,000–80,000 kcal total). Women carrying more than one fetus must add extra kilocalories to support multiple births.
- Prevent or correct hypoglycemia and ketosis.
- Provide adequate amino acids to meet fetal and placental growth. Approximately 950 g of protein are synthesized for the fetus and placenta. Low protein intake may lead to a smaller infant head circumference.
- Promote development of an adequate fetal immune system.
- Prevent or correct deficiencies of iron, which are common in 50–75% of pregnancies. Iron deficiency may cause low infant birth weight and premature birth (Luke, 2005).

- Folate deficiency and elevated homocysteine levels may lead to miscarriage, club foot, structural heart disease, anencephaly and neural tube defects (Wilson et al, 2008). A woman with a history of spontaneous abortion in her immediate prior pregnancy and short interpregnancy interval is especially vulnerable. L-methylfolate is the natural, active form of folate used for DNA reproduction and regulation of homocysteine levels. Women with altered genetic alleles may not have sufficient methyl-tetrahydrofolate (MTHFR) enzymes to use folic acid properly; these women may benefit from using special prenatal supplements, such as Neevo®. Vitamins B<sub>6</sub> and B<sub>12</sub> will also be needed if homocysteine levels are elevated.
- Vitamin A deficiency is strongly associated with depressed immune system and higher morbidity and mortality due to infectious diseases such as measles, diarrhea, respiratory infections. On the other hand, doses of 10,000–30,000 IU vitamin A/d may cause birth defects.
- Avoid zinc, vitamin D, or calcium deficiencies.
- Supply sufficient iodine (250 µg) to prevent cretinism with mental and physical retardation (Angermayr and Clar, 2004). Systematic provision of iodine supplementation is recommended, especially if women are cutting back on intake of iodized salt (Glinioer, 2007).
- Limit caffeinated beverage intake to two cups daily.
- Avoid alcohol. Mothers who drink relatively high levels of alcohol around the time of conception increase the risk for orofacial clefts and spina bifida.
- Support the individual patient; pregnant women who are fatigued, stressed, and anxious tend to consume more macronutrients and decreased amounts of micronutrients (Hurley et al, 2005).
- Develop or improve good eating habits to prevent or delay onset of chronic health problems postnatally. The interaction between genes, nutrition, and environmental stimuli has been found to cause permanent changes in metabolism; these Developmental Origins of Health And

Disease (DHOaD) are just beginning to be understood (Waterland and Michaels, 2007).

- Discuss the importance of a high-quality prenatal diet. Fetal under-nutrition can predispose to hypercholesterolemia and program food preferences that are more atherogenic (Lussana et al, 2007).
- Women should drink plenty of fluids to remain adequately hydrated (Klein, 2005).
- Multiple gestation creates new challenges and magnified nutritional requirements (Luke, 2005). There are more risks for adverse outcomes, including diabetes, hypertension, eclampsia, delivery of a premature or LBW infant (Klein, 2005; Luke, 2005). For twins, weight gain should reflect the period of gestation and prepregnancy BMI; 35–45 lb is often recommended with twins, and 50 lb overall is recommended for triplets.
- Monitor BP and blood glucose regularly to prevent or to identify complications such as preeclampsia or gestational diabetes.
- Monitor or treat other complications, such as nausea and vomiting of pregnancy (NVP) and hyperemesis gravidarum. See appropriate disorder entries.

## FOOD AND NUTRITION

- Include in diet: 1 g protein/kg body weight daily (or 10–15 g above recommended dietary allowances for age). Young teens: 11–14 years (1.7 g/kg); 15–18 years (1.5 g/kg); over 19 years of age (1.7 g/kg); high risk (2 g/kg).
- Energy: In women of normal weight, energy requirements increase minimally in the first trimester, by 350 kcal/d in the second trimester, and by 500 kcal/d in the third trimester (Butte et al, 2004). Add more or less, depending on level of physical activity. Evaluate teens individually according to age and prepregnancy weight. With twins, dietary prescription of 3000 to 4000 kcal/d may be needed (Luke et al, 2003). See nutrient chart.

Recommendations for Pregnant Women

Nutrient	Age 18 Years or Under	Ages 19–30 Years	Ages 31–50 Years
Energy	1st tri = +0 kcal/d; 2nd tri = +340 kcal/d; 3rd tri = +452 kcal/d	1st tri = +0 kcal/d; 2nd tri = +340 kcal/d; 3rd tri = +452 kcal/d	1st tri = +0 kcal/d; 2nd tri = +340 kcal/d; 3rd tri = +452 kcal/d
Protein	71 g/d	71 g/d	71 g/d
Calcium	1300 mg/d	1000 mg/d	1000 mg/d
Iron	27 mg/d	27 mg/d	27 mg/d
Folate	600 µg/d	600 µg/d	600 µg/d
Phosphorus	1250 mg/d	700 mg/d	700 mg/d
Vitamin A	750 µg	770 µg	770 µg
Vitamin C	80 mg/d	85 mg/d	85 mg/d
Thiamin	1.4 mg/d	1.4 mg/d	1.4 mg/d
Riboflavin	1.4 mg/d	1.4 mg/d	1.4 mg/d
Niacin	18 mg/d	18 mg/d	18 mg/d

Data from: Food and Nutrition Board, Institute of Medicine. *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids (macronutrients)*. Washington, DC: National Academy Press, 2002.

- The diet and supplement should include 27 mg of ferrous iron and a 5-mg increase in intake of zinc, easily obtained from meat or milk.
- Encourage use of vitamin C foods with iron-rich foods or an iron sulfate supplement.
- Use adequate vitamins A and D to match DRIs for age; avoid hypervitaminosis, which may lead to fetal damage. Monitor use of dietary supplements and fortified foods carefully.
- Be sure to use iodized salt, but avoid salt intake greater than that recommended for healthy adults.
- Desired pattern of food intake: Two to three servings of milk–yogurt–cheese group (for calcium, protein); 6 oz of meat or protein substitute (protein, iron, zinc); 3 fruits and 4 vegetables, including citrus (vitamin C) and rich sources of vitamin A and folacin; 9 servings of grains and breads, 3 of which are whole-grain or enriched breads/substitutes (iron, energy); 3 servings of fat.
- Omit alcohol. Reduce caffeine intake to the equivalent of two cups of coffee or less per day; this includes intake from colas, chocolate, and tea.
- Use cereal grains, nuts, black beans, green vegetables, and seafood for magnesium. Magnesium plays a role in preventing or correcting high BP; follow the Dietary Approaches to Stop Hypertension (DASH) diet whenever possible.
- Essential fatty acids (EFAs) from fats, such as corn oil or safflower oil and walnuts, should equal 1–2% of daily calories. Arachidonic acid and docosahexaenoic acid (DHA) are essential for brain growth and cognitive development; supplementation supports higher IQ in young children (Helland et al, 2008). Fish and seafood (e.g., tuna, mackerel, salmon) can be encouraged for their omega-3 fatty acids twice weekly, if allergies and cautions about mercury intake have been considered.
- Extra vitamin B<sub>6</sub> and copper are readily obtained from a planned diet and a prenatal supplement.
- See Table 1-4 for a description of special problems in pregnancy.
- buclizine (Bucladin-S), metoclopramide (Reglan), meclizine (Antivert), prochlorperazine (Compazine), promethazine (Phenergan), or antihistamines such as Benadryl. Side effects vary but may include sedation, dizziness, changes in BP, and/or tachycardia.
- Women who have chronic diseases such as epilepsy, thyroid disorders, diabetes and cardiac disorders will need to manage all medications with careful medical supervision.
- Women who develop preterm labor are often treated with one of several drugs (tocolytics) to stop premature labor. Drugs include calcium channel blockers, terbutaline, ritodrine, magnesium sulfate, indomethacin, ketorolac, and sulindac. Use is short term, and side effects are not significant.
- Neevo<sup>®</sup> contains 1.13 mg L-methylfolate Calcium (as Metafolin<sup>®</sup>). It may be used for women who have MTHFR alleles.

### Herbs, Botanicals, and Supplements

- Pregnant women should not use herbs, botanical supplements, and herbals teas. There are no rigorous scientific studies of the safety of dietary supplements during pregnancy. The Teratology Society has stated that it should not be assumed that they are safe for the embryo or fetus (Marcus and Snodgrass, 2005). Women who are using such supplements should stop immediately when they discover they are pregnant.
- Pregnant women should avoid supplements containing aloe, apricot kernel, black cohosh, borage, calendula, chaparral, chasteberry, comfrey, dong quai, ephedra, euphorbia, feverfew, foxglove, gentian, ginseng, golden seal, hawthorne, horehound, horseradish, juniper, licorice root, nettle, plantain, pokeroor, prickly ash, red clover, rhubarb, sassafras, saw palmetto, senna, skullcap, St. John's wort, tansy, wild carrot, willow, wormwood, yarrow, or yohimbe (American Dietetic Association, 2008). Willow bark, which contains salicin, may cause stillbirth, prolonged gestation, and LBW.
- Ginger may be an effective treatment for nausea and vomiting in pregnancy (Borrelli et al, 2005). Sips of ginger ale or use of small amounts of ginger in cooking may be useful. However, when taking blood thinners or preparing for surgery, discontinue use.

### Common Drugs Used and Potential Side Effects

- After the fourth month, encourage use of a basic vitamin-mineral supplement between meals (with liquids other than milk, coffee, or tea) for better utilization. Supplements vary greatly; read labels carefully. Discuss the relevance of tolerable upper intake levels (ULs) from the latest dietary reference intakes of the National Academy of Sciences. These levels were set to protect individuals from receiving too much of any nutrient from diet and dietary supplements.
- Iron is the only nutrient that cannot be met from diet alone (30 mg needed after the first trimester). Avoid taking iron supplements with antacids; bedtime is often the best time.
- Avoid taking isotretinoin (Accutane,) 13-*cis*-retinoic acid (CRA) or vitamin A as 10,000 IU or more, especially in the first trimester, as birth defects may result.
- Insulin may be needed with consistently high blood glucose levels over 120 mg/dL; monitor and avoid overfeeding.
- Antiemetic agents may be used to control NVP and include ondansetron (Zofran), cyclizine (Marezine),

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Describe adequate patterns and rates of weight gain in pregnancy; explain the rationale. Individualize according to goals (e.g., shorter women at lower range of gain). Excess equals more than 6.5 lb gained monthly after 20 weeks. Inadequate intake is 2 lb or less gained monthly after the first trimester.
- Encourage adequate calcium intake. If needed, discuss what to do for milk allergy/intolerance and lactose intolerance.
- Discourage trendy diets, pica, fads, and the habit of skipping breakfast. Discuss ketosis related to low glucose levels and its undesirable effect on fetal brain development.

**TABLE 1-4 Special Issues in Pregnancy**

Issue	Considerations
Allergies, personal or family history	Avoidance of common food allergens during pregnancy does not prevent allergies in offspring (Kramer and Kakuma, 2003). Women may wish to take probiotics to stimulate health-producing microbes in their fetuses and to delay onset of eczema and allergies (Kukkonen et al, 2007; Wickens et al, 2008).
Hyperemesis (intractable, dehydrating vomiting)	This affects 20% of pregnancies in the first trimester. Half of these patients have some liver dysfunction (Hay, 2008). Early hospitalization with tube feeding may be needed (Paauw et al, 2005; Quinla and Hill, 2003). Metoclopramide (Reglan) may help. When eating orally, liquids taken between meals, extra B-complex vitamins and vitamin C, and limited fat may be beneficial. Low birth weight and greater length of hospital stay are common (Paauw et al, 2005). Avoid electrolyte imbalances.
Liver dysfunction such as viral hepatitis, gallstones or intrahepatic cholestasis in pregnancy	With pruritus, elevated bile acids in the second half of pregnancy, high levels of aminotransferases and mild jaundice, immediate delivery may be needed (Hay, 2008).
Multiple gestation	Energy regimen of 20% protein, 40% carbohydrate, and 40% fat may be particularly useful (Luke, 2005). Supplement with calcium, magnesium, and zinc, as well as multivitamins and essential fatty acids (Luke, 2005).
Nausea and vomiting of pregnancy (NVP)	Initial treatment of nausea and vomiting should be conservative with dietary changes, emotional support, and perhaps use of ginger (Quinla and Hill, 2003). NVP affects 80% of pregnancies. It is reasonable to suspect <i>H. pylori</i> (Goldberg et al, 2007). Frequent, small meals should be consumed separately from fluids. Offer high-protein snacks, such as cheese or lean meat. Avoid lying down immediately after meals and suggest not skipping meals. Do not force eating; suck on ice chips or other frozen items and make up lost calories later. Eat meals and snacks in a well-ventilated area, free of odors; avoid strong spices and aromas. Eat and drink slowly and rest after meals. Try lemonade and potato chips or saltines. Avoid large meals, very sweet, spicy or high-fat foods if not tolerated. Eat dry crackers before rising in the morning. If necessary, drink fluids between meals rather than with meals. Multivitamin-mineral supplements may also trigger NVP; it may be helpful to try a different brand. Minimize offensive odors. Rehydration may be essential. NVP often abates by 17 weeks of pregnancy.
Pica (intake of nonnutritive substances)	Intake of ice, freezer frost, baking soda, baking powder, cornstarch, laundry starch, baby powder, clay, or dirt. As pica practices are associated with significantly lower hemoglobin levels at delivery, WIC and prenatal counselors must be aware. Discussion of practices should be nonjudgmental because pica may have strong cultural implications. Food cravings and aversions usually subside after pregnancy.
Severe gastrointestinal problems	Consider total parenteral nutrition with adequate lipids (10–20% of energy) for the fetus, as well as protein and carbohydrate. Check blood sugar regularly. Use adequate fluid according to estimated needs. Complications may include bacteremia, decreased renal function with preexisting disease, neonatal hypoglycemia, or subclavian vein thrombosis.
Vegan vegetarians	Vitamin B <sub>12</sub> , zinc, calcium, and vitamin D supplements may be needed.
Women with high levels of inflammatory cytokines	Reduced placental perfusion and a tendency toward preeclampsia (LaMarca et al, 2007). New tests and treatments are being identified.
Women who have previously given birth to an infant with neural tube defect or anencephaly	Test for folic acid alleles; consider use of Neevo® or 600 µg folate daily throughout PG.
Women with preeclampsia	Test for folic acid alleles; consider use of Neevo® or 600 µg folate daily throughout pregnancy (Klein, 2005).

- Encourage intake of high-density nutrients, especially among women with pregravid obesity, as their diets tend to be poorer quality (Laraia et al, 2007).
- Encourage pleasant meal times and a healthy appetite. Stress has negative effects on nitrogen and calcium.
- Encourage breastfeeding. Explain the reasons for doing so (e.g., immunological benefits, bonding, and weight stabilization). Mothers who are HIV-positive should consider HAART, which can drastically reduce the risk of transmission of HIV; infant prophylaxis can also reduce the transmission rate (Slater et al, 2010).
- For excessive weight gain, the goal should be to restore eating patterns to match a normal growth curve. Severe

calorie restriction should be avoided. At least 175 g of CHO will be needed.

- A balanced intake of fluoride and iodine from water, table salt, and seafood is needed. Avoid excesses.
- Discuss effects of tobacco and drug use (cocaine, alcohol, and marijuana), such as decreased birth weight and congenital malformations.
- Eligible women should be referred to the WIC Program, especially to prevent LBW. Many barriers hinder participation in nutrition education programs, including lack of transportation or child care. Facilitated discussions, support groups, cooking classes, and websites may be useful.

**TABLE 1-5 March of Dimes Campaign to Reduce Preterm Births**

- Consume a multivitamin containing 400 µg of the B vitamin folic acid before and in the early months of pregnancy. Women who need L-methylfolate should receive that special formulation.
- Stop smoking, drinking and/or using illicit drugs; avoid prescription or over-the-counter drugs (including herbal preparations) unless prescribed by a doctor who is aware of the pregnancy.
- Once pregnant, get early regular prenatal care, eat a balanced diet with enough calories (about 300 more than a woman normally eats), and gain enough weight (usually 25–35 lb).
- Talk to a doctor about signs of premature labor and what to do if warning signs are evident.

Source: [http://www.marchofdimes.com/pnhec/240\\_48590.asp](http://www.marchofdimes.com/pnhec/240_48590.asp); accessed January 2, 2009.

- For constipation, suggest extra fiber, activity, and fluid (35–40 cc/kg); avoid laxatives.
- For swelling of ankles, hands, and legs, become more physically active. Avoid excessive salt at the table but do not restrict salt severely.
- For heartburn, eat smaller meals more frequently, eat slowly, and cut down on spicy or high-fat foods. Avoid antacids unless approved by the physician.
- All infections are cause for concern among pregnant women because they pose a risk to the health of the baby. Prostaglandins may stimulate early labor and cause delivery of an LBW infant. Women should have a periodontal evaluation to rule out gum disease and to eliminate infection.
- Discuss postpartum issues, including physical activity, breastfeeding, anemia, and control of hyperglycemia. Adherence to dietary guidelines may be limited in low-income women because of neglect of self-care, weight-related distress, negative body image, stress, and depressive symptoms (George et al, 2005). Attention to psychosocial needs may help to improve dietary intakes.
- The March of Dimes has launched a campaign to reduce rates of preterm birth; see Table 1-5.

### Patient Education—Food Safety

- *Helicobacter pylori* should be suspected as one possible cause of nausea and vomiting (Goldberg et al, 2007). Hepatitis A, *Salmonella*, *Shigella*, *Escherichia coli*, and *Cryptosporidium* are common causes of diarrhea during pregnancy (American Dietetic Association, 2008). Careful hand washing is recommended.
- Avoid soft cheeses such as feta, brie, camembert, Roquefort, and Mexican soft cheese; they may have been contaminated with *Listeria*, which can cause fetal death or premature labor.
- Avoid raw or undercooked eggs, fish or shellfish, and meats because of potential foodborne illnesses.
- Do not eat or drink raw (unpasteurized) milk or products made from it.
- Avoid eating unpasteurized juices and raw sprouts.

- Pregnant women should not eat shark, swordfish, king mackerel, and tilefish. These long-lived larger fish contain the highest levels of methyl mercury, which may harm an unborn baby's developing nervous system. Pregnant women should select a variety of other kinds of fish, such as shellfish, canned fish, smaller ocean fish, and farm-raised fish. They can safely eat 12 oz of cooked fish per week, with a typical serving size being 3–6 oz. Keep fish and shellfish refrigerated or frozen until ready to use.

## LACTATION

### NUTRITIONAL ACUITY RANKING: LEVEL 1

Reprinted with permission from: Moore KL, PhD, FRSM, FIAC & Dalley AF II, PhD. *Clinical Oriented Anatomy*, 4th ed. Baltimore: Lippincott Williams & Wilkins 1999.

### DEFINITIONS AND BACKGROUND

Breastfeeding should be supported and encouraged because of its immunological, physiological, economic,

social, and hygienic effects on mother and infant. Exclusive breastfeeding for the first 6 months of life provides the best form of nutrition (James et al, 2005). Because maternal intake and breastfeeding practices vary over the duration of lactation, assess regularly and determine whether or not the infant needs supplemental foods or nutrients. Only rarely is supplementation needed. In fact, adding formula or solids to the diet of the exclusively breastfed infant almost guarantees lactation failure. Unless mom is severely malnourished, she can keep making good milk.

Breastfeeding is an anabolic state, requiring extra energy. The composition of breast milk varies over time. Colostrum contains mainly immunological factors (days 1–4); a short transition occurs (days 5–9); breast milk secreted between days 9 and 28 is primarily nutritional; and breast milk content is equally valuable for immunity and nutrition thereafter.

Human milk is better digested and absorbed by infants than other forms of milk; it has more DHA and arachidonic acid for normal cognitive and visual development, and carnitine for mitochondrial oxidation of these long-chain fatty acids. It also has less sodium and a proper protein ratio. Levels of DHA and arachidonic acid are lower in women who have diabetes; insulin resistance is higher among their infants (Min et al, 2005).

Breast milk has 1.5 times as much lactose as cow's milk; consequently, protein is absorbed better. The whey to casein ratio of 80:20 is more desirable than that of many formulas. In comparison, cow's milk has twice as much protein and mineral content. The composition of breast milk changes to meet the developing baby's needs (i.e., the fat content decreases over time). In many cases where a mother cannot breastfeed, the use of banked human milk may be a better option than cow's milk formulas (Wojcik et al, 2009). See Table 1-6 for the nutrient content of human milk.

**TABLE 1-6 Nutrient Content of Mature Human Milk**

Nutrients	Units	1 Cup/ 240 g	Nutrients	Units	1 Cup/ 240 g
<b>Proximates</b>			<b>Vitamins</b>		
Water	g	215.25	Vitamin C	mg	12.300

Sources: U.S. Department of Agriculture, November 1999; Jensen RG, ed. *Handbook of milk composition*. New York: Academic Press, 1995; Scrimshaw NS. *Food Nutr Bull*. 17(4), 1996.

Food allergies are less frequent in infants who are exclusively breastfed, even more so if maternal diets are higher in omega-3 fatty acids. Compared with cow's milk formulas, breast milk has more antibodies and over 45 bioactive factors such as digestive enzymes, hormones, immune factors, and growth factors. The promotion of breastfeeding has played an important role in improving child health by providing optimum nutrition and protection against common childhood infections and by promoting child spacing.

Breast milk is a living fluid. Infants receive beneficial nucleotides, macrophages, leukocytes, lymphocytes, and neutrophils from human milk, which protect against diarrhea, allergies, ear infections, necrotizing enterocolitis, urinary tract infection, and pneumonia. Bacterial flora of breastfed infants are generally *Lactobacillus*, not *Escherichia coli* like those of formula-fed infants. Formula-fed infants may be more prone to wheezing, Gastroesophageal (GE) reflux, urinary tract infection, influenza, sepsis, and *Giardia*; therefore, exclusive breastfeeding for 6 months or longer is highly recommended.

If the mother uses alcohol or illicit drugs, is receiving chemotherapy or has HIV infection, or if the infant has galactosemia, breastfeeding is not recommended unless HAART therapy is given (Slater et al, 2010). Women must be fully informed about the risks of breastfeeding transmission of HIV versus the expense and availability of obtaining formula.

Women should be encouraged to breastfeed until the child is 1 year of age or as long as mutually desirable. In developing countries, mothers may be encouraged to increase the breastfeeding time to 2 years, but mothers should not deprive themselves. The volume of milk decreases in a poorly nourished mother (American Dietetic Association, 2009).

New mothers who are breastfeeding should try not to lose weight rapidly. Women who are obese before pregnancy need extra encouragement to breastfeed. Prolonged breastfeeding helps to lower postpartum weight, although this benefit may slow in older mothers.

The long-term effects of breastfeeding an infant include lower incidences of type 2 diabetes, Crohn's disease, some types of cancer, allergies, and neurological disabilities. The relation of vitamin D insufficiency in the fetus or neonate to long-term outcomes such as type 1 diabetes and other chronic diseases needs to be investigated (Kovacs, 2008). Several minerals and peptides found in milk have a BP lowering effect, which may be protective later in life. Exclusive and prolonged breastfeeding is also associated with higher cognitive development than formula feeding, likely from long-chain fatty acids Docosahexaenoic acid (DHA) and Eicosapentaenoic acid (EPA) (Kramer et al, 2008).

Breastfeeding reduces the risk of breast and ovarian cancers, protects bone density in the mother, improves glucose profiles in gestational diabetes, and saves money not spent on formula (James et al, 2005). While it has been proposed that breastfeeding helps adults maintain a desirable BMI, this needs further evaluation (Owen et al, 2005). A recent study found that breastfeeding did not reduce adiposity at age of 6.5 years (Kramer et al, 2009).

There is an essential role for dietetics professionals in promoting and supporting breastfeeding by providing up-to-date, practical information to pregnant and postpartum women, involving family and friends in breastfeeding education and counseling, removing institutional barriers to breastfeeding, collaborating with community organizations

that promote and support breastfeeding, and advocating for policies that position breastfeeding as the norm (James et al, 2005). Because prenatal WIC participation is associated with a greater likelihood of providing babies infant formula rather than breastmilk after birth, it is critical to educate these women about the health risks of introducing cow's milk complementary foods too early (Ziol-Guest and Hernandez, 2010).

The nutrition counselor should encourage mothers to continue breastfeeding for 6–12 months, and somewhat longer in developing countries. The Ten Steps to Successful Breastfeeding (WHO/UNICEF) provide an evidence-based standard used to assess individual hospitals and their support for mothers to breastfeed (Grizzard et al, 2006). Billions of dollars would be saved if breastfeeding were increased to 6 months or longer to reduce otitis media, gastroenteritis, and necrotizing enterocolitis.

In a survey of physicians about their breastfeeding promotion practices, over half indicated that they had had little or no education about breastfeeding; more education for solving common problems is desired (Krogstrand and Parr, 2005). See Table 1-7 for common problems that occur during breastfeeding and guidance to support the mother.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Each individual has a unique genetic profile and phenotype. Mothers with galactosemia should not breastfeed.

Clinical/History	Goal for return to usual body weight	Protime or INR
BP	Diet history	Chol
Smoking		Triglycerides (Trig)
Height		Homocysteine
Current weight	<b>Lab Work</b>	Ca <sup>++</sup>
Weight history	Glucose	Serum
Prepregnancy weight	Albumin (Alb) or transthyretin (if needed)	phosphorus
Healthy body weight (HBW) range for height	H & H, serum Fe	Serum 25-hydroxyvitamin D [25(OH)D]
Date of birth (DOB) for infant	Alk phos	

## INTERVENTION

### OBJECTIVES

- Support adequate lactation (usual secretion, 750–800 mL/d). Human milk provides 67 kcal/dL. Good energy intake improves milk production, especially in undernourished women.

**TABLE 1-7 Common Problems in Breastfeeding and Reasons Why Women Discontinue Breastfeeding**

**Birth Control Pills:** High estrogen-types are not recommended as they can decrease milk supply. A progestin-only pill is usually recommended by a physician.

**Colic and Fussiness:** A randomized, controlled trial of a low-allergen maternal diet was conducted among exclusively breastfed infants presenting with colic; when mothers excluded cow's milk, eggs, peanuts, tree nuts, wheat, soy, and fish from their diet, crying/fuss duration was reduced by a substantially greater amount in the low-allergen group (Hill et al, 2005).

**Engorgement:** The best way to prevent engorgement is to begin breastfeeding as soon as possible after birth followed by nursing regularly throughout the day. Rapid filling of the breasts and blocked mammary ducts may cause a painful engorgement. Frequent nursing, breast massage or warm shower before feedings, use of cold packs shortly after nursing, wearing a firm bra that is not too tight, and avoiding the use of nipple shields can help alleviate this condition.

**Inadequate Milk Supply:** Poor milk supply can be a cause of failure to thrive in breastfeeding infants. Maternal causes of poor milk supply are hypothyroidism, excessive antihistamine use, smoking, oral contraceptive use, illness, inadequate intake after gastric bypass surgery, poor diet, decreased fluid intake, infrequent nursing, or fatigue. Correction of any of these causes may improve milk supply. Increasing frequency of nursing is the best way to increase milk supply.

**Jaundice:** Breast milk jaundice occurs in about 1% of the population of breastfeeding newborns, is caused by the presence of a substance that alters liver function, and may cause red cell hemolysis. Mothers should breastfeed 10–12 times per day to correct elevated serum bilirubin levels.

**Latching On:** For problems with baby latching on, the trick is to have the baby open his or her mouth wide. Brush baby's lips with the nipple to encourage him or her to open wide, as if yawning. Once baby's mouth is open wide, quickly pull the baby onto the breast by pulling the baby toward mom with the arm that is holding him or her (not moving mom towards the baby). Baby's gums should cover an inch of the areola behind the nipple. Be sure the baby's lips are everted and not inverted (turned in). Almost the entire areola should be in the baby's mouth.

**Mastitis:** Breast infection causes fever, chills, redness, flu-like symptoms, and breast sensitivity. A clogged mammary duct, maternal anemia, stress, or an infection carried from the baby may cause mastitis. The primary goal is emptying the infected breast; frequent nursing (every 1–3 hours during the day and 2–3 hours at night) is encouraged. The physician should be notified so that antibiotics or pain relievers can be prescribed. Application of heat to the breast, drinking plenty of fluids, and adequate rest are useful measures for treatment.

**Nipple Confusion:** Infants who are breastfed may refuse to take a bottle as the weaning of breastfeeding occurs. Mothers should be encouraged to continue attempts at breastfeeding.

**Sore Nipples:** Frequent, short nursing, repositioning the infant at the breast, applying cold packs or heat to breasts, avoiding irritating soaps or lotions on nipples, air-drying nipples after nursing, exposing nipples to direct sunlight or 60-watt bulb for 15 minutes several times per day, applying vitamin E squeezed from capsules or ointment such as vitamin A and D or pure lanolin cream to nipples, and avoiding the use of nipple shields may help ease the pain. Occasionally, sore nipples are caused by *Candida albicans*; the breasts may not appear to have a fungal infection, but cultures of nipple surfaces will be positive for *Candida albicans*.

#### *Reasons Why Women Discontinue Lactation*

##### Acute infections in the mother

Employer attitudes toward breastfeeding mothers; lack of private space with a locking door, adequate time to express milk, inadequate refrigeration (Stewart-Glenn, 2008)

Hospital practices that do not support breastfeeding (Grizzard et al, 2006) including physician and nurse apathy or misinformation

Infant's inability to nurse due to weakness or oral anomalies

Lack of information and support and/or inadequate preparation

Lack of part-time jobs, flexible scheduling, and convenient day care for mothers who must work

Maternal depression

Mother's chronic illness (e.g., tuberculosis, severe anemia, chronic fevers, cardiovascular or renal disease) and/or use of medications

Mother's inability to provide 50% of the infant's needs

Mother's return to work by 12 weeks postpartum (Taveras et al, 2003)

Obesity: poor infant feeding behavior and reduced hormonal responses in the early postpartum period result in delayed lactogenesis and early cessation of breastfeeding (Lovelady, 2005)

- Breast milk can meet nutrient needs during the first 6 months, with possible exception of vitamin D and iron in certain populations.
- Exclusive breastfeeding for 6 months has many nutritional benefits. Have the mother continue breastfeeding for up to 1 year when possible. Exclusive breastfeeding should be encouraged for at least 4–6 months in infants at risk of atopy (Friedman and Zeigler, 2005).
- Decrease nutritional risks from use of alcohol, stimulants, and medications while mother is breastfeeding. Alcohol intake inhibits the letdown reflex from oxytocin. Discourage excessive use of stimulants, including caffeine from coffee (limit to 2 cups daily) and from tea, colas, and chocolate.
- Omit known food allergens while breastfeeding if infant shows signs of colic (Hill et al, 2005). Eliminate cow's milk, eggs, peanuts, tree nuts, wheat, soy, and fish, especially if members of the immediate family have allergies.
- Promote adequate infant growth and development, including bone mineralization. Lactation increases the normal daily loss of calcium for the mother, yet is generally beneficial for protecting bone health.
- Normalize body composition gradually so that the mother returns to ideal weight. Promote gradual weight

## SAMPLE NUTRITION CARE PROCESS STEPS

**Harmful Beliefs about Food and Nutrition**

**Assessment Data:** Food records; signs of infant GI distress or excessive sleep.

**Nutrition Diagnosis (PES):** Harmful beliefs/attitudes about food or nutrition-related topics related to consumption of 4 beers daily while breastfeeding as evidenced by food diary, discussion with mom about “beer making more breastmilk,” and reports that the infant is lethargic during daytime.

**Intervention:** Education about appropriate dietary and substance intake for pregnancy. Counseling about dangers of consuming alcohol.

**Monitoring and Evaluation:** Omission of alcohol intake while breastfeeding. Infant weight and infant growth charts; reports about infant sleep and GI patterns.

loss even in obese women. Weight loss by the mother of 0.5 kg per week after delivery does not affect the growth of breastfed infants (Lovelady, 2005).

- Support brain health and visual acuity by including fatty acids in the mother’s diet (Anderson et al, 2005; Lauritzen et al, 2005). Both EPA and DHA should be included.

## FOOD AND NUTRITION

- In the first 6 months, increase the mother’s energy by 330 kcal over RDA for age. In the next 6 months, increase energy by 400 kcal over RDA for age. Recommendations may vary because individuals vary in prepregnancy weights, activity levels, and rates of weight gain.
- Consider the special needs of adolescents or women older than 35 years of age. Energy and nutrient requirements will change accordingly.
- Increase the mother’s intake of protein (approximately 65 g daily), especially sources of high-quality protein.

Recommendations for Lactation

Nutrient	Age 18 Years or Under	Ages 19–30 Years	Ages 31–50 Years
Energy, 1st 6 months	+330 kcal/d	+330 kcal/d	+330 kcal/d
Energy, 2nd 6 months	400 kcal/d	400 kcal/d	400 kcal/d
Protein	61 g/d or 1.1 g/kg/d	61 g/d or 1.1 g/kg/d	61 g/d or 1.1 g/kg/d
Calcium	1200 mg/d	1300 mg/d	1300 mg/d
Iron	10 mg/d	9 mg/d	9 mg/d
Folate	500 µg/d	500 µg/d	500 µg/d
Phosphorus	1250 mg/d	700 mg/d	700 mg/d
Vitamin A	1200 µg	1300 µg	1300 µg
Vitamin C	115 mg/d	120 mg/d	120 mg/d
Thiamin	1.4 mg/d	1.4 mg/d	1.4 mg/d
Riboflavin	1.6 mg/d	1.6 mg/d	1.6 mg/d
Niacin	17 mg/d	17 mg/d	17 mg/d

Data from: Food and Nutrition Board, Institute of Medicine. *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids (macronutrients)*. Washington, DC: National Academy Press, 2002.

- Encourage intake of usual sources of vitamins and minerals. Intake of calcium should be 1200–1300 mg/d. Increases of B-complex vitamins, vitamins A and C should be included. Supplementation may be needed for women with poor dietary intakes or chronic illnesses.
- Adequate vitamin D is needed for the infant if maternal intake is poor, if infant receives little sunshine exposure or has high levels of skin pigmentation. Daily vitamin D supplements of 400 IU/L will keep serum 25(OH)D concentrations higher than 50 nmol/L and prevent rickets in infants and young children (Greer, 2008).
- Levels of both iron and copper decrease with progression of lactation; there is no evident need for supplementation in the first 6 months.
- Increase intake of fluids. Omit alcohol unless permitted by a physician.
- After 3 months of lactation, mothers should increase energy intake if weight loss has been excessive.
- Women who follow vegan diets may need zinc, calcium, vitamin D, or vitamin B<sub>12</sub> supplementation. These diets also may be low in carnitine.
- If tube feeding is needed using breast milk, some fat losses can occur. Formula enhancers may be added if long-term use is required.
- Breastfeeding by adolescent mothers is associated with greater bone mineral density (BMD) during young adulthood; lactation may be protective to their bone health.

## Common Drugs Used and Potential Side Effects

- Discuss the relevance of tolerable ULs from the latest dietary reference intakes of the National Academy of Sciences. These levels were set to protect individuals from receiving too much of any nutrient from diet and dietary supplements. Lactating mothers should be especially aware of what they are consuming between diet and supplements to avoid hypervitaminosis A and D. Read food and supplement labels carefully.
- Alcohol and nicotine are transmitted through breast milk to infants; discourage use. Cigarette smoking reduces the amount of milk produced.
- Moderate amounts of caffeine are acceptable in the equivalent of 2 cups of coffee.
- Cimetidine, Prozac, lithium, cyclosporine, cold medicines, and some other drugs may be contraindicated. Otherwise, prescribed medications are used only under supervision of the doctor.
- Drugs that may be used during breastfeeding include acetaminophen, some antibiotics and antihistamines, codeine, decongestants, insulin, quinine, ibuprofen, and thyroid medications.
- Parlodel (bromocriptine mesylate) inhibits secretion of prolactin and decreases lactation; it is used for women who do not wish to breastfeed. Constipation or anorexia may result.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without first discussing with the physician. In general, these supplements have not been proven to be safe for breastfeeding mothers and their infants. Fenugreek, anise, fennel, garlic, and echinacea have been suggested for breastfeeding but have not been studied in this population for side effects. Lactating women should not take kava, chasteberry, dong quai, Asian ginseng, licorice root, or saw palmetto.
- IgM-, IgA-, and IgG-secreting cells are higher in infants who are breastfed exclusively for at least for 3 months and supplemented with probiotics compared with breastfed infants receiving placebo; use of probiotics during breastfeeding may positively influence gut immunity (Rinne et al, 2005).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- “Best practice” counseling includes one prenatal and one postpartum home contact and telephone consultation by a lactation consultant (Bonuck et al, 2005). Explain the composition of breast milk, the benefits of breastfeeding, nipple care, and what to do during illness or infection.
- Self-esteem is crucial. Help mom believe that she can do it; give positive feedback and help her handle negative comments from others. Promotion of self-efficacy is useful. To prevent early discontinuation, lay support (peer counseling) is effective (Chung et al, 2008). Primary care physicians should support breastfeeding efforts during early, routine visits (Labarere et al, 2005).
- Help mom address barriers, such as short maternity leave, lack of private places to pump, coworker comments, minor health barriers, lack of support from doctor or nurses, and old wives’ tales (e.g., breastfeeding spoils the baby, restrictive diet).
- Women with delayed onset of lactation need additional support during the first week postpartum; recommend frequent nursing.
- To ensure baby receives enough milk, mom should nurse at least eight times in each 24-hour period, no longer than one hour at a time. Baby should be able to rest for about 2 hours between feedings.
- Breastfed infants should have at least five wet diapers in each 24 hours. Stools of breastfed babies differ from formula-fed infants by being more loose. By day 4, there should be three stools a day, yellowish in hue.
- Explain the meaning of a balanced diet. Stress food sources of nutrients often limited in their diets: calcium, zinc, folate, and vitamins E, D, and B<sub>6</sub>.
- Breastfed infants may be deficient in vitamin B<sub>12</sub>, especially after 6 months (Hay et al, 2008). Vegetarian women may need supplemental vitamin B<sub>12</sub> and vitamin D.
- Amounts of food antigens in breast milk may be controlled by modifying the maternal diet (Hill et al, 2005). Infants fed formulas of intact cow’s milk or soy protein compared with breast milk have a higher incidence of type 1 diabetes autoantibodies, atopic dermatitis and wheezing in early childhood; exclusive breastfeeding should be encouraged (Friedman and Zeigler, 2005; Kull et al, 2005).
- Encourage the mother to normalize weight after delivery, but not start a weight loss program while she is nursing. Other than postpartum diuresis, average loss is 0.67 kg/month. Total weight gained during pregnancy affects weight loss afterwards. Mothers should try to maintain their postpartum weight during lactation. Weight loss should not be initiated until breastfeeding is discontinued, with no more than 1 lb/wk.
- Moderate exercise has no adverse effects on breastfeeding among healthy mothers. However, extra energy intake is needed with vigorous exercise (Lovelady, 2004).
- Exercise alone is not always sufficient to promote the desired level of weight reduction. Once lactation is established, overweight women can reduce energy intake by 500 kcal per day to allow gradual weight loss of 0.5 kg/wk (Lovelady, 2004).
- Lactating women are at high risk for energy and nutrient inadequacies, especially in low-income communities. Strategies must ensure adequate intakes. For example, in 2009, the WIC food package changed to use lower fat milk, whole grains, canned beans, salmon and tuna, a fruit/vegetable cash voucher. The program now offers the formula/BF option to encourage breastfeeding.
- Depressive symptoms in postpartum mothers should be identified and addressed (Hatton et al, 2005).
- Exposure to pesticides and polychlorinated biphenyls (PCBs) is undesirable. Some exposure occurs from breastmilk, with similar content in both colostrum and mature milk (Yu et al, 2007).
- Discuss issues related to safe handling of breast milk (see the following Food Safety recommendations).

### Patient Education—Food Safety

- Avoid soft cheeses such as feta, brie, camembert, Roquefort, and Mexican soft cheese; they may have been contaminated with *Listeria*, which can cause fetal death or premature labor. If they are used, cook until boiling first.
- Avoid raw eggs, raw fish, and raw and undercooked meats because of potential viral and bacterial foodborne illnesses. *Helicobacter pylori* should be suspected as one possible cause of nausea or vomiting; careful hand washing is recommended.
- Nursing mothers should not eat shark, swordfish, king mackerel, and tilefish. These long-lived larger fish contain the highest levels of methyl mercury, which may harm a baby's developing nervous system. Nursing women should select a variety of other kinds of fish, such as shellfish, canned fish, smaller ocean fish, or farm-raised fish. They can safely eat 12 oz of cooked fish per week, with a typical serving size being 3–6 oz.
- After expressing milk, it should be stored in a clean, tightly enclosed container. An opaque container may help to protect riboflavin more than a clear container if there is any exposure to light.
- Human milk can be stored safely if refrigerated but not at room temperature because bacterial growth and lipolysis are rapid. Milk to be used within 48 hours can be refrigerated; if milk is to be used after 48 hours, try freezing (up to 6 months) immediately.

## INFANCY, CHILDHOOD, AND ADOLESCENCE

## INFANT, NORMAL (0–6 MONTHS)

## NUTRITIONAL ACUITY RANKING: LEVEL 1

## DEFINITIONS AND BACKGROUND

Normal gestation is 40 weeks. The average birth weight of an infant ranges between 5.5 and 10 lb; the average is approximately 7–7.5 lb. Healthy, full-term infants lose some weight in the first days after birth but tend to regain it within the first week. Infants often double their birth weight by 4–6 months and triple it within 1 year. For assessment of an infant, monitoring growth is the best way to evaluate intake. Head circumference increases about 40% during the first year, and brain weight should almost double.

Breastfeeding takes longer than cup or bottle feeding but has more benefits and is the preferred method. (American Dietetic Association, 2009). When breastfeeding is not possible or not desired, formula feeding is used. For formula feedings in infants with oral or developmental problems, administration times, amounts ingested, and physiological stability of infants are similar when newborn infants are fed using a bottle or a cup. Section 3 describes conditions where alternative feeding methods may be needed.

Infants are composed of approximately 75–80% water, whereas adults are composed of 60–65% water. Infants may become dehydrated easily, especially in hot weather or after bouts of diarrhea.

When infants are ill, special techniques (doubly labeled water studies or test weighing) may be used to determine intakes of breast milk.

Mineral status should be carefully assessed. Infants are born with a 4- to 6-month supply of iron if maternal stores were adequate during gestation. Anemia from severe iron deficiency (ID) is the most prevalent and widespread nutrition-related health problem in infants and young children in low-income countries (Lutter, 2008). Correcting ID anemia may prevent developmental and behavioral delays.

Calcium is another important mineral during infancy to set the stage for healthy bones. Zinc and copper may also be nutrients that are insufficient, especially in low-income populations (Schneider et al, 2007). Infants of vegan mothers may require calcium, zinc, and vitamin B<sub>12</sub> supplementation (American Dietetic Association and Dietitians of Canada, 2003; Weiss et al, 2004). Another common problem in infancy is low vitamin D intake in breast milk, leading to growth failure, lethargy, irritability and rickets (Hollis and Wagner, 2004). Excesses of vitamin D should also be avoided.

The American Academy of Pediatrics supports the following practices during infancy (American Academy of Pediatrics, 2009):

- Breastfeed exclusively for the first 6 months. Supplement with vitamin D from birth and use iron supplementation as ferrous sulfate drops or iron-fortified cereal after 4 months of age. Fluoride supplementation may be required after 6 months of age, depending on the fluoride content of the city water. Feeding of iron-fortified commercial infant formula may be done for the first year as an alternative to breastfeeding.

- Delay the use of whole cow milk until after 1 year of age. Early introduction of whole cow milk protein during infancy may contribute to ID anemia by increasing gastrointestinal (GI) blood loss. Whole cow milk has an increased renal solute load compared to infant formulas.
- Reduced-fat milks should be delayed until after the second year of life. Adequate fat intake is important for the developing brain, and milk is usually the primary source of fat for infants and toddlers.
- Delay the introduction of semisolid foods until 4–6 months of age or until the infant demonstrates signs of developmental readiness, such as head control and ability to sit with support.

## CLINICAL INDICATORS

## Clinical/History

Birth weight  
Birth length  
Present weight for gestational age  
Height-weight percentile  
Head circumference  
Feeding pattern

## Appetite

changes  
No. of wet diapers in 24 hours  
No. of dirty diapers in 24 hours  
BP  
Pink, firm gums  
Use of vitamins, herbs, supplements

## Lab Work

H & H, serum ferritin  
Glucose  
Cholesterol  
Other labs as indicated by medical exam or family history

## INTERVENTION

## OBJECTIVES

- Promote normal growth and development: assess sleeping, eating, and attentiveness habits. Compare infant's growth to the chart of normal growth patterns. Weight for length (height) is the most meaningful measurement. Use updated Centers for Disease Control and Prevention

## SAMPLE NUTRITION CARE PROCESS STEPS

## Inadequate Iron Intake

**Assessment Data:** Food records; lab reports for H & H, serum ferritin.

**Nutrition Diagnoses (PES):** Inadequate mineral intake related to intake of insufficient amounts of iron-fortified formula as evidenced by mother's report of diluting formula with cow's milk for infant at 3 months of age to save money.

**Intervention:** Education about appropriate preparation and use of formula for infants. Referral to WIC program if eligible.

**Monitoring and Evaluation:** Lab reports for H & H, serum ferritin; dietary history indicating proper use of iron-fortified formula.

(CDC) growth charts and monitor growth trends, not a singular value. Chronic malnutrition results in decreased weight, then height, and then head circumference.

- Overcome any nutritional risk factors or complications, such as otitis media or dehydration.
- Evaluate use and discourage early introduction of cow's milk and solids, including gluten-containing cereals. Follow recommended guidelines for timing of introduction of new foods.
- Encourage the mother to use breast milk as the infant's main source of nutrition for the first 6 months, introducing solids and juices slowly beginning at approximately 4 months of age.
- If the infant is breastfed, assess the mother's prepregnancy nutritional status and risk factors, weight gain pattern, food allergies, and medical history (such as preeclampsia, chronic illnesses, or anemia). Discuss any current conditions that may affect lactation (e.g., smoking, use of alcohol, family history of allergies).
- If the infant is formula fed, the mother should learn about early childhood caries (ECC) prevention and about potential overfeeding problems.
- Promote growth and development through adequate fatty acid intake, especially for visual acuity.
- Effects of soy formulas on the thyroid must be monitored in infants with hypothyroidism. Iodine has been added to most infant formulas; check labels. Iodized salt has been found to be beneficial for maintaining desirable infants, especially in developing countries (Zimmerman, 2007).

## FOOD AND NUTRITION

- *Breastfed infants:* discourage the mother from using drugs and alcohol; limit caffeine intake to the equivalent of 2 cups of coffee per day. Breast milk yields an 80:20 whey to casein ratio and approximately 20 kcal/oz. These infants will need information on vitamin D (Casey et al, 2010), fluoride, and sometimes iron supplements (at about 3 months of age). Mothers of infants predisposed to allergies should avoid fish, cow's milk, and nuts. Teach parents about use of diluted fruit juice (perhaps apple) at 4 months of age. Introduce cow's milk only after 12 months of age.
- *Formula-fed infants:* Review type of formula, such as milk-based, soy; significant ingredients; and volume for 24 hours. No sweetened beverage or calorie-containing formula should be given in between meals or at bedtime. Warm bottles carefully because folic acid and vitamin C may be destroyed by heat. Iron-fortified formula can be used after 2–3 months (American Academy of Pediatrics, 2009). Discourage use of evaporated milk formula, which is low in vitamin C and high in protein, sodium, and potassium. Standard formulas have a 60:40 whey to casein ratio, which is desirable; they provide 20 kcal/oz. Standard formulas include Enfamil, Similac, Gerber Formula, Good Start, and other products. Fluoride supplements are needed only if the water supply provides less than 0.3 ppm, or if unfluoridated bottled water is used to prepare formula.
- Soy formulas are available for cow's milk allergies; they are fortified with zinc, iron, and carnitine. Nutramigen, Alimentum, or Pregestimil are used for complex GI problems. Nutramigen may also be used for allergies to both soy and cow's milk protein. Alimentum and Pregestimil are for malabsorption with inclusion of medium-chain triglycerides (MCT).
- Ensure that the daily requirements are being met for all nutrients for each stage of growth. When in doubt, a liquid multivitamin–mineral supplement is advisable.
- For tube-feeding, several products are available. Formula should contain 10–20% protein, 30–40% fat, and 40–60% carbohydrates.
- An elemental diet may be needed for severe protein intolerance or cow's milk allergy. Monitor carefully for hydration; do not modify nutrients because of altered osmolality. Breast milk has an osmolality of 285 mOsm/kg; formulas vary from 150 to 380 mOsm/kg. Formulas with over 400 mOsm/kg can cause diarrhea or vomiting.
- Minimal enteral feeding (MEF) protects against necrotizing enterocolitis and other infection and should be started early.
- TPN may be used when the infant cannot tolerate oral or tube feedings. Include 1–2% EFAs (linoleic and linolenic acids) to prevent outcomes of deficiency, such as inadequate wound healing, growth, immunocompetence, and platelet formation.
- *Introduction of solids:* At 4–6 months, introduce plain (not mixed, sweetened, or spiced) strained or pureed baby cereals, then nonallergenic vegetables (such as carrots or green beans), and then fruits. Start with 1–2 teaspoons, and progress as appetite indicates. Try a single new item for 7–10 days to detect any signs of food allergy. The intake of solids should not decrease breast milk or formula intake to less than 32 oz daily. Avoid giving too much juice; 4–6 oz daily is sufficient.

Nutrient	Recommendation for Infants Ages 0–6 Months
Energy	570 kcal/d males; 520 kcal/d females
Protein	9.1 g/d or 1.52 g/kg/d
Calcium	210 mg/d
Iron	0.27 mg/d
Folate	65 mg/d
Phosphorus	100 mg/d
Vitamin A	400 µg
Vitamin C	40 mg
Thiamin	0.2 mg/d
Riboflavin	0.3 mg/d
Niacin	2 mg/d

Data from: Food and Nutrition Board, Institute of Medicine. *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids (macronutrients)*. Washington, DC: National Academy Press, 2002.

## Herbs, Botanicals, and Supplements

- Infants and children may be highly susceptible to some of the adverse effects and toxicity of herbs and botanical products because of their physiology, immature metabolic enzyme systems, and different doses for body weights.
- Most topical preparations are benign; however, garlic poultices can cause burns. Internal use of herbs containing saturated pyrrolizidine alkaloids (comfrey) should be avoided.
- Discuss the relevance of tolerable ULs from the latest dietary reference intakes of the National Academy of Sciences. These levels were set to protect adults from receiving too much of any nutrient from diet and dietary supplements; infants are especially at risk for toxicities.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain the proper timing and sequence of feeding. Discuss successful feeding as trusting and responding to cues from the infant about timing, pace, and eating capacity.
- Explain growth patterns (e.g., an infant who is 4–6 months of age should double his or her birth weight). Discuss problems related to inadequate growth.
- Emphasize the importance of adequate bonding between mother and child.
- Explain the proper care of infant's teeth, including risks of early childhood caries. Ad lib nocturnal feeding should be discontinued after the first teeth erupt. Bottle-fed infants should not be put to sleep with the bottle.
- Explain the proper timing and sequence of solid food introduction. Avoid use of stringy foods or foods such as peanut butter that are hard to swallow. Hard candies, grapes, and similar foods may increase the risk of aspiration.
- Discuss the rationale for delaying introduction of cow's milk (risks for allergy, GI bleeding).
- Discuss why fluid intake is essential; explain that infant needs are much greater (as a percentage of total body weight) than for adults. Breastfed infants usually have 4–6 soft stools each day. After the first month, they will tend to have fewer bowel movements than before; by 2 months, they have even fewer. However, a doctor should be consulted if the baby has not had a bowel movement in 3 days, or whenever diarrhea occurs.
- For resolution of special feeding problems, see Table 1-8.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before breastfeeding or before formula preparation. Use clean utensils and containers for mixing formula. Wash the top of cans before opening.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Well water should not be used since it may contain bacteria.
- Follow the 2-hour rule: discard any formula that has been left at room temperature for 2 hours or longer. Do not reuse.
- Avoid honey to decrease potential exposure to botulism in infancy.
- Avoid using raw or partially cooked eggs, raw or undercooked fish or shellfish, and raw or undercooked meats because of potential foodborne illnesses.
- Avoid using raw (unpasteurized) milk or products made from it.
- Avoid using unpasteurized juices and raw sprouts.

**TABLE 1-8 Special Problems in Infant Feeding<sup>a</sup>**

**Allergy.** Dietary exposures in pregnancy and the early postnatal period can modify gene expression and disease susceptibility. Avoidance of food allergens in infancy has provided no clear evidence in allergy prevention and is no longer recommended; focus is on their role in tolerance induction (West et al, 2010.)

**Colic.** Check for hunger, food allergy, incorrect formula temperature, stress, or other underlying problems. Give small, frequent feedings and parental encouragement. Colic is equally common in breastfed or formula-fed infants. If breastfed, continue to breastfeed. Rarely, removal of cow's milk products from the mother's diet is useful. If formula fed, discontinue expensive elemental formulas if symptoms do not improve. Curved bottles allow infants to be fed while they are held upright. Collapsible bags decrease swallowing of air. Infants should be burped regularly during feedings.

**Constipation.** The doctor will make a careful assessment and may suggest adding 1 teaspoon of a carbohydrate source to 4 oz of water or formula, one to two times daily. Avoid use of honey and corn syrup to prevent infant botulism.

**Diarrhea.** Replace fluids and electrolytes (e.g., Pedialyte) as directed by the doctor. After an extended period of time, have the doctor rule out allergy. Monitor weight loss and fluid intake carefully. FDA approved a vaccine (RotaTeq) to prevent rotavirus, which causes severe diarrhea and fever and dehydration in infants and results in many hospitalizations each year (Glass and Parashar, 2006).

**Regurgitation.** Position the infant in an upright, 40–60° position after feeding for approximately 30 minutes; have the doctor rule out other problems. Use smaller, more frequent feedings to avoid overfeeding. Use prethickened formulas if the doctor thinks it is necessary.

**Pale, oily stools.** Check for fat malabsorption. Use a formula containing medium-chain triglycerides if necessary.

**Spitting Up or Reflux.** If there is no weight loss concern, just offer encouragement that the problem will resolve in a few months. Positioning is an important consideration during feeding. Feed more slowly and burp often. Use feeding volumes and a schedule that is set. Avoid exposure to second-hand smoke. Offer parental reassurance.

## INFANT, NORMAL (6–12 MONTHS)

**NUTRITIONAL ACUITY RANKING: LEVEL 1–2****DEFINITIONS AND BACKGROUND**

Infants older than 6 months of age are beginning the developmental stages that will lead to walking and talking. Many of the same principles associated with infant feeding during the first 6 months will continue with the greater use of solids. The growth pattern of breastfed and formula-fed infants differs in the first 12 months of life. The new CDC growth charts were developed with a larger proportion of breastfed infants.

Timing of the introduction of complementary foods (solids) is an important consideration. The Feeding Infants and Toddlers Study (FITS) evaluated the introduction of complementary foods into the diets of young children, and the findings show that healthcare professionals play an important role in improving feeding practices (Stang, 2006). Early introduction is considered to be at 3–4 months of age, and late introduction is considered to be at 6 months of age. Many foods that are introduced are of low nutritional value, including sweetened beverages, cookies, processed meats, cakes, and pies (Stang, 2006).

Introduction of cow's milk at 12 months of age brings new problems and risks related to EFA deficiency if low-fat or skim milks are used. Long-chain fatty acids are useful in normal growth and development of infants and young children. It is not necessary to alter the diets of infants to prevent heart disease or to lower cholesterol. Breastfed and formula-fed infants maintain a characteristic serum cholesterol ester fatty acid pattern after age 7 months even after they begin to receive solid food; breastfed infants have higher levels of arachidonic acid and DHA with better cognitive development (Daniels et al, 2004).

Growth and development at this stage are affected by underlying or acute illnesses, nutritional intake, and related factors. Breast-fed infants have a strong prevalence of bifidobacteria and lactobacilli, which stimulate formation of oligosaccharides with a protective prebiotic effect (Coppa et al, 2004). Infants who are breastfed for four months or longer also have stronger lung function (Ogbuanu et al, 2009).

Sodium and chloride intakes may be higher than desirable in infants and toddlers; delaying the introduction of

cows' milk, limiting the amount of salt used in food processing and preparation, and increasing intake of fruits and vegetables are reasonable measures that can be applied (Heird et al, 2006). Overall, interventions for improving the diets of young children should focus on breastfeeding and the whole continuum of diet in order to promote healthy guidelines (Couch and Falciglia, 2006).

Lead poisoning should be monitored in growing children, especially children who live in older homes or spend time in older buildings or day care centers. Toddlers may eat lead-based paint that is chipping away from walls. Lead depletes iron and replaces calcium in the bone; deposition may be seen in x-rays of the knee, ankle, or wrist.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Each individual has a unique genetic profile and phenotype. Because both parents contribute genes and chromosomes to the fetus, a genetic history may be beneficial.

#### Lab Work

Glucose  
Cholesterol  
H & H, serum  
ferritin

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Energy Intake

**Assessment Data:** Food records; weight loss or failure to thrive on growth charts.

**Nutrition Diagnoses (PES):** Inadequate energy intake related to mother's withholding of formula and infant cereal when infant cries "excessively" as evidenced by intake diary and perceptions of colic.

**Intervention:** Education about appropriate dietary intake for age of infant. Counseling about desired foods for a healthy growth; tips for introducing new foods to the diet and for handling an infant with colic.

**Monitoring and Evaluation:** Weight and growth charts; successful growth for child; lab reports for H & H, serum ferritin; dietary history indicating improved variety of food choices.

## INTERVENTION

### OBJECTIVES

- Continue to promote normal growth and development during this second stage of very rapid growth. Use updated CDC growth charts. Monitor trends in growth, not a singular value.
- Prevent significant weight losses from illness or inadequate feeding. Malnutrition results in decreased weight, then height, and then head circumference.
- Avoid dehydration.
- Prevent or correct such complications as diarrhea, constipation, and otitis media.
- Begin to encourage greater physical activity; prepare for walking by ensuring adequate energy intake.
- Continue to emphasize the role of good nutrition in the development of healthy teeth.
- Delay food allergens until 12 months of age (e.g., citrus, egg white, cow's milk, corn, peanut and nut butters.)
- Use of follow-up formulas with higher percentage of kilocalories from protein and carbohydrates (CHO) and less from fat have questionable benefits at this time.
- Prevent nutrient deficiencies upon weaning (e.g., zinc, iron). Iron supplementation, even during breastfeeding, may be beneficial.
- Support feeding skills and introduce solids, at appropriate periods of time, singly.

### FOOD AND NUTRITION

Start Healthy Feeding Guidelines for Infants and Toddlers (Butte et al, 2004; [http://www.bcm.edu/cnrc/consumer/nyc/vol\\_2004\\_3/guidelines\\_ADA.pdf](http://www.bcm.edu/cnrc/consumer/nyc/vol_2004_3/guidelines_ADA.pdf))

- Repeated exposure to a particular food is usually necessary before it is accepted by the infant or toddler; up to 10–15 exposures may be necessary. Introduction of a variety of flavors in the first 2 years of life may lead to acceptance of a wider variety of flavors in later childhood.
- After 6 months, most breastfed infants need complementary foods to meet current recommendations (DRI) for energy, manganese, iron, fluoride, vitamin D, vitamin B<sub>6</sub>, niacin, zinc, vitamin E, magnesium, phosphorus, biotin, and thiamin; amounts needed from complementary foods will vary depending upon the intake of human milk or formula.
- Although iron-fortified infant formula provides the recommended intakes of energy and nutrients until about 1 year of age depending on intake, all infants need complementary foods for exposure to flavors and textures as well as to master eating skills. Complementary foods such as meats and fortified cereals contribute significant amounts of iron; this is helpful in preventing deficiency, which is common in toddlers under the age of 2 years; see Table 1-9 for additional tips on feeding infants.
- Because rickets due to vitamin D deficiency has been observed recently in dark-skinned, breastfed infants and other infants without adequate sun exposure, 200 IU of vitamin D<sub>3</sub> is recommended as a supplement for breastfed infants and infants receiving less than 500 mL of formula

**TABLE 1-9 Feeding Babies in the First Year of Life**

Foods	Birth	1	2	3	4	5	6	7	8	9	10	11	12 Months
Breast milk or iron-fortified formula	Breast milk or formula				Continue breast milk or iron fortified formula								Start whole cow's milk from cup
Cereals and grain products					Iron-fortified plain infant cereal (no fruit flavor or mixed grains). Start with rice, then oatmeal or barley			Teething biscuits		Mixed grain cereals. Noodles, rice. Bread and toast strips			
Vegetables					Strained, single vegetables					Cooked vegetables, mashed or chopped		Sliced cooked vegetables for finger-feeding	
Fruit and fruit juices					Strained, single fruits			Unsweetened fruit juices		Cooked, canned, or soft fresh fruits, mashed or chopped		Sliced soft fruit for finger feeding	
Meat and other protein foods					Strained single meats. Pureed dried beans, peas. Plain yogurt					Same foods, chopped or mashed. Cottage cheese, mashed egg yolk		Same foods, bite-sized pieces for finger feeding. Creamy peanut butter	
Egg white and fish												Egg white. Tender, flaked boneless fish	

The infant's developmental readiness, age, appetite, and growth rate are factors that help determine when to feed solid foods.

Before feeding solid foods, the baby should be able to swallow and digest solid foods, sit with support and have neck and head control, and close their lips over a spoon. Semisolid foods and juices are a significant change and should not be started until 4–6 months.

Introduce single-ingredient foods one at a time; wait 5–7 days before introducing a new food. This process helps identify any food sensitivities the child might have. Offer new food when baby is in a good mood, not too tired and not too hungry. Serve solids after the baby has had a little breast milk or formula. Hold the baby on the lap or use an infant seat or feeding chair if the baby can sit. Use a baby spoon and place a small amount (about 1/2 teaspoon) of food on the baby's tongue. Give the baby time to learn to swallow these foods and get used to the new tastes.

The sequence of new foods is not critical, but rice cereal mixed with breast-milk or formula is a good first choice. Add vegetables, fruits, and meats to the infant's diet one at a time. Serving mixed foods is not recommended in the beginning.

Introduce juices when the baby can drink from a cup, around 6–9 months. Dilute adult juices half and half with water or strain them before giving to a baby. Avoid sweet drinks; they can promote tooth decay. In addition, avoid sweetened foods because they also can promote tooth decay and may cause a preference for sweets. Do not offer fruit desserts that contain unnecessary sugar.

Food can be homemade or commercially prepared. Choose plain, strained fruit such as applesauce, peaches or mashed ripe bananas. Boil fruits until tender; cool; blend until there are no lumps. If it is too thick, add breast milk, baby formula or a little water. Use the same process for vegetables.

Feed the baby when he or she is hungry, but do not overfeed. Make meal time a happy time. Never force a child to finish bottles or food; watch for cues that he or she is full.

Delay introduction of the major food allergens, such as eggs, milk, wheat, soy, peanuts, tree nuts, fish, and shellfish, until well after the first year of life.

Foods that are associated with lifelong sensitization (e.g., peanuts, tree nuts, and shellfish) should not be introduced until even later years.

Combination foods (instead of single-ingredient foods) may be given to older infants after tolerance for the individual components has been established.

Hungry toddlers may point at foods or beverages, ask for foods or beverages, or reach for foods. Full toddlers may slow the pace of eating, become distracted or notice surroundings more, play with food, throw food, want to leave the table or chair, and/or not eat everything on the plate. To help avoid underfeeding or overfeeding, parents and caregivers must be sensitive to the hunger and satiety cues of the healthy infant and young child.

Avoid raw carrots, nuts, seeds, raisins, grapes, popcorn, and pieces of hot dogs during baby's first year as they may cause choking.

Age-appropriate, daily physical activity in a safe, nurturing environment may help promote physical development and movement skills and teach the healthy habit of activity. Encourage parents and caregivers to promote enjoyment of movement and motor skill confidence at an early age. Fundamental motor skills (e.g., walking, running, jumping, etc.) begin to develop. When activity is encouraged, these skills can further develop into advanced patterns of motor coordination.

Television viewing should be discouraged for children under 2 years of age.

<sup>a</sup>Start Healthy Feeding Guidelines for Infants and Toddlers (Butte et al, 2004).

per day. Intakes of EFAs may require emphasis once breast milk or formula is replaced with cow's milk.

- Children often eat small frequent meals and snacks throughout the day, generally three regular meals and two to three appropriate, healthy snacks. Portions should provide essential nutrients but not exceed energy requirements for the child.
- Occasional picky eating, a normal stage of development, is not associated with changes in nutrient intake or height and weight. Consuming a single food or foods for extended periods of time (food jag) may require monitoring of growth more frequently if it persists for a long time.

### OTHER GUIDELINES

- For energy needs, the current DRI recommends about 743 kcal/d for males and 676 kcal/d for females. Monitor according to the CDC growth charts, and identify problems early.
- Continue to provide breast milk or iron-fortified formula during this stage. The presence of DHA and arachidonic acid (ARA) in human milk, along with reports of higher IQ in individuals who were breastfed versus formula fed as infants, suggest that exogenous DHA and ARA are essential for optimal development (Heird and Lapillone, 2005).
- Special milk substitutes are not necessary unless there is an allergy to soy protein or cow's milk.
- Fluid requirements may include approximately 125–150 mL/kg up to 1 year of age. Fluid needs may begin to decline slightly during this stage.
- Protein requirement for a 6-month-old infant is generally 1.5 g/kg and changes as the infant grows; this equals about 13.5 g/d. By 12 months, the need is only 1.1 g/kg. See nutrient recommendations chart:
- As tolerated, introduce coarsely ground table foods by 10–12 months of age.
- Introduce cow's milk at 12 months of age, ensuring that intake does not go above 1 quart daily to prevent anemia. Use whole milk to include sufficient access to fatty acids.
- Begin to offer fluids by cup at approximately 9–12 months of age; weaning often occurs by about 1 year of age. Avoid sweetened beverages at this age whenever possible.
- Spicy foods often are not liked or not tolerated. Taste buds are very acute at this stage. This is also affected by culture and the seasoning of foods that are introduced.
- Continue use of iron-fortified baby cereal after 12 months of age to ensure adequate intake. Approximately 10 mg of iron is required. WIC-approved cereals are iron fortified. Adult cereals often are inappropriate for infants and children younger than 4 years of age.
- Discourage use of low-density, high-energy foods such as carbonated beverages, French fries, candy, and other sweets.
- Generally, healthy infants and toddlers can achieve recommended levels of intake from food alone; use foods rather than supplements as the primary source of nutrients for children (Briefel et al, 2006). When indicated, vitamin-mineral supplements can help infants and toddlers with special nutrient needs or marginal intakes. However, avoid excessive intakes of vitamin A, zinc, and folate, which are commonly fortified in the food supply (Briefel et al, 2006).
- Children who require tube feeding require specialty care. If the infant needs a tube feeding (e.g., for poor weight gain, low volitional intake, 5th percentile or lower for weight for height and age, slow and prolonged feeding times over 4–6 hours because of oral/motor problems), a standard isotonic tube feeding formula that provides 30 kcal/oz of intact proteins may be used. If necessary, lactose-free and gluten-free formulas are available. Added fiber and a mix of long- and medium-chain fatty acids may be useful. Osmolality of 260–650 mOsm/kg is common; monitor tolerances regularly. Be sure to use sufficient water. The infant may tolerate bolus feedings in the day and continuous feedings at night.

Nutrient	Recommendation for Infants Ages 6 Months to 1 Year
Energy	743 kcal/d males; 676 kcal/d females
Protein	13.5 g/d
Calcium	270 mg/d
Iron	11 mg/d
Folate	80 mg/d
Phosphorus	275 mg/d
Vitamin A	500 µg
Vitamin C	50 mg/d
Thiamin	0.3 mg/d
Riboflavin	0.4 mg/d
Niacin	4 mg/d

Data from: Food and Nutrition Board, Institute of Medicine. *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids (macronutrients)*. Washington, DC: National Academy Press, 2002.

- Avoid raw vegetables and fruits (other than ripe banana or soft, peeled apple). Beware of foods that may cause choking (e.g., hot dogs, popcorn, nuts, grapes, seeds) because toddlers do not have molars for proper chewing (Morley et al, 2004).

### Common Drugs Used and Potential Side Effects

- Drugs and medications used for infants should be prescribed only by a physician.

### Herbs, Botanicals, and Supplements

- Infants and children may be even more susceptible to some of the adverse effects and toxicity of these products because of differences in physiology, immature metabolic enzyme systems, and dose per body weight.
- Herbs and botanical supplements should not be used without discussing with the physician. In general, these types of supplements have not been proven to be safe for infants.
- Discuss the relevance of tolerable ULs from the latest dietary reference intakes of the National Academy of Sciences. These levels were set to protect adults from receiving

too much of any nutrient from diet and dietary supplements; infants are even more at risk for toxicities.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Early childhood is a critical time for development of appropriate food choices and eating habits, which are complex processes for parents to understand (Stang, 2006).
- Discuss adequate weight pattern: infants generally double or triple birth weight by 12 months of age; body length increases by about 55%; head circumference increases by about 40%; and brain weight doubles.
- Discuss the healthy guidelines that are available.
- For lunches at home, parents will need suggestions about appropriate and easy to serve foods, homemade or commercial, for toddler lunches and snacks (Ziegler et al, 2006).
- Special attention should be given to counsel mothers who are single, whose child is in day care, whose education or literacy is limited, or who are enrolled in the Special Supplemental Nutrition Program for Women, Infants, and Children (Hendricks et al, 2006).
- Assure parents and caregivers that, while infants and toddlers have an innate ability to regulate energy intake, there is potential for environmental cues to diminish natural hunger-driven eating behaviors, even among young toddlers (Fox et al, 2006). Overfeeding may result if children are not taught to recognize their natural cues about hunger and satiety.
- Encourage consumption of milk at home and other locations, such as restaurants and friends' homes, in place of fruit-flavored drinks or other sweetened beverages (Ziegler et al, 2006).
- All day care providers should be encouraged to use menu planning aids, such as those available from the U.S. Department of Agriculture (Ziegler et al, 2006).
- Discuss iron intake, fluid intake, and other nutritional factors related to normal growth and development, including calcium for bone health.
- Plan toddler snacks to complement meals by including additional fruits, vegetables, and whole grains that are culturally appropriate rather than fruit drinks, cookies, and crackers; this will increase fiber intake and limit fat and sugar intakes (Ziegler et al, 2006).
- To develop healthful eating patterns, introduce toddlers to foods 8 to 10 times to increase food acceptance and the likelihood of establishing healthful eating patterns (Ziegler et al, 2006).
- Discuss the role of fat-soluble vitamins, their presence in whole milk, and the role of EFAs in normal growth and development of the nervous system.
- Bottled waters are not a substitute for formula. Hyponatremia may result.
- Fluoridated water is recommended; check the community status. Fluoride supplements are not needed when the water supply is fluoridated and the infant receives adequate water from this source. Note that well water and most bottled waters are not fluoridated; supplementation should be discussed with the physician.
- When brushing teeth, be carefully not to use a large amount of fluoridated toothpaste. A very small amount suffices.
- For planning vegan diets in infancy, breast milk should be the sole food, with soy-based formula as an alternative. Breastfed vegan infants may need supplements of vitamin B<sub>12</sub>, zinc, and vitamin D. Protein sources for older vegan infants may include tofu and dried beans.
- Intensive nutrition education can help mothers provide more effective feeding practices. This is especially important in developing countries where inappropriate feeding, poor hygiene, and poor health often lead infants to a malnourished state (Roy et al, 2007).

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before breastfeeding or before formula preparation. Use clean utensils and containers for mixing formula. Wash the top of the can before opening.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Well water should not be used since it may contain bacteria.
- Follow the 2-hour rule: discard any formula, beverage, or food that has been left at room temperature for 2 hours or longer. Do not reuse.
- Do not use honey in the diets of infants to decrease potential exposure to botulism.
- Avoid using raw or partially cooked eggs, raw or undercooked fish or shellfish, and raw or undercooked meats because of potential foodborne illnesses.
- Do not use raw (unpasteurized) milk or products made from it.
- Avoid using unpasteurized juices and raw sprouts.
- For hospital preparation of infant formula, use available guidelines.

# CHILDHOOD

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

### DEFINITIONS AND BACKGROUND

The American Dietetic Association (2008) has taken the position that children between the ages of 2 and 11 years should have appropriate eating habits so they can achieve optimal physical and cognitive development, a healthy weight, enjoyment of their meals, and reduction of the risk for chronic disease.

While children are not “little adults” and should be treated individually, conversation with an adult is usually required to discuss actual food intake by a child. The ability to recall by children is often limited because of vocabulary and attention span. Children benefit from training, such as with pictures, food models and cups.

Growth during this stage involves changes in appetite, physical activity, and frequency of illnesses. The CDC growth charts provide a guideline for monitoring successful growth related to weight, height, and age. Body mass index (BMI) calculations are now available for use with children, and calculations may be used to identify underweight, potential stunting, or obesity. Prevalence of low height for age (stunting) low weight for age (wasting) and health issues can be higher than desirable.

During the early years of life, eating occurs primarily as a result of hunger and satiety cues. Evidence suggests that, by the time children are 3 or 4 years of age, eating is no longer driven by real hunger but is influenced by a variety of environmental factors, including presentation of larger por-

tions (Rolls et al, 2000) and parenting behaviors. Girls with mothers who are dieting have more ideas about dieting than girls with moms who do not diet (Abramovitz and Birch, 2000).

Children from underserved population groups may have increased risk for obesity, increased serum lipids, and poor dietary consumption patterns of dairy products, fruits, and vegetables. In the past few decades, children's dietary intakes have changed dramatically, and children are eating more meals away from home (Nicklas et al, 2004). Children are becoming more overweight and less active, often from physical inactivity and intake of energy-rich, nutrient-poor foods (American Dietetic Association, 2008). Intake of foods that are less healthful than desired (such as sugar-sweetened beverages, high-fat foods, and refined carbohydrates) plays a role in displacing nutrient-dense foods and can contribute to the risk of childhood obesity, type 2 diabetes, and adult chronic diseases (Stroehla et al, 2005). See Section 3 for childhood obesity and Section 9 for type 2 diabetes in children.

Many children live in poverty; some may be exposed to lead poisoning, others risk ID anemia. The preschool period (1–5 years of age) is a time of rapid and dramatic postnatal brain development, neural plasticity, and of fundamental acquisition of cognitive development such as working memory, attention and inhibitory control (Rosales et al, 2009). Because even mild undernutrition affects brain growth and function, food assistance programs should be

used whenever possible. Children need nutritious snacks to eliminate transient hunger. Attention is easily diverted at this age; total intake may vary from day to day. Scheduling of lunch after physical activity encourages greater intake of all foods and energy.

Misconceptions must be corrected, such as “good foods/bad foods” or “foods that are good for you taste bad.” Dietary fat restriction may compromise growth and should not be implemented. There is no proof of long-term safety and efficacy for restricting fat in children’s diets; lowered calcium, zinc, magnesium, phosphorus, vitamins E and B<sub>12</sub>, thiamin, niacin, and riboflavin intakes can be a problem.

The National Academy of Sciences recommends adequate dietary intake of calcium for the development of peak bone mass and prevention of fractures and osteoporosis later in life (Food and Nutrition Board, 2002). The current recommended adequate intake for children 9–18 years of age is 1300 mg/d, based on calcium-balance studies that show that, in healthy children of this age, maximal net calcium balance is achieved with this intake (Food and Nutrition Board, 2002).

Adequate calcium and vitamin D are essential during growth and into puberty, especially during rapid bone growth and mineralization. Current mean dietary intakes are below desired levels; families may need information (Greer and Krebs, 2006). Dietary calcium needs of children who take medications that alter bone metabolism are likely higher than usual.

Infectious diseases of childhood may be related to poor nutrition, especially lack of vitamin C, zinc, and vitamin A (Long et al, 2007). Children who are prone to repetitive illness may benefit from a basic multivitamin–mineral supplement in addition to a carefully planned diet. ID is another major concern in young children (Skalicky et al, 2006). Participation in WIC programs may be helpful (Altucher et al, 2005). Children should have access to an adequate supply of healthful and safe foods that promote optimal physical, cognitive, and social growth and development; nutrition assistance programs play a vital role (American Dietetic Association, 2010).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Each individual has a unique genetic profile and phenotype. Because both parents contribute genes and chromosomes to the fetus, a genetic history may be beneficial.

Clinical/History	Growth	Dental status
Age	percentile	Physical
Weight	for age	handicaps
Height	Diet/intake history	Appetite

Hydration (I & O)	Lab Work	Homocysteine
Triceps skinfold (TSF)	Glucose	Alk phos
Midarm muscle circumference (MAMC), midarm circumference (MAC)	H & H, serum Fe	Ca <sup>++</sup>
	Chol, Trig (check family history for risks)	Alb (if needed)

## INTERVENTION

### OBJECTIVES

- Assess growth patterns, feeding skills, dietary intake, activity patterns, inherited factors, and cognitive development. Promote adequate growth and development patterns such as increased independence at 12–18 months (stop bottle, begin eating with a spoon) and growth slowdown from 18 months to 2 years (less interest in food, begin eating with utensils); energy intake varies from 2 to 3 years (control exerted), and brain growth triples by age 6.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Lead Poisoning in Childhood

**Assessment Data:** Dietary recall; labs such as H & H, serum ferritin, and serum lead levels; growth charts.

**Nutrition Diagnosis (PES):** Excessive bioactive substance intake related to lead consumption from lead-based paint exposure in environment as evidenced by high serum lead levels, documented ID anemia, and deposition seen on x-rays.

**Intervention:** Education and counseling tips on avoiding accidental lead intake; increasing sources of iron and calcium in the diet; tips on reducing environmental lead sources; running water awhile before drinking.

**Monitoring and Evaluation:** Reduced intake of sources of lead; improved lab values, improved weight gain on growth grid; successful growth and development.

### Limited Fruit-Vegetable Consumption

**Assessment Data:** Dietary recall; growth charts; physical signs of malnutrition.

**Nutrition Diagnosis (PES):** Inadequate vitamin intake (vitamin C) related to minimal consumption of fruits and vegetables as evidenced by diet history, no use of children’s vitamins or fortified foods, and signs of bleeding gums, petechiae, irritability, and easy bruising.

**Intervention:** Education and counseling tips on improving intake of fruits and vegetables; recipes and tips for increasing citrus fruits and good sources of vitamin C in foods well accepted by children. Referral to WIC program if eligible.

**Monitoring and Evaluation:** Improved signs of nutrition and resolution of bleeding gums, etc; diet history and mother’s description of improved vitamin C intake and financial assistance from WIC.

- Avoid food deprivation, which may decrease ability to concentrate, cause growth failure or anemia, aggravate stunting, and lead to easy fatigue.
- Monitor long-term drug therapies and related side effects, such as use of anticonvulsants and the effects on folate, vitamin D and growth.
- Assess nutritional deficiencies, especially iron. If possible, detect and correct pica (eating nonfood items or any one food to the exclusion of others—even ice chips). Prevent “milk anemia” from drinking too much milk with meals and not consuming enough iron-rich meats, grains, and vegetables.
- Evaluate status of the child’s dental health. Prevent dental decay.
- Support adequate nutritional immunity through a balanced diet; encourage vaccinations to prevent infectious diseases such as measles, mumps, and tetanus.
- Promote adequate intake of calcium, vitamin D, fiber, and zinc, which are nutrients that are often poorly consumed by young children.
- Help reduce onset of chronic diseases later in life by prudent menu planning and meal intakes. Early lesions of atherosclerosis begin in childhood; diet, obesity, exercise, and certain inherited dyslipidemias influence progression of such lesions (American Heart Association,

2006; Holmes and Kwiterovich, 2005). Good nutrition, a physically active lifestyle, and absence of tobacco use can delay or prevent the onset of cardiovascular disease (American Heart Association, 2006).

- Avoid mislabeling overweight children as “fat,” which may trigger eating disorders (EDs) later. All providers should be aware of the problems of childhood obesity and refer accordingly. See entry in the text about childhood obesity.
- To promote proper growth, especially for stature, parents and caretakers should limit sweetened beverage intake to 12 fl oz/d; fruit juice should be only 4–6 oz daily for proper dental health and to prevent diarrhea. Encourage sufficient calcium intake from dairy beverages.
- Emphasize food variety to reduce fear of new foods (neophobia), which may reduce nutritional status. Introduction of many new foods and flavors before age 4 may be an important way to enhance children’s acceptance of new food items (Nicklas et al, 2005).

## FOOD AND NUTRITION

- Energy and nutrient requirements vary by age and sex; see charts below.

### Recommendation

Nutrient	Ages 1–3 Years	Ages 4–8 Years	Ages 9–13 Years
Energy	1046 kcal/d	1742 kcal/d	2279 kcal/d males; 2071 females
Protein	13 g/d or 1.1 g/kg	19 g/d or 0.95 g/kg	34 g/d or 0.95 g/kg
Calcium	500 mg/d	800 mg/d	1300 mg/d
Iron	7 mg/d	10 mg/d	8 mg/d
Folate	150 µg/d	200 µg/d	300 µg/d
Phosphorus	460 mg/d	500 mg/d	1250 mg/d
Vitamin A	300 µg	400 µg	600 µg
Vitamin C	15 mg/d	25 mg/d	45 mg/d
Thiamin	0.5 mg/d	0.6 mg/d	0.9 mg/d
Riboflavin	0.5 mg/d	0.6 mg/d	0.9 mg/d
Niacin	6 mg/d	8 mg/d	12 mg/d
Fiber	19 g	25 g	26 g females; 31 g males
Sodium	<1500 mg	<1900 mg	<2200 mg
Potassium	3000 mg	3800 mg	4500 mg

Data adapted from: A Report of the Panel on Macronutrients, Subcommittees on Upper Reference Levels of Nutrients and Interpretation and Uses of Dietary Reference Intakes, and the Standing Committee on the Scientific Evaluation of Dietary Reference Intakes; Food and Nutrition Board; and Institute of Medicine. *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids*. Washington, DC: The National Academies Press, 2005:1357.

- The American Dietetic Association (2008) supports the following macronutrient distribution:

**Carbohydrates**—45–65% of total calories. Added sugars should not exceed 25% of total calories (to ensure sufficient intake of essential micronutrients).

**Fat**—30–40% of energy for 1–3 years and 25–35% of energy for 4–18 years.

**Protein**—5–20% for young children and 10–30% for older children. Include protein foods with 50% high biological value when possible.

- The American Heart Association and the American Academy of Pediatrics support portion control and energy intake as shown in Table 1-10. Where there is evidence or high risk for cardiovascular disease, start with a diet low

**TABLE 1-10 Daily Estimated Calories and Recommended Servings in Children and Teens**

	1 Year	2–3 Years	4–8 Years	9–13 Years	14–18 Years
Kilocalories <sup>a</sup>					
Female	900	1000	1200	1600	1800
Male	900	1000	1400	1800	2200
Fat, % of total kcal	30–40	30–35	25–35	25–35	25–35
Milk/dairy, cups <sup>b</sup>	2 <sup>c</sup>	2	2	3	3
Lean meat/beans, oz	1.5	2		5	
Female			3		5
Male			4		6
Fruits, cups <sup>d</sup>	1	1	1.5	1.5	
Female					1.5
Male					2
Vegetables, cups <sup>d</sup>	3/4	1			
Female			1	2	2.5
Male			1.5	2.5	3
Grains, oz <sup>e</sup>	2	3			
Female			4	5	6
Male			5	6	7

Calorie estimates are based on a sedentary lifestyle. Increased physical activity will require additional calories: increase of 0–200 kcal/d if moderately physically active and increase of 200–400 kcal/d if very physically active.

<sup>a</sup>For child 2 years and older; adapted from Tables 2 and 3 and Appendix A-2 in U.S. Department of Health and Human Services, U.S. Department of Agriculture. *Dietary guidelines for Americans*. 6th ed. Washington, DC: U.S. Government Printing Office, 2005; [www.healthierus.gov/dietaryguidelines](http://www.healthierus.gov/dietaryguidelines). Nutrient and energy contributions from each group are calculated according to the nutrient-dense forms of food in each group (e.g., lean meats and fat-free milk).

<sup>b</sup>Milk listed is fat free (except for children under the age of 2 years). If 1%, 2%, or whole-fat milk is substituted, this will use, for each cup, 19, 39, or 63 kcal of discretionary calories and add 2.6, 5.1, or 9.0 g of total fat, of which 1.3, 2.6, or 4.6 g are saturated fat, respectively.

<sup>c</sup>For 1-year-old children, calculations are based on 2% fat milk. If 2 cups of whole milk are substituted, 48 kcal of discretionary calories will be utilized. The American Academy of Pediatrics recommends that low-fat/reduced-fat milk not be started before 2 years of age.

<sup>d</sup>Serving sizes are 1/4 cup for 1 year of age, 1/3 cup for 2–3 years of age, and 1/2 cup for ≥4 years of age. A variety of vegetables should be selected from each subgroup over the week.

<sup>e</sup>Half of all grains should be whole grains.

Sources: American Heart Association, 2006, and Pediatrics Web site, <http://pediatrics.aappublications.org/cgi/content/full/117/2/544/T3>; accessed February 2, 2009.

in total and saturated fat, trans fats, and cholesterol; use water-soluble fiber and plant sterols; promote weight control and exercise (Holmes and Kwiterovich, 2005). For example, select lower fat foods, use low-fat cooking techniques, spread jelly on bread instead of butter.

- Offer calcium to increase mineral density. Yogurt, plain or flavored milks, calcium-fortified juices or soy milk, soft-serve ice cream, and cheeses are generally well accepted by children. If dairy foods are not used, include foods such as 1 oz of cooked dried beans (161 mg), 10 figs (169 mg), spinach (120 mg), 1 packet of oatmeal (100 mg), 1 medium orange (50 mg), 1/2 cup of mashed sweet potato (44 mg), or 1/2 cup of cooked broccoli (35 mg).
- Phosphorus intake should be relatively similar to calcium intake.
- Give 50–60 mL/kg of fluids daily. Milk, fruit juice, vegetable juices, and water should be the basic fluids offered. Cut out carbonated beverages as much as possible.
- Encourage exposure to sunlight and monitor dietary intake of vitamin D. Adequate folate, magnesium, selenium, and vitamin E are important to obtain from dietary sources.
- Day care meals given for a 4- to 8-hour stay should provide for one third to one half of daily needs. School lunch

programs generally provide one third of daily needs. Meals at home should be planned carefully to make up the difference.

- Fiber from fruits, vegetables, grains, and legumes may help to prevent or alleviate constipation. Ensure that adequate fluid is consumed each day.

### Common Drugs Used and Potential Side Effects

- Anticonvulsants may cause problems with the child's growth and normal body functions. Diet should be adjusted carefully, such as increasing intake of folate.
- Corticosteroids may cause growth stunting if given over an extended time in large doses.
- Drug therapy with inhibitors of hydroxymethylglutaryl CoA reductase, bile acid sequestrants, and cholesterol absorption inhibitors may be considered in those with a positive family history of premature coronary artery disease and a low-density lipoprotein (LDL) cholesterol level above 160 mg/dL after dietary and lifestyle changes (Holmes and Kwiterovich, 2005).
- Nutritional supplements should be taken only when prescribed by a physician, although over-the-counter use is

common. Avoid serving cereals to children that fulfill the adult RDAs for vitamins and minerals. Poly-Vi-Fluor contains fluoride; use caution in areas where water is fluoridated. Too much can cause fluorosis.

- Stimulants such as methylphenidate (Ritalin) or dextroamphetamine (Dexedrine) work on dopamine levels and may cause anorexia, growth stunting, nausea, stomach pain, or weight loss; use frequent snacks. Strattera (atomoxetine) works on norepinephrine; it may also decrease appetite.
- Tofranil (imipramine,) used for bedwetting, can cause dry mouth. Include adequate liquids.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements have not been proven to be safe for children. While not needed or desirable, use of nutrient supplements is common in the first 2 years of life (Eichenberger Gilmore et al, 2005).
- Discuss the relevance of tolerable ULs from the dietary reference intakes of the National Academy of Sciences. These levels were set to protect individuals from receiving too much of any nutrient from diet and dietary supplements.
- Children are more prone to toxicity than adults. For example, jinhuan causes bradycardia and CNS and respiratory depression and is to be avoided in children; fenugreek may trigger asthma in susceptible individuals.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Children should be treated respectfully. Converse with the child and not only with parents or caregivers. A personalized conversation elicits the most effective response. Review Erikson's developmental phases of childhood (1963): toddlers 1–3 years of age want autonomy; preschoolers 4–6 years of age seek initiative; and school-age children (6–12 years of age) are industrious. Age-appropriate games, projects, or tasks help in learning nutrition concepts.
- Explain the age-appropriate diet for children. Encourage parents to use finger foods for toddlers. Young children have food jags, and they often prefer single foods. Older children need nutritious snacks such as cheese cubes and iron-rich desserts. Avoid use of high-energy foods with low nutrient value.
- Encourage a relaxed atmosphere at mealtime, without pressure to eat, hurry, or finish meals. Bribery or rewards for eating should not be used; rewards can actually decrease acceptance. Parents must not “control” meals or foods; disordered eating may result.
- Education is needed to support optimal nutrition and physical activity; see Table 1-11 (American Heart Association, 2006).
- With toddlers, continue use of iron-fortified cereal and juices that are naturally high in vitamin C.
- Children should be allowed to vary in their food acceptance, choices, and intake. An authoritative feeding style is generally more effective than an authoritarian style (Patrick et al, 2005).
- Proper atmosphere is important to children since their eating patterns are strongly influenced by both the physical and social environment. Children are more likely to eat foods that are available and easily accessible; they tend to eat greater quantities when larger portions are provided; and structured family mealtimes are important (Patrick and Nicklas, 2005).
- Many children skip breakfast each day. Discuss the importance of eating breakfast for enhancing the abilities to concentrate, learn, and retain new information. Breakfasts should contain a variety of foods, with high-fiber and nutrient-rich whole grains, fruits, and dairy products (Rampersaud et al, 2005).
- Promote healthy meals at school. School-aged children need adequate meals and snacks to eliminate transient hunger. Recess before lunch is a good way to increase intake.
- Both school and the community have a shared responsibility to provide students with high-quality foods and school-based nutrition services (American Dietetic Association, 2006). Establish at least one “champion” for nutrition issues at school (e.g., a parent, the principal, the foodservice manager), and promote teamwork (Making It Happen, 2009). Standards should allow children to have access to nutritious choices.
- Knowledge and training are needed to improve food consumption patterns as children consume foods away from home and as they take on greater responsibility for meal preparation and food selection.
- Zinc absorption is improved when consumed with dairy products (Baylor, 2009).
- Vegan children should be encouraged to consume adequate sources of vitamin B<sub>12</sub>, riboflavin, zinc, and calcium, and vitamin D if sun exposure is not adequate.
- Children who have chronic illnesses fare better if parents give them responsibilities, such as meal planning and taking their own medications. Tasks should be age appropriate. Section 3 addresses pediatric illnesses in greater detail.
- Nutrition education targeting low-income African-American parents should address planning and preparing convenient and economical meals and snacks that include fruits and vegetables using social support strategies (Hildebrand and Shriver, 2010).
- Specific considerations about lead poisoning and measles are found in Table 1-12.
- Adult diseases often have a fetal or childhood onset. Childhood height, growth, diet and BMI have been associated with breast cancer later in life (Ruder et al, 2008). Size at birth, rapid weight gain, and childhood growth patterns affect the onset of type 2 diabetes (Dunger et al, 2007). Elevations in homocysteine levels begin in childhood and have implications for stroke and heart disease (Kerr et al, 2009).
- A dramatic increase in childhood obesity is related to many things, including decreased physical activity and fitness. Too much time in front of the television or computer results in low energy expenditure. Promote healthy forms of activity; the USDA Kids' Activity MyPyramid Food Guidance System is a useful guide. Table 1-13 provides suggestions for increasing physical activity.

**TABLE 1-11 General Dietary Recommendations for Children Aged 2 years and Older**

Balance dietary calories with physical activity to maintain normal growth.

Get 60 minutes of moderate to vigorous play or physical activity daily.

Use fresh, frozen, and canned vegetables and fruits and serve at every meal.

Limit high-calorie sauces such as Alfredo sauce, cream sauces, cheese sauces, and hollandaise.

Use canola, soybean, corn, safflower, or olive oils in place of solid fats during food preparation.

Reduce the intake of sugar-sweetened beverages and foods. Limit juice intake to 1–2 servings.

Use nonfat (skim) or low-fat milk and dairy products daily.

Remove the skin from poultry before eating.

Use only lean cuts of meat and reduced-fat meat products.

Introduce and regularly serve fish as an entree, especially oily fish, broiled, or baked.

Use recommended portion sizes on food labels when preparing and serving food.

Eat whole-grain breads and cereals rather than refined products; read labels and ensure “whole grain” as the first ingredient on the food label (Thane et al, 2005).

Eat more legumes (beans) and tofu in place of meat several times a week.

Reduce salt intake, including salt from processed foods (breads, breakfast cereals, soups).

Read food labels and choose high-fiber, low-salt/low-sugar alternatives.

### **Patient Education—Food Safety**

- Children should be taught to wash their hands before eating and after use of the toilet, sneezing, etc., to prevent foodborne illness and the spread of various infections.
- Children can be taught to avoid food and beverages that have an unusual flavor or odor.
- Avoid raw or partially cooked eggs, raw or undercooked fish or shellfish, and raw or undercooked meats because of potential foodborne illnesses.
- Five of the most commonly eaten varieties of fish are low in mercury (shrimp, canned light tuna, salmon, pollack, and catfish); AHA continues to recommend two servings of fish weekly (American Heart Association, 2006).

**TABLE 1-13 Tips for Encouraging Children to Enjoy Nutrition and Physical Activity**

Children should be empowered to make food choices that reflect the Dietary Guidelines for Americans.

Good nutrition and physical activity are essential to children’s health and educational success.

School meals that meet the Dietary Guidelines for Americans should appeal to children and taste good.

Programs must build upon the best science, education, communication, and technical resources available.

School, parent, and community teamwork is essential to encouraging children to make food and physical activity choices for a healthy lifestyle.

Messages to children should be age appropriate and delivered in a language they speak, through media they use, and in ways that are entertaining and actively involve them in learning.

Focus on positive messages regarding the food choices children can make.

Support education and action at national, state, and local levels to improve children’s eating behaviors.

Source: USDA Team Nutrition, <http://www.fns.usda.gov/tn>; accessed January 31, 2009.

- Do not use raw (unpasteurized) milk or products made from it.
- Avoid serving unpasteurized juices and raw sprouts.
- Only serve certain deli meats and frankfurters that have been reheated to steaming hot temperature.
- Child care centers should follow guidelines for safe food handling and for inclusion of nutritious meals and snacks (American Dietetic Association, 2010). A safe and sanitary setting is needed.

**TABLE 1-12 Special Considerations in Children: Lead Poisoning and Measles**

**Lead Poisoning:** Lead poisoning is the most common environmental health problem affecting American children. Exposure occurs through ingestion of lead-contaminated household dust and soil in older housing containing lead-based paint. Lead replaces calcium in the bone; deposition may be seen in x-rays of the knee, ankle, or wrist. Anemia may also occur. Lead is also a confirmed neurotoxicant; lower arithmetic scores, reading scores, nonverbal reasoning, and short-term memory deficits occur. Nutritional interventions suggest regular meals with adequate amounts of calcium, and iron supplementation. Parents need education about lead exposure, hygiene, and housekeeping measures to prevent ingestion of dust and soil. Use drinking water from the cold tap, not hot water tap. Bottled water is not guaranteed as a safe alternative. Blood lead screening may be recommended universally at ages 1 and 2 years. For more information, visit the CDC website: <http://www.cdc.gov/nceh/lead/lead.htm> and the Environmental Protection Agency website at: <http://www.epa.gov/lead/pubs/nlic.htm>.

**Measles and Blindness in Children:** Childhood blindness and visual impairment in developing countries remains a significant public health issue (Maida et al, 2008). Control of blindness in children is a priority within the World Health Organization’s VISION 2020 program. Vitamin A supplementation and measles immunizations have caused a decrease in xerophthalmia; cataract is more treatable (Maida et al, 2008).

# ADOLESCENCE

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Adolescents need to consume food and beverages that provide adequate energy and nutrients to reduce risk for poor outcomes including growth retardation, ID anemia, poor academic performance, development of psychosocial difficulties, and an increased likelihood of developing diseases such as heart disease and osteoporosis (American Dietetic Association, 2010). Breakfast consumption is important to enhance cognitive function related to memory, test grades, and school attendance (Rampersaud et al, 2005).

Physiological growth is more accurately assessed by using Tanner Stages than by chronological age alone. Girls often

start their growth spurt by age 10–11 and generally stop by age 15, whereas boys begin at 12–13 and generally stop by age 19. Teens require increased nutrients for accelerated growth; deficiencies can lead to loss of height, osteoporosis, and delayed sexual maturation.

Skeletal growth is unpredictable, and girls may gain 3.5 inches in 1 year, and boys may gain 4 inches in 1 year. When the teen years begin, the adolescent has achieved 80–85% of final height, 53% of final weight, and 52% of final skeletal mass. Teens may almost double their weight and can add 15–20% in height. Maintaining adequate calcium intake during childhood and adolescence is necessary for the development of peak bone mass, which may be important in

reducing the risk of fractures and osteoporosis later in life (Greer and Krebs, 2006).

Some teens develop more rapidly than others (early maturers), while others may develop more slowly (late maturers). The Tanner stages of development are more useful than just use of chronological age. Girls who mature early may be prone to depression, EDs, and anxiety. Obesity is an increasing trend. Parental pressure and weight status concerns are evident among girls who are “picky eaters” (Galloway et al, 2005).

Intakes change often during teen years, especially during growth spurts and stages of physical maturation. Sociocultural influences affect adolescent eating patterns and behaviors. Some teens reject a meat-based diet to become vegetarians; others take up dieting to lose weight or develop an ED. Meal skipping, snacks at odd hours, laxative or diuretic use, fasting, bulimia, self-induced vomiting, and sports requirements are issues that should be addressed in a nutritional assessment. Food choices established during childhood and adolescence tend to persist into adulthood (Fitzgerald et al, 2010). Adolescents need improved diets. Fast food is one factor that impacts adolescents’ intake of nutrient-dense foods (Sebastian et al, 2009).

Daily requirement tables separate preteens as ages 9–13 years and teen years as ages 15–18 years. The growth spurt of girls occurs at 9½ to 13½ years of age; menarche generally occurs at 12½ years. For boys, the growth spurt occurs between 11 and 14½ years. Sexual maturation occurs at ages 10–12 years for girls and at ages 12–14 years for boys. The increase in percentage of total body fat in girls is 1.5–2 times that in boys at this time. Boys have greater increases in lean body mass (LBM, muscle) and greater increases in height before epiphyseal closure of long bones occurs. Most skeletal growth is completed by 19 years of age. Girls have more total body fat and less total body water than boys.

According to Erickson’s psychological stages of development (1968), teens (12–18 years of age) are working on “identity.” In cognitive development, the concrete, “here and now” stage lasts from ages 11 to 14 years in girls and from ages 13 to 15 years in males. Early abstract thinking and daydreams are common among 15- to 17-year-old females and 16- to 19-year-old males. True abstract thinking and idealism (faith, trust, and spirituality) occur for young women at ages 18–25 years and for males at 20–26 years of age.

The brain continues developing through late adolescence, especially with the nerve fiber system that transmits messages from one hemisphere to the other. There is an increase in gray matter at the onset of adolescence, followed by a substantial loss in the frontal lobes from the mid-teens through the mid-twenties, where inhibiting impulses and regulating emotions may be altered. Teens should make the most of their brains during this time, when they can “hard wire” their ability to process skills in academics, sports, and music. Among adolescents, parental control begins to diminish; teens exercise more autonomy over their food choices as compared with children (Fitzgerald et al, 2010).

Dietary intake and body size influence age at menarche and growth patterns in teen girls. Puberty comes early for some girls because of a gene (*CYP11B1*) that speeds up the body’s breakdown of androgens as well as percentage of energy intake from dietary protein. These factors have implications for later development of diseases, including breast

cancer and heart disease. Another concern is polycystic ovarian syndrome (PCOS). The genetic polymorphisms are not yet clearly identified, but the risks for metabolic syndrome, diabetes, infertility and heart disease must be managed. Diet, physical activity, insulin-sensitizers or anti-androgen medications may be useful. Weight loss of 5–10% may help improve blood functions and ovarian function.

Teens should have access to an adequate supply of healthful and safe foods that promote optimal physical, cognitive, and social growth and development; nutrition assistance programs play a vital role (American Dietetic Association, 2010).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Each individual has a unique genetic profile and phenotype. Because both parents contribute genes and chromosomes to the fetus, a genetic history may be beneficial.

Clinical/History	Tanner stage of sexual maturation	Sleep disorder screening
Age		
Height	Hydration status	<b>Lab Work</b>
Weight	(I & O)	H & H, serum
Weight/height percentile	Physical activity level or athletics	Fe
BMI or HBW	Physical handicaps	Glucose
Waist to hip ratio	Disordered eating patterns	Chol
Recent changes (height, weight)	GI complaints	Trig
Diet history	Signs of PCOS in girls	Albumin (if needed)
		Na <sup>+</sup> , K <sup>+</sup>
		Ca <sup>++</sup> , Mg <sup>++</sup> , phosphorus
		Homocysteine

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Disordered Eating Pattern

**Assessment Data:** Dietary recall; labs such as H & H, serum ferritin; growth charts; recent growth spurt; age at menarche.

**Nutrition Diagnosis (PES):** Disordered eating pattern related to dieting behavior as evidenced by restricted eating, skipping breakfast, frequent infections, BMI of 19, low H & H, irregular intake of nutrient-dense foods and daily consumption of fast foods.

**Intervention:** Education and counseling tips on desirable nutritional intake in adolescence; consequences on energy, appearance and health from poor dietary habits.

**Monitoring and Evaluation:** Improved intake of nutrient-dense foods; improved lab values, improved quality of life (energy for school, recreation, and physical activity) and fewer illnesses.

## INTERVENTION

## OBJECTIVES

- Provide adequate energy for growth and development, especially for current and future growth spurts.
- Evaluate the patient's weight status. Offer appropriate guidance.
- Prevent or correct nutritional anemias. Determine a girl's sexual maturity, onset of menstruation, and growth spurts, which are often associated with iron depletion. Alter diet accordingly to provide sufficient vitamins and minerals.
- Evaluate use of fad diets, skipping meals, unusual eating patterns, or tendency toward EDs. If problems are noted, seek immediate assistance. Family therapy may be beneficial.
- To prevent obesity in a teen whose parents are obese, a family approach focused on regular breakfast consumption is most beneficial (Fiore et al, 2006).
- Prevent future tendency toward osteoporosis. Because of the influence of the family's diet on the diet of children and adolescents, adequate calcium intake by all members of the family is important; low-fat dairy products, fruits and vegetables, and appropriate physical activity are important for achieving good bone health (Greer and Krebs, 2006).
- Encourage healthy food choices according to the factors of greatest interest to teens (taste and appearance). Health, energy, and price are often not viewed as essential at this stage. Introduce food changes one at a time.
- Vegetarians should be encouraged to consume adequate sources of vitamin B<sub>12</sub>, riboflavin, zinc, iron, calcium, protein, and energy for growth. Cobalamin deficiency, in the absence of hematologic signs, may lead to impaired cognitive performance. Vegan children tend to have higher intakes of fiber and lower intakes of saturated fatty acids and cholesterol than omnivore children; they may need to increase intake of omega-3 fatty acids.
- Girls may have higher total serum cholesterol concentration than boys, somewhat related to differences in male and female hormones.

## FOOD AND NUTRITION

- The MyPyramid Food Guidance System: 4 cups of milk or equivalent source of calcium; 2–3 servings of meat or equivalent; 6–12 servings from the bread group; 2–4 servings of fruit or juices; 3–5 servings from vegetable group.
- Protein intake should be sufficient to support growth. For energy needs, see nutrient recommendation charts.

Nutrient	Recommendation	
	Males 14–18 Years	Females 14–18 Years
Energy	3152 kcal/d	2368 kcal/d
Protein	52 g/d or 0.85 g/kg/d	46 g/d or 0.85 g/kg/d
Calcium	1300 mg/d	1300 mg/d
Iron	12 mg/d	15 mg/d
Folate	400 µg/d	400 µg/d
Phosphorus	1250 mg/d	1250 mg/d
Vitamin A	900 mg	700 mg
Vitamin C	75 mg/d	75 mg/d
Thiamin	1.2 mg/d	1.0 mg/d
Riboflavin	1.3 mg/d	1.0 mg/d
Niacin	16 mg/d	14 mg/d

Data from: Food and Nutrition Board, Institute of Medicine. *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids (macronutrients)*. Washington, DC: National Academy Press, 2002.

- Snacks should be planned as healthy options. Snacking frequency affects intake of macronutrients and a few micronutrients and promotes consumption of fruits; an excess of discretionary calories as added sugars and fats (Sebastian et al, 2009).
- Adequate zinc and iodine are needed for growth and sexual maturation; use iodized salt and foods such as meat and dairy products.
- Calcium is needed for bone growth; vitamins D and A are also essential in this age group. Iron is needed for menstrual losses in girls.
- Debut age of drinking alcohol is important to note. If drinking begins before age 15, there is twice the risk of substance abuse and four times the risk of dependence.
- Diet for athletes: an acceptable diet for the athlete would be a normal diet for age, sex, and level of activity plus adequate intake of carbohydrates and fluids. Avoid excess of protein and inadequate replacement of electrolytes (see Sports Nutrition entry).
- For pregnant teens, follow guidelines listed in Table 1-14.

**TABLE 1-14 Special Considerations for Adolescent Pregnancy**

Issue	Comments
Mother is still growing	Check gynecological age (chronological age less age of menarche) to determine future potential growth of the mother.
Low birth weight (LBW) and prematurity	Fetuses grow more slowly in 10- to 16-year-olds. Increased weight in the last trimester is helpful in lessening the incidence of LBW.
Fetal growth and optimal nutritional status during and after gestation	By the end of the pregnancy, the mother's desired weight gain should be between 25 and 35 lb. Add desired increments for energy for requirements of same-age nonpregnant teens, or monitor the weight gain pattern to assess the adequacy of the present diet. Adolescents are at high risk of gaining an excessive amount of weight during pregnancy and should be monitored during pregnancy by dietetics professionals.
Protein requirements	Protein requirement is 1.1 g/kg body weight for most adolescents.
Prenatal supplements	The physician will prescribe prenatal vitamins.
Meal patterns	Mom will need 5 cups of milk, 3 servings of protein or meat, 4 servings of fruits/vegetables, 4 servings of breads/cereals. Three snacks daily will be needed.
Nutrients needed	Frequently missing nutrients include calcium, zinc, iron, folate, vitamins A and B <sub>6</sub> and C. Nutrient-dense choices include: Vitamin A: Chicken liver, cantaloupe, mango, spinach, apricots. Vitamin C: Citrus fruits and juices, broccoli, spinach, melon, strawberries. Calcium: Low-fat milk, yogurt, broccoli, cheddar cheese, low-fat shakes, skim-milk cheeses. Iron: Liver, rice, whole milk, raisins, baked potatoes, enriched cereal. Vitamin B <sub>6</sub> : White meats, bananas, potatoes, egg yolks. Folacin: Wheat germ, spinach, asparagus, strawberries. Zinc: Apples, chicken, peanut butter, tuna, rice, whole milk.
Bad habits, cravings, and aversions	Discourage skipping of meals. Cravings are common, especially for chocolate, fruit, fast foods, pickles, and ice cream. Watch for aversions to meat, eggs, and pizza during this time.
Iron deficiency anemia (IDA) during pregnancy	Women who conceive during or shortly after adolescence are likely to enter pregnancy with low or absent iron stores. IDA during pregnancy is associated with significant morbidity for mothers and infants; supplementation is a strategy to improve iron balance in pregnant teens.
Smoking	Pregnant teens are more likely to smoke, to deliver preterm infants, and to have their infants die in the first year than other mothers (Markovitz et al, 2005).
Resistance to authority figures	Encourage the teen to see herself as having a key role in providing good nutrition for her new family. Allow her to express her feelings and concerns.
WIC Program	Encourage enrollment in programs such as WIC where an individualized nutrition risk profile is developed for each pregnant teen. Positive outcomes are noted in birth weight, rates of low or very low birth weight, preterm delivery, maternal morbidity, and perinatal morbidity/mortality (Dubois et al, 1997).

## Common Drugs Used and Potential Side Effects

- Vitamin-mineral supplements are not needed, except for pregnant teens or teens whose diets are generally inadequate (such as those following an unplanned vegetarian pattern or restricted energy plans). The majority of American teens do not use supplements; those who do use them tend to eat a more nutrient-dense diet than those who do not. Vitamins A and E, calcium, and zinc tend to be low regardless of use of supplements. In addition, excesses of these nutrients are not recommended and may lead to toxic levels of vitamins A and D if taken indiscriminately.
- Discuss the relevance of tolerable ULs from the dietary reference intakes of the National Academy of Sciences. These levels were set to protect individuals from receiving too much of any nutrient from diet and dietary supplements.
- Monitor use of nonprescription medications (such as aspirin and cold remedies) and use of illegal drugs, including marijuana and alcohol. Side effects may include poor oral dietary intakes of several nutrients. Smoking cigarettes tends to decrease serum levels of vitamin C.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. In general, these supplements have not been proven to be safe for adolescents. There may be subgroups that are at risk for inappropriate use of these products (e.g., individuals with EDs and athletes).
- The use of multivitamin–mineral preparations is most common. More males than females use creatine and diuretics. Females consume herbal weight control products significantly more than males.
- Athletes reported supplementing with creatine and protein. There may be misguided beliefs in performance enhancement by these products.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain the MyPyramid Food Guidance System and the rationale behind the concepts. School-based interventions to promote healthy choices are beneficial.

- Diets of teens are often low in vitamins A and C, folate, and iron. Discuss the concept of nutrient density; food comparison charts are useful. Encourage a minimum of five servings of fruits and vegetables daily. Having easy access to ready-to-eat, appealing fruits and vegetables is important (Befort et al, 2006). Educate about desirable snacks; link discussions to dental and oral health.
- Limit intake of sweetened beverages (soda, sweetened tea, fruit drinks) to improve nutrient density (Nelson et al, 2009) and to prevent or correct obesity (Dubois et al, 2007).
- Explain the relation of diet to the needs of the adolescent athlete, as well as its influence on skin, weight control, and general appearance.
- Discuss body image, heroes, and peer pressure. Boys generally want larger biceps, shoulders, chests, and forearms. Girls often want smaller hips, waistlines, and thighs, and larger bustlines.
- The 5-year period between adolescence and adulthood is a time of potential weight gain. Emphasize the importance of not skipping meals, especially breakfast. Discourage obsessions with dieting and weight and promote safe dieting practices when needed.
- Discuss calcium and vitamin D; many adolescent girls consume inadequate amounts. Assess current intake by asking questions such as: How many times a day do you drink milk or eat cheese and yogurt? Have you had any bone fractures? Low-fat dairy products may be helpful for maintaining or achieving a HBW; use 3–4 servings daily. Teens who live in northern climates may need extra vitamin D intake (Sullivan et al, 2005).
- Teens respond well to discussions that respect their independence, sense of justice, and idealism. One of their roles is to establish a clear identity of how they fit into the world. Teens spend increased amounts of time with their friends but still tend to conform to parental ideals when it comes to values, education, and long-term life plans. Help the family recognize the adolescent's need for independence in choosing meals and snack items.
- Teens often feel that "it can't happen to me," prompting them to take unnecessary risks like drinking and driving ("I won't crash this car"), having unprotected sex ("I can't possibly get pregnant"), or smoking ("I can't possibly get cancer"). Effects of various nutrients on appearance or energy levels may be helpful.
- Encourage family meals and discuss options for nourishing meals eaten away from home ("portable foods"). Parents play a large role in modeling eating behavior; today's access to low density, high-energy foods must be carefully managed to prevent obesity (Savage et al, 2007). Parents need to limit soft drink consumption and encourage intake of calcium-rich beverages (Cluskey et al, 2008).
- Parents need to work closely with physicians when there are childhood-onset disorders, especially when it is time to change from a pediatrician to a doctor treating young adults (Peter et al, 2009).
- Consumption of fast food is common and may contribute to weight gain if not carefully monitored. A focus on eating or physical activity behaviors without discussing weight specifically is preferred over direct approaches about weight (Shrewsbury et al, 2010).

### Patient Education—Food Safety Tips

- Since teens may not think about the consequences of their actions, gentle reminders about hand washing and safe food handling may be important. Use of hand sanitizers may be popular among teen girls.
- Avoid raw or partially cooked eggs, raw or undercooked fish or shellfish, and raw or undercooked meats because of potential foodborne illnesses.
- Do not use raw (unpasteurized) milk or products made from it.
- Avoid serving unpasteurized juices and raw sprouts.
- Only serve processed deli meats and frankfurters that have been reheated to steaming hot temperature.
- Safe food handling is an important part of school food service (American Dietetic Association, 2006).

## PHYSICAL FITNESS AND STAGES OF ADULthood

# SPORTS NUTRITION

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Many athletes are involved in active sports (running, jogging, weight lifting, or wrestling) when they seek nutritional guidance. Questions about weight control, disordered eating patterns, and wellness are common; fewer athletes have questions about conditions such as diabetes. During high physical activity, energy and protein intakes must be met to maintain body weight, replenish glycogen stores, and provide adequate protein for building and repairing tissues (American Dietetic Association, 2009). Use of carbohydrate drinks can maintain energy intake and prevent dehydration.

Female children and adolescent athletes may develop nonanemic ID (Unnithan and Gouloupoulou, 2004), disordered eating, menstrual dysfunction, or decreased BMD. Pediatricians need to carefully monitor their health. All athletes should be screened for ID using serum ferritin, serum transferrin receptor, and hemoglobin (Sinclair and Hinton, 2005).

Female athletes who are under intense pressure to have a low percentage of body fat for performance, may have disordered eating with subsequent amenorrhea and osteoporosis, the "female athlete triad." This triad is serious and requires a multidisciplinary approach. Perfectionism enhances the risk for disordered eating, especially in varsity athletes. Prevention requires de-emphasis on percentage of body fat and adequate emphasis on good nutrition. The consequences of lost BMD can be devastating; premature osteoporotic fractures can occur, and lost BMD might never be regained. Winter sports may protect bone density because of the vigor required.

The primary fuel for athletic events using less than 50%  $VO_{2max}$  (or aerobic capacity) is fat. Muscle glycogen and blood glucose supply half of the energy for aerobic exercise during a moderate workout (at or below 60% of  $VO_{2max}$  or aerobic capacity) and nearly all the energy during a hard workout (above 80% of aerobic capacity). In short-duration events of more than 70%  $VO_{2max}$  (as in events like swimming or sprint running), glycogen is the key fuel. In long-duration events or activities of more than 70%  $VO_{2max}$  (such as long-distance running, cycling, or swimming), muscle glycogen

can be depleted in 100–120 minutes; maintaining a high-carbohydrate daily diet while training for adequate glycogen replenishment is necessary.

Carbohydrate (CHO) ingestion during prolonged exercise and CHO loading before exercise can have different effects on fuel substrate kinetics. The glycemic index of the carbohydrates consumed during the immediate postexercise period might not be important as long as sufficient carbohydrate is consumed; high insulin concentrations following a high-glycemic index meal later in the recovery period could facilitate further muscle glycogen resynthesis (Stevenson et al, 2005). Elite athletes may metabolize CHO more effectively than nonathletes, but nutritional factors still affect glycemic control (Chou et al, 2005).

Performance in endurance events depends upon maximal aerobic power, sustained by the availability of substrates (carbohydrates and fats). Fatigue is associated with reduced muscle glycogen; increasing muscle glycogen or blood glucose prolongs performance, while increasing fat and decreasing CHO decreases performance.

A sports diet aligns 20% protein, 30% CHO, and 30% fat, with the remaining 20% of the energy distributed between CHO and fat based on the intensity and duration of the sport. Table 1-15 lists the position statements of the International Society of Sports Nutrition.

Trained individuals have higher levels of fat oxidative capacity, which spares glycogen during endurance sports. Endurance runners who eat a low-fat diet may not consume enough energy, EFAs, and some minerals, especially zinc; these inadequate intakes may compromise their performance. Gymnasts often have a lower weekly calorie intake but a higher dietary protein intake than nonathletes; this places them at risk of malnutrition and immunosuppression.

A qualified sports dietitian who is Board-Certified Specialist in Sports Dietetics can provide individualized nutrition direction and advice following a comprehensive nutrition assessment (American Dietetic Association, 2009). Athletes should be well hydrated before the start of exercise and should drink enough fluid during and after exercise to balance fluid losses. Consumption of sports drinks containing

**TABLE 1-15 International Society of Sports Nutrition Position Statements**

Individuals engaged in regular exercise training require more dietary protein than sedentary individuals. Protein intakes of 1.4–2.0 g/kg/d for physically active individuals are not only safe, but may improve the training adaptations to exercise training. When part of a balanced, nutrient-dense diet, protein intakes at this level are not detrimental to kidney function or bone metabolism in healthy, active persons.

While it is possible for physically active individuals to obtain their daily protein requirements through a varied, regular diet, supplemental protein in various forms are a practical way of ensuring adequate and quality protein intake for athletes. Different types and quality of protein can affect amino acid bioavailability; superiority of one protein type over another in terms of optimizing recovery and/or training adaptations remains to be demonstrated.

Appropriately timed protein intake is an important component of an overall exercise training program, essential for proper recovery, immune function, and the growth and maintenance of lean body mass. Under certain circumstances, specific amino acid supplements, such as branched-chain amino acids (BCAAs), may improve exercise performance and recovery from exercise.

Maximal endogenous glycogen stores are best promoted by following a high-glycemic, high-carbohydrate diet (600–1000 g CHO or 8–10 g CHO/kg/d). Ingestion of free amino acids and protein (PRO) alone or in combination with CHO before resistance exercise can maximally stimulate protein synthesis.

Ingesting CHO alone or in combination with PRO during resistance exercise increases muscle glycogen, offsets muscle damage, and facilitates greater training adaptations after either acute or prolonged periods of supplementation with resistance training.

Nutrient timing incorporates methodical planning and eating of whole foods, nutrients extracted from food, and other sources. The timing of the energy intake and the ratio of ingested macronutrients allow for enhanced recovery and tissue repair following high-volume exercise, augmented muscle protein synthesis, and improved mood states when compared with unplanned or traditional strategies of nutrient intake.

Sources: Kerkick et al, 2008; Campbell et al, 2007.

carbohydrates and electrolytes during exercise will provide fuel for the muscles, help maintain blood glucose and the thirst mechanism, and decrease the risk of dehydration or hyponatremia (American Dietetic Association, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Each individual has a unique genetic profile and phenotype. Because both parents contribute genes and chromosomes to the fetus, a genetic history may be beneficial.

Clinical/History	Lab Work	
Height	H & H, serum	Total Chol
Weight	Fe	High-density lipoprotein (HDL)
Goal weight	Transferrin	LDL
BMI	Na <sup>+</sup> , K <sup>+</sup> , chloride	Trig
HBW range for height	Serum glucose	Serum insulin
Diet/intake history	BP	Ca <sup>++</sup> , Mg <sup>++</sup>
Hydration (I & O)	Alb, transthyretin (if needed)	Alk phos
		Homocysteine

### INTERVENTION

### OBJECTIVES

- Promote healthy, safe eating habits and activities that can be continued throughout life. Aerobic activity and resistance training are especially beneficial. Participation in

sports activity can be an important component of obesity prevention.

- Because physical activity, athletic performance, and recovery from exercise are enhanced by optimal nutrition, adequate energy intake is needed to support peak performance (American Dietetic Association, 2009).
- Correct faddist beliefs, dangerous dieting trends, meal skipping, and other unhealthy eating behaviors.
- Prevent or correct amenorrhea, which may result from poor energy and fat intake. Runners may be especially vulnerable (Barrack et al, 2008). Monitor or correct EDs, including bulimia and anorexia nervosa.
- Help prevent injuries, dehydration, overhydration, and hyponatremia.
- Enhance overall health and fitness. A certain amount of fat is essential to bodily functions. Fat regulates body temperature, cushions and insulates organs and tissues. Fat intake provides EFAs and fat-soluble vitamins, as well as energy for weight maintenance (American Dietetic Association, 2009).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Fluid Intake in Athlete

**Assessment Data:** Dietary recall; labs (BUN, sodium); I & O descriptions.

**Nutrition Diagnosis (PES):** Inadequate fluid intake related to marathon preparation as evidenced by altered labs, poor skin turgor, frequent headaches, reports of dehydration and limited intake of fluids on workout days.

**Intervention:** Education on fluid intake for body size, extent of training, and types of physical activities. Counseling on use of any supplements or sports drinks.

**Monitoring and Evaluation:** Improved hydration status; improved lab values (BUN, sodium); fewer headaches and signs of dehydration; I & O levels that are balanced.

**TABLE 1-16 Percent Body Fat Standards<sup>a</sup>**

Stages	Men	Women
Essential for life	4–5%	10–12%
Athletes	6–13%	14–20%
Very lean/Underweight	≤8%	≤21%
Recommended	8–20%	21–32%
Overweight	20–25%	32–38%
Obese	>25%	>38%
Children <sup>b</sup>	14% newborn 13% 10-year-old boy	14% newborn 19% 10-year-old girl

<sup>a</sup>These standards are for 20–40 years of age. Add approximately 1% body fat for each additional decade above 40 years of age.

<sup>b</sup>Shils M, et al. *Modern nutrition in health and disease*. 9th ed. Philadelphia: Lippincott Williams & Wilkins, 1999, p. 799.

Ranges of body fat standards are listed below to evaluate and counsel accordingly (see Table 1-16).

- Body weight and composition should not be a criterion for sports performance and daily weigh-ins are discouraged (American Dietetic Association, 2009).

## FOOD AND NUTRITION

- For active individuals, use a normal diet for age and sex with special attention to energy needs for the specific activity and frequency. Most athletes should consume 6–10 g of CHO per kg of body weight on a daily basis. Female athletes may not consume sufficient levels of protein and energy, often because they want to lose weight.
- Maintain total fat intake at a level determined by age, medical status, type of performance and endurance required. Focus on heart healthy fats such as olive oil and canola oil.
- Protein eaten in excess of recommendations is used by the body as a fuel; the body will store the excess as fat tissue. Athletes who eat many high-protein foods and take protein supplements in addition may be at risk for dehydration or kidney problems. Protein requirements should be calculated by age and sex, with a slightly higher requirement in endurance sports activity (Gleeson, 2005). Table 1-17 provides a chart for calculating protein needs.
- Vitamin and mineral supplements are not needed if adequate energy to maintain body weight is consumed from a variety of foods, but may be needed if the individual's diet is imbalanced (American Dietetic Association, 2009). Extra riboflavin may be needed to meet muscle demands; this is easily met by dairy products (Manore, 2000).
- Fluid replacement may be essential with a calculation of 1 mL/kcal used for an average. With too much, there is a risk for hyponatremia in slow runners and marathon walkers; drink too little, risk dehydration as in marathon runners.
- Electrolytes must be carefully monitored and replaced. Sports drinks are formulated to have between 6 and 8% CHO along with an appropriate amount of electrolytes;

they should not be diluted. Newer sports drinks on the market contain glucose polymers with lower osmolality than sugared drinks or fruit juice. Gatorade and other recently formulated sports drink products are acceptable.

- When athletes omit meat from their diets, other sources of zinc and heme iron must be obtained. Dried beans, nuts, seeds, peanut butter, soy products, tofu, and enriched cereals provide protein and some iron. A good rule of thumb is to consume twice the iron in nonheme foods as would have been available from heme sources.
- Adequate calcium intake may prevent osteoporosis, reduce muscle cramping and protect against stress fractures. For maximum bone density, include 4 servings of dairy or calcium-fortified foods (or 3 servings plus a 500 mg calcium supplement) until age 24.
- Avoid skipping meals. Breakfast is especially important; small meals or frequent snacks are useful for some individuals.
- Glucose loading is not recommended for athletes who train daily for endurance sports. Complex CHO in the form of starch promotes glycogen storage. Table 1-18 lists tips on planning meals for athletes.

## Common Drugs Used and Potential Side Effects

- If an athlete is in a sport that requires drug testing, check first with the U.S. Olympic Committee or the National Collegiate Athletic Association (NCAA) before using any drug. Androstenedione and anabolic steroids do promote muscle mass enhancement but are not allowed. Steroids affect numerous nutritional parameters. Take a careful drug history and discuss all side effects.
- Salt tablets should be discouraged. A balanced sports drink is more desirable.
- Discuss the relevance of tolerable ULs from the latest dietary reference intakes of the National Academy of

**TABLE 1-17 Protein for Athletes**

Protein Needs: Group	Protein Intake Per Day
Sedentary men and women	0.8–1.0 g/kg or 0.4 g /lb body weight
Moderate-intensity endurance athletes, 45–60 minutes 4–5 times per week	1.2 g/kg or 0.6 g/lb body weight
Elite male endurance athletes	1.6 g/kg or 0.8 g/lb body weight
Competitive sports which emphasize building muscle mass	1.4 g/kg or 0.7 g/lb body weight
Recreational endurance athletes, 30 minutes at <55% VO <sub>2</sub> peak 4–5 times per week	0.8–1.0 g/kg or 0.5 to 0.6 g/lb body weight
Football, power sports	1.4–1.7 g/kg
Resistance athletes (early training)	1.5–1.7 g/kg
Resistance athletes (steady state)	1.0–1.2 g/kg

Adapted from: Burke L, Deakin V. *Clinical sports nutrition*. 3rd ed. McGraw-Hill, 2006, pp. 73–112; Clark N, *Nancy Clark's sports nutrition guidebook*. 4th ed. Champagne, IL: Human Kinetics Publishers, 2008, pp. 127–146.

**TABLE 1-18 Guidelines for Planning Meals for Athletes**

	Number of Servings Per Day		
	Female Nonathletes	Female Athletes, Male Nonathletes	Male Athletes
Bread/Grains Group	6–11	9–15	11–18
Vegetable Group	3+	3+	3+
Fruit Group	2–4	3–5	4–8+
Dairy Group	4	4+	4–5+
Protein/Meat Group	2 (= 5 oz)	2 (= 6 oz)	3 (= 7–11 oz)
Fats/Lipids	20–35% calories	20–35% calories	20–35% calories

Source: U.S. Department of Agriculture and the U.S. Department of Health and Human Services.

#### Preexercise

- Consumption of a CHO + PRO supplement may result in peak levels of protein synthesis.
- Eat lightly before an athletic competition; chew foods well. Remember, it takes 4–5 hours to fully digest a meal. Focus on complex carbohydrates (about 65% of the meal).
- Avoid bulky foods (raw fruits and vegetables, dry beans and peas, and popcorn), which may stimulate bowel movements; avoid gas-forming foods (cabbage family and cooked dry beans).
- Drink water to be adequately hydrated: drink 2 cups of cool water 1–2 hours before the event and 1–2 cups of fluid 15 minutes before the event.
- Avoid drastic changes in normal diet routine immediately prior to competition; focus on well-tolerated or favorite foods.

#### During Exercise

- CHO should be consumed at a rate of 30–60 g of CHO/hour in a 6–8% CHO solution (8–16 fluid ounces) every 10–15 minutes. CHO:PRO ratio of 3–4:1 may increase endurance performance and maximally promotes glycogen resynthesis during acute and subsequent bouts of endurance exercise.

#### Postexercise (within 30 minutes)

- Consumption of CHO at high dosages (8–10 g CHO/kg/d) stimulates muscle glycogen resynthesis. Adding 0.2–0.5 g protein/kg/d to CHO at a ratio of 3–4:1 (CHO: PRO) further enhances glycogen resynthesis. Fruits, juices, and high-carbohydrate drinks are examples (Kerksick et al, 2008).
- Replace fluids that have been lost; drink 2 cups of fluids for every lost pound. Replace any potassium or sodium that has been lost during competition or training; fruits and vegetables are excellent sources of potassium. Replace sodium by eating salty foods; if activity was vigorous and exceeded 2 hours, a sports beverage may be useful (Kerksick et al, 2008).

#### Postexercise Ingestion (immediately to 3 hours post)

- Protein (essential amino acids) has been shown to stimulate robust increases in muscle protein synthesis, while the addition of CHO may stimulate even greater levels of protein synthesis (Kerksick et al, 2008).
- Meat and soy substitutes have 7 g protein/serving; dairy products have 8 g protein/serving; and breads/cereals/grains have 3 g protein/serving.

#### During Consistent, Prolonged Resistance Training

- Postexercise consumption of CHO plus PRO supplements in varying dosages have been shown to stimulate improvements in strength and body composition when compared to control or placebo conditions. The addition of creatine (0.1 g Cr/kg/day) to a CHO + PRO supplement may facilitate even greater adaptations to resistance training (Kerksick et al, 2008).
- The following list estimates for carbohydrates (CHO):

##### 5 g CHO

1 serving of nonstarchy vegetables

##### 12 g CHO

1 serving of milk and dairy products

##### 15 g CHO

1 serving each of breads, cereals, grains, “starchy” vegetables  
corn, peas, lima beans; fruits

##### 40–45 g CHO

4 graham crackers

4 fig newtons

1 Power Bar

12 oz can soda

1 cup cranberry juice cocktail

1 baked potato with skin

3 oz pretzels

20 saltine crackers

6 cups popcorn (any kind)

1 cup rice (any kind)

1 large flour tortilla

2 hamburger buns

16 oz PowerAde

22 oz Gatorade

8 graham crackers, 2–1/2” squares

3 slices of bread (any kind)

Sciences. These levels were set to protect individuals from receiving too much of any nutrient from diet and dietary supplements. Discuss the fact that excessive use of vitamin-mineral supplements can lead to toxicity, especially for vitamins A and D.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician, especially for underlying medical conditions. Use of supplements is common in athletes, and there may be undesirable side effects (Burns et al, 2004). FDA has taken steps to implement the Dietary Supplementation Health and Education Act (DSHEA) with a stronger stance than in the past.
- Some supplements may be contaminated with banned substances. If an athlete is found to have taken a banned substance, actions are taken by the regulatory agency (such as the International Olympic Committee, NCAA, or other sports sanctioned agencies). Athletes must be advised accordingly.
- Because regulations specific to nutritional ergogenic aids are poorly enforced, they should be used with caution, and only after careful product evaluation for safety, efficacy, potency, and legality (American Dietetic Association, 2009). Athletes often use supplements such as those found in Table 1-19 (Brown University, 2009).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- A well-balanced diet will suffice for most events (American Dietetic Association, 2009). Dispel myths, such as “milk is for children only,” “meat is bad for you,” “carbohydrates are fattening,” or “dieting is the key to fluid control.”
- Athletes with traits such as perfectionism, compulsive or controlling behaviors, and a need for attention may need referral to counseling from an appropriate health provider. Restrictive eating behaviors practiced for physical activities that emphasize leanness are a concern. Educate athletes, parents, coaches, trainers, judges, and administrators about the dangers of restrictive eating (Nattiv et al, 2007). Where there are weight problems, address body weight, family genetics, body type, parenting styles, socioeconomic issues, and environmental cues.
- Pre-event diets should be eaten up to an hour before the activity. Complex carbohydrates should be consumed, using less fat and protein because of their effect on digestive processes. After an event, recovery carbohydrate intake is suggested.
- There is no such thing as “quick energy.” The habit of eating candy before a game can cause an insulin overshoot, leading to hypoglycemia. A balanced diet is more practical. Discuss how to obtain a high-calorie, high-complex carbohydrate diet with attention to individual preferences. In vigorous training programs such as ultramarathons, 3000–6000 kcal may be needed.
- Prevent dehydration. Drink fluids before, during, and after exercising. Weigh before and after events and replace lost weight (such as 2 cups of fluid per pound lost). Avoid use of alcoholic beverages as they do nothing to promote performance and may negatively affect neurologic and cardiac systems.
- Some populations have lower resting metabolic rates and physical activity energy expenditures than others. If confirmed, target interventions to decrease energy intake and to increase physical activity (Gannon et al, 2000).

**TABLE 1-19 Supplements Commonly Used by Athletes**

Androstenedione “andro” (hormone)	Banned by the NCAA, the IOC, the U.S. Olympic Committee, the National Football League, and the Association of Tennis Professionals.
Caffeine	Ergogenic aid for endurance athletes when taken before and/or during exercise in moderate quantities, such as 3–6 mg/kg body mass (Ganio et al, 2009). However, caffeine use is limited in competitive sports.
Chromium Picolinate (CrPI)	Widely available in many foods; supplements are not necessary.
Creatine	Increases the capacity of skeletal muscle to perform work during periods of alternating intensity exercises, possibly because of increased aerobic phosphorylation (Rico-Sanz and Mendez Marco, 2000). Creatine is useful for strength training (Becque et al, 2000), but not for endurance sports. If used, use 20–25 g daily for 5–7 days, followed by maintenance at 5 g/d. It requires a month to completely leave the bloodstream after stopping.
Ephedra/Ephedrine (Ma Huang)	Raises heart rate. Does not increase energy. Removed from the market by FDA.
Ginseng	Often used for performance enhancement. Avoid use with warfarin, insulin, oral hypoglycemics, CNS stimulants, caffeine, steroids, hormones, antipsychotics, aspirin, or antiplatelet drugs.
Tryptophan	Precursor to serotonin. Sometimes used for performance enhancement. May cause psychosis if used with antidepressants, MAO inhibitors
Yohimbe, smilax, tribulus, and wild yams	Cannot be converted by the body to anabolic steroids or enhance muscle mass.
Zinc	Sometimes taken to enhance performance. Zinc should not be taken with immunosuppressants, fluoroquinolones, and tetracycline.

- Women who are breastfeeding can exercise reasonably without adverse effects and may find that return to normal weight is easier than while being sedentary (Lovelady et al, 2004).
- Female athletes with subclinical EDs tend to have dietary intakes of energy, protein, and CHO below desired levels. Micronutrient status is generally unaffected, probably due to use of supplements (Hinton et al, 2004). The aim here is to increase energy intake or reduce excessive energy expenditure (Nattiv et al, 2007). Signs that someone is exercising excessively include rigid rules about exercising, anxiousness, or restlessness when off schedule, working out more than a coach or athletic trainer recommends, rigid or calculated eating patterns to exactly match calories expended on exercise (Brown University, 2009).

### Patient Education—Food Safety Tips

- Reminders about hand washing and safe food handling may be important, especially for athletes with busy lifestyles. Use of hand sanitizers can be encouraged.
- Athletes who are on the road may find that they are vulnerable to foodborne illnesses. They should be advised to choose foods carefully when traveling.
- Athletes who compete in other countries should become aware of potential risks where they will be traveling. For example, food and water sources are not always reliably safe.

# ADULTHOOD

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Nutrition is involved in the 10 leading causes of death in women. Heart disease is the number one disabler and killer of women in the United States, whereas cancer is the leading cause of premature death. Table 1-20 lists special considerations for men.

From the Human Genome project, scientists know that variations occur in all humans, even though they are 99.5% identical for DNA sequencing. At a particular chromosome, slight variations can occur; these are recognized as single nucleotide polymorphisms (SNPs). Some of these changes (alleles) lead to chronic diseases such as heart disease, cancer, diabetes, and others. There are 2400 known phenotypes affecting disease onset; 3700 more are suspected to have a genetic origin (McKusick, 2007) or have gene–environmental interactions (see <http://www.ncbi.nlm.nih.gov/Omim/mimstats.html>). Many diseases are caused by different mutations in genes, with

variable age of onset, severity and outcome. Polymorphisms can lead to differences in susceptibility of individuals to adverse environments or to reproductive success. For example, methylenetetrahydrofolate reductase (MTHFR) and folate metabolism affects early pregnancy loss and infertility. Table 1-21 lists some of the disorders that have a genetic link for which mutations have been identified.

“Healthy life expectancy” measures the distribution of health status within a population. People living in poor countries face low life expectancy and a life of poor health. Changes in health and nutritional behaviors can improve quality of life and promote longevity; peer support may be needed. In young adulthood between 18 and 40 years, careers are a priority. In middle adulthood (40–65 years,) family is the primary focus. Peer pressure and family persuasion can promote long-term changes in behavior.

Weight control is another major concern. Over the past 40 years, height, BMI, and weights have increased in both sexes, all ethnic groups, and all ages. There are health implications with this weight increase. Both men and women should attempt to maintain a HBW.

Up to 60% of adults may have prehypertension, especially African Americans, older people, individuals with low socioeconomic status, and overweight individuals. Lifestyle modification and appropriate medications may be needed.

Both genetics and conditioning influence taste preferences and intake. Taste seems to be innate, whereas responses to odors are more conditioned. The influence of genetic variation in taste on food intake depends on how perceptible sweet, fat, or bitter components are in foods and beverages (Duffy and Bartoshuk, 2000). Bitterness “supertasters” may avoid high-fat or sweet foods because the oral sensations are too intense and less pleasant. Supertasters may taste more bitterness in vegetables but still enjoy eating them if condiments are added (Duffy and Bartoshuk, 2000).

It is important to work with individuals to identify foods and taste preferences that will help to achieve healthy eating patterns. When adults are hospitalized, nutritional declines occur and lead to higher hospital charges and more complications. Longstanding dietary habits from childhood, confusion about oral instructions, coexisting depression, inadequate referral or information, literacy deficits, social influences or barriers, and even the right to refuse treatment make it difficult for patients to follow a modified diet (Stein, 2005).

Understanding why patients refuse to follow a diet prescription is a priority. The use of the Standardized Language and Nutrition Care Process from the American Dietetic Association promotes thorough assessment, selection of nutrition diagnoses, targeted goals and interventions, and careful monitoring for evaluation of outcomes.

**TABLE 1-20** Leading Causes of Death and Nutritional Implications for Men in the United States

- Heart disease:** hyperlipidemia and hypertension are commonly related (see appropriate entries).
- Cancer:** prostate, testicular, esophageal, and stomach cancers have special nutritional implications (see appropriate entries). Increasing intake of soy products, fruits, and vegetables and reducing red meat intake may be beneficial.
- Stroke:** high intake of sodium and alcohol are problematic, as is chronic hypertension that is untreated (see appropriate entry).
- Accidents:** excessive alcohol intake may be related (see appropriate entry).
- Chronic lower respiratory diseases:** weight loss or gain may aggravate breathing problems.
- Diabetes:** carbohydrate intake should be consistent and consumed at regular intervals.
- Influenza and pneumonia:** infectious diseases burn more energy; weight loss can occur if energy intake is poor.
- Suicide:** depression and excessive alcohol intake may play a role (see appropriate entries).
- Kidney disease:** many renal diseases have implications for control of protein, sodium, electrolytes, and fluid. Kidney stones are more common in men than in women and drinking plenty of fluids and consuming adequate calcium may prevent onset or recurrence (see appropriate entries).
- Chronic liver disease and cirrhosis:** excessive alcohol intake is often related (see appropriate entry).

**TABLE 1-21 Disorders and Their Related Genes**

<b>Neurological Disorders</b>	<b>Related Genes</b>
Premature family Alzheimer's disease	<i>APP</i> gene <i>PSEN1</i> gene <i>PSEN2</i> gene
Late-onset Alzheimer's disease	<i>APOE</i> gene
Huntington's disease	CAG triplet-repeat expansion in the IT15 region of the <i>HD</i> gene
Frontotemporal dementia	<i>MAPT</i> gene
Tay-Sachs disease	<i>HEXA</i> gene
Pantothenate kinase neurodegeneration	<i>PANK2</i> gene
Hereditary neuropathy with pressure palsies (HNPP)	17p11.2 deletion in the <i>PMP22</i> gene <i>PMP22</i> gene
Familial Parkinson disease (PARK1)	<i>SNCA</i> gene
Early-onset Parkinson disease (PARK2)	<i>PARK2</i> gene
Autosomal dominant Lewy body parkinsonism (PARK4)	<i>SNCA</i> gene
Rett syndrome	<i>MECP2</i> gene
Fragile X syndrome (FRAX)	CGG triplet-repeat expansion analysis of the <i>FMR-1</i> gene
<b>Hematological and Cardiovascular Disorders</b>	
Thrombophilia	Mutation of G1691 A (Arg506Gln) in the <i>Factor V (Leiden)</i> gene Mutation of G20210 A in the <i>Prothrombin (Factor II)</i> gene Mutation C677 T (Ala222Val) and A1298 C (Glu429Ala) in the <i>MTHFR</i> gene <i>PAI1</i> gene, plasminogen activator inhibitor Angiotensin enzyme converter gene
Fanconi anemia (complementation group A)	<i>FANCA</i> gene
Fanconi anemia (complementation group C)	Mutation of IVS4+4 A-T in the <i>FANCC</i> gene <i>FANCC</i> gene
Hemophilia	Intron 22 inversion mutation of <i>F8</i> gene <i>F8</i> gene Type A; <i>F9</i> gene in Type B
Glucocorticoid-remediable aldosteronism type 1	<i>CYP11B1/CYP11 B2</i> chimeric gene
Marfan syndrome	<i>FBN1</i> gene
Congenital thrombocytopenia	<i>MPL</i> gene
<b>Metabolic Disorders</b>	
Pituitary hormone deficiency	<i>POU1F1</i> and <i>PROP1</i> genes
Alpha-1-antitrypsin deficiency	Mutation of E264 V (Allele S) and E342 K (Allele Z) in the <i>PI</i> gene
Fructose-1,6-diphosphatase deficiency	<i>FBP1</i> gene
Growth hormone deficiency	<i>GH1</i> gene
Hereditary hemochromatosis	Mutation of C282Y, H63D and S65 C in the <i>HFE</i> gene
Familial hypercholesterolemia	<i>LDLR</i> gene Mutation of Arg3500Gln, Arg 3531Cys and Arg3480Trp in the <i>APOB</i> gene Mutations of the <i>CYP11B1</i> gene and <i>CYP21A2</i> gene
Homocystinuria	Mutation of Gly307Ser and Ile278Thr in the <i>CBS</i> gene Mutation of C677 T and A1298 C in the <i>MTHFR</i> gene
<b>Muscular and Skeletal Disorders</b>	
Achondroplasia	Mutation of G1138 A, G1138 C and G375 C in the <i>FGFR3</i> gene
Myoclonus-dystonia (DYT11)	<i>SGCE</i> gene
Rapid-onset dystonia-parkinsonism (DYT12)	<i>ATP1A3</i> gene
Duchenne/Becker muscular dystrophy	<i>DMD</i> gene
Amyotrophic lateral sclerosis (ALS1)	<i>SOD1</i> gene
Osteoporosis	BsmI, ApaI, TaqI and FokI polymorphism in the <i>VDR</i> gene Pro463Leu polymorphism detection in the <i>CTR</i> gene PCOL2 (-1997 G/T) and Sp1 (1546 G/T) polymorphisms in <i>COL1A1</i> gene PvuII (397 T>C) and XbaI (351 C>G) polymorphism in <i>ESR1</i> gene Polymorphisms in the <i>IL-6</i> gene

(continued)

**TABLE 1-21 Disorders and Their Related Genes (*continued*)**

<b>Reproductive Disorders</b>	<b>Related Genes</b>
Preeclampsia, eclampsia, Hellp syndrome or recurrent spontaneous pregnancy loss	Mutation of G1691 A (Arg506Gln) in the <i>Factor V</i> gene Mutation of G20210 A in the <i>Factor II</i> gene Mutation of C677 T (Ala222Val) and A1298 C (Glu429Ala) in the <i>MTHFR</i> gene
<b>Neoplastic Disorders</b>	
Breast/ovarian cancer	Mutation in exons 2, 3, 5, 8, 11, 18, 20, and 23 of the <i>BRCA1</i> gene <i>BRCA1</i> gene Mutation in exons 2, 10, 11, and 23 of the <i>BRCA2</i> gene <i>BRCA2</i> gene
Hereditary nonpolyposis colon cancer—Lynch syndrome	Microsatellites instability <i>MLH1</i> gene or <i>MSH2</i> gene
Medullary thyroid carcinoma	Mutation in exons 10, 11, 13, 14, and 16 of the <i>RET</i> gene <i>RET</i> gene
Cutaneous malignant melanoma 2	<i>CDKN2 A</i> gene
Familial adenomatous polyposis (FAP)	<i>APC</i> gene
Colorectal polyposis	<i>MUTYH</i> (MYH) gene
Retinoblastoma	<i>RB1</i> gene
Wilms' tumor	<i>WT1</i> gene
<b>Multisystemic Disorders</b>	
Cystic fibrosis	30 prevalent European mutations of the <i>CFTR</i> gene IVS8-Tn (poli-T) polymorphism detection in the <i>CFTR</i> gene
Polycystic kidney disease	<i>PKD1</i> gene <i>PKD2</i> gene
<b>Pharmacogenetics</b>	
Breast cancer	<i>HER2</i> (NEU) overexpression detection and Herceptin (trastuzumab) treatment
Nonsmall cell lung cancer (NSCLC)	Mutation screening in exons 18–21 of the <i>EGFR</i> gene and Gefinitib treatment
CYP2D6 for psychiatric and cardiovascular disorders treatment	Polymorphism of the <i>CYP2D6</i> gene. This gene is involved in metabolizing different drugs such as, Prozac, Zoloft, Haldol, Metoprolol, Tagamet, Tamoxifen, Paxil, Effexor, Hydrocodone, Amitriptyline, Claritin, Cyclobenzaprine, Allegra, Dytuss, Tusstat, Rythmol
CYP2C9 linked to thrombosis, diabetes and other disorders treatment	Polymorphism of the <i>CYP2C9</i> gene. This gene is involved in metabolizing Coumadin (Warfarin), Viagra, Amaryl, Isoniazid, Sulfa, Ibuprofen, Amitriptyline, Dilantin, Hyzaar, Tetrahydrocannabinol, Naproxen
CYP2C19 linked to psychiatric diseases, epilepsies, malaria and anesthesia	Polymorphism of the <i>CYP2C19</i> gene. This gene is involved in metabolizing different drugs: Carisoprodol, Diazepam, Dilantin, Premarin and Prevacid
Chronic myeloide leukemia	Mutation screening in exons 4–10 of the <i>ABL</i> gene, for the treatment with Gleevec (Imatinib)
Acute myeloide leukemia	Mutation in the <i>KIT</i> (CD117) gene, for the treatment with Gleevec (Imatinib) Mutation of the <i>FLT3</i> gene
5-Fluorouracil toxicity	Allele 2 A (IVS14+1G-A) determination in the <i>DPD</i> gene
Thiopurines toxicity	For the treatment of thrombosis, diabetes, and a variety of diseases. The <i>TPMT</i> gene is associated to the different thiopurines metabolism: azathioprine (Imuran,) 6-mercaptopurina (PurinetoL,) and 6-thioguanina (Lanvis)
<b>Mitochondrial Disorders</b>	
Neuropathy, ataxia and retinitis pigmentosa (NARP)	Mutation of T8993G and T8993 C in the <i>MTATP6</i> gene
Maternal hereditary deafness	Mutation of A1555G, A827G, T961 C, T961insC, T961delT+C(n)ins, T1005 C, A1116G and C1494 T in the <i>MTRNR1</i> gene Mutation screening of T7445 C and A7443G in the <i>MTCO1</i> gene

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Each individual has a unique genetic profile and phenotype. Because both parents contribute genes and chromosomes to the fetus, a genetic history may be beneficial.

Clinical/History	Lab Work	C-reactive protein (CRP)
BP	Glucose	Alb,
Height	Chol—HDL, LDL, total	transferrin
Weight, current	Trig	(if needed)
Weight, usual	Na <sup>+</sup> , K <sup>+</sup>	BUN, Creat
BMI and waist to hip ratio	Mg <sup>++</sup> , Ca <sup>++</sup>	Sleep disorder screening
Recent weight changes	H & H, serum Fe	
HBW range	Homocysteine	
Diet history	Serum folic acid and vitamin B <sub>12</sub>	
Body fat analysis		
Smoking		
Alcohol use		

## INTERVENTION

### OBJECTIVES

- Maintain quality of nutrition while compensating for energy needs that are lower than those during periods of growth.
- Maintain a healthy lifestyle, which offers greater longevity than genetics alone. Losing excess weight, exercising, and eating a nearly meat-free diet are tips shared by many centenarians.
- Prevent obesity resulting from a sedentary lifestyle where relevant. Highly sedentary people lose 20–24% of overall muscle mass and strength. Every adult should accumulate 30 minutes or more of moderate-intensity physical activity on most days of the week. Also useful are strength training (resistance or weight training with 8–12 repetitions), isotonic, and aerobics (20 minutes of walking, jogging, swimming, or bicycling).
- Prevent or delay the onset of conditions such as, hypertension, osteoporosis, cardiovascular disease, diabetes, renal disorders, Alzheimer's disease, and cancers. Focus on a plant-based diet, rich in colorful fruits and vegetables plus nuts, seeds, and whole grains. Include fish and sources of omega-3 fatty acids, including walnuts, flaxseed, and dark-green leafy vegetables. The Mediterranean diet is a good pattern to follow.
- Improve nutrient density of meals, especially those eaten away from home. The average American eats 3–4 meals away from home each week. Making “each calorie count more” is a message that encourages selecting foods that offer more quality per “bite.” The Naturally Nutrient

### SAMPLE NUTRITION CARE PROCESSES

#### Imbalance of Nutrients

**Assessment Data:** Dietary recall, nutrient analysis for vitamins and minerals, results of genetic testing.

**Nutrition Diagnosis (PES):** Imbalance of nutrients related to low micronutrient intake (vitamins A and C, magnesium, and potassium) and C>T genetic allele of methyltetrahydrofolate reductase (MTHFR) as evidenced by consistent omission of fruits and vegetables in dietary intake records, genetic inability to metabolize folic acid, and history of three miscarriages in past 5 years.

**Intervention:** Education about a healthy diet for promoting optimal reproductive health. Counseling about use of L-methylfolate and multivitamin–mineral supplement in preparation for a healthy pregnancy.

**Monitoring and evaluation:** Dietary intake records, increased intake of fruits and vegetables; successful pregnancy where possible.

#### Menopause

**Assessment Data:** Dietary recall, side effects of taking multiple herbs, weight history, labs.

**Nutrition Diagnosis (PES):** Harmful beliefs about food/nutrition related to regular intake of dietary supplements as evidenced by dietary recall indicating use of large doses of Chinese herbal remedies that are unsubstantiated by medical efficacy.

**Intervention:** Education about safe use of herbs and supplements for menopausal symptoms (soy, black cohosh, multivitamin–mineral supplements). Counseling about acceptable choices.

**Monitoring and Evaluation:** Dietary recall, dietary supplement usage pattern, side effect reports, improvement of symptoms of menopause.

Rich (NNR) approach is also helpful; encourage “super foods” such as salmon, blueberries, bananas, whole-wheat grains, fat-free yogurt, broccoli, and top round steak (Drewnoski, 2004).

- Use of a multivitamin–mineral supplement can assure that the basics are met, but a balanced diet provides other beneficial phytochemicals. Lutein and zeaxanthin from food protect against age-related eye diseases such as macular degeneration.
- Promote adequate bone mass density, which peaks at 25–30 years of age. Osteopenia is common in women over age 40, and testing of bone density is recommended. Men are also at risk as they age.
- Identify food insecurity and its relationship to availability of varied foods and intake patterns. For example, food insecurity is common among migrant workers and farm worker households. The impact of hunger varies by factors such as participation in food banks, dependence on family members or friends outside the household for food, inadequate transportation, and not having a garden (Holben et al, 2010).

**TABLE 1-22 Special Nutrition-Related Concerns of Adult Women<sup>a</sup>**

Fibrocystic breast changes	50–60% of all women present with breast nodularity, swelling, and pain with monthly hormonal changes. A low-fat (15–20% kcal), adequate fiber diet (30 g/d) and soy isoflavones seems to be useful. Fruit and vegetable intake should be high. Studies fail to support nutrition interventions with decreased sodium or fluid and caffeine; increased use of primrose oil, herbal teas, vitamins A, C, E, B <sub>6</sub> , iodine, selenium.
Infertility	Women desiring to become pregnant should stop smoking and drinking alcohol, and increase intakes of folate and vitamin B <sub>12</sub> (American Dietetic Association, 2004).
Premenstrual syndrome (PMS) and premenstrual dysphoric disorder (PMDD)	Up to 40% of women experience symptoms including edema, migraines, depression, and mastalgia. PMDD is generally more severe, although women experience anxiety and irritability in both conditions. A basic multivitamin–mineral supplement can help assure adequacy of all micronutrients, especially calcium, vitamin B <sub>6</sub> and magnesium (American Dietetic Association, 2004). Herbal supplements have limited supporting evidence (Johnson, 2007).
Perimenopause	In the 2- to 10-year stage before menopause, women may experience hot flashes, night sweats, fatigue, insomnia, weight gain, loss of libido, irregular periods, fibroids or heavy bleeding, breast pain, mood swings and irritability, cravings for sweets or alcohol, digestive problems, hair loss, stiffness or joint pain, anxiety, and depression. Women should exercise regularly and consume a balanced, healthy diet. Herbal remedies are not very effective.
Menopause	Declining levels of estrogens and other hormones, cessation of menstrual periods, and a decreased need for iron. Hormone replacement therapy is no longer the mainstay for preventing osteoporosis and fractures because of the risk for cancer. Exercise, calcium, vitamin D and physical examinations are needed. A diet that is moderate in carbohydrate slows insulin shifts; lean proteins and moderate fat help to prevent weight gain. Food sources of selenium, vitamins C and E contribute antioxidant benefits. Whole grains, flax seed, and other omega-3 fatty acids may reduce the inflammation that aggravates hot flashes. Phytoestrogens from isoflavones, lignans, and coumestans (soy foods, flaxseed, and red clover) are useful for some women. Avoid large amounts of soy if breast cancer is a known risk. Black cohosh has some merit but may also have undesirable side effects (see herbal guidelines).
Postmenopause	Older women may be at risk for poor nutritional intake because their diets tend to be more limited; they may have difficulty chewing; and they may no longer enjoy cooking (American Dietetic Association, 2004). Nutrient supplementation may be beneficial, especially for calcium, zinc, and the vitamins.

<sup>a</sup>See related disorder sections for specific disease advice.

- ID affects approximately one half of all women. Correct through diet as far as possible. Avoid iron excesses in men and in post menopausal women. Table 1-22 provides a summary of conditions that affect women specifically.

## FOOD AND NUTRITION

- Ensure intake from the MyPyramid Food Guidance System: 2–3 servings of milk, 2–3 servings of meat or substitute, 3–5 servings of vegetables, 2–4 servings of fruits, and 6–12 bread group servings. Control fats, oils, sugars, alcohol, and sweets as needed to increase or decrease energy intake; foods from this group often replace nutrient-dense foods in the American diet. Limit or eliminate foods that contain trans-fatty acids.
- Follow the dietary guidelines. Modify diet as needed for special medical conditions, such as hypertension, heart disease, and osteoporosis.
- Energy needs will vary by sedentary or active status; 30 kcal/kg/d is average. Use 20–25 kcal/kg/d when weight loss is desired and 35–40 kcal/kg/d when weight gain is needed. Adults are encouraged to maintain weight rather than gaining weight after reaching adulthood. See nutritional recommendation charts.

### Nutrient Recommendations for Adults

Nutrient	Males 19–50 Years	Males 51–70 Years
Energy	3067 kcal/d	3067 kcal/d
Protein	56 g/d or 0.8 g/kg/d	56 g/d or 0.8 g/kg/d
Calcium	1000 mg/d	1200 mg/d
Iron	8 mg/d	8 mg/d
Folate	400 mg/d	400 mg/d
Phosphorus	700 mg/d	700 mg/d
Vitamin A	900 µg/d	900 µg/d
Vitamin C	90 mg/d	90 mg/d
Thiamin	1.2 mg/d	1.2 mg/d
Riboflavin	1.3 mg/d	1.3 mg/d
Niacin	16 mg/d	16 mg/d

- For most healthy adults, 0.8 g of protein/kg will suffice. Use fish, poultry, and nonmeat entrees (e.g., dry beans, peas, nuts as tolerated) regularly instead of just meat-centered meals. Soy products such as tofu, textured soy protein, soy nut butter, or tempeh can be useful. The Continuing Survey of Food Intakes by Individuals (CSFII) has found that households with higher income tend to use more chicken and less beef and pork (Guenther et al, 2005).

- For carbohydrate, the Institute of Medicine has set the minimum intake at 130 g daily. In general, use of whole grains, fresh fruits or vegetables, and low-fat dairy products will provide high-quality carbohydrate. Refined carbohydrates in sweetened beverages, desserts, and candy should be limited.
- Mineral and phytochemical balance is important, including sodium, potassium, calcium, and magnesium. The DASH diet may be useful for designing meal patterns to lower BP and lipids, when needed.
- Eat a balanced diet. The most recent national study of What We Eat in America (United States Department of Agriculture, 2006) identified that vitamins A, C, and E and magnesium tend to be low in most diets; teen girls and older men and women tend to be low in zinc intakes; and potassium, calcium, vitamin D, vitamin K, and fiber are low as well.
- Hyperhomocysteinemia is an independent risk factor for cardiovascular disease in men and women as well as for Alzheimer's disease, and stroke. B-complex vitamins (folic acid, vitamins B<sub>6</sub> and B<sub>12</sub>) are needed. If an individual has an MTHFR allele, L-methylfolate may be needed.
- Women of childbearing age should include foods rich in folic acid, now available through fortification of grains, to prevent neural tube defects. Men may need to eat more folic acid-rich foods to lower risk for colorectal cancer. Cold cereals, cooked pinto or navy beans, asparagus, spinach, orange juice, lentils, and avocado should be planned into the diet regularly.
- Fiber-rich foods may help protect against heart disease, stroke, diabetes, high BP, some types of cancer, constipation, and diverticulosis. They are also helpful with management of weight by increasing satiety with meals. Soluble fiber is found in pectins, gums, plums, apples, berries, figs, broccoli, potatoes, and okra. Insoluble fibers are found in bran cereal, whole-wheat bread, brown rice, legumes, vegetables, and many fruits. Nuts and seeds are also good sources of fiber.
- Favorable dietary habits promote health, whereas unfavorable habits are linked to various chronic diseases; an individual's "sense of coherence" (SOC) correlates with prevalence of some diseases to which dietary habits are linked (Lindmark et al, 2005).
- Family meals are associated with positive dietary intakes and healthy behaviors. Family interaction can lower risks for obesity, enhance language skills and academic performance, and improve social skills. A positive atmosphere is beneficial; see <http://www.cfs.purdue.edu/CFF/promotingfamilymeals/index.html>.
- Use spices and herbs liberally in cooking. Oregano, cinnamon, dill, savory, coriander, cumin, and other herbs have potent antioxidant properties.
- A Mediterranean-style diet can enhance cholesterol-lowering plans; design menus accordingly.
- Adequate vitamins A, C, and E and selenium foods should be consumed for their antioxidant properties. Foods rather than supplements are recommended because of the phytochemical and biological properties that may prevent or delay some chronic diseases.
- Functional food ingredients, including fortified, enriched, or enhanced foods, have a potentially beneficial effect on

health when consumed as part of a varied diet on a regular basis (American Dietetic Association, 2005). Functional foods may reduce the risk of coronary heart disease, cancers, hypertension, and osteoporosis. Each food or ingredient should be assessed individually for its relative merit. Soybeans, fruits, and vegetables seem to yield the greatest risk reductions. Soy protein, as in tofu and meat extenders, may reduce serum cholesterol and possibly reduce risks of some forms of cancer. Quercetin (found in apples, broccoli, oranges, tomatoes, kale, and onions) may help protect against cataracts. Phytosterols in sunflower seeds, pistachio nuts, sesame seeds, and wheat germ are good for the heart. Plant sterols and stanols help to lower serum cholesterol levels and are less expensive than statin drugs. Polyphenols (flavonoids from tea, cocoa, red wine, Concord grape juice, blueberries, and chocolate) also support heart health. See Table 1-23 for a list of functional food ingredients and their beneficial effects.

### Common Drugs Used and Potential Side Effects

- In general, discuss the relevance of tolerable ULs from the latest dietary reference intakes of the National Academy of Sciences. These levels were set to protect individuals from receiving too much of any nutrient from diet and dietary supplements. Table 1-24 provides a useful chart.

### Herbs, Botanicals, and Supplements

- Herbs, botanical products, and supplements should not be used without discussing with a physician, especially with underlying medical conditions (Boullata, 2005). The Food and Drug Administration implement guidelines for DSHEA.
- Supplement use is common among middle-aged men and women in the United States, it should be recognized that micronutrient intakes of vitamins A, C, and E, niacin, folate, and iron are often higher than from foods alone (Archer et al, 2005). Section 2 provides an extensive list of herbs and botanicals; see Table 2-1.
- Use of multivitamins/minerals (MVMs) has grown rapidly; dietary supplements are now used by more than half of the adult population in the United States (NIH, 2006). The NIH consensus report (2006) reported that fortification of foods has reduced vitamin and mineral deficits. Now there are safety concerns about exceeding upper levels and there is limited evidence for beneficial health-related effects of supplements taken singly, in pairs, or in combinations of three or more (NIH, 2006).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help plan a diet in accordance with individual lifestyle. Explain nutrient density, food cost, and portion sizes. Meal and snack patterns are markers for nutrient intakes and diet quality (Kerver et al, 2006).

**TABLE 1-23 Functional Foods and Ingredients**

Food	Function
Almonds	Lower LDL and total cholesterol to reduce heart disease. Source of potassium, vitamin E, riboflavin, magnesium, and zinc.
Apples	Good source of fiber, quercetin in the skin. May protect against cancer, asthma, and Alzheimer's disease.
Apricots	Good source of vitamins A and C, as well as lycopene. Cancer prevention.
Avocado	Reduces risk of heart disease, high blood pressure, and osteoporosis. Contains vitamins B <sub>6</sub> and E, folate, potassium, and fiber.
Bananas	Good source of potassium and magnesium, which are helpful to prevent heart disease, bone loss, and hypertension.
Barley	Good whole grain source.
Blueberries and other berries	Reduce risk of cancer; may improve cognitive function. Contain vitamin C as well as anthocyanins, fiber, and ellagic acid.
Brazil nuts	Supply of selenium, which is a cancer preventive. Use no more than 2 per day.
Broccoli	Reduces risk of cancer and maintains healthy immune system. Sulforaphane detoxifies carcinogens. Source of quercetin.
Brown rice	Rich whole grain with phosphorus and potassium in greater amounts than white rice.
Brussels sprouts	Source of sulforaphane to prevent cancer; also good source of vitamin K.
Cabbage	Contains sulforaphane; consume often as a cancer prevention measure.
Canola oil	Good source of fatty acids, which reduce heart disease and cancer.
Cantaloupe	Great source of beta-carotene and vitamin C.
Carrots	Rich source of beta-carotene.
Cauliflower	Rich in sulforaphane and vitamin C; may protect against cancer.
Cheese	May decrease risk of colon cancer because of calcium content.
Chicken or turkey breast	Skinless poultry is a great source of protein and zinc; turkey is also high in B vitamins and selenium.
Chocolate	May decrease risk for cardiovascular disease; flavonoid content is a powerful antioxidant.
Cinnamon	May lower LDL cholesterol and blood glucose levels. Anti-clotting effect. Anti-inflammatory effect in arthritis.
Citrus fruits	Limonoids reduce risk of certain cancers. Oranges are a source of quercetin.
Cloves	Ground cloves are the richest source of polyphenols among the spices.
Cocoa	Rich source of flavonols; reduces risk of cancer and heart disease.
Collard greens and kale	Great source of carotenoids, vitamin C, lutein, sulforaphane, and calcium.
Cranberries	Improves urinary tract health and prevents infection; reduces risk of heart disease; may reduce periodontitis/gingivitis.
Cruciferous vegetables	Sulforaphane content helps to prevent cancer. Brussels sprouts, cauliflower, broccoli, and bok choy are in this family.
Edamame	Green soybeans, a staple in Asia. They can lower LDL cholesterol and may protect against colon cancer.
Fatty fish	Source of omega-3 fatty acids; helpful for brain, eye, and neurological health.
Flaxseed	Reduces risk of heart disease, high blood pressure, and osteoporosis. Provides lignans and alpha linolenic acid, an omega-3 fatty acid.
Garlic	Reduces risk of cancer; lowers cholesterol levels and blood pressure.
Kale	High in antioxidants lutein and zeaxanthin; protects eye health. Source of quercetin.
Kiwifruit	High in potassium, vitamin C, fiber, folate, magnesium, vitamin E, copper, and lutein. Great antioxidant fruit.
Legumes and beans	Lentils, dried beans, and peas provide folate, which reduces DNA damage and helps with cancer prevention. Rich in fiber, magnesium, potassium, protein, iron.
Lycopene	Lycopene is especially rich in tomatoes, pink grapefruit. A substance called Fru-his in rehydrated tomato products protects against prostate cancer.
Marjoram	Good source of polyphenols.
Milk, nonfat	Reduces risk of osteoporosis, high blood pressure, and colon cancer. Good source of vitamin D, calcium, and potassium.
Nuts, Seeds	Good source of arginine, magnesium, fiber.
Oatmeal	Reduces total and LDL cholesterol levels.
Olive oil	Good source of monounsaturated fatty acids (MUFA), which reduce heart disease risk by improving cholesterol levels.
Onions	Sulfur-rich and full of quercetin (red or yellow are richer). Blood thinning to help lower blood pressure and LDL cholesterol levels.
Oranges	Great source of potassium and vitamin C. Source of quercetin.
Oregano	Good source of polyphenols.
Peaches	Good source of vitamin C, carotenoids, niacin, and potassium.
Peanut butter	Good source of protein, MUFA, and niacin.

(continued)

**TABLE 1-23 Functional Foods and Ingredients (continued)**

Food	Function
Pistachio nuts	Good source of phytosterols for heart health.
Pomegranate	Antioxidant that protects against hormonal and lung cancers, Alzheimer's disease and heart disease.
Pork loin	Leanest cut of "red meat" sources. Protein, zinc, and iron source.
Prunes	Great source of antioxidants, fiber, potassium, and vitamins A and B <sub>6</sub> .
Pumpkin seeds	Good source of phytosterols; B vitamins, along with C, D, E, and K; calcium, potassium, niacin, and phosphorous. May protect against depression and learning disabilities. Excellent source of magnesium.
Pycogenol	Antioxidant plant extract from the bark of a French pine tree; reduces blood sugar in type 2 diabetes patients, allows people to lower their antihypertensive medication, and improves cardiovascular disease risk factors.
Quinoa	Seed containing high amounts of protein, fiber, magnesium, potassium, vitamin E, riboflavin, zinc, copper, and iron.
Sage, tarragon, thyme	Moderately good sources of polyphenols.
Salmon, sardines, mackerel	Improve mental and visual function; reduce risk of heart disease and may prevent cancers. Rich omega-3 fatty acid source.
Shredded wheat	Great source of whole-grain fiber, as well as magnesium; helpful in maintaining normal blood glucose levels.
Soy	Reduces risk of heart disease by lowering LDL cholesterol; eases menopausal symptoms. Isoflavones have weak estrogenic effects.
Spinach and romaine lettuce	Great source of lutein, carotenoids, and vitamin C; maintain healthy vision.
Squash, acorn	Rich in carotenoids, folate, vitamin C, and potassium; all helpful in reducing heart disease and cancer risk.
Strawberries	May lower blood pressure, reduce the risk of heart disease and some cancers, and improve memory.
Sunflower and sesame seeds	Good source of phytosterols for heart health.
Tea, black, green or white	Reduces risk for stomach, esophageal, and skin cancers, and heart disease. Flavonoids neutralize free radicals.
Tofu	Great meat substitute; rich in protein and isoflavones and may be high in calcium.
Tomatoes	Reduce risk of prostate cancer and heart attack; rich in lutein, lycopene, and vitamin C. Lycopene protects cell membranes. Source of quercetin.
Tuna	Reduces risk of heart disease; high in vitamins B <sub>6</sub> and B <sub>12</sub> , omega-3 fatty acids, and protein.
Turmeric	Natural anti-inflammatory that reduces cancer risk. Thought to slow Alzheimer's disease.
Walnuts	Lower total and LDL cholesterol and reduces risk of heart disease. Good source of vitamin E, alpha linolenic acid, minerals, and folate.
Whey protein	Immune-enhancing properties including lactoferrin, beta-lactoglobulin, alpha-lactalbumin, and immunoglobulins. Useful for intracellular conversion of cysteine to glutathione, a powerful antioxidant. Whey protein is found naturally in milk.
Whole grains	Reduce risk of certain cancers and heart disease. Contain saponins, flavonoids, and lignans.
Wine, red, grapes and grape juice	Reduce risk of cardiovascular disease and cancer because of resveratrol, a flavonoid (polyphenol).
Winter squash	Butternut squash is one example. Good source of beta-carotene, calcium, potassium, and folate.
Yogurt	Improves intestinal health because of bacterial (probiotic) content; reduces risk of cancer; lowers cholesterol. Rich source of calcium, vitamin B <sub>12</sub> , magnesium, and protein. May also use cultured dairy products.

Derived from: Functional Foods List, [http://www.mealsmatter.org/EatingForHealth/FunctionalFoods/func\\_list.aspx](http://www.mealsmatter.org/EatingForHealth/FunctionalFoods/func_list.aspx); accessed February 9, 2009; Fruits and Veggies More Matters, <http://www.fruitsandveggiesmorematters.org/>; accessed February 9, 2009.

- Explain the benefits of weight management for adults to prevent or delay the onset of chronic diseases. Start with BMI; select a healthy weight goal as needed. Successful weight losers tend to follow a low-fat, high-carbohydrate food plan with high levels of physical activity; they eat breakfast regularly.
- Popular low-carbohydrate, high-protein diet plans may contribute to problems such as kidney stones and are not advised for most adults. The South Beach diet, by recommending olive oil and fatty fish, mimics the Mediterranean diet plan more than the Atkins plan.
- Encourage planned meals. Skipping breakfast may lead to overeating later at night.
- Describe the effects of alcohol at the "business lunch;" alcohol intake may equal 300 calories or more. Discourage intake of more than two alcoholic drinks per day for men or one drink for women.
- Being physically fit can improve the odds against chronic diseases. Goal setting may be an effective strategy. The Surgeon General recommends 1 hour daily of physical activity. Using a pedometer to count steps is very motivating; "10,000 steps a day" is the goal; one mile is approximately 2000 steps. Other forms of exercise should be encouraged as well; yoga, pilates, and Tai chi can help increase flexibility.
- Fluid intake may be lower than desirable. Dehydration can contribute to kidney stones, strain on the heart and cardiovascular system, or even drug toxicity. Encourage daily intake of 30 mL/kg of water and other liquids.

**TABLE 1-24 Medications Commonly Used by Adult Women and Men**

<b>Infertility</b>	Smoking can reduce the ability of sperm to bind to an egg and can also reduce fertility in women (Bordel et al, 2006). Oxidative stress is detrimental to sperm function and a significant factor in male infertility. Dietary and supplementary intake of the antioxidants vitamin C, vitamin E, and beta-carotene on sperm chromatin integrity (Silver et al, 2005).
<b>Women: Childbearing Age</b>	
Infertility and miscarriages	Genetic defects in the MTHFR (methyltetrahydrofolate reductase) enzyme can cause spontaneous abortions and infertility; forms of L-methylfolate (such as Deplin® or Neevo®) may be needed.
Intrauterine devices	May increase menstrual losses of iron and vitamin C.
Interstitial cystitis (IC)	Acidic foods and beverages such as coffee, alcoholic beverages, fruit juices, carbonated beverages, tomato products, hot peppers, and other spicy foods or beverages may cause irritation. Use buffering products or pain relievers.
<b>Women: Menopause</b>	
Bone density loss	Low doses of Megace (megestrol acetate) may be used to decrease hot flashes in postmenopausal women who cannot take estrogen. Megace can cause increased appetite, edema, and sodium retention.
<b>Men: Baldness</b>	
	Alendronate (Fosamax) may be used to maintain bone density without breast cancer risk.
	Androgenic alopecia (baldness) may suggest higher risk for prostate cancer or for early, severe coronary heart disease.
	Rogaine (minoxidil) can cause diarrhea, low blood pressure, nausea, vomiting, and weight gain; it is a vasodilator. A low-sodium, low-calorie diet may be beneficial.
	5-Alpha reductase catalyzes the conversion of testosterone to dihydrotestosterone. Disturbances in 5-alpha reductase activity in skin cells might contribute to male pattern baldness, acne, or hirsutism. Plant homologs are being tested.
<b>Men: Prostate Problems</b>	
	Proscar (finasteride) and other medications are used with some relief. Monitor blood pressure; no nutritional side effects are noted. Saw palmetto may be useful (see following herb section).
	Antioxidant foods may help protect against prostate cancer (Kranse et al, 2005). Brazil nuts, seafood, and whole grains are natural sources of selenium. Lycopene from dietary sources (tomato sauce, pink grapefruit) are preferable over supplements. Broccoli and cauliflower also be protective.

- Coffee and tea contain antioxidants that can be preventive against cancers, diabetes, heart disease, and Parkinson's disease; moderate daily inclusion may be promoted.
- Annual doctor visits are reasonable. Cholesterol, dental check-ups, BP screening should start at age 20; women need Pap smears and vaccinations against Human papilloma virus (HPV) and cervical cancer (Gardasil®). Women more than 35 years of age should be tested for thyroid status (as with the thyroid stimulating hormone (TSH) test) and should schedule mammograms at least every 3 years. Periodic electrocardiograms (EKGs) and fasting blood glucose are useful after age 40. After age 50, a fecal occult blood test, bone density scan, and (for men), a prostate-specific antigen test should be added. Vaccines for tetanus, flu, shingles, and pneumonia are useful after age 60.
- Help clarify conflicting information about a "serving" and a "portion" on food labels.
- The American Council on Science and Health (ACSH) ranks consumer magazines as sources of reliable nutrition information; *Parents*, *Cooking Light*, and *Good Housekeeping* rank highly.
- Discuss food choices when eating away from home. For travelers who experience jet lag, adjust meal times to match new time zone, which may help the liver adjust more readily.
- Discuss calcium alternatives for people who exclude milk products. There are calcium-fortified foods and beverages,

such as fortified orange juice, cereals, mineral waters, and margarine.

- For people living in northern climates, taking vitamin D<sub>3</sub> may be important.
- Discuss the role of managing BP and how diet can help. Ignoring high BP can set the stage for stroke, dementia, and heart disease later in life. Intensive diet and physical activity modifications can greatly reduce disease risk (Aldana et al, 2005).
- Determine psychological readiness for dietary and lifestyle change and the individual's current stage. The Transtheoretical Model for Stages of Change (precontemplation, contemplation, preparation, action, maintenance, or termination) is a useful tool that defines motivation as a dynamic process (Prochaska and DiClemente, 1982). People in the action stages tend to display healthier eating; demographic and psychosocial factors help to mediate readiness to change dietary factors; and precontemplators need individually tailored interventions.
- Many primary care patients are ready to lose weight, improve diet, and increase exercise (Wee et al, 2005). Concentrate on small changes with the client.
- The "Slow Food" movement is trying to counter the fast-food culture by returning to traditional foods, having pleasurable mealtimes, and enjoying the aroma and flavors of foods more fully.

**TABLE 1-25 Tips for Eating More Fruits and Vegetables**

- Eat at least one vitamin A–rich fruit or vegetable, such as apricots, cantaloupe, carrots, sweet potatoes, spinach, collards, or broccoli each day.
- Eat at least one vitamin C–rich fruit or vegetable such as oranges, strawberries, green peppers, or tomatoes each day.
- Eat several high-fiber fruits or vegetables daily, such as apples, grapefruit, broccoli, baked potato with skin, or cauliflower.
- Eat berries often; blueberries have been highly rated for their antioxidant properties (anthocyanins). Other berries are equally nutritious and contain fiber, quercetin, and other flavonoids.
- Eat cabbage family vegetables, such as cauliflower, broccoli, Brussels sprouts, and cabbage, several times every week.
- Add fruit to cereal or plain yogurt.
- Use fruit juice instead of water when preparing cakes and muffins.
- Drink 100% fruit juice instead of soda.
- Eat a piece of fruit for a morning snack; choose a grapefruit or an orange for an afternoon snack.
- Choose the darkest green or red leaf lettuce greens for salads; add carrots, red cabbage, and spinach.
- Add more vegetables or add tomato juice to soups and stews for vitamins A and C.
- Choose pizza with extra mushrooms, green pepper, onion, broccoli, and tomatoes.
- Munch on raw vegetables with a low-fat dip for an afternoon snack.
- When dining out, choose a side dish of vegetables.
- Fill up most of the plate with vegetables at lunch and dinner.
- Choose fortified foods and beverages, such as juice with added calcium.
- Snack on dried fruits, such as dried apricots, peaches, raisins, or “craisins.”
- Use dried plums (prunes) for a natural laxative.
- Use dried plum puree as a butter or margarine substitute in recipes to reduce fat; use half the measure required.

Refer clients to: (1) *Centers for Disease Control and Prevention. Resources for Fruits and Vegetables.* [http://www.fruitsandveggiesmorematters.org/?page\\_id=71](http://www.fruitsandveggiesmorematters.org/?page_id=71)

- If needed, provide resources to alleviate food insecurity (American Dietetic Association, 2006).
- Discuss fiber, nonmeat vegetarian meals, cooking methods for nutrient preservation, and phytochemicals. Nutrition messages that lead to increased consumption of dietary fiber need to be strengthened.
- The “Total Diet” message is important to share with consumers (American Dietetic Association, 2007). Peer support is effective for increasing fruit and vegetable intake; Table 1-25 lists ways to include more fruits and vegetables and Table 1-26 describes their key nutrients.
- Nutrition information on packaged food labels is useful to teach point-of-purchase tips, and adults can be encouraged to use them (Satia et al, 2005). However, many adults do not know how to use the food label as well as they might. Consumers are confronted with food and dietary supplement products that claim to improve health, manage conditions, and reduce disease risks (Turner et al, 2005). Label reading may be a marker for other dietary behaviors that predict healthful food choices. Table 1-27 describes food labeling terms. Table 1-28 briefly describes Health Claims that are approved and under review by the Food and Drug Administration.
- Avoid food preparation when sick with viral or bacterial infections. Use latex gloves if there are any cuts on the hands. Thoroughly cook meat, poultry, and fish entrees. Keep cold foods cold and hot foods hot.
- Bacteria are commonly found on foods such as green onions (scallions), cantaloupe, cilantro, and many types of imported produce. Wash all fresh fruits and vegetables. Scrub the outside of produce such as melons and cucumbers before cutting.
- Avoid tap water and ice made from tap water; uncooked produce such as lettuce, and raw or undercooked seafood when traveling. Moderate use of alcoholic beverages may prevent foodborne illness; studies are under way to determine why.
- Airline water may not be free from contamination. Use of bottled water is recommended. Coffee and tea may not be hot enough to kill all bacteria.
- Throw out cooked foods that have been at room temperature for longer than 2 hours.
- Consumption of sulforaphane in foods such as broccoli, cauliflower, cabbage and Brussels sprouts may reduce the presence of *Helicobacter pylori*.
- Avoid raw or partially cooked eggs, raw or undercooked fish or shellfish, and raw or undercooked meats because of potential foodborne illnesses.
- Do not use raw (unpasteurized) milk or products made from it.
- Avoid serving unpasteurized juices and raw sprouts.
- Only serve processed deli meats and frankfurters that have been reheated to steaming hot temperature.

### **Patient Education—Food Safety Tips**

- Reminders about hand washing and safe food handling may be important, especially for those adults who prepare and serve meals for others.

**TABLE 1-26 Key Nutrients in Fruits and Vegetables<sup>a</sup>**

Food	Vitamin A, >500 IU	Vitamin C, >6 mg	Folate, >0.04 mg	Potassium, >350 mg	Dietary Fiber, >2 g
<b>Fruits</b>					
Apple, with skin (1 medium)		X			X
Apricot, dried (3)	X	X		X	X
Banana (1 medium)		X		X	X
Blackberries (1/2 cup)					X
Blueberries (1 cup)		X			X
Cantaloupe (1 cup)	X	X		X	
Grapefruit (1/2 medium)		X

Used with permission.<sup>a</sup>X indicates that the item provides 10% or more of the daily value in the serving size specified or at least 2 g of dietary fiber.

**TABLE 1-27 Food Labeling Terms***Labeling Terms*

% Fat free	Food must be a low-fat or fat-free food to include this value
Free	Food contains 0% of the indicated nutrient
Good source	Contains 10–19% of the daily value (DV) for a nutrient
High	Contains 20% or more DV for a nutrient
Lean	Contains 10 g fat or less and 95 mg cholesterol or less (extra lean 5% fat by weight)
Less	Food contains 25% less than original food
Light/lite	Food contains fewer calories or 50% less fat than original food OR description of color (if indicated on the label)
Low	Low fat as 3 g or less; low sodium as 140 mg or less; very low sodium as 35 mg or less; low cholesterol as 20 mg or less; low calorie as 40 calories or less
More	Food contains 110% or more DV than original food
Reduced	Product has 25% or less of a nutrient or the usual calories of that food
Reduced cholesterol	The food contains 75% or less of the cholesterol found in the original product

Source: U.S. Food and Drug Administration.

**TABLE 1-28 Health Claims***(1) Authorized Health Claims*

**Health claims must be supported by significant scientific agreement among experts that the proclaimed benefit of a food or food component on a disease or health-related condition is true (Turner et al, 2005).**

Diet	Disease	Model Claim
Calcium	Osteoporosis	Regular exercise and a healthful diet with enough calcium help teens and young adult white and Asian American women maintain good bone health and may reduce their risk of osteoporosis.
Sodium	Hypertension	Diets low in sodium may reduce the risk of high blood pressure, a disease associated with many factors.
Dietary fat	Cancer	Development of cancer depends on many factors. A diet low in total fat may reduce the risk of some cancers.
Dietary saturated fat and cholesterol	Coronary heart disease	While many factors affect heart disease, diets low in saturated fat and cholesterol may reduce the risk of this disease.
Fiber-containing grain products, fruits, and vegetables	Cancers	Low-fat diets rich in fiber-containing grain products, fruits and vegetables may reduce the risk of some types of cancer, a disease associated with many factors.
Fruits, vegetables, and grain products that contain fiber, particularly soluble fiber	Coronary heart disease	Diets low in saturated fat and cholesterol and rich in fruits, vegetables, and grain products that contain some types of dietary fiber, particularly soluble fiber, may reduce the risk of heart disease, a disease associated with many factors.
Fruits and vegetables	Cancer	Low-fat diets rich in fruits and vegetables may reduce the risk of some types of cancer, a disease associated with many factors.
Folate	Neural tube birth defects	Healthful diets with adequate daily folate may reduce a woman's risk of having a child with a brain or spinal cord birth defect.

(continued)

**TABLE 1-28 Health Claims (*continued*)**

<b>(2) Authorized Health Claims after Petition</b>		<b>When significant scientific agreement is lacking, qualifying statements may be required on the label to describe the strength of the evidence that supports the claim (Turner et al, 2005).</b>
<b>Diet</b>	<b>Disease</b>	<b>Approved Health Claim</b>
Sugar alcohols	Dental caries	"Frequent eating of foods high in sugars and starches as between-meal snacks can promote tooth decay. The sugar alcohol [name of product] used to sweeten this food may reduce the risk of dental caries."
Foods that contain fiber from whole-oat products	Coronary heart disease	"Diets low in saturated fat and cholesterol that include soluble fiber from whole oats may reduce the risk of heart disease."
Foods that contain fiber from psyllium	Coronary heart disease	"Diets low in saturated fat and cholesterol that include soluble fiber from psyllium seed husk may reduce the risk of heart disease."
Soy protein	Coronary heart disease	"Diets low in saturated fat and cholesterol that include 25 g of soy protein a day may reduce the risk of heart disease. One serving of [name of food] provides 6.25 g of soy protein."
Plant sterol/stanol esters	Coronary heart disease	Plant sterols: "Foods containing at least 0.65 g per serving of plant sterols, eaten twice a day with meals for a daily total intake of at least 1.3 g, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [name of the food] supplies ____ g of vegetable oil sterol esters."  Plant stanol esters: "Foods containing at least 1.7 g per serving of plant stanol esters, eaten twice a day with meals for a total daily intake of at least 3.4 g, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [name of the food] supplies ____ g of plant stanol esters."
<b>(3) Qualified Health Claims NOT Approved by FDA</b>		<b>Qualified health claims, where FDA has found some support but not enough clear evidence to allow an approved health claim.</b>
<b>Diet–Disease Relationship</b>	<b>Disease</b>	<b>Qualified Health Claim</b>
Omega-3 fatty acids	Coronary heart disease	Consumption of omega-3 fatty acids may reduce the risk of coronary heart disease. FDA evaluated the data and determined that, although there is scientific evidence supporting the claim, the evidence is not conclusive.
Folic acid, B <sub>6</sub> , B <sub>12</sub>	Vascular disease	As part of a well-balanced diet that is low in saturated fat and cholesterol, Folic Acid, Vitamin B <sub>6</sub> and Vitamin B <sub>12</sub> may reduce the risk of vascular disease. FDA evaluated the above claim and found that, while it is known that diets low in saturated fat and cholesterol reduce the risk of heart disease and other vascular diseases, the evidence in support of the above claim is inconclusive.
Selenium	Cancer	Selenium may reduce the risk of certain cancers. Some scientific evidence suggests that consumption of selenium may reduce the risk of certain forms of cancer. However, FDA has determined that this evidence is limited and not conclusive.
Phosphatidylserine	Dementia	Very limited and preliminary scientific research suggests that phosphatidylserine may reduce the risk of dementia [cognitive dysfunction] in the elderly. FDA concludes that there is little scientific evidence supporting this claim.

# NUTRITION IN AGING

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Aging involves a progression of physiological changes with cell loss and organ decline. Decreased glomerular filtration rate (GFR) and creatine-height index (CHI), constipation, decreased glucose tolerance, and lowered cell-mediated immunity can occur. Energy needs for basal metabolism decrease as much as 10% for ages 50–70 years and by 20–25% thereafter.

Life span is the length of time an organism could live; for humans, this is between 120 and 140 years. But life expectancy (average life span) is seldom beyond 114 years. Many gerontologists prefer to have patients start out a little overweight to support immunity. Nutrition density is an integral part of successful aging; culturally appropriate food and nutrition services should be customized to the individual's needs (American Dietetic Association, 2005).

It is estimated that most of the older population have one or more chronic conditions that would benefit from nutrition interventions. Challenges of nutritional assessment in older adults include limited recall, hearing and vision losses, changes in attention span, and variations in dietary intake from day to day. The inability to perform activities of daily living can be a major concern. Older adults may need assistance with shopping, meal preparation, and in ensuring adequate intake. Food insecurity exists among senior citizens and should be addressed (American Dietetic Association, 2006).

According to the U.S. Census Bureau, people older than 65 years of age comprise 13% of the United States population. Only about 5% of senior citizens are in nursing homes, the others live in the community, often alone. Approximately 20–50% of patients admitted to hospital are malnourished, especially older adults. Although the stress response to surgery (decrease in albumin and transferrin) is not affected by age, serum protein levels return to normal more slowly in older individuals, a factor to consider in older surgical patients. In addition, it is important to consider the wishes of the individual about nutrition and hydration (American Dietetic Association, 2008).

Loss of teeth, decreased salivation, lower nutrient absorption, as well as declining taste and smell, are common problems in the aged. More importantly, BMR declines 2% with each decade of life. LBM declines with each decade, generally replaced by fat. Being too thin is risky to the immune system; weight loss is not desirable in older adults because it is usually difficult for them to recover lost muscle mass. Essentially, older persons consume less food, about one third few calories, than younger people. Over 30% of seniors consume less energy than recommended levels, and 50% have low mineral and vitamin intakes. Lower food intake by this population appears to be a result of smaller meals eaten at a slower rate. In addition, protein intake is below the desired levels in many older adults.

Inflammatory chronic conditions such as obesity, cardiovascular disease, insulin resistance, and arthritis are associated with aging (Jensen, 2008). Seniors exhibit loss of muscle strength, easy fatigue, physical inactivity, slow or unsteady gait, poor appetite, unintentional weight loss, impaired cognition, depression and mortality. Muscle loss with aging (sarcopenia) comes from changes in anabolic hormones, decreased intake of dietary protein, a decline in physical activity, and inflammation driven by cytokines and oxidative stress with elevated levels of interleukin-6 and CRP (Jensen, 2008).

Protein-energy undernutrition contributes to pressure ulcers, immune dysfunction, infections, hip fractures, anemia, muscle weakness, fatigue, edema, cognitive changes, and mortality. While weight loss, depression, dehydration, and feeding problems are the easy to detect, elevated CRP levels should also be noted. Interventions for sarcopenia include enhanced physical activity, resistance exercise, calorie restriction, use of anabolic hormones, anti-inflammatory agents, nutritional supplements, and antioxidants (Jensen, 2008). Nutrition alone is not sufficient.

Growth hormone (GH) supports appetite and intake. Because GH secretion declines after puberty, researchers have developed oral ghrelin mimetics to improve intake, prevent declines in fat-free muscle mass, and reduce abdominal visceral fat in older adults (Hanauer, 2009). Multivitamin-mineral supplementation should be recommended; extra vitamins E, B<sub>12</sub>, B<sub>6</sub>, folate, calcium, and zinc are needed to counteract gastric atrophy, decreased levels of hydrochloric acid, and poor nutrient intakes. Folate and vitamin D<sub>3</sub> seems to play a role in depression and dementia.

Use of medications including digoxin, furosemide, warfarin, paroxetine, nifedipine, ranitidine, theophylline, amlodipine, ciprofloxacin, and sertraline may cause anorexia or nausea. Scrutiny of the rationale of all medications should be undertaken.

Always follow abnormal lab work with evaluation of nutritional intake. Request labs that are truly warranted or cost effective. Low albumin may indicate infection or a draining wound, and not dietary inadequacy. Precipitously declining cholesterol (<150 mg/dL) appears to be a marker for depression, poor nutrition, or mortality. At the opposite end of the spectrum, lowering high cholesterol and homocysteine levels, obesity management, smoking cessation are

beneficial for heart and brain health. The Mediterranean diet has been found to be especially useful. This diet improves cholesterol levels, blood sugar levels and blood vessel health, and reduces inflammation (Scarmeas et al, 2009).

When done properly, medical nutritional therapy can save thousands of dollars *per patient, per hospital stay*. Studies by the American Dietetic Association demonstrate that for every dollar spent on nutrition screening and intervention, at least \$3.25 is saved in healthcare costs.

Common factors used for nutritional risk assessments are found in Table 1-29. The CNAQ, MNA and DETERMINE assessments are short, simple appetite assessment tools that predict anorexia-related weight loss in community-dwelling adults and long-term care residents (Wilson et al, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Each individual has a unique genetic profile and phenotype. Because both parents contribute genes and chromosomes to the fetus, a genetic history may be beneficial.

Clinical/History		
Age	Skin condition and pressure ulcers	Ca <sup>++</sup> , Mg <sup>++</sup> Urinary N Na <sup>+</sup> , K <sup>+</sup>
Height (actual)	Hx of surgery, radiation, chemotherapy	H & H, serum Fe
Weight, current	Mini-Mental	Serum vitamin B <sub>12</sub> , methylmalonic acid
Weight, usual	State Examination	Serum folate
Recent weight changes	Hydration status, I & O	Serum homocysteine
BMI	Clinical signs of malnutrition	Chol, Trig
Waist circumference	DXA for sarcopenia or osteopenia	Alb or transthyretin (can be high in dehydration)
Diet history	Changes in appetite	TSE, MAC, MAMC
Temperature (hypothermia?)	Nausea, vomiting, indigestion	BUN, Creat
BP	Pain	Transferrin
Dentition	Infection	TLC
Eyesight	Abnormal gait or motor coordination	Protime (PT) or international normalized ratio (INR)
Hearing	Sleep disorder screening	
Difficulty in chewing		
Dysphagia		
Constipation, diarrhea		
Fecal impaction		
Changes in bowel habits or incontinence		
Urinary incontinence or indwelling catheter		

#### Lab Work

Glucose  
CRP

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Unintentional Weight Loss In Long-Term Care

**Assessment:** Intake reports and food preferences, I & O records, weight changes, lab values, psychological issues.

**Nutrition Diagnosis (PES):** Involuntary weight loss related to inadequate food and beverage intake as evidenced by 24-lb weight loss and dining room records indicating intake less than 50% at meals.

**Intervention:** Offer more favorite foods; promote consumption of between-meal nourishments, collaboration with social worker.

**Monitoring and Evaluation:** Changes in weight, verbalized improvement in appetite, dining room food intake records.

#### Palliative Care Nutrition

**Assessment:** Individual not eating or drinking; physician-ordered palliative care; resident wishes to have “no heroic measures” including tube feeding as per Advanced Directives.

**Nutrition Diagnosis (PES):** Inadequate food and beverage intake related to patient’s choice to withdraw nutritional support as evidenced by minimal oral intake and palliative care status.

**Intervention:** Make food and fluids available upon patient or family request.

**Monitoring and Evaluation:** Check measures taken for meeting patient or family requests.

### INTERVENTION

#### OBJECTIVES

- Provide proper nutrition for weight control, healthy appetite, prevention of acute illness, and complications of chronic diseases such as osteoporosis, fractures, anemia, obesity, diabetes, heart disease, and cancer.
- Avoid rapid unintentional weight loss, which often indicates underlying disease and accelerated muscle loss (Miller and Wolfe, 2008). Determine baseline functional level and evaluate changes over time.
- Monitor signs of malnutrition. Prevalence increases with age, is more common in institutionalized individuals, and is associated with susceptibility to infection, longer hospital stay, and increased mortality (Hudgens and Langkamp-Henken, 2005). Malnutrition may be caused by poverty, ignorance, chronic disease, poor dietary intake, chewing or swallowing problems, polypharmacy, mental or physical disability, even depression. MIA syndrome reflects the triad of malnutrition, inflammation, and atherosclerosis that often includes oxidative stress and elevated cytokines.
- Correct existing nutritional deficiencies. Avoid restrictive diets as much as possible (Niedert, 2005).
- Recognize cachexia syndromes that are not reversible by hypercaloric feeding. Sometimes failure of nonpharmacologic therapies warrant consideration of orexigenic drug therapy. Malnourished older adults benefit from receiving oral supplemental beverages.
- Vitamin B<sub>12</sub> deficiency in older people is most often from malabsorption of food-bound vitamin B<sub>12</sub> (Johnson, 2007). High serum folate levels along with vitamin B<sub>12</sub> deficiency

**TABLE 1-29 Nutrition Assessment Tools for the Elderly**

<b>DETERMINE Checklist</b>	<b>Warning signs for malnutrition</b> (from the Nutrition Screening Initiative, a project of the American Academy of Family Physicians, The American Dietetic Association and the National Council on the Aging, Inc., and Abbott Laboratorie, 1994. No longer published.)	<b>Nonphysiological Causes of Undernutrition</b>	
D	Disease (illness affects nutritional intake)	Social factors	Poverty Inability to shop Inability to prepare and cook meals Inability to feed oneself Living alone, social isolation, or lack of social support network Failure to cater to ethnic food preferences
E	Eating poorly, especially fewer than two meals daily	Psychological factors	Dementia Alcoholism Bereavement Depression Phobia about cholesterol, fat, calories
T	Tooth loss, mouth pain, chewing difficulty		
E	Economic hardship (too few dollars to buy food)	Medical factors	Anorexia, early satiety, malabsorption, increased metabolism, cytokine-mediated and impaired functional status
R	Reduced social contact; eating meals alone		Cancer Alcoholism Cardiac failure Chronic obstructive pulmonary disease Infection Dysphagia Rheumatoid arthritis Parkinson disease Hyperthyroidism, HIV or AIDS
M	Multiple medicines (three or more prescribed or over-the-counter medications)		
I	Involuntary weight loss or gain (10 lb in 6 months)	Gastrointestinal issues	Malabsorption syndromes Dyspepsia, atrophic gastritis, vomiting Diarrhea or constipation Poor dentition
N	Needs assistance with self-care (shopping, cooking, eating)		
E	Elderly years (older than 80 years of age), with increasing frailty		
<b>MNA: Mini Nutrition Assessment</b>	MNA is a reliable and easy-to-use nutritional assessment tool for physicians, dietitians, medical students, or nurses to quickly evaluate the nutritional status of an individual (Nestle.) <a href="http://www.mna-elderly.com/clinical-practice.htm">http://www.mna-elderly.com/clinical-practice.htm</a>	<b>CNAQ: Council on Nutrition Appetite Questionnaire</b>	Eight questions from the Council on Nutrition <a href="http://medschool.slu.edu/agingsuccessfully/pdfsurveys/appetitequestionnaire.pdf">http://medschool.slu.edu/agingsuccessfully/pdfsurveys/appetitequestionnaire.pdf</a> .
18 questions, 4 categories: anthropometric assessment, general assessment, dietary assessment, subjective assessment	Asks questions relating to the last 3 months, such as: <ul style="list-style-type: none"> <li>• Weight loss; BMI</li> <li>• Mobility problems; psychological stress; acute disease</li> <li>• Food intake, digestive problems, chewing or swallowing difficulties</li> <li>• Depression or dementia</li> </ul>	<b>A. My appetite is</b>	1. Very poor 2. Poor 3. Average 4. Good 5. Excellent
		<b>B. When I eat, I feel full after</b>	1. Eating only a few mouthfuls 2. Eating about $\frac{1}{3}$ of a plate or meal 3. Eating over $\frac{1}{2}$ of a plate or meal 4. Eating most of the food 5. Hardly ever
<b>SGA: Subjective Global Assessment</b>	SGA classification technique can aid in the recognition of undernutrition by assessing a patient's nutritional status based on features of the medical history and physical examination. See Section 13 for examples of the SGA.	<b>C. I feel hungry</b>	1. Never 2. Occasionally 3. Sometimes 4. Most of the time 5. All of the time
		<b>D. Food tastes</b>	1. Very bad 2. Bad 3. Average 4. Good 5. Very good
<b>SNAP: Malnutrition Screening in Senior Citizens</b>	Common factors to assess (adapted from the Australian College of Royal General Practitioners. SNAP: a population guide to be behavioral risk factors in general practice. <i>Austr Fam Phys.</i> 33:1, 2004.)	<b>E. Compared to when I was 50, food tastes</b>	1. Much worse 2. Worse 3. Just as good 4. Better 5. Much better
Protein and muscle mass	Impaired synthesis of new tissue Decline of the protein reserve of the body Diminished capacity to meet the extra demand of protein synthesis associated with disease or injury Increased frailty Sarcopenia	<b>F. Normally, I eat</b>	1. Less than one regular meal a day 2. One meal daily 3. Two meals daily 4. Three meals daily 5. Over three meals daily including snacks
Nutrient deficits	Decreased energy intake; anorexia of aging	<b>G. I feel sick or nauseated when I eat</b>	1. Most times 2. Often 3. Sometimes 4. Rarely 5. Never
Changes in mobility	Falls Illness Hospitalization Immobilization	<b>H. Most of the time my mood is</b>	1. Very sad 2. Sad 3. Neither happy nor sad 4. Happy 5. Very happy
		<b>Total Score</b>	Add the numbers associated with the patient's response. 8–16 at risk for anorexia and needs nutrition counseling 17–28 patient needs frequent reassessment >28 patient is not at risk at this time.

exacerbate anemia and can worsen cognitive symptoms, therefore careful monitoring is important (Clarke et al, 2007; Johnson, 2007; Tangney et al, 2009).

- Provide foods of proper consistency by dental status. Dentures alter the taste of foods by increasing bitter and sour taste sensations (Duffy et al, 1999). Chop foods as needed; puree only if necessary.
- Provide a diet of correct texture; exclude hard, sticky foods that are difficult to chew and swallow.
- Older individuals have fewer taste buds. More sweet flavors and stronger seasonings may be required to satisfy the appetite.
- Evaluate for laxative and enema use or abuse; recommend suitable alternatives and interventions, such as oat fiber, prunes or other dried fruits, extra liquid.
- Evaluate for alcohol abuse; make appropriate referrals as needed.
- “If the gut works, use it.” Maintain oral diet as much as possible. For individuals who are unable to regain unintentional weight losses, artificial nutrition may be needed. Review advance directives and proceed accordingly.
- Investigate hydration status and any major weight shifts. Diminishing thirst mechanisms and incontinence contribute to dehydration. Generally, older adults should ingest 25–30 mL/kg of fluids per day. Alterations would be needed for heart, liver, or renal failure.
- Indices of overweight and obesity such as BMI do not correlate as strongly with adverse health outcomes in older as compared to younger individuals (Miller and Wolfe, 2008).
- Assess the behavioral and environmental situations (i.e., Who shops? Who cooks? How are finances handled? How often are meals eaten away from home? Is this person dependent or independent?). Evaluate family and social support. If there is a need for assistance, make appropriate referrals.
- Correct frailty where possible by addressing depression, use of multiple medications, underlying medical illnesses. Low levels of serum cholesterol (<189 mg/dL) may indicate signs of occult disease or rapidly declining health.
- Encourage physical activity, especially resistance training. This can help to maintain metabolically active tissue, stimulate appetite, improve sleep, correct mild constipation, improve cognitive function, enhance nitrogen balance, and promote positive outcomes in memory, self-esteem, and independence.

## FOOD AND NUTRITION

- Ensure intake of the MyPyramid Food Guidance System: 3–4 servings of milk, dairy products, or calcium substitutes; 2–3 servings of protein foods (meat or substitute); 3–5 servings of vegetables; 2–4 servings of fruits; and 6–12 bread group servings. Recommend fats, oils, alcohol, sugars, and sweets to increase or decrease energy intake, as appropriate for the individual.
- Diet should provide adequate intake of protein: 0.8–1 g/kg body weight. This may mean 63 g for men and 50 g for women. Considering liver and renal impairments, decrease protein intake if needed. Increase protein intake in case of pressure ulcers, cancers, infections and other conditions requiring tissue repair.
- Energy: 25–35 kcal/kg. The Institute of Medicine suggests that the average 75-year-old female and male need

2403 and 3067 kcal, respectively, if ambulatory. Fewer kilocalories are needed if nonambulatory (e.g., living in an institution). Nutritional supplements may provide needed energy and protein for nursing home residents (Avenell and Handoll, 2010). See Table 1-30.

- Consume 1200 mg of calcium from milk, yogurt, and related dairy products when possible. Include sources of the B vitamins and zinc. Iron needs are lower in women after menopause, but include at least the RDA. Ensure sufficiency of other nutrients according to the patient's age and sex, using Table 1-29.
- If patient has heart disease or hypertension, encourage the Mediterranean diet or the DASH diets. Liberalize where possible to keep intake at a sufficient level. Extra natural vitamin E may be used from nuts, olive and canola oils, and some fruits and vegetables.
- The consistency of the food should be altered (i.e., ground, pureed, or chopped) only as required. Try to maintain whole textures as often as possible to enhance the food's appeal and to increase chewing with saliva. Mechanically altered diets are often not necessary, may have been started inappropriately, and may compromise taste, acceptability, and micronutrient intake.
- Adequate fiber and fluid intakes are necessary. Prudent increases in fiber (e.g., from prunes and bran) can reduce laxative abuse. Dehydration is a common cause of confusion and should be identified or avoided.
- A low-fat, vegan diet is associated with significant weight loss in overweight postmenopausal women, even without prescribed limits on portion size or energy intake (Barnard et al, 2005). If obesity is present, this change may improve health status.
- Adequate amounts of vitamins C and D, folic acid, and iron are often deficient in the diets of older individuals. Vitamin C levels must be increased for those individuals who smoke. Consider a multivitamin–mineral supplement.
- When taste and olfactory sensations are weak, the diet should provide adequate intake of zinc, folate, and vitamins A and B<sub>12</sub>. Season with herbs and spices; add butter-flavored seasonings, garlic, maple or vanilla extract, and cheese or bacon-flavored seasonings. Consider all possible taste enhancers.
- Increased thiamin may be needed because of decreased metabolic efficiency. Men are especially susceptible.
- Reduce intake of excessive sweets; poor glucose tolerance and insulin resistance are common after 65 years of age.
- If early satiety is a problem, serving the main meal at noon may help with overall intake.
- Encourage socialization at mealtimes. Healthy individuals have food intakes that are greater when eating with other people, especially family or friends.
- Offer substitutes for major foods not consumed. If the individual resides in an institution, it is recommended to try other menu alternatives before offering a nutritional supplement as a meal replacement. Consult a dietitian if intake is chronically poor. If necessary, liquid supplements can provide needed energy, protein, and micronutrients.
- Offer tips for those who must eat alone. Menus and shopping tips may be needed, such as cooking in batches and freezing extra portions.
- For hospice patients, provide comfort foods and liquids as requested.

**TABLE 1-30 Dietary Reference Intakes for Older Adults (continued)**

		Elements and Macronutrients						Drinking Water, Beverages, Water in Food (L)	
		Energy (kcal) <sup>b</sup>	Protein (g) <sup>c</sup>	Carbohydrates (g) <sup>d</sup>	Total Fat (% kcal) <sup>e,f</sup>	<i>n</i> -6 PUFA (g)	<i>n</i> -3 PUFA (g)		Total Fiber (g)
RDA or AI <sup>a</sup>									
Age 51–70	Male	2204	56	130		14*	1.6*	30*	3.7*
	Female	1978	46	130		11*	1.1*	21*	2.7*
Age 70+	Male	2054	56	130		14*	1.6*	30*	2.6*
	Female	1873	46	130		11*	1.1*	21*	2.1*
AMDR <sup>a</sup>			10–35%	45–65%	20–35%	5–10%	0.6–1.2%		

<sup>a</sup>Recommended dietary allowances (RDAs) are in **bold type** and adequate intakes (AIs) are in ordinary type followed by an asterisk (\*).

<sup>b</sup>Values are based on Table 5-22 estimated energy requirements (EER) for men and women 30 years of age. Used height of 5'7", "low active" physical activity level (PAL), and calculated the median BMI and calorie level for men and women. Caloric values based on age were calculated by subtracting 10 kcal/d for males (from 2,504 kcal) and 7 kcal/d for females (from 2,188 kcal) for each year of age above 30. For ages 51–70, calculated for 60 years old, for 70+, calculated for 75 years old. 80 year old male calculated to require 2,004 kcal, female, 1,838 kcal.

<sup>c</sup>The RDA for protein equilibrium in adults is a minimum of 0.8 g/kg body weight for reference body weight.

<sup>d</sup>The RDA for carbohydrate is the minimum adequate to maintain brain function in adults.

<sup>e</sup>Because percentage of energy consumed as fat can vary greatly and still meet energy needs, an AMDR is provided in absence of AI, EAR, or RDA for adults.

<sup>f</sup>Values for mono- and saturated fats and cholesterol not established as "they have no role in preventing chronic disease, thus not required in the diet."

<sup>g</sup>Acceptable macronutrient distribution ranges (AMDRs) for intakes of carbohydrates, proteins, and fats expressed as percentage of total calories.

The values for this table were excerpted from the Institute of Medicine, *Dietary reference intakes: Applications in dietary assessment*, 2000, and *Dietary reference intakes for energy, carbohydrates, fiber, fat, protein and amino acids (macronutrients)*, 2002.

<sup>h</sup>Recommended dietary allowances (RDAs) are in bold type and adequate intakes (AIs) are in ordinary type followed by an asterisk (\*).

ND—Indicates values not determined.

The values for this table were excerpted from the Institute of Medicine, *Dietary reference intakes: Applications in dietary assessment*, 2000, and *Dietary reference intakes for energy, carbohydrates, fiber, fat, protein and amino acids (macronutrients)*, 2002.

	Electrolytes		
	Potassium (g)	Sodium (g)	Chloride (g)
RDA or AI <sup>a</sup>			
Age 51–70 Male	4.7	1.3*	2.0*
Female	4.7	1.3*	2.0*
Age 70+ Male	4.7	1.2*	1.8*
Female	4.7	1.2*	1.8*
Tolerable upper intake levels <sup>a</sup>			
Age 51–70 Male		2.3	3.6
Female		2.3	3.6
Age 70+ Male		2.3	3.6
Female		2.3	3.6

<sup>a</sup>Recommended dietary allowances (RDAs) are in bold type and adequate Intakes (AIs) are in ordinary type followed by an asterisk (\*).

ND—Indicates values not determined.

The values for this table were excerpted from the Institute of Medicine, *Dietary reference intakes: Water, potassium, sodium, chloride, and sulfate*, 2004.

## Common Drugs Used and Potential Side Effects

- Discuss the relevance of tolerable ULs from the latest dietary reference intakes of the National Academy of Sciences. These levels were set to protect individuals from receiving too much of any nutrient from diet and dietary supplements.
- Many drugs affect the nutritional status of the patient. A thorough drug history is needed.
- Drug metabolism and detoxification require an adequate diet containing methionine and other sulfur amino acids; vitamins A, B<sub>12</sub>, C, and E; choline; folate and selenium.
- Polypharmacy is common in older adults, especially those living in institutionalized settings.

- Long-term use of high-carbohydrate, low-protein diets is undesirable when protein-bound drugs are prescribed. Drug metabolism is slowed, a potentially dangerous occurrence. See Table 1-31.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician, especially for underlying medical conditions.
- Older people should be encouraged to report the use of herbs and nutritional supplements to their doctors. Doctors should provide comprehensive and current information about potential herb–drug interactions. Among older

**TABLE 1-31** Drugs with Potentially Undesirable Side Effects in Seniors

Effect	Medications
Addiction	Amphetamines, anorexic agents, and barbituates
Anorexia	Antibiotics, digoxin
Calcium and fat-soluble vitamin depletion	Mineral oil as a laxative
Confusion	Cimetidine (Tagamet) can decrease vitamin B <sub>12</sub> levels
Constipation	Opiates, iron supplements, diuretics
Decreased sense of taste	Metronidazole, calcium channel blockers, angiotensin-converting enzyme (ACE) inhibitors, metformin
Diarrhea	Laxatives, antibiotics
Dysphagia	Potassium supplements, NSAIDs, bisphosphonates, prednisolone
Early satiety	Anticholinergic drugs, sympathomimetic agents
Hypotension	Cardiac drugs (amiodarone, guanethidine, guanadrel, doxazosin, nifedipine, and clonidine)
Hypermetabolism	Thyroxine, ephedrine
Nausea/vomiting	Antibiotics, opiates, digoxin, theophylline, nonsteroidal anti-inflammatory drugs (NSAIDs)
Neurological effects	Indomethacin
Reduced feeding ability	Sedatives, opiates, psychotropic agents
Renal clearance, decreased	Digoxin
Urinary excretion of electrolytes and water-soluble vitamins	Diuretics: thiamin deficiency; a low-dose thiamin supplement may be useful to prevent subclinical beri-beri (McCabe-Sellers et al, 2005). Diuretics can also decrease serum levels of potassium, magnesium, calcium, and zinc.
Vitamin C, iron and folic acid depletion	Large amounts of aspirin
Vitamin K and B-complex depletion	Sulfonamides

adults, herbal supplement users are more likely to perceive their supplements as safe and to consider conventional medicine to be less effective than nonusers (Shahrokhi et al, 2005).

- Increases in prostaglandin E<sub>2</sub> production contribute to the decline in T-cell-mediated function with age. Black currant seed oil is rich in both gamma and alpha linoleic acids.
- Creatine supplements have been used to increase strength in older individuals; results are mixed.
- Echinacea may be used as an immune system stimulant. It should not be taken with steroids, cyclosporine, or immunosuppressants. It may aggravate allergies in susceptible individuals.
- Ginkgo biloba is proposed for memory support; studies show no effectiveness.
- Ginseng may be used for stress adaptation, impotence, or as a digestive aid. It should not be taken with warfarin, insulin, oral hypoglycemics, CNS stimulants, caffeine, steroids, hormones, antipsychotics, aspirin, or antiplatelet drugs.
- Kava is sometimes used as a sleep aid. Discourage use with sedatives, alcohol, antipsychotics, or other CNS depressants.
- Vitamin E supplements may ward off colds or flu in older people (Meydani et al, 2004).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Efforts to correct malnutrition in seniors are beneficial. Numerous tools are available and can be used in a variety of settings.
- Dietitians should handle nutritional discharge planning (Baker and Wellman, 2005). Senior citizens often improve protein intake after appropriate counseling (Rousset et al, 2006).
- Emphasize the need to consume adequate amounts of calcium, folic acid, vitamins A, E, and D. Review the desired nutrient intakes with the client; supplemental iron is not often needed unless there is anemia. Vitamin B<sub>12</sub> and thiamin may be needed, depending on medications used and concurrent chronic disease.
- Be aware of income limitations when planning a menu—less-expensive protein sources may be necessary. Discuss shopping and meal preparation tips.
- Prevent excessive use of caffeine from coffee, colas, and tea if it prevents intake of other desirable juices and beverages. Three 6- to 9-oz cups of coffee per day pose no specific health risk and caffeine may also promote improved cognition.
- Make every effort to determine whether the patient is using alcohol because multiple deficiencies may result, especially for thiamin, vitamin B<sub>12</sub>, folate, and zinc. Make appropriate referrals. Older adults may not admit the true amount of alcohol being consumed because of embarrassment.
- Encourage participation in Meals on Wheels, SNAP (food stamps), congregate feeding programs, and Senior Farmers' Market programs.
- Ensure adequate fluid intake for age and medical condition. Ensure that the diet provides adequate fluid and fiber to alleviate constipation.
- Encourage physical activity such as strength conditioning and walking. Yoga may help to prevent weight gain with aging.

**TABLE 1-32 Weight Table for Men Aged 70 and Over**

Height (inches)	Ages 70–74	Ages 75–79	Ages 80–84	Ages 85–89	Ages 90–94	Ages Over 94
61	128–156	125–153	123–151	120–145	118–142	113–139
62	130–158	127–155	125–153	122–148	119–143	114–140

73	164–200	160–196	158–192	157–189	156–187	155–177
74	169–205	165–201	163–197	162–190	160–188	158–181

Adapted from: *J Am Med Assoc.* 177:658, with permission of American Medical Association, Copyright 1960.

- Olfactory decline is common. Flavorful foods release endorphins, which boosts the immune system (Duffy et al, 1999). Discuss adding herbs, spices, and other flavor enhancers to foods.
- Hypothermia (body temperature of 95°F or lower) can occur, with fatigue, weakness, poor coordination, lethargy, slurred speech, and drowsiness. Give hot beverages and keep patient in a warm bed. If body temperature reaches 90°F, death is likely.
- Support intake of antioxidants to protect the aging brain. Top choices include: grape juice, blueberries, pomegranate, papaya, kiwifruit, cantaloupe, mango, apricot, broccoli, spinach, tomato, sweet potato, and collards.
- Encourage physical activity. Peer and leader encouragement for strength training is especially beneficial in this age group (Layne et al, 2008).
- Restorative dining may require attention. The American Dietetic Association has suggested three visits for medical nutrition therapy for restorative dining procedures.
- For patients with a history of, current status of, or risk for dehydration, the American Dietetic Association recommends two or more medical nutrition therapy visits.
- For end of life, advanced directives document a patient's wishes, regardless of the setting. If advance directives

**TABLE 1-33 Weight Table for Women Aged 70 and Over**

Height (inches)	Ages 70–74	Ages 75–79	Ages 80–84	Ages 85–89	Ages 90–94	Ages Over 94

**TABLE 1-34 Formula for Calculating Stature Using Knee Height**

Knee height can be used to estimate standing height in a bedridden or handicapped person. Knee height is not affected by aging. Different populations may require the use of different equations; equations derived from taller statured populations (e.g., Caucasians) may be less accurate when applied to shorter statured populations. Sample formulas are as follows:

Stature for Caucasian men =  $64.19 - (0.04 \times \text{age in years}) + (2.02 \times \text{knee height in cm})$

Stature for Japanese men =  $71.16 - (0.56 \times \text{age in years}) + (2.61 \times \text{knee height in cm})$

Stature for Caucasian women =  $84.88 - (0.24 \times \text{age in years}) + (1.83 \times \text{knee height in cm})$

Stature for Japanese women =  $63.06 - (0.34 \times \text{age in years}) + (2.38 \times \text{knee height in cm})$

Sources: Chumlea, 1984; Chumlea et al, 1994; Knous and Arisawa, 2002; and Mendoza-Nunez et al, 2002.

indicate “no heroic measures,” be sure to identify if that includes tube feeding and hydration. Both terminally ill patients and their caregivers need education, information, advocacy, and emotional support. Effective end of life discussions lead to earlier hospice referral and less-aggressive treatments (Wright et al, 2008).

- Depression affects 20–40% of older Americans but is not a normal part of aging. It causes a lot of weight loss in nursing homes and in the community and must be treated. Tables 1-32, 1-33, and 1-34 can be used to follow weight changes in older adults.

### Patient Education—Food Safety Tips

- Reminders about hand washing and safe food handling may be important, especially for adults who prepare and serve meals for older adults. Check out the home food safety website at <http://www.homefoodsafety.org/pages/tips/tips/adults.jsp>
- Avoid food preparation when sick with viral or bacterial infections; use gloves if needed.
- Thoroughly cook meat, poultry, and fish entrees. Keep cold foods cold and hot foods hot.
- Because bacteria are commonly found on foods such as green onions (scallions), cantaloupe, cilantro, and imported produce, wash all fresh fruits and vegetables. Scrub the outside of produce such as melons and cucumbers before cutting.
- When traveling, avoid tap water and ice made from tap water, uncooked produce such as lettuce, and raw or undercooked seafood.
- Airline water may not be free from contamination. Use of bottled water is recommended. Coffee and tea may not be hot enough to kill all bacteria.
- Throw out cooked foods that have been at room temperature for longer than 2 hours.
- Consumption of sulfuraphane in foods such as broccoli, cauliflower, cabbage, and Brussels sprouts may reduce the presence of *Helicobacter pylori*, which is beneficial.
- Avoid raw or partially cooked eggs, raw or undercooked fish or shellfish, and raw or undercooked meats because of potential foodborne illnesses.
- Do not use raw (unpasteurized) milk or products made from it.
- Avoid serving unpasteurized cider, juices, and raw sprouts because they may contain *Escherichia coli*.

- Only serve processed deli meats and frankfurters that have been reheated to steaming hot temperature. If the patient is immunocompromised, it may be best to avoid deli meats and ready-to-eat meat and poultry products; smoked fish; and soft cheese such as brie and blue-veined varieties because of the risk for *Listeria*. Homemade egg nog, cookie and cake batter, and other foods prepared with raw eggs should be avoided because of the risks of *Salmonella*.
- Raw seafood such as oysters, clams, and mussels may contain *Vibrio* bacteria. Caution or avoidance is recommended.

# Nutrition Practices, Food Safety, Allergies, Skin and Miscellaneous Conditions

## CHIEF ASSESSMENT FACTORS

- Complementary and Integrative Medicine, Including Use of Herbs, Spices, and Botanical Products
- Cultural or Religious Preferences with Special Diets or Practices
- Vegetarian Diets (see also Table 2-4)
- Mouth: Dental Problems, Periodontal Diseases, Dentures (Ill-Fitting), Missing or Loose Teeth, Caries, Oral Hygiene and Dental Care, Increased or Decreased Salivation, Dryness, Lesions (see also Tables 2-5 and 2-6)
- Problems with Self-Feeding
- Vision: Cataracts, Visual Field Changes, Diplopia, Glaucoma, Macular Degeneration, Blindness (see also Table 2-7)
- Skin: Texture or Color Changes, Dryness, Ecchymoses, Lesions, Masses, Petechiae, Pressure Ulcers (see also Table 2-8)
- Physical Signs of Nutrient Deficiencies
- Head/Face: Pain, Past Trauma, Syncope, Unusual or Frequent Headaches
- Ears: Hearing Problems, Discharge, Infections, Tinnitus, or Vertigo
- Food Allergies or Intolerances
- Food-Borne Illnesses

## Possible Nutrition Diagnoses

- Inadequate intake of bioactive substances?
- Excessive intake of bioactive substances?
- Harmful beliefs about food and nutrition?
- Inadequate oral food and beverage intake (if foods served are unfamiliar or forbidden)?
- Harmful beliefs about food and nutrition (such as pica)?
- Inadequate protein intake?
- Inadequate mineral (iron, calcium, zinc) or vitamin intakes ( $B_{12}$ , D)?
  - Disordered eating pattern (unusual diet excluding multiple food groups)?
  - Underweight or involuntary weight loss?
  - Excessive fiber intake (phytates)?
  - Inadequate intake of fat (omega 3 fatty acids)?
  - Difficulty chewing?
    - Inadequate oral food and beverage intake?
    - Difficulty swallowing?
    - Involuntary weight loss?
    - Excessive carbohydrate intake (sugars, sweets, beverages)?

- Inadequate vitamin or mineral intakes?
- Self-feeding difficulty (functional, physical, psychological)?
- Malnutrition?
- Inadequate oral food and beverage intake?
- Involuntary weight loss?
- Altered nutrition-related lab values?
- Inadequate protein intake?
- Inadequate fluid intake?
- Underweight?
- Inadequate protein intake or increased nutrient needs (protein)?
- Inadequate vitamin intake (list specifics)?
- Increased nutrient needs (vitamins)?
- Excessive sodium intake?
- Inadequate oral food and beverage intake (from nausea, anorexia)?
- Intake of unsafe food (allergens)?
- Altered GI function (diarrhea)?
- Intake of unsafe food (pathogens)?

## COMPLEMENTARY OR INTEGRATIVE NUTRITION

# COMPLEMENTARY OR INTEGRATIVE NUTRITION

## NUTRITIONAL ACUITY RANKING: LEVEL 2 (NUTRITIONAL ADVISING)

### DEFINITIONS AND BACKGROUND

The philosophy that food can be health promoting beyond its nutritional value has gained acceptance within the public arena. Functional foods are so named because whole foods and fortified, enriched, or enhanced foods have a potentially beneficial effect on health when consumed as part of a varied diet on a regular basis, at effective levels (American Dietetic Association, 2009). Fish provides fish oils; fermented dairy products have probiotics; and beef has conjugated linoleic acid. Oats provide beta-glucan, soy provides isoflavones, flaxseed provides lignins and alpha-linolenic acid, garlic provides organosulfur compounds, broccoli and cruciferous vegetables provide isothiocyanates and indoles, citrus fruits provide limonoids, cranberry provides polymeric compounds, tea provides catechins, and wine provides phenolics (American Dietetic Association, 2009).

Many plants and herbs contain biologically active phytochemicals with potential for disease prevention. Patients may use herbal medicines but not tell their healthcare providers (van der Voet et al, 2008). About one third of Americans take a vitamin-mineral supplement daily (Thomson et al, 2005). Nutrition is an integral part of many complementary therapies for cancer, arthritis, chronic pain, human immunodeficiency (HIV) virus, and gastrointestinal (GI) problems. Dried culinary herbs (e.g., oregano, sage, peppermint, garden thyme, lemon balm, clove, allspice, and cinnamon) contain very high concentrations of antioxidants (i.e., >75 mmol/100 g) and

contribute significantly to the total intake of plant antioxidants by many people (Dragland et al, 2003).

Dietitians are uniquely qualified to translate sound scientific evidence into practical applications, yet many are not confident about the roles of herbs in prevention and treatment of illnesses. Education and training are important for the dietetic practitioner in preparing to answer questions about complementary nutrition. Dietitians should be able to describe implications of FDA structure/function claims, explain how to read labels, identify sound resources, associate common dietary supplements and their appropriate uses, and assess the science behind the supplement claims (Thomson et al, 2005).

Dietetics professionals are trained to assess dietary adequacy and the need for nutrient modifications (American Dietetic Association, 2005). Therefore, this text focuses on herbs, spices, and botanical products and does not cover the additional concepts and practices of homeopathy, acupuncture, traditional Chinese or Indian medicine. While some individuals need dietary supplements because of disease states, certain life stages, or chronic conditions, it is important to respect those cultural patterns and habits in which herbs and botanicals are used as medical or dietary enhancements. Clinicians should be aware of all the dietary supplements that their patients consume, and help their patients make informed decisions (Sadovsky et al, 2008). Table 2-1 lists questions to ask and Table 2-2 lists products that are used. Consider any adverse effects and discuss as needed.

**TABLE 2-1 Herbal, Botanical, and Dietary Supplement Intake**

- Identify types of supplements that you use:** \_\_\_None \_\_\_Multivitamin/mineral supplement \_\_\_Vitamin C \_\_\_Calcium/Vitamin D \_\_\_Protein supplement \_\_\_Fiber supplement \_\_\_Fish oil \_\_\_Herbal supplement (such as aloe, black cohosh, calcium, ginseng, ginkgo biloba, valerian) specify: \_\_\_\_\_
- For how long?** \_\_\_1 month or less \_\_\_3–6 months \_\_\_6–12 months \_\_\_>1 year
- How long will you use these supplements?** \_\_\_Indefinitely \_\_\_1–6 months \_\_\_6–12 months
- Why do you take this supplement(s)?** \_\_\_Prevention against disease \_\_\_General wellness \_\_\_Energy \_\_\_Weight loss \_\_\_Other reason (specify) \_\_\_\_\_ To help treat a disease. If so, what are your medical symptoms? \_\_\_\_\_ and how long have you had this medical condition? \_\_\_<week \_\_\_1–3 months \_\_\_3–12 months \_\_\_>1 year
- How have symptoms improved since you started taking this supplement?** \_\_\_Feel better \_\_\_More energy \_\_\_Fewer symptoms \_\_\_Other (explain): \_\_\_\_\_
- List any allergies to medications, foods, plants, or flowers** \_\_\_\_\_
- List any additional illnesses or medical conditions** \_\_\_\_\_ **Women: pregnant or breastfeeding?** \_\_\_No \_\_\_Yes
- List other over-the-counter and prescription medications (such as aspirin, diuretics, heart medicines, fish oil, oral contraceptives) that you take** \_\_\_\_\_
- How much alcohol do you drink in a day?** \_\_\_None \_\_\_1 glass \_\_\_2 glasses \_\_\_More than 2 glasses
- How much do you smoke in a day?** \_\_\_None \_\_\_Less than one pack \_\_\_One pack or more
- Name any diet or eating plan you follow** \_\_\_\_\_ **How long?** \_\_\_\_\_ **Was this prescribed for you?** \_\_\_No \_\_\_Yes

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Alfalfa ( <i>Medicago sativa</i> )	Used for diuretic properties in asthma, diabetes, thyroid gland malfunction, arthritis, high cholesterol, and peptic ulcers. Said to promote menstruation and lactation.	Rats fed with this are prone to colon cancer. Fatalities reported due to ingestion of contaminated Alfalfa.
Alpha Lipoic Acid	Used to prevent cancer, HIV, AIDS, and liver disease. Used to lower triglycerides by reducing endothelial dysfunction. Most studies have been done with rats; more human studies are needed. Contained in broccoli, spinach, and tomato.	Its antioxidant activity may antagonize the effects of chemotherapy.
Aloe Vera ( <i>Aloe barbadensis</i> )	Topical administration of Aloe vera gel for burns is generally safe. It may help reduce radiation-induced skin changes, but clinical trials are inconsistent.	FDA rules that it is not safe as a stimulant laxative; causes strong GI cramping. Chronic use can lead to loss of potassium. Do not use with diuretics, corticosteroids, or antihyperglycemic or cardiovascular agents.
Arnica ( <i>Arnica montana</i> )	Used as a topical ointment for bruises, osteoarthritis in homeopathy preparations.	If taken orally, causes hypotension and shortness of breath; can be fatal.
Artemesia ( <i>Wormwood</i> )	Used as an antimalarial; also used in cancer, fever, infections.	GI upset is a common side effect; causes hyperacidity.
Avlimil	Used to alleviate symptoms of female sexual dysfunction. Contains cloves, capsicum, black cohosh, ginger, and licorice.	Contraindicated in women having hormone-sensitive cancers. Stomach upset is an adverse reaction.
Ayurveda	Used in diabetes, rheumatoid arthritis (RA), Parkinson's disease, obesity, cancer, anemia, edema, and postpartum complications of pregnancy. Meditation helps in reducing anxiety, lowering blood pressure, and enhancing general well-being. The herbs show antioxidant, antitumor, antimicrobial, hypoglycemic, and anti-inflammatory properties.	Lead poisoning is a potential complication.
Barberry	Used as a coagulant herb.	May inhibit effects of anticoagulant medications such as warfarin.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Bilberry ( <i>Vaccinium myrtillus</i> )	Used in Europe as an antioxidant to prevent diabetic retinopathy; improves visual acuity and retinal function. Used for cataracts, cancer, circulatory disorders, diabetic retinopathy, glaucoma, macular degeneration, hemorrhoids, and varicose veins. Relative of blueberry. Do not use with anticoagulants or antiplatelet medications. No adverse reactions reported.	Exhibits antiplatelet activity. May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding.
Bitter Melon ( <i>Momordica charantia</i> )	Used in cancer prevention, diabetes, fever, HIV, infections, menstrual disorders.	Contraindicated in children and pregnant women because it causes bleeding, contraction of the uterus, and abortion. Adverse reactions include hypoglycemia and hepatotoxicity, headache, fever, abdominal pain, and coma.
Black Cohosh ( <i>Cimicifuga racemosa</i> )	Used with hot flashes, headaches, vaginal dryness, mood swings, cough, dysmenorrhea, RA, and sedation. It functions as an antispasmodic, sedative, or relaxant. Controversial whether black cohosh possesses estrogenic activity.	May cause hypotension, vomiting, headache, dizziness, GI distress, and limb pain. May increase the toxicity of doxorubicin and docetaxel or interact with drugs that are metabolized by CYP3A4 enzyme. <b>Warning: should not be confused with blue cohosh (<i>Caulophyllum thalictroides</i>), which is toxic and may be used in attempts to induce abortion.</b>
Borage Oil ( <i>Borago officinalis</i> )	Used for RA, infantile seborrheic dermatitis, cough, chest congestion, and menopausal symptoms.	Contains pyrrolizidine alkaloid and amabiline, which are hepatotoxic. Unsafe during pregnancy due to teratogenic effects and premature labor. Adverse effects include constipation and hepatotoxicity after chronic administration.
Boswellia ( <i>Boswellia serrata</i> )	Used for arthritis, asthma, colitis, inflammation, and menstrual cramps.	Long-term effects on humans are unknown, but it has cytotoxic activity.
Brewer's Yeast	Used as a natural source of chromium.	Avoid supplement use with MAO inhibitors such as Nardil, Parnate.
Bromelain, from pineapple stem ( <i>sulphydryl proteolytic enzyme</i> )	Used for arthritis, bruises, burns, cancer prevention and treatment, edema, indigestion, and circulatory disorders. Exhibits antiplatelet activity.	Diarrhea, GI disturbances, allergic reactions. May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding.
Buckthorn Bark	Used as laxative herb to speed digestion, which reduces absorption time of drugs.	Chronic use results in a loss of potassium, thereby strengthening effects of cardiac glycosides and antiarrhythmic agents. Use with thiazide diuretics, corticosteroids, or licorice root increases potassium loss.
Bupleurum ( <i>Bupleurum chinense</i> , <i>B. scorizonae</i> — <i>raefolium</i> )	Used for colds, fever, infections, cirrhosis, hepatitis, liver disease, malaria, and cancer treatment.	<b>Warning: may be associated with interstitial pneumonitis</b> as an ingredient of shosaiko. Adverse reactions include nausea, vomiting, edema, GI disturbance.
Burdock ( <i>Arctium majus</i> )	Used for arthritis, HIV, AIDS, psoriasis, diabetes, eczema, and anorexia; no human studies on these proposed claims. Promotes urination.	Contraindicated in pregnancy, lactation or allergy to chrysanthemum. <b>Warning: burdock tea sometimes is contaminated</b> with belladonna alkaloids.
Butcher's Broom ( <i>Ruscus aculeatus</i> )	Used for hemorrhoids, varicose veins, circulatory diseases, lymphedema, leg cramps, constipation, and inflammation.	Diarrhea.
Calendula ( <i>Calendula officinalis</i> )	Used for conjunctivitis, eczema, GI disturbance, inflammation, menstrual cramps, and radiation therapy.	Contraindicated in pregnancy and lactation. Possible allergic reactions.
Capsicum, Capsaicin ( <i>Capsicum frutescens</i> and <i>C. annuum</i> )	Used as a circulatory stimulant to aid in digestion. Used externally to relieve pain, as from arthritis, circulatory disorders, and diabetic and herpes zoster neuropathy. Suggested to lower high cholesterol or to lessen motion sickness, muscle pain, or toothache.	Avoid contact with eyes and irritated or broken skin. Burning skin, urticaria, and contact dermatitis. Drug interactions: increases the incidence of cough associated with ACE inhibitors.
Cascara ( <i>Rhamnus purshiana</i> )	Used for cancer treatment and constipation. Often found in over-the-counter laxatives. <b>FDA has ruled that cascara is not safe as a stimulant laxative.</b>	Contraindications: should not be used in intestinal obstruction, undiagnosed abdominal symptoms, and inflammatory bowel disease. Adverse reactions include vomiting, intestinal cramps; excessive use can cause diarrhea, weakness, or cholestatic hepatitis. Drug interactions: excess loss of K <sup>+</sup> with digoxin that potentiates cardiac effects; avoid use with cardiovascular agents.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Cayenne	Used for muscle spasms and relief of pain in arthritis. Large doses may lead to chronic gastritis and kidney or liver damage. Exhibits anticoagulant activity.	May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding; avoid with anticoagulants or antiplatelet medications.
Chamomile ( <i>Matricaria recutita</i> )	Used for colic, GI disturbance, hemorrhoids, infections, skin ulcers, mucositis. Chamomile soothes indigestion, flatulence. Topical and oral administration is safe except in patients with allergies to ragweed or chrysanthemum.	Contact dermatitis or anaphylaxis in those allergic to ragweed or chrysanthemum. Drug interactions: increases anticoagulant effects due to its natural coumarin content; avoid with warfarin.
Chasteberry ( <i>Vitex agnus castus</i> )	Used for premenopausal symptoms, dysmenorrhea, or menopause.	GI upset, nausea, rash, urticaria, and headache. Should not be taken with hormone replacement therapy or oral contraceptives; an itchy rash can occur. It may interact with dopamine antagonists.
Chinese Asparagus ( <i>Asparagus cochinchinensis</i> )	Used for cancer treatment, constipation, cough, and hepatitis.	No adverse reactions or drug interactions reported.
Chitosan	Used as an ingredient in many weight loss supplements, with claims to bind and trap dietary fat.	It is clinically insignificant (Gades and Stern, 2005).
Cholesterol Spinach ( <i>Gynura crepioides</i> )	Used for control of high cholesterol; no scientific evidence.	Contraindications: immunocompromised patients due to the possibility of contamination.
Chondroitin	Used to support healthy connective tissue and synovial fluid that lubricates joints. Improves functional status of people with hip or knee osteoarthritis, relieves pain, and reduces joint swelling and stiffness. Used with glucosamine in many products. Third most widely used supplement by elderly (Wold et al, 2005).	
Chromium Picolinate	Often used by athletes. May have some merit in diabetes management. Naturally found in mushrooms, nuts, bread, yeast.	Chronic use may lead to impaired iron and zinc metabolism, GI intolerance, nephritis, or chromosomal damage.
Cinnamon	Increases sensitivity of insulin to help manage diabetes (Anderson et al, 2004).	
Chrysanthemum ( <i>Chrysanthemum morifolium</i> )	Used for angina, hypertension, fever, common cold. No human studies.	Contraindications: those with allergy to ragweed. Adverse reactions include contact dermatitis, photosensitivity.
Coenzyme Q10	Used for patients with heart failure or early signs of Parkinson's disease.	Coenzyme Q10, superoxide dismutase (SOD), S-adenosyl-L-methionine methionine (SAM-e), and other products have not been proven to reduce the effects of aging.
Coleus or Forskolin	Exhibits antiplatelet activity.	May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding.
Cone Flower ( <i>Echinacea purpurea</i> , <i>E. pallida</i> , <i>E. augustifolia</i> )	Used for common cold, immunostimulation, infections, viral infections, wound healing.	Contraindications: patients with autoimmune disorders (systemic lupus erythematosus, RA, multiple sclerosis, tuberculosis, HIV). Adverse reactions include headache, dizziness, nausea, rash, dermatitis, anaphylaxis.
Cranberry	Used to prevent urinary tract infection caused by <i>Escherichia coli</i> bacteria, especially after menopause.	
Creatine	Used to increase strength in some older individuals and in athletes. More studies are needed.	Heavy use may lead to cardiomyopathy, hypertension, renal impairment.
Curcumin and Curry	Used for antioxidant effects in cystic fibrosis, cognitive function in Alzheimer's disease, cancer prevention, and other conditions.	
Dandelion ( <i>Taraxacum mongolicum</i> )	Used for diabetes, lactation stimulation, promote urination, rheumatoid arthritis, liver disease. Used as salad greens and in teas. Only a few clinical studies.	Allergic reactions, contact dermatitis, dyspepsia. Contraindication in patients with obstruction of the bile duct or gallbladder. Drug interactions: additive effect on hypoglycemic activity.
Da Qing Ye ( <i>Isatis tinctoria</i> )	Used for cancer treatment, diarrhea, GI disorders, hepatitis, HIV and AIDS, respiratory infections.	Adverse reactions include nausea, vomiting, hematuria following injection.
Devil's Claw ( <i>Harpagophytum procumbens</i> )	Used for analgesic, anti-inflammatory, osteoarthritis, muscle pain, GI disturbances.	Contraindication in pregnancy. Adverse reactions include dyspepsia, diarrhea, bradycardia.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Dong Quai ( <i>Angelica sinensis</i> )	Used as Chinese tonic for menstrual cramps, peripheral vasodilator, and pain reliever. It has not shown effectiveness for reducing hot flashes.	Exhibits anticoagulant activity. May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding. It should not be used in pregnancy. Increased doses are carcinogenic. Adverse effects include bloating, loss of appetite, diarrhea, photosensitivity, gynecomastia.
Echinacea (see <i>Cone Flower</i> )	Used as an immune system stimulant. Echinacea is no more effective for upper respiratory tract infections than placebo. Avoid taking for longer than 2 months at a time.	Avoid with corticosteroids, cyclosporine, or immunosuppressants. It may trigger allergies since it is related to the ragweed family (as are butterbur, chamomile, goldenrod, and yarrow).
Eucalyptus	Used for asthma, coughs, arthritis in small doses.	Overdoses can be fatal.
Evening Primrose Oil ( <i>Oenothera biennis</i> )	Used for RA, mastalgia, eczema, fatigue, diabetic neuropathy, premenstrual syndrome, menopausal symptoms, cancer treatment. Contains essential fatty acid known as gamma linolenic acid (GLA), which may be useful in cardiac or arthritic conditions.	Contraindication: pregnant women. Adverse reactions are headache, nausea, GI upset. Drug interactions: may lower the seizure threshold in patients taking phenothiazines. Avoid use also with chlorpromazine, fluphenazine, mesoridazine, anticoagulants or antiplatelet medications.
Fenugreek ( <i>Trigonella foenum-graecum</i> )	Used for laxatives, lactation stimulation, diabetes, high cholesterol, wounds, alopecia, arthritis, GI disturbance, induce child birth.	Contraindication: infants and pregnant women. Adverse reactions: flatulence, diarrhea, bleeding, bruising, hypoglycemia.
Feverfew ( <i>Tanacetum parthenium</i> )	Used for migraine, psoriasis, arthritis, dysmenorrhea. DISCONTINUE 2 WEEKS BEFORE SURGERY	Avoid use with nonsteroidal anti-inflammatory drugs (NSAIDs) because they negate its usefulness (Miller, 1998). Avoid use with warfarin, antiplatelet, or migraine headache medicines. Contraindicated in those who are allergic to ragweed or marigold. Adverse reactions are mouth ulcers. Withdrawal causes anxiety, muscle stiffness, and pain.
Flaxseed ( <i>Linum usitatissimum</i> )	Used for cancer prevention, constipation, high cholesterol, menopausal symptoms, periodontal diseases.	Exhibits antiplatelet activity. May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding. Avoid with radiation therapy.
Folk Remedy Oils	Used for childhood ailments in Mexican culture.	May cause pneumonia in infants and children.
Forskolin ( <i>Coleus forskohlii</i> )	See Coleus.	
Gamma Linolenic Acid (GLA)	Used for reducing signs of PMS or menopause. Black currant oil contains GLA.	Avoid with anticonvulsants or anabolic steroids. Liver toxicity may occur.
<i>Garcinia cambogia</i> (hydroxycitric acid)	Used as ingredient of many weight loss products.	
Garlic	Used to help lower cholesterol. Antibacterial, antifungal, antiviral, and hypotensive benefits have also been noted. Fourth most widely used supplement by elderly (Wold et al, 2005). DISCONTINUE 2 WEEKS BEFORE SURGERY	Garlic appears to induce cytochrome P450 3A4 and may enhance metabolism of many medications such as cyclosporine and saquinavir. Avoid using capsules with warfarin and with diabetes medications (may cause drop in blood glucose).
Ginger ( <i>Zingiber officinale</i> )	Used as a treatment for nausea, motion sickness, vomiting, anorexia, drug withdrawal, RA.	Adverse reactions include heartburn, dermatitis, CNS effects, depression, arrhythmias. Drug interactions: increases risk of bleeding if used with anticoagulant or antiplatelet medications. Additive effects with hypoglycemic drugs and histamine antagonists.
Ginkgo Biloba	Used to improve blood flow to the brain; to help with memory, hearing loss, dementias, circulatory disturbance, Raynaud's disease, sexual dysfunction, stress, tinnitus, asthma. Second most widely used supplement by elderly (Wold et al, 2005). DISCONTINUE 2 WEEKS BEFORE SURGERY	Ginkgo biloba may cause allergic skin reactions or bleeding. Avoid use with warfarin, antihyperglycemic agents, vitamin E, or aspirin. Warning: discontinue before surgery. Adverse reactions include headache, dizziness, GI upset, diarrhea, and seizures in patients predisposed to seizures or on medications that lower seizure threshold.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Ginseng ( <i>panax</i> )	American ginseng ( <i>panax quinquefolius</i> ) is often used for stress adaptation, cognitive or performance enhancement, impotence, a digestive aid, protection against cancer. Siberian ginseng ( <i>Acanthopanax senticosus</i> ) is used for lessening chemotherapy side effects; for health maintenance, strength, stamina, and immunostimulation. DISCONTINUE 2 WEEKS BEFORE SURGERY	It should not be taken with warfarin, insulin, oral hypoglycemics, CNS stimulants, caffeine, steroids, hormones, antipsychotics, aspirin, cardiovascular agents, warfarin, or other antiplatelet drugs. May interfere with digoxin action (Miller, 1998). Ginseng may add to the effects of estrogens or corticosteroids and can elevate BP. Contraindicated in hypertension and in perimenopausal, pregnant or lactating women.
Glehnia ( <i>Glehnia littoralis</i> )	Used for bronchitis, chest congestion, whooping cough.	Photosensitivity may occur due to psoralens component. Contraindicated in radiation therapy.
Glucosamine Sulfate	Used to build new cartilage, rebuild old cartilage, lubricate joints, mount a healthy inflammatory response, and ease symptoms of osteoarthritis. It is often taken with chondroitin. Most widely used supplement by elderly (Wold et al, 2005).	Side effects are mild.
Gotu Kola ( <i>Centella asiatica</i> , <i>Hydrocotyle asiatica</i> )	There are wide variations in terpenoid concentrations depending on the location in which gotu kola is grown. Used for burns, cancer treatment, circulatory disorders, GI disorders, hypertension, memory loss, psoriasis, scars, sedation, varicose veins. Gotu kola should not be confused with kolanut; gotu kola does not contain any caffeine and has not been shown to have stimulant properties. Products should be standardized as to asiaticoside, asiatic acid, madecassic acid, and madecassoside content.	Adverse effects: contact dermatitis, pruritus, photosensitization, and headache; reduced fertility may occur in women wishing to become pregnant. With toxic levels, hyperglycemia, hyperlipidemia, and sedation have occurred.
Green Tea	Used for activation of thermogenesis, fat oxidation, or both (Dulloo et al, 1999). Green tea is popular in several cultures. Both black and green tea may be preventive for cancers and strokes; they are also a good source of fluoride. Green tea contains a class of polyphenols called catechins, which consist mainly of epigallocatechin gallate (EGCG), epicatechin gallate, and galocatechin gallate with various physiological and pharmacological properties. Green tea extract (GTE) may improve endurance capacity and may support weight loss (Nagao et al, 2005). GTE boosts exercise endurance by using fat as energy source, accompanied by higher rates of fat oxidation. Results come from the equivalent of about 4 cups of tea a day.	Avoid use with MAO inhibitors and warfarin since green tea contains vitamin K. Avoid use in pregnancy and infants.
Guggul	Used to treat osteoarthritis and bone fractures; suppresses the nuclear factor- $\kappa$ B activation induced by various carcinogens (Ichikawa and Aggarwal, 2006). Guggul may induce CYP3A4 activity.	Not enough scientific evidence to support the use of guggul for any medical condition. Guggul may cause stomach discomfort or allergic rash. It should be avoided in pregnancy and lactation and in children.
Hawthorn ( <i>Crataegus monogyna</i> )	Used for angina, atherosclerosis, heart failure, HTN, indigestion. It seems to be safe for long-term use.	Contraindications: pregnancy, lactation. Adverse reactions: nausea, sweating, fatigue, hypotension, arrhythmia. Because hawthorn lowers blood pressure and cholesterol levels, never take with digoxin. In high doses, it can cause hypotension and sedation and should be monitored carefully. Avoid use with cardiovascular agents.
Horseradish	Used as a natural decongestant.	
Horse Chestnut	Exhibits anticoagulant activity.	May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding.
Huang Lian ( <i>Coptis chinensis</i> )	Used for diarrhea, hypertension, bacterial and viral infections, ear infections, and cancer treatment.	Contraindications in jaundiced neonates. Adverse reactions: nausea, vomiting, dyspnea. Toxicity: seizures, hepatotoxicity, cardiac toxicity.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Indirubin ( <i>Indigofera tinctoria</i> )	Used for cancer treatment, inflammation. There are limited clinical data	Adverse reactions: nausea, vomiting, abdominal pain. Long-term treatment has caused pulmonary arterial hypertension and cardiac insufficiency
Juniper	Used as a diuretic or for indigestion in some cultures.	Avoid in pregnancy and kidney disease.
Karela	Used to lower blood glucose.	Because it effect blood glucose levels, it should not be used by patients with diabetes mellitus.
Kava	May cause drowsiness, dizziness, and intoxication.	Avoid with sedatives or hypnotics.
Kudzu ( <i>Pueraria mirifica</i> , <i>P. thunbergiana</i> , <i>P. montana</i> var. <i>lobata</i> , <i>P. montana</i> var. <i>thomsonii</i> )	Used for estrogenic effects. Promoted for alcoholism, common cold, diabetes, eye pain, fever, menopausal symptoms, neck pain.	Avoid in hormone-sensitive cancers, tamoxifen use, hypersensitivity to kudzu, and estrogen receptor-positive (ER+) breast cancer.
Kyushin	Used as a cardiotonic medicine in China.	Kyushin may interfere with digoxin.
Licorice ( <i>Glycyrrhiza glabra</i> , <i>G. uralensis</i> )	Used for bronchitis, chest congestion, constipation, GI disorders, hepatitis, inflammation, menopausal symptoms, microbial infection, peptic ulcers, primary adrenocortical insufficiency, prostate cancer. Active ingredient (glycyrrhizin) has an anti-inflammatory role.	Avoid in renal or liver dysfunction, pregnancy and breast-feeding. Licorice can offset the pharmacological effect of spironolactone or digoxin. Large doses can produce headache, lethargy, or high blood pressure. May increase sodium retention and potassium losses when used with thiazide diuretics. Avoid use in cirrhosis, hypertension, cholestatic liver disease, hypokalemia, kidney failure.
Lycium ( <i>Lycium barbarum</i> ; <i>L. chinense</i> ; <i>L. europeum</i> )	Used for anemia, burns, cancer treatment, cough, inflammation, pain, sedation, skin infections, visual acuity.	May prolong bleeding time in some individuals.
Mayapple	Common in Native American medicine. Used for venereal warts (condyloma acuminata); it contains podophyllotoxins.	
Meadowsweet	Exhibits antiplatelet activity.	May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding.
Melatonin	Used as a sleep aid or a jet lag adjuster	Avoid use with CNS depressants such as alcohol, barbiturates, corticosteroids, or immunosuppressants.
Milk Thistle ( <i>silymarin</i> )	Used for alcoholic liver disease, cirrhosis, infectious hepatitis, drug-induced hepatitis. Best administered by injection. Serves as a natural antidote for death-cap mushroom poisoning.	It may have a mild laxative effect or can cause uterine or menstrual stimulation.
Mint	Used in oil form for colds, bronchitis, fever, indigestion.	Mild GI distress may result. Worsens gastroesophageal reflux disease (GERD) or hiatal hernia symptoms.
Motherwort	Exhibits antiplatelet activity.	May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding.
Mushrooms, Edible	Used to prevent hormone-related cancers (breast, prostate). AHCC is obtained from mycelia of several species of basidiomycetes mushrooms. <i>Agaricus blazei</i> , native to Brazil and Japan, is used to treat arteriosclerosis, hepatitis, hyperlipidemia, diabetes, dermatitis, and cancer. Oral administration of <i>Agaricus</i> extract may improve natural killer cell activity and quality of life in cancer patients undergoing chemotherapy.	May enhance resistance to <i>Klebsiella pneumoniae</i> due to its antioxidant effects.
N-Acetyl-L-Cysteine (NAC)	Used to fight aging, alleviate allergies, and fight viruses. It may work as an antioxidant to protect against sun damage and skin lesions. May be useful in managing addictions.	
Oregano	Used for antioxidant effect. Destroys <i>Helicobacter pylori</i> and <i>Giardia</i> .	
Oregon Grape Root	Coagulant herb.	May inhibit effects of anticoagulant medications such as warfarin and potentiate bleeding.
Parsley	Used for flatulence, indigestion, topical antibiotic. Breath freshener after a meal.	Avoid use in pregnancy as it may stimulate uterine contractions. May work as a diuretic in large doses.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Peppermint	Used to relieve excess gas as a digestive aid (Koretz and Rotblatt, 2004). It has antispasmodic action which can be useful for irritable bowel syndrome and GI cramping.	
Policosanols	Used to protect against cancers, cardiovascular disease, and obesity (Awika and Rooney, 2004) by reducing platelet aggregation and hepatic synthesis of cholesterol (Varady et al, 2003). Policosanols are phytochemicals extracted from sugar cane.	
Poplar	Exhibits antiplatelet activity.	May enhance effects of anticoagulant medications such as warfarin and potentiate bleeding.
Probiotics (Good bacteria such as <i>Lactobacillus</i> and <i>Lactobacillus acidophilus</i> )	Used in inflammatory bowel disease and other GI disorders or to replenish gut flora after antibiotic use. May reduce presence of harmful bacteria in the gut and may decrease vaginal infections. Select yogurt and products made with live cultures.	
Psyllium	Use as a laxative to alleviate chronic constipation.	Avoid use with cardiovascular agents.
Red Clover	Used for hot flashes because it contains isoflavones. It may also be used for coughs, eczema, and psoriasis.	Evidence suggests that it has limited effectiveness (Krebs et al, 2004).
Rhodiola ( <i>Rhodiola rosea</i> ), arctic root	Used for depression, fatigue.	Side effects are insomnia and irritability.
Rhubarb or Da-Huang ( <i>Rheum palmatum</i> , <i>R. officinale</i> )	Used for cancer treatment, constipation, fever, hypertension, immunosuppression, inflammation, microbial infection, peptic ulcers.	Avoid prolonged stimulant laxative use over 7 days without medical supervision. Patients with arthritis, kidney or hepatic dysfunction, history of kidney stones, inflammatory bowel disease, or intestinal obstruction should not take this herb. Rhubarb may cause uterine stimulation; avoid in pregnancy. Reported effects include abdominal cramps, nausea, vomiting, diarrhea with possible hypokalemia, anaphylaxis, and renal and hepatic damage.
Rice Bran Oil	It contains tocotrienols, powerful antioxidants in the vitamin E family that protect against coronary heart disease and some forms of cancer.	
Rosemary	Used for antioxidant and anticarcinogenic potential. Often used for lowering blood pressure.	Do not use in pregnancy in large doses.
Royal Jelly	It is a milky substance secreted by young worker honey bees. Apalbumin 1 (Apa1) is the major royal jelly and honey glycoprotein and has various biological properties, such as cancer prevention. It seems to stimulate macrophages to release TNF- $\alpha$ .	Avoid use with asthma; may cause allergic reactions.
Saw Palmetto	Used with benign prostatic hyperplasia to increase urine flow. Tannic acids are present.	Saw palmetto should not be taken with oral contraceptives, estrogens, or anabolic steroids. Can cause GI upset in rare cases.
Schisandra ( <i>Schisandra chinensis</i> )	Used for asthma, cough, influenza, diarrhea, indigestion, liver disease, premenstrual syndrome, strength, and stamina.	Adverse reactions include depression and heartburn.
Senna	Used as a laxative herb; it contains anthraquinone, which stimulates bowel contractions. Safe for constipation, but dependence or obstruction can occur with long use. Psyllium and other naturally high-fiber foods (such as prunes), extra fluids, and exercise are better choices.	Laxative herbs speed digestion, which reduces absorption time of drugs. Chronic use results in a loss of potassium, thereby strengthening effects of cardiac glycosides and antiarrhythmic agents. Simultaneous use of thiazide diuretics, corticosteroids, or licorice root increases potassium loss. Because fluid and electrolyte losses may be severe, avoid during pregnancy and lactation.
Sheep Sorrel ( <i>Rumex acetosella</i> )	Used for cancer treatment, diarrhea, scurvy, fever, inflammation.	Contraindications: patients with kidney stones should not use this herb. Adverse reactions: abdominal cramps, gastroenteritis, diarrhea leading to hypokalemia, adrenal and liver damage.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Shepherd's Purse	Coagulant herb.	May inhibit effects of anticoagulant medications such as warfarin and potentiate bleeding.
Slippery Elm ( <i>Ulmus rubra</i> )	Used for bronchitis, cancer treatment, cough, diarrhea, fever, inflammation, peptic ulcer, skin abscess, skin ulcers, sore throat.	Adverse reactions: none known, but no human studies have been done to evaluate its actions.
Spirulina (Blue-green algae)	Used to treat cancers, viral infections, weight loss, oral leucoplakia, increased cholesterol, attention-deficit hyperactivity disorder (ADHD). Sold as an immune enhancer or to lower cholesterol levels.	Expensive as a protein source. Adverse effects are uncommon unless contaminated; if contaminated, it is hepato-, nephro-, and neurotoxic. Adulterated form can cause allergies or gastroenteritis.
Stillingia ( <i>Stillingia sylvatica</i> )	No clinical data to support its uses in bronchitis, chest congestion, cancer treatment, hemorrhoids, constipation, skin abscess, laryngitis, spasm, syphilis.	Warning: the diaterpene esters in this herb are irritants to the skin and mucous membranes. Adverse reactions: vertigo, burning sensation over the mucous membrane, diarrhea, nausea, vomiting, pruritus, skin eruptions, cough, fatigue, and sweating.
St. John's Wort ( <i>Hypericum perforatum</i> )	Laboratory reports have suggested but not confirmed that the mechanism of action for St. John's wort may involve monoamine oxidase (MAO) inhibition, SSRI reuptake inhibition, increased melatonin production, and others. Used to alleviate anxiety and nervousness; does not alleviate depression. This herb has been shown to induce the drug-metabolizing enzyme cytochrome p4503A4 and has the potential to interact with many medications. DISCONTINUE 2 WEEKS BEFORE SURGERY	It can inhibit iron absorption. May enhance effects of narcotics and selective serotonin reuptake inhibitors (SSRIs). Increases side effects of photosensitizing drugs, alcohol, and melatonin. Avoid use with statins, blood pressure medications, donepezil, antidepressants and other CNS medications, and chemotherapy.
Tannins and Saponins ( <i>Acacia pennata</i> , <i>Hibiscus spp.</i> , <i>Lasianthica africana</i> , <i>Gouanialupiloides</i> )	Used for dental hygiene and to treat gingivitis.	
Tea Tree Oil	Used for acne treatment, wound healing, or as an antiseptic for thrush (as in HIV infection). Natural fungicide.	Topical use only; toxic if consumed. Allergy is possible in sensitive individuals.
<i>Tribulus terrestris</i>	Used by athletes. Contains steroidal glycosides and saponins that cause secretion of luteinizing hormone, testosterone.	It is phototoxic, cytotoxic, and neurotoxic.
Tryptophan	Used to promote sleep or to correct depression.	L-tryptophan is the precursor to serotonin. It should not be used with MAO inhibitors, antidepressants, or serotonin receptor antagonists; it can exaggerate psychosis.
Turmeric ( <i>Curcuma longa</i> )	Used for immune system enhancement, correcting anorexia, carcinoma prevention, reducing infections (such as reducing <i>H. pylori</i> ) and inflammation, kidney stones.	Warning: breast cancer patients on cyclophosphamide should restrict intake because it inhibits the antitumor action of chemotherapeutic agents. Contraindications: patients with bile duct obstruction, gallstones, GI disorders.
Ukrain ( <i>Chelidonium majus</i> alkaloid-theophosphoric acid derivative)	Used for cancer prevention and treatment, hepatitis, HIV and AIDS, immunostimulation.	Warning: it is not regulated by FDA. Adverse reactions: soreness at the injection site, nausea, diarrhea, dizziness, fatigue, drowsiness, polyuria, hematological side effects, and tumor bleeding have been reported.
Valerian ( <i>Valeriana officinalis</i> , <i>Valerianae radix</i> , garden heliotrope)	Used for insomnia, anxiety, colic, menstrual cramps, migraine treatment, sedation, spasms, stomach and intestinal gas. Effective as a sleep aid and is not habit forming. DISCONTINUE 2 WEEKS BEFORE SURGERY	Headache, uneasiness, cardiac disturbances, morning drowsiness, and impaired alertness can occur. Benzodiazepines, sedatives, alcohol, antipsychotics, and antidepressants should not be used at the same time because of the risk of additional sedation. Long-term use can cause headaches, sleeplessness, cardiac dysfunction, hepatotoxicity. Patients should be warned not to drive or operate dangerous machinery when taking valerian. Valerian should be stopped about 1 week before surgery because it may interact with anesthesia.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
Vanadium ( <i>vanadyl sulfate</i> )	Used to mimic insulin; it may restore plasma DHEA and seems to improve insulin action. There may be a role for its use in the metabolic syndrome. Found in mushrooms and shellfish.	May cause GI bleeding.
Vitex (chaste tree)	Used for relief of menstrual disorders. Fruits are used; approved for use in Germany.	
White Willow	Used for fever, headache, pain, and rheumatic complaints. Aspirin is derived from white willow.	GI irritation or stomach ulcers can occur with long-term use; similar reactions as aspirin. Avoid use with alcohol, methotrexate, phenytoin, and valproate. Do not use in pregnancy or lactation.
Wild Yam ( <i>Dioscorea villosa</i> )	Used for amenorrhea, dysmenorrhea, colic, cough, GI symptoms, rheumatoid arthritis, menopausal symptoms, urinary tract disorders, sexual dysfunction, spasms.	Efficacy of hormonal actions is not proven. Topical creams that say that they contain yam extracts as a source of natural progesterone are not accurate.
Willow Bark ( <i>Salix alba</i> )	Used for fever, headache, inflammation, influenza, muscle pain.	Adverse reactions: nausea, vomiting, GI bleed, tinnitus, renal damage. Drug interactions: increases risk of bleeding with anticoagulants and GI bleed with NSAIDs.
Witch Hazel	Used as astringent with bruises or varicose veins. Approved for use with hemorrhoid products.	Not for oral use.
Yew ( <i>Taxus baccata</i> , <i>T. wallachiana</i> , <i>T. media</i> )	Used in treatment of some breast tumors. Cultivated varieties are being used to prepare triterpenoid precursors which are used to create paclitaxel and docetaxel, which in turn, have an antiestrogenic effect.	
Zinc	Used to prevent viral illness, enhance performance, and correct male infertility.	It should not be taken with immunosuppressants, fluoroquinolones, or tetracycline. Large doses may also conflict with copper metabolism.
<b>Hazardous Products</b>	These products should never be consumed.	
<b>Aristolochic acid</b> ( <i>Aristolochia</i> , birthwort, snakeweed, snagree root, sangrel, serpentary, wild ginger)	<b>Definitely Hazardous</b>	Documented human cancers. Also linked to kidney failure.
<b>Belladonna</b>	<b>Definitely Hazardous</b>	Causes GI pain and spasms; contains toxic alkaloids, which can cause coma and death.
<b>Very Likely Hazardous</b>	<b>These are banned in other countries, have an FDA warning, or show adverse effects in studies.</b>	
<b>Androstenedione</b> (4-androstene-3, 17-dione, andro, androstene)	<b>Very Likely Hazardous</b>	Increased cancer risk and decrease in “good” HDL cholesterol have been reported.
<b>Chaparral</b> ( <i>Larrea divaricata</i> , creosote bush, greasewood, hediondilla, jarilla, larreastat)	<b>Very Likely Hazardous</b> Often used for anti-inflammatory and anticancer effects, arthritis, carcinoma treatment, inflammation, spasm.	Abnormal liver function and hepatitis or even cirrhosis have been linked to use.
<b>Comfrey</b> ( <i>Symphytum officinale</i> , ass ear, black root, blackwort, bruisewort, <i>Consolidae radix</i> , consound, gum plant, healing herb, knitback, knitbone, salsify, slippery root, <i>Symphytum radix</i> , wallwort)	<b>Very Likely Hazardous</b> Used for bronchitis, cancer treatment, rheumatoid arthritis, wound healing.	Abnormal liver function or damage, often irreversible. It contains pyrrolizidine alkaloids and causes hepatic veno-occlusive disease or death. Avoid in infants, pregnancy, lactation. FDA has asked all manufacturers to remove products containing comfrey because it is hepatotoxic.
<b>DHEA</b>	<b>Very Likely Hazardous</b> Used as an immune enhancer or to prevent heart disease. No evidence that it works.	Can actually aggravate heart disease and have effects like steroids; may promote cancers in breast, prostate, or ovaries.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
<b>Ephedra</b> (ma huang)	<b>Very Likely Hazardous</b> Often used in weight loss products. Banned by FDA. DISCONTINUE 2 WEEKS BEFORE SURGERY	Contains cardiac toxins linked to dozens of deaths. Ephedra can cause stroke, insomnia, hypertension, or heart attack. Avoid taking with caffeine, sedatives, antipsychotics, antidepressants, antihyperglycemic agents, decongestants, and cardiovascular agents.
<b>Germander</b> ( <i>Teucrium chamaedrys</i> , wall germander, wild germander)	<b>Very Likely Hazardous</b> Germander contains flavanoids.	Abnormal heart and liver function have been linked to use.
<b>Goldenseal</b> ( <i>Hydrastis canadensis</i> )	<b>Very Likely Hazardous</b> Used for anorexia, heart disease, coughs, upset stomach, menstrual problems, and arthritis. It has long been used by Native Americans for antiseptic and wound-healing properties. DISCONTINUE 2 WEEKS BEFORE SURGERY	GI complaints are common side effects. With toxicity: stomach ulcerations, constipation, convulsions, hallucinations, nausea, vomiting, depression, nervousness, bradycardia, respiratory depression, seizures. It can raise blood pressure, complicating treatment for those taking beta-blockers. For patients taking medication to control diabetes or kidney disease, this herb can cause dangerous electrolyte imbalance. Patients with hypertension or cardiovascular disease and women who are pregnant should not take this herb.
<b>Kava</b> ( <i>Piper methysticum</i> , ava, awa, gea, gi, intoxicating pepper, kao, kavain, kawapfeffer, kew, long pepper, malohu, maluk, meruk, milik, rauschpfeffer, sakau, tonga, wurzelstock, yagona, yangona)	<b>Very Likely Hazardous</b> Used as a stimulant.	Abnormal liver function has been linked to use.
<b>Kelp</b>	<b>Very Likely Hazardous</b>	If ingested as a source of iodine, it may interfere with thyroid replacement therapies. May worsen hyperthyroidism.
<b>Red yeast rice</b>	<b>Very Likely Hazardous</b> The fermented product of rice on which red yeast has been grown. A dietary staple in Asian countries to lower total cholesterol levels (Heber et al, 1999).	It has been removed from the market in the United States. Avoid use with grapefruit juice or niacin.
<b>Likely Hazardous</b>	<b>These have adverse event reports or theoretical risks.</b>	
<b>Astragalus</b>	<b>Likely Hazardous</b> Used in Chinese and Indian medicine for its immune enhancement.	Do not take with antihyperglycemic agents. Not recommended for use, especially in immunosuppressed patients.
<b>Bitter orange</b> ( <i>Citrus aurantium</i> , green orange, kijitsu, neroli oil, Seville orange, shangzhou zhiqiao, sour orange, zhi oiao, zhi xhi)	<b>Likely Hazardous</b>	High blood pressure and increased risk of heart arrhythmias, heart attack, and stroke are risks associated with use.
<b>Borage</b>	<b>Likely Hazardous</b>	May cause liver toxicity or even cancers.
<b>Horse chestnut</b> ( <i>Aesculus hippocastanum</i> ; aescin 50 mg)	<b>Likely Hazardous</b> Studies have shown clinical efficacy in chronic venous insufficiency, but no data support the reversal of varicose veins.	Patients with compromised renal or hepatic functions should not consume horse chestnut. It may also interact with anticoagulants and increase the risk of bleeding.
<b>Kombucha tea</b>	<b>Likely Hazardous</b> It is sometimes suggested for acne or insomnia or in AIDS.	Can cause liver damage or intestinal problems or death.

(continued)

**TABLE 2-2 Herbs, Botanicals, Spices, Commentary and Adverse Effects (continued)**

Herb, Botanical, Spice	Common Uses	Adverse Effects
<b>Lobelia</b> ( <i>Lobelia inflata</i> , asthma weed, bladderpod, emetic herb, gagroot, lobelie, Indian tobacco, pukeweed, vomit wort, wild tobacco)	<b>Likely Hazardous</b>	Difficulty breathing and rapid heart rates are associated with lobelia. Large doses can lead to rapid heartbeat, paralysis, coma, or death. Avoid in children, infants, pregnant women, smokers, and people with cardiac diseases.
<b>Mistletoe/Eurixor</b> ( <i>Viscum album</i> )	<b>Likely Hazardous</b> Used for arthritis, cancer treatment, hepatitis, HTN, spasm, immunostimulation.	Warning: berries and leaves are highly poisonous. Contraindication in pregnancy. Adverse reactions include fever, headache, chest pain, bradycardia, hypotension, coma.
<b>Organ/glandular extracts</b> (brain/adrenal/pituitary/placenta/other gland “substance” or “concentrate”)	<b>Likely Hazardous</b>	Theoretical risk of mad cow disease, particularly from brain extracts.
<b>Passion flower</b>	<b>Likely Hazardous</b> Sometimes recommended for sedative use.	It can cause seizures, hypotension, hallucinations.
<b>Pennyroyal oil</b> ( <i>Hedeoma pulegioides</i> , lurk-in-the-ditch, mosquito plant, pilioleria, pudding grass, pulegium, run-by-the-ground, squaw balm, squawmint, stinking balm, tickweed)	<b>Likely Hazardous</b>	Liver and kidney failure, nerve damage, convulsions, abdominal tenderness, and burning of the throat are risks; deaths have been reported.
<b>Poke root</b>	<b>Likely Hazardous</b>	May cause low blood pressure and respiratory depression. Extremely toxic.
<b>Sassafras</b> ( <i>Sassafras albidum</i> )	<b>Likely Hazardous</b> Used for detoxification, inflammation, health maintenance, rheumatoid arthritis, mucositis, sprain, syphilis, urinary tract disorders.	Produces sweat and contains safrole, which is banned as a carcinogen. Warning: risk of liver cancer with prolonged use, so it is not safe to use. Adverse reactions: hot flashes, diaphoresis, hallucinations, hypertension, tachycardia, liver cancer, and death.
<b>Skullcap</b> ( <i>Scutellaria lateriflora</i> , <i>S. baicalensis</i> , baikal, blue pimpernel, helmet flower, hoodwort, mad weed, mad-dog herb, mad-dog weed, quaker bonnet, scutellaria, skullcap)	<b>Likely Hazardous</b> Used for epilepsy, hepatitis, infections, cancer.	Toxicity causes stupor, confusion, seizures. Adverse reactions include hepatotoxicity and pneumonitis.
<b>Wheat grass</b> ( <i>Triticum aestivum</i> )	<b>Likely Hazardous</b> Used for carcinoma treatment, chronic fatigue syndrome, immunostimulation, ulcerative colitis. An antioxidant.	Adverse reactions: nausea because of contamination. No safety guidelines available.
<b>Yohimbe</b> ( <i>Pausinystalia yohimbe</i> , johimbi, yohim-behe, yohimbine, yohimbe bark)	<b>Likely Hazardous</b> May be used for male impotence. It causes CNS stimulation and vasodilation. In high doses, it is an MAO inhibitor. It is to be avoided in individuals with hypotension, CHF, diabetes, and kidney and liver diseases.	Blood pressure changes, heartbeat irregularities, heart attacks, and paralysis have been reported. Yohimbe is not effective for male impotence and can cause side effects such as hypertension and kidney failure; it can also aggravate bipolar disorder or decrease antidepressant effectiveness.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

<b>Clinical/History</b>	Knowledge of food and nutrition	Blood urea nitrogen (BUN)
Use of vitamin/mineral supplements	Family or genetic history	Creatinine (Creat)
Herbs and botanical products—amount, frequency	<b>Lab Work</b>	Homocysteine (tHcy)
Special diets or nutrition support	Hemoglobin and hematocrit (H & H)	Cholesterol (Chol), triglycerides (TG)
Dietary pattern for food and alcohol	Serum Fe	Other values as determined by products consumed
Over-the-counter and prescribed medications	Glucose	
	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>	
	Ca <sup>++</sup> , Mg <sup>++</sup>	
	Albumin (Alb)	
	T3, T4, TSH	

## INTERVENTION

### OBJECTIVES

The White House Commission on Complementary and Alternative Medicine Policy Executive Summary (2002) supported the following guiding principles for counseling individuals:

- Apply a “wholeness orientation” in health care delivery. Health involves all aspects of life—mind, body, spirit, and environment.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Harmful Beliefs about Food or Nutrition-Related Topics

**Assessment Data:** Food records; adverse side effects with specific products and amounts taken; blood pressure (BP), lab reports for serum electrolytes.

**Nutrition Diagnoses (PES):** Harmful beliefs/attitudes about food or nutrition-related topics related to intake of unsafe substances as evidenced by intake of ephedra in products otherwise removed from the market by FDA and complaints of rapid heart-beat and undesirable changes in BP.

**Intervention:** Education about appropriate use of herbs and botanical products; dangers of consuming substances with unknown side effects. Counseling about desired foods and use of evidence-based complementary products.

**Monitoring and Evaluation:** Improved quality of life and reduced symptoms; improvements in heart rate and BP.

- Evaluate for evidence of safety and efficacy. Promote the use of science and appropriate scientific methods to help identify safe and effective CAM services and products.
- Identify the healing capacity of the individual person. People have a remarkable capacity for recovery and self-healing; support and promote this capacity.
- Respect individuality, recognizing that each person is unique and has the right to health care that is appropriately responsive to him or her, respecting preferences and preserving dignity.
- Recognize patient rights. Each has the right to choose treatment; to choose freely among safe and effective care or approaches; and to choose among qualified practitioners who are accountable for their claims and actions and responsive to the person's needs.
- Support health promotion, self-care, and early intervention for maintaining and promoting health.
- Develop partnerships. Good health care requires teamwork among patients, health care practitioners (conventional and CAM), and researchers committed to creating optimal healing environments and to respecting the diversity of all health care traditions.
- Educate about prevention, healthy lifestyles, and the power of self-healing.
- Disseminate comprehensive and timely information. The quality of health care can be enhanced by promoting efforts that thoroughly and thoughtfully examine the evidence on which CAM systems, practices, and products are based and make this evidence widely, rapidly, and easily available.
- Integrate public involvement. The input of informed consumers and other members of the public must be incorporated in setting priorities for health care and health care research and in reaching policy decisions.

## FOOD AND NUTRITION

- Promote the appropriate use of herbal and botanical products that have shown efficacy and safety. The best strategy for promoting optimal health and for reducing chronic disease is to choose a wide variety of foods (American Dietetic Association, 2005).
- Functional foods are available that have health benefits beyond basic nutrition (e.g., omega-3-enriched eggs, stanol- and sterol-fortified soft chews and related margarines, or high-flavanol chocolate snacks). Use relevant products and recipes.
- Special attention may be needed for intake of iron and folic acid for females in teen and childbearing years; vitamin B<sub>12</sub> for adults over age 50; and vitamin D for older adults, those with dark skin, and those exposed to ultraviolet radiation (American Dietetic Association, 2005).

### Common Drugs Used and Potential Side Effects

- Plants have been used throughout history to improve health. Modern medicines often come from plants (e.g., aspirin from willow bark). Therefore, herbs used for health purposes are drugs and chemicals that affect the human body (O'Hara et al, 1998).

- About 15 million Americans are at risk for drug-supplement interactions (Boullata, 2005). Natural health products often interfere with medications, and caution is necessary.

## Herbs, Botanicals, and Supplements

- Many cultures use herbs and botanicals as part of their meal patterns, rituals, and celebrations. Remember that plant products are not necessarily safe, even if they are “natural” or “organic.”
- Individual reports of safety for any herbal product are not reliable; some people who use a herb will feel better even if there is no evidence of its efficacy (the placebo effect).
- The use of dietary supplements may be associated with adverse events (Sadovsky et al, 2008). Although there are new regulatory requirements for dietary supplements, these products do not require FDA approval, submission of efficacy and safety data prior to marketing, or prospective, randomized clinical trials (Sadovsky et al, 2008). Check [www.consumerlab.com](http://www.consumerlab.com) to identify brand names that are reliable before making recommendations.
- Herbs commonly used by children enrolled in the Women-Infants-Children (WIC) program include aloe vera, chamomile, garlic, peppermint, lavender, cranberry, ginger, echinacea, and lemon, as recommended by family or friends (Lohse et al, 2006). Identify those that are used and monitor for potential side effects. Because herbs with safety issues, such as St. John’s wort, dong quai, and kava, may also be used, herbal education is highly recommended for WIC clinics, especially for Latinos (Lohse et al, 2006).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Demonstrate respect for the beliefs, values, and practices of the patient and family members. Discuss CAM in a nonjudgmental way; encourage sharing the information with their primary physician.
- Discuss evidence that is known about different types of herbs and botanical products. Counsel that herbs are considered dietary supplements and not medicines, that FDA has no oversight on ingredients or safety and efficacy, and that there is no guarantee that the herb will work.
- Many physicians are not aware of the frequency of use and adverse events related to dietary supplements (Ashar et al, 2007).
- Alcohol interacts with many medications and possibly with herbs. Mix with caution.

## Patient Education—Food Safety

- Discuss food handling, preparation, and storage of herbs and botanical products.
- Because bacteria are commonly found on foods such as green onions (scallions), cilantro, and imported produce, wash all fresh fruits and vegetables.
- Store spices as directed and discard after shelf-life expiration. Spices such as paprika are easily contaminated.

## CULTURAL FOOD PATTERNS, VEGETARIANISM, RELIGIOUS PRACTICES

# CULTURAL FOOD PATTERNS

## NUTRITIONAL ACUITY RANKING: LEVEL 2 (DIETARY ADAPTATIONS, ADVISEMENT)

Reprinted with permission from: Weber J RN, EdD and Kelley J RN, PhD. *Health Assessment in Nursing*, 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

## DEFINITIONS AND BACKGROUND

Varied dietary intakes by age, culture, gender, and years in the United States are common. Assessment of a patient's cultural food preferences is essential to determine adequacy of nutritional intake. Nutrition planning will be more effective if tailored to the individual (Sucher and Kittler, 2007). Dis-

ease prevention strategies must use available knowledge about individual cultures.

Soon, over half of the U.S. population will consist of people from different cultural backgrounds (Goody and Drago, 2010). The process by which immigrants adopt the dietary practices is multidimensional, dynamic, complex, varying by personal, cultural, and environmental factors (Unger et al, 2004). Adoption of U.S. dietary patterns that are high in fat and low in fruits and vegetables is not positive. Neighborhood grocery stores may have limited availability of fresh produce, making healthy choices a struggle (Larson et al, 2009).

Dietetics practitioners can use the information to study nutrition education efforts directed toward ethnic-specific groups. It is important to become aware of diverse traditions and preferred food resources. Clinicians should be able to offer a wide variety of self-management support systems to meet the needs of diverse patient populations that vary by race/ethnicity, language proficiency, and health literacy (Sarkar et al, 2008).

The Joint Commission has set the standard for meeting individual needs for cultural and religious preferences. Whereas most hospitals attend to the religious (97%), dietary (85%), and psychosocial (78%) cultural needs of patients, fewer institutions respond to patients' cultural needs related to health literacy (57%); complementary/alternative medicine (43%); cultural brokers, folk remedies, traditions, rituals and traditional healers (Stein, 2009). It is important to reinforce positive traditional habits while encouraging inclusion of new, healthy ones.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Unintentional Weight Loss**

**Assessment Data:** Food records indicating lack of appetite for new foods; weight records; low blood glucose and Chol levels.

**Nutrition Diagnoses (PES):** Unintentional weight loss related to limited access to preferred foods as evidenced by 15# weight loss since moving to this country 6 months ago with a current BMI of 17.

**Intervention:** Education about where to find ethnic food choices for protein choices, whole grains, fruits and vegetables. Counseling about culturally appropriate choices that are accessible in neighborhood or area stores.

**Monitoring and Evaluation:** Improved BMI and weight for height; lab reports showing improvement in glucose and Chol.

**ASSESSMENT, MONITORING, AND EVALUATION**

Race/ethnicity  
Language proficiency  
Health literacy  
Cultural food preferences  
Traditional dietary habits

**INTERVENTION****OBJECTIVES**

- Be aware of personal cultural values but avoid imposing them on others. For example, the desire to be thin is more common among Caucasians than people from many other ethnic backgrounds.
- Assess values, attitudes, beliefs, practices, and rituals of the client before attempting to discuss any lifestyle changes. Observe and interact appropriately.
- Provide individualized patterns when they differ from the local standard. Be prepared to understand the differences from a “typical American” diet.
- Determine which habits, if any, are detrimental for a healthy lifestyle. Review patterns or foods that aggravate existing or predisposed conditions for each person. Build on healthy practices.
- Correct dietary intake patterns for nutrient deficits, such as calcium and riboflavin where dairy products or milk are excluded or not tolerated. Identify other nutrients that are at risk for insufficiency.
- Offer suggestions for changes in food preparation (e.g., ways for reducing fat or salt) rather than changing the foods themselves, whenever possible.
- Each culture has functional foods and ingredients that have special attributes. Identify and acknowledge these foods or ingredients.
- Understand customs, festive occasions, fasting, ceremonial activities, and celebrations. Promote the traditions and welcome special events or activities, as appropriate for the setting.

**FOOD AND NUTRITION**

- Review and identify specific ethnic and religious food patterns. Table 2-3 lists a brief overview of religious dietary patterns and common practices. More extensive information can be found on the internet and in many cookbooks.
- The WIC food package was updated to include foods to help families from diverse backgrounds. Most participants prefer whole versus low-fat milk; whole grain products and peanut butter are preferred over beans or soy foods (Black et al, 2009).
- *African/African American patterns.* Foods such as peanuts, peppers, and corn are traditional, as are fruits, vegetables, meats, and milk. Starch is a main consideration in the diet. Access to healthy foods such as fruits, vegetables, and whole grains should be noted as some community resources may be limited (Franco et al, 2009). In the South, dietary habits may include healthy foods prepared with unhealthy ingredients (such as fried chicken, greens prepared with lard). Spices and seasonings may vary. Alterations in recipes may be needed for taste and acceptance if healthier choices are offered.
- *Asian patterns.* Asian diets vary from one country to another. Diets may be low in calcium and riboflavin because milk often is not tolerated or consumed. Encourage use of tofu, green vegetables, and fish containing small bones. Diet may be high in sodium if monosodium glutamate (MSG) and soy sauces are used. The traditional Chinese diet contains 80% grains, legumes, and vegetables. Stir-frying, deep fat frying, and steaming are common cooking methods. Pork is the preferred meat. Hot peppers may be used daily. “Hot” and “cold” foods may be used during pregnancy or illness but these terms do not refer to food temperatures. Korean Americans tend to have a greater intake of carbohydrates, vitamins A and C than of saturated and total fat or Chol (Goody and Drago, 2010).
- *Hmong (Southeast Asian) patterns.* Milk is seldom used, related to lactose intolerance; calcium intake may be low. Fish, chicken, and pork are common entrees. Rice may be eaten at nearly every meal. A highly salted fish sauce is used. Snacking is rare in the family diet. Anemia may result from parasite infestation in those individuals who have been refugees. Like Chinese patterns, hot-cold patterns are often observed. A website for Vietnamese food is available at <http://www.ivietbusiness.com/vietnamese-food-recipe.htm>
- *Hispanic/Latino patterns.* Whole milk is used rarely, but cheese is a common additive to meals. Chili peppers, mangos, and avocados are the primary fruits and vegetables consumed. The main starch is corn or flour tortilla. Rice is the major contributor of energy among the elderly. The diet may be high in sugar and saturated fat (lard). A common main dish is beans with rice. Hot and cold foods are concepts commonly found. Salsa or sofrito seasonings are used frequently. Obesity, type 2 diabetes, hypertension, cardiovascular disease, dental caries, snacking, and undernutrition may be problems. Most Hispanic countries use folk remedies, such as garlic to treat hypertension and cough; chamomile to treat nausea, gas, colic, and anxiety; and peppermint to treat dyspepsia.

**TABLE 2-3 Common Religious Food Practices**

	Seventh-Day Adventist	Buddhist	Eastern Orthodox	Hindu	Jewish	Mormon	Moslem	Roman Catholic
Beef	A	A		X				
Pork	X	A		A	X		X	
All meat	A	A	R	A	R		R	R
Eggs/dairy	O	O	R	O	R			
Fish	A	A	R	R	R			
Shellfish	X	A	O	R	X			
Alcohol	X			A		X	X	
Coffee/tea	X					X	A	
Meat and dairy at same meal					X			
Leavened foods					R			
Ritual slaughter of meats					+		+	
Moderation	+	+					+	
Fasting <sup>a</sup>		+	+	+	+	+	+	+

<sup>a</sup>Fasting varies from partial (abstention from certain foods or meals) to complete (no food or drink).

X, prohibited or strongly discouraged; A, avoided by the most devout; R, some restrictions regarding types of foods or when a food may be eaten; O, permitted, but may be avoided at some observances; +, practiced.

#### REFERENCES

<http://asiarecipe.com/religion.html>.

[http://www.betterhealth.vic.gov.au/bhcv2/bhcarticles.nsf/pages/Food\\_culture\\_and\\_religion?open](http://www.betterhealth.vic.gov.au/bhcv2/bhcarticles.nsf/pages/Food_culture_and_religion?open).

- *Indian/Pakistani patterns.* India has some of the most diverse populations and diets in the world. In India, rates for oral and esophageal cancers are high. Indian immigrants in the United States are largely Hindus; Pakistani immigrants are mostly Muslims. Vegetarianism is a primary practice among Indians, deriving from religious beliefs in which the cow is sacred. Lentils and legumes are a primary source of protein; sometimes milk, eggs, fish, shrimp are consumed. Sattvic foods are believed to create a healthy life; these include milk products (except cheese made from rennet), rice, wheat, and legumes. Rajasic foods are believed to contribute to aggression; these include meats, eggs, and rich or very salty foods. Tamasic foods are believed to contribute to slothfulness or dullness; these include garlic, pickled foods, stale or rotten foods, and alcohol used for pleasure or to excess. Lack of portion control may be a factor in diabetes, which is common (Goody and Drago, 2010). Combination foods include biryani (grain, meat), samosas (grain, vegetable, meat, fat), kheer “rice pudding” (grain, milk), and curry (meat, vegetable). Turmeric (curcumin) is an ingredient in Indian curry spice that has strong antioxidant properties.
- *Mediterranean diet pattern (MDP).* The MDP reflect the habits of populations of Italy, Crete, and Greece. Olive oil; fish, poultry, and eggs rather than beef; breads, fruits, and vegetables in abundance; and lots of beans/legumes, yogurt, and cheeses make up this pattern. Exercise and wine are also mainstays. MDP is more often found among older people and people in rural areas, among males more than females, and among people who are more physically active (Tur et al, 2004). A Mediterranean-style

diet rich in whole grains, fruits, vegetables, legumes, walnuts, and olive oil is effective in reducing both the prevalence of the metabolic syndrome and cardiovascular risks. Urban young people should be encouraged to return to this pattern.

- *Middle Eastern patterns.* Countries usually include Egypt, Iran, Jordan, Lebanon, Saudi Arabia, and Turkey. Lamb and beef are consumed; pork is eaten only by Christians. Yogurt and cheese provide calcium sources as lactose intolerance is prevalent. Because olive oil is commonly used, lower BP is often found (Goody and Drago, 2010).
- *Native American patterns (American Indian and Alaskan Native).* Food has great religious and social significance and is commonly part of many celebrations. Fried foods, fried bread, corn, mutton, and goat are frequently used by American Indians, whereas seafood and game are more common among Alaskan natives. Obesity and type 2 diabetes are very common (Goody and Drago, 2010). For recipes, see website <http://www.kstrom.net/isk/food/recipes.html>. More information is available at <http://www.usda.gov/news/pubs/indians/open.htm>

### Common Drugs Used and Potential Side Effects

- Drugs may interact with various herbs botanicals and supplements. Individualize care and counseling.
- In the Multi-Ethnic Study of Atherosclerosis, white, African-American, Hispanic, and Chinese-American participants aged 45–84 years were studied; some met DRI guidelines for calcium, vitamin C, and magnesium but

effects of supplementation varied according to ethnicity and sex (Burnett-Hartman et al, 2009). Counselors should always ask about use of vitamin–mineral supplements.

## Herbs, Botanicals, and Supplements

- Knowledge of integrative medicine incorporates herbal and botanical products that are used for preventive or medicinal purposes. Different cultures apply different herbs and practices in folk medicine.
- Many cultures use herbs and botanicals as part of their meal patterns, rituals, and celebrations. Identify those that are used and monitor for potential side effects. See the first part of this chapter, which describes complementary medicine products.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Culturally appropriate counseling and awareness of religious practices are important for improving health issues, such as obesity and intake of fruits and vegetables (Goody and Drago, 2010). Different methods may be needed for dietary modification for obesity, diabetes, and hypertension, taking into account differences in cultural understanding and food practices. First, demonstrate respect for the beliefs, values, and practices of the patient and family members.
- Interpreters may be needed. Bilingual staff or community volunteers are helpful. Speak directly to the individual and not to the interpreter during sessions to show respect.
- Alternative solutions to dietary patterns must be gently offered. There is no “one right way” for dietary patterns. Understanding background, health problems, statistics, social issues, and disease patterns is useful when providing multicultural education.
- Build relationships through sensitivity and communication. Remove assumptions and stereotypes; cultures are changing, growing, and dynamic.
- Family beliefs and behaviors may sabotage a client’s efforts; be aware and be helpful. Develop an intuitive counseling style, reading body language, eye contact, and other behaviors.
- Offer tips on food selection, preparation, and storage; identify available resources, ethnic stores, and agencies.
- Interpreting food labels and preparing unfamiliar foods can be part of the educational session.
- Body language differs between cultures. For example, Hispanic/Latino cultures prefer being close to others in space; sitting within 2 feet demonstrates interest. Oriental cultures may prefer a greater distance to demonstrate respect.
- Avoid raw or partially cooked eggs, raw or undercooked fish or shellfish, and raw or undercooked meats because of potential foodborne illnesses.
- Do not use raw (unpasteurized) milk or products made from it. Avoid serving unpasteurized juices and raw sprouts.

### Patient Education—Food Safety

- Discuss food handling, preparation, and storage within a cultural context.
- When traveling, avoid tap water and ice made from tap water, uncooked produce such as lettuce, and raw or undercooked seafood.

# VEGETARIANISM

## NUTRITIONAL ACUITY RANKING: LEVEL 2 FOR MEAL PLANNING

### DEFINITIONS AND BACKGROUND

Vegetarian diets are plant-based with large amounts of cereals, fruits, vegetables, legumes, seeds, and nuts (Key et al, 2006). These diets generally omit meat, poultry, and fish. The vegan plan is a very strict vegetarian food pattern ("pure" vegetarianism); lacto is a vegetarian food pattern using milk; and lacto-ovo, a vegetarian food pattern using milk and eggs. While a Macrobiotic diet consists mainly of beans and whole grains, some individuals also consume fish. Conscious combining of complementary protein sources does not appear to be necessary on a regular basis (American Dietetic Association, 2003).

Vegetarian diets can be healthful when carefully planned. The Institute of Medicine recommends 25–35 g of fiber per day; vegetarian diets can easily provide this level. Individuals following vegetarian diets tend to have less obesity, constipation, diabetes, hypertension, diverticular disease, appendicitis, hiatal hernia, hemorrhoids, and varicose veins. Vegetarians usually consume less-saturated fats and Chol and often have more favorable lipid levels. Long-term vegetarians have a better antioxidant status and coronary heart disease risk profile than do apparently healthy omnivores; plasma ascorbic acid is a useful marker of overall health status (Szeto et al, 2004). Finally, there may be fewer kidney stones among vegetarians. A balanced diet with a moderate animal protein and purine content, an adequate fluid intake, and a high-alkali load with fruits and vegetables results in low risk of uric acid crystallization (Siener and Hesse, 2003).

Hindus, Seventh Day Adventists, Buddhists, and some other religious groups may suggest following a vegetarian lifestyle. Vegetarian diets are usually rich in carbohydrates, n-6 fatty acids, dietary fiber, carotenoids, folic acid, vitamin C, vitamin E and Mg, and relatively low in protein, saturated fat, long-chain n-3 fatty acids, retinol, vitamin B<sub>12</sub> and Zn (Key et al, 2006). See Table 2-4 for guidance on nutrients that are at risk.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

Clinical/History	Serum Fe and ferritin	tHcy
Height	Transferrin	Ca <sup>++</sup> , Mg <sup>++</sup>
Weight	Albumin (alb),	Na <sup>+</sup> , K <sup>+</sup>
BMI	transferrin	Serum zinc
Diet history	chol, Trig	Alkaline phosphatase (alk phos)
	Glucose (gluc)	Serum vitamin D
	Serum folate	
	Serum B <sub>12</sub>	
Lab Work		
Mean cell volume (MCV)		

**TABLE 2-4 Potential Complications of a Vegetarian Diet**

**Calcium** absorption may be inhibited as a consequence of the presence of phytates in plant foods; vegetarian diets are a risk for pregnant women, children, and adolescents if calcium intake is not carefully planned.

**Iron Deficiency Anemia.** Females should be sure to obtain an adequate amount of absorbable iron (Sharma et al, 2003). The iron in dairy, eggs, and plant foods is largely nonheme, of which only about 2–20% is absorbed.

**Excess Fiber or Inadequate Energy Intake.** In some circumstances, this regimen can restrict energy intake in the first few years of life (Murphy and Allen, 2003). This is also true for adults who consume large amounts of fiber to the extent that other nutrients are not able to be absorbed in the small intestine.

**Omega-3 Fatty Acids** and essential amino acids **methionine** and **lysine** are found in significantly lower amounts in vegetarian diets (Mezzano et al, 2000). It may be necessary to use a supplemental form.

**Protein** may be limited. Suggest complementary food combinations to acquire all amino acids.

**Vitamin B<sub>12</sub> Deficiency.** An individual following a vegan diet should use supplements to obtain this vitamin (Stabler and Allen, 2004).

**Vitamin D Deficiency or Rickets.** The human body can synthesize vitamin D from sunlight, but this is only possible when the sun reaches a certain intensity level. For people who live in northern latitudes, for a few months of the year, they will have to seek other sources of vitamin D. Milk is generally fortified with vitamin D; for vegans who do not consume dairy products, supplements are necessary (Outila et al, 2000). A very low-fat vegan diet can be nutritionally adequate with the exception of vitamin D; supplementation is needed (Dunn-Emke et al, 2005).

**Zinc** intake may be lower in vegetarian diets (Hunt, 2003).

## INTERVENTION

### OBJECTIVES

- Encourage use of a wide variety of foods in adequate quantity with a mix of nutrients and amino acids throughout the day.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Fiber Intake

**Assessment Data:** Food records; adverse side effects from high fiber intake; low BP; altered nutritional labs for calcium and iron.

**Nutrition Diagnoses (PES):** Excessive fiber intake related to vegan lifestyle as evidenced by complaints of excessive gas at night and intake of 45+ g of fiber daily, especially with large amounts at dinner.

**Interventions: Food and Nutrition Delivery:** ND 3.2.1 and ND 3.2.3 provide supplementation of a multivitamin and vitamin B<sub>12</sub>; ND-1.4 educate and counsel patient on following a healthy vegan diet and teach patient how to plan and monitor diet carefully.

**Nutrition Education:** E-2.2 Registered dietitian (RD) to provide recommend modifications to patient's diet through instruction and training to lead to a better understanding of the importance of monitoring vegan diet and supplementing to get required nutrients not supplied through diet.

**Counseling:** C-2.4 Problem Solving: RD will teach and counsel patient on how to get nutrients she needs while continuing to follow a vegan diet. They will discuss solutions to patient's vitamin B<sub>12</sub> deficiency by discussing vegan foods that are fortified with vitamin B<sub>12</sub> and foods such as nutritional yeast that will provide her with a source of vitamin B<sub>12</sub> in her diet.

**Coordination of Care:** RC-1.2 Refer patient to RD specializing in vegetarianism.

**Monitoring and Evaluation:** Improved quality of life with reduced symptoms of gas; lab reports for calcium, iron, ferritin; diet history revealing intake of fiber within desired range of 25–35 g/d.

- Provide nutritionally adequate menus with sufficient energy for weight goals. Discourage excessive use of sweets.
- Monitor the vegetarian diet carefully if the client is a pregnant woman, lactating mother, or elderly person. Infants, children, and teens on vegan diets should be monitored even more closely to ensure adequate energy intake and mineral and vitamin intakes (Perry, 2002). High-fiber diets may replace calories and cause some stunting or other growth deficits.
- Monitor fiber intake in general; excesses may interfere with absorption of calcium, zinc, and iron.
- Prevent or correct anemias, which could be either microcytic or macrocytic.
- The limiting amino acids in typical protein foods include wheat (lysine), rice (lysine and threonine), corn (lysine and tryptophan), beans (methionine), and chickpeas (methionine). Vary food mixtures such as using bread with milk, rice with cheese, or pasta with cheese; rice with beans, bread with beans, or corn and beans; garbanzo beans with sesame seeds (as in dips or in roasted snacks). Serve vegetables with nuts, dairy products, rice, sunflower seeds, or wheat germ. Different food combinations provide essential amino acids that produce higher quality proteins (American Dietetic Association, 2003).
- Plant sources of protein can provide adequate amounts of essential amino acids. Using a variety of plant foods is key, and energy needs should readily be met. Although vegetarian diets are lower in total protein, protein intake in both lacto-ovo-vegetarians and vegans appears to be adequate (Messina and Messina, 1996).
- Soy foods can be useful in reducing elevated Chol as part of a healthy vegetarian diet (Rosell et al, 2004).

## FOOD AND NUTRITION

The American Dietetic Association recommends that vegetarians consult with a registered dietitian or other qualified nutrition professional, especially during periods of growth, breastfeeding, pregnancy, or recovery from illness.

- For a balanced diet, minimize intake of less nutritious foods such as sweets and fatty foods. Choose whole or

unrefined grain products instead of refined products. Choose a variety of nuts, seeds, legumes, fruits, and vegetables, including good sources of vitamin C to improve iron absorption. Choose low-fat or nonfat varieties of dairy products, if they are included in the diet.

- Vegetarian foods rich in iron include many breakfast cereals, oatmeal, raisins, black beans, cashews, lentils, kidney beans, black-eyed peas, soybeans, hempseed, sunflower seeds, chickpeas, molasses, whole-wheat bread. Follow the food guide for North American vegetarians by including: 6–12 servings from the bread group, 2–3 servings of protein-rich foods such as legumes, nuts and seeds, or eggs (if used), 2–3 servings from the dairy group as tofu, yogurt, or fortified soy milk, 4 or more servings of vegetables, 3 or more servings of fruits, 2–3 servings of fats and oils, including olives and avocado.

### Common Drugs Used and Potential Side Effects

- Monitor use of medications that deplete vitamins and minerals, especially iron and B-complex vitamins.

### Herbs, Botanicals, and Supplements

- Many cultures use herbs and botanicals as part of their meal patterns, rituals, and celebrations. Identify those that are used and monitor side effects. Counsel about use of herbal teas, especially regarding toxic substances.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Beneficial changes to diet may occur on changing to a self-selected vegetarian diet; for example, it is one way of achieving a better blood lipid profile (Robinson et al, 2002).
- Explain patterns of food intake that provide complementary amino acids. Whole grains, legumes, seeds, nuts, and vegetables contain sufficient essential and nonessential amino acids if taken in the right combinations.
- Emphasize the importance of a balanced diet.
- Describe the role vegetarian diets play in lowering serum Cholesterol (Chol), Triglycerides (TG), and glucose. These are beneficial changes that can result after starting a vegetarian diet (Phillips et al, 2004).
- Counsel about appropriate products for infants and children, as protein may be the biggest problem. Soy milk should be fortified with calcium and vitamin B<sub>12</sub>.
- Unless otherwise advised by a doctor, those taking dietary supplements should limit the dose to 100% of the Daily Reference Intakes.

### Patient Education—Food Safety

- Discuss food handling, preparation, and storage, especially careful washing of fruits and vegetables. Spinach and sprouts have been contaminated in recent years; wash produce thoroughly. Discuss hand washing.

- Starches such as hot cereals and rice should not be prepared and held in large batches because of the risks of *Bacillus cereus*.

## EASTERN RELIGIOUS DIETARY PRACTICES

### NUTRITIONAL ACUITY RANKING: LEVEL 2 (ADVISEMENT/PLANNING)

#### DEFINITIONS AND BACKGROUND

##### Hinduism, Jainism, and Sikhism

**Hindus** may be vegetarian while adhering to *ahimsa*, related to nonviolence as applied to the infliction of pain on animals. Beef is never eaten (the cow is considered sacred), and pork is usually avoided. Foods prohibited may include snails, crab, poultry, cranes, ducks, camels, boars, and some types of fish. The Brahmins, “high caste” folk, have stricter rules and practices, and there are differences between the North Indian Brahmins and the South Indian Brahmins. Some foods promote purity of the body, mind, and spirit. Devout Hindus avoid alcoholic beverages and foods that stimulate the senses, such as garlic and onions. Feast days include Holi, Dusshera, Pongal, and Divali (varying each year according to the lunar calendar). In addition, personal feast days include the anniversaries of birthdays, marriages, and deaths. Fasting depends on a person’s social standing (caste), family, age, gender, and degree of orthodoxy. Fasting can be complete, adopting a completely vegetarian diet, or it can be abstaining from favorite foods.

**Jainism** is a branch of Hinduism that also promotes the nonviolence of *ahimsa*. Jains are expected to practice nonviolence, including against animals. Devout Jains are complete vegans. They avoid blood-colored foods (tomatoes) and avoid root vegetables, which may result in the death of insects clinging to the vegetable when it is harvested. Jains drink only boiled water. Fasting is a tool for connecting with the inner being during festivals. Fasting is based on three

levels of austerity: Uttam, Madhyam, and Jaghanya. When one has finished with the roles of life, he or she willingly gives up food and drink; this can take up to 12 years with a gradual decline in eating.

**Sikhs** participate in many Hindu practices but differ by their belief in a single God. Sikhs abstain from beef and alcohol, but pork is permitted. Everyone is equal, no matter what color, sex, race, wealth, height, weight or religion; there is only one true race, the human race. Everyone sits on the floor when eating, as equals.

##### Buddhism

Buddhist dietary customs vary considerably depending on sect (Theravada or Hinayana, Mahayana, Zen) and on country of origin. Most Buddhists also subscribe to the concept of *ahimsa*, and many are lacto-ovo-vegetarians. Some eat fish, whereas some only abstain from beef. Some believe that unless they personally slaughter an animal, they may eat its meat.

Buddhist monks fast completely on the days of the new moon and full moon each lunar month; they also avoid eating any solid food after the noon hour. Buddhist feasts vary from one region to another. Celebrations include the birth, enlightenment, and death of Buddha in Mahayana Buddhism; the 3 days are unified into the single holiday of Vesak for Theravada Buddhism.

Buddhist vegetarian diets tend to allow more natural insulin sensitivity, so diabetes is less common (Kuo et al, 2004). However, serum tHcy should be monitored because of possibly lower intakes of vitamin B<sub>12</sub> (Hung et al, 2002).

#### ASSESSMENT, MONITORING, AND EVALUATION

##### CLINICAL INDICATORS

###### Clinical/History

Height

Weight

BMI

Recent weight changes

Diet history  
BP

## SAMPLE NUTRITION CARE PROCESS STEPS

**Inadequate Mineral (Iron) Intake**

**Assessment Data:** Food records showing low intake of heme iron; altered nutritional labs for iron and ferritin; normal folate and B<sub>12</sub> levels; complaints of easy fatigue and irritability.

**Nutrition Diagnoses (PES):** Inadequate iron intake related to Hindu (vegan) lifestyle as evidenced by intake of 4–5 g nonheme iron daily and low-serum Fe and ferritin levels.

**Intervention:** Education about increasing intake of iron-rich foods while decreasing excess of wheat bran. Counseling about using iron-fortified cereals or a supplement that provides 100% DRI for iron.

**Monitoring and Evaluation:** Improved energy and less fatigue; improved lab reports for iron and ferritin; diet history revealing improved intake of nonheme iron with supplements as needed.

## INTERVENTION

## OBJECTIVES

- Serve appropriate menu choices, and omit foods or beverages that are not permitted.
- Respect traditions and preferences of the individual and family members.

## FOOD AND NUTRITION

- Support dietary practices as followed by the individual and family members.
- Counsel about specific nutritional changes according to the medical diagnosis and current condition.

## Common Drugs Used and Potential Side Effects

- During periods of fasting, identify potential interactions from drugs that are dependent on energy sources for their metabolism.

## Herbs, Botanicals, and Supplements

- Many cultures use herbs and botanicals as part of their meal patterns, rituals, and celebrations. Identify those that are used and monitor side effects.

- Counsel about use of herbal teas, especially regarding toxic substances.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Show the patient how to prepare foods to reduce Chol, fat, or sodium if heart disease or hypertension is present.
- Various types of cancer may prevail in different parts of the world and in different cultures. Discuss diet in relationship to what is common.
- While medical students and physicians with healthful personal practices (such as vegetarianism) are more likely to encourage such behaviors in their patients, these beliefs do not affect their actual nutrition counseling (Spencer et al, 2007).

## Patient Education—Food Safety

- Discuss safe preparation and storage of foods to reduce likelihood of bacterial contamination.

# WESTERN RELIGIOUS DIETARY PRACTICES

## NUTRITIONAL ACUITY RANKING: LEVEL 2 (ADVISEMENT/PLANNING)

### DEFINITIONS AND BACKGROUND

#### Judaism (Edited by Rabbi Allan Bernstein)

Jewish congregations in the United States are either identified as Orthodox, Conservative, or Reform. Orthodox Jews believe the laws are the direct commandments of God, to be explicitly followed by the faithful. Reform Jews follow the moral law but believe that the laws are still being interpreted (some are considered dated or currently irrelevant) and may be observed selectively. Conservative Jews fall in between the other congregations in their beliefs and adherence to the laws. About 25–30% of Jews in America keep kosher to one extent or another (<http://www.jewfaq.org/kashrut.htm>).

Jewish dietary laws are known as *Kashrut* and are among the most complex of all religious food practices. The term *kosher*, or *kasher*, means “fit” and describes all foods that are permitted for consumption. Kosher is loosely used to identify Jewish dietary laws, and to “keep kosher” means that the laws are followed. The dietary laws are complex. Briefly, they include what foods are fit to eat, what foods are prohibited (a lengthy list that includes pork, shellfish, and other foods), how animals must be slaughtered, how they must be prepared, and when they may be consumed (specifically, rules regarding when milk products can be consumed with meat products).

Jewish feast days include Rosh Hashanah, Sukkot, Hanukkah, Purim, Passover, and Shavout (dates vary because Judaism uses a lunar calendar). Specific foods are associated with the feasts but may differ nationally. Complete fast days (no food or water from sunset to sunset) include Yom Kippur and Tisha b’Av. Partial fast days (no food or water from sunrise to sunset) include Tzom Gedaliah, Tenth of Tevet and Seventeenth of Tamuz, Ta’anit Ester, and Ta’anit Bechorim. Special kosher laws are observed during Passover, including the elimination of any products that can be leavened.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

<b>Clinical/History</b>	Diet history	Serum Na <sup>+</sup> , K <sup>+</sup>
Height	BP	Ca <sup>++</sup> , Mg <sup>++</sup>
Weight		Alk phos
BMI	<b>Lab Work</b>	H & H, serum
Recent weight changes	Gluc	Fe
	Chol, Trig	

### INTERVENTION

#### OBJECTIVES

- Observe dietary practices as followed by the laws of Judaism: meats are limited to cud-chewing animals with cloven hooves (cows and sheep) that are properly slaughtered. Pork (including ham and all pork products), shellfish, and scavenger fish are forbidden.
- Separate utensils are used for preparation and eating and especially for separating meat and milk foods.
- Monitor the kosher diet, which tends to be high in Chol, saturated fats, and sodium. Encourage application of the DASH diet principles where possible, but reduce lactose and sodium if necessary.

### FOOD AND NUTRITION

The Jewish dinner table follows these guidelines (<http://www.jewfaq.org/kashrut.htm>):

- Certain animals may not be eaten at all. This restriction includes the flesh, organs, eggs, and milk of the forbidden animals. No pork, ham, bacon, pork products, rabbit, shellfish, or eel may be eaten.
- Of the animals that may be eaten, the birds and mammals must be killed in accordance with Jewish law. All blood must be drained from the meat or broiled out of it before it is eaten. Certain parts of permitted animals may not be eaten. Sheep, cattle, goats, and deer are kosher.
- Meat (the flesh of birds and mammals) cannot be eaten with dairy. Fish, eggs, fruits, vegetables, and grains can be eaten with either meat or dairy. According to some views, fish may not be eaten with meat.
- Dairy: Milk may be consumed before a meal, but once meat is eaten, 3–6 hours (depending on individual traditions) must pass before dairy products can be consumed. Omit lactose if not tolerated; provide other sources of calcium and riboflavin.
- Utensils that have come into contact with meat may not be used with dairy and vice versa. Utensils that have come into contact with nonkosher food may not be used with kosher food.
- Fruits, vegetables, and grains can be used, except that breads made with milk products are forbidden with meat meals. Grape products made by non-Jews may not be eaten.
- Leavened (raised) bread is forbidden during Passover. Matzoh bread or crackers may be used. Haroset and fried matzoh are traditional Passover foods. Seder plates and other items appropriate for the Seder dinner are important additions to the menu at this time.
- Common food choices include matzoh ball soup, chicken soup with kreplach, gefilte fish with beet horseradish,

cheese blintz with sour cream, flanken tzimmes, chopped liver, noodle Kugel, and kishka. Frozen kosher meals may be available in some areas.

- Fasting is common during Yom Kippur.
- Traditional Hanukkah foods include latkes and sour cream or applesauce.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Show the patient how to limit foods high in Chol/fat if weight and elevated lipid levels are a problem.
- Discuss sodium and obesity in relationship to hypertension, as appropriate. Recommend other herbs, spices, and cooking methods.
- Low-fat cheeses should be substituted for high-fat cheeses such as cream cheese.
- Note that food labels with a “U” with an “O” encircling it are considered kosher. Many other foods are considered kosher, but an inquiry should be made.
- Discuss holiday preferences and alternatives when needed.

### Patient Education—Food Safety

- Discuss safe preparation and storage of foods to reduce likelihood of bacterial contamination.

### Christianity

There are three major branches of the Christian faith: Roman Catholicism, Eastern Orthodox Christianity, and Protestantism. Dietary practices vary; some are minimal.

(1) **Roman Catholicism:** Devout Catholics observe several feast and fast days during the year. Feast days include Christmas, Easter, the Annunciation (March 25th), Palm Sunday (the Sunday before Easter), the Ascension (40 days after Easter), and Pentecost Sunday (50 days after Easter). Catholics in each country observe many food traditions. Fasting (one full meal per day permitted; snacking according to local custom) and/or abstinence (meat is prohibited, but eggs, dairy products, and condiments with animal fat are permitted) may be practiced during Lent, on the Fridays of Advent, and Ember Days (at the beginning of the seasons) by some Catholics; some fast or abstain only on Ash Wednes-

day and Good Friday. Today, Catholics may avoid meat only on the Fridays of Lent (40 days before Easter). Food and beverages (except water) are to be avoided for 1 hour before communion is taken.

(2) **Eastern Orthodox Christianity:** The 14 self-governing churches that form the Orthodox Church differ from Catholicism in their interpretation of the Biblical theology, including the use of leavened bread instead of unleavened wafers in communion. Numerous feast and fast days are observed (dates vary according to whether the Julian or Gregorian calendar is used). Feast days include Christmas, Theophany, Presentation of the Lord into the Temple, Annunciation, Easter, Ascension, Pentecost Sunday, the Transfiguration, Dormition of the Holy Theotokos, Nativity of the Holy Theotokos, and Presentation of the Holy Theotokos. In addition, Meat Fare Sunday is observed the third Sunday before Easter (all meat in the house is consumed, and none is eaten again until Easter). Cheese Fare Sunday is observed on the Sunday before Easter (all cheese, eggs, and butter are consumed). On the next day, Clean Monday, the Lenten fast begins. Food and drink are avoided before communion.

Meat and all animal products (milk, eggs, butter, and cheese) are prohibited on fast days; fish is avoided, but shellfish is permitted. Some devout followers may avoid olive oil on fast days, too. Fast days include every Wednesday and Friday (except for three fast-free weeks each year), the Eve of Theophany, the Beheading of John the Baptist, and Elevation of the Holy Cross. Fast periods include Advent, Lent, the Fast of the Apostles, and Fast of the Dormition of the Holy Theotokos.

(3) **Protestantism:** The only feast days common in most Protestant religions are Christmas and Easter. Few practice fasting.

(4) **Mormons (Church of Jesus Christ of Latter Day Saints):** Mormons avoid alcoholic beverages, hot drinks (coffee and tea), and caffeine-containing drinks. Followers are encouraged to eat mostly grains and to limit meats. Some Mormons fast 1 day a month and donate that food money to the poor.

(5) **Seventh-Day Adventists** avoid overeating. Most are lacto-ovo-vegetarians, but when meat is consumed, most avoid pork. Tea, coffee, and alcoholic beverages are prohibited. Water is consumed before and after meals. Eating between meals is discouraged. Strong seasonings and condiments, such as pepper and mustard, are avoided.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

Clinical/History	Lab Work	H & H, serum
Height	Gluc	Fe
Weight	Chol, Trig	C-reactive
BMI	Serum Na <sup>+</sup> , K <sup>+</sup>	protein
Recent weight changes	Ca <sup>++</sup> , Mg <sup>++</sup>	(CRP)
Diet history	Alk phos	
BP		

**INTERVENTION****OBJECTIVES**

- Observe dietary practices as followed by the individual. Discuss the role of special meals, fasting, or events and plan menus accordingly.
- Assist guests and immigrants in maintaining their healthy dietary practices and religious traditions, as appropriate (Kaplan et al, 2004).

**FOOD AND NUTRITION**

- Promote a healthy diet. For example, principles of a Mediterranean diet may be suitable for many individuals (Bilenko et al, 2005).
- Fasting may be common during special holidays. Discuss concerns related to pregnancy, children, the elderly or those in a malnourished state.
- Some individuals avoid caffeine and alcohol as part of their religious preferences; honor those wishes.
- Determine if any foods are avoided on special days of the week and plan alternatives accordingly.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Show the patient how to limit foods high in Chol/fat if weight and elevated lipid levels are a problem.

- Discuss sodium and obesity in relationship to hypertension, as appropriate. Recommend other herbs, spices, and cooking methods.
- Discuss holiday preferences and alternatives where needed.
- There tend to be few specific relationships between religion, fat intake, and physical activity in contemporary U.S. society; religion may play only a small role in the context of how diet and exercise are developed and maintained (Kim and Sobal, 2004).

**Patient Education—Food Safety**

- Discuss safe preparation and storage of foods to reduce likelihood of bacterial contamination.

# MIDDLE EASTERN RELIGIOUS DIETARY PRACTICES

**NUTRITIONAL ACUITY RANKING: LEVEL 2 (ADVISEMENT/PLANNING)****DEFINITIONS AND BACKGROUND**

Islam is an Arabic word that means submission, surrender, and obedience; it also means peace, as it is derived from the word “Salam,” which means peace. As a religion, Islam stands for complete submission and obedience to God. Followers of the Islamic faith are known as Muslims. Muslims promote the concept of eating to live, not living to eat. They advise sharing food.

Prohibited foods as described in the Koran are called *haram*; those in question are *mashbooh*. Pork and birds of prey are *haram*; meats must be slaughtered properly. Alcohol is prohibited, and stimulants, such as coffee and tea, are allowed. *Halal* is the term for all permitted foods. The flesh of animals must be slaughtered according to Islamic law or *halal*; kosher items may be used for this reason. Feast days (dates vary according to the lunar calendar) include Eid al-Fitr, Eid al-Azha, Nau-Roz (a Persian holiday), Al-Ghadeer, and Maulud n’Nabi. Fasting is considered an opportunity to earn the approval of Allah, to wipe out sins, and to understand the suffering of the poor. Fasting includes abstention from all food and drink from dawn to sunset. Voluntary fasting is

common on Mondays and Thursdays; it is undesirable to fast on certain days of the month and on Fridays. Muslims are required to fast during the entire month of Ramadan and are encouraged to fast 6 days during the month of Shawwal, on the Al-Ghadeer day, and on the 9th day of Zul Hijjah.

**ASSESSMENT, MONITORING, AND EVALUATION****CLINICAL INDICATORS****Clinical/History**

Alk phos  
H & H, serum Fe

## INTERVENTION

## OBJECTIVES

- During fasting, eating occurs only before dawn and after sunset. Plan accordingly.
- Monitor dietary patterns, which include fasting 3 days a month. Pregnant and breastfeeding mothers need not fast.
- Monitor need for vitamin D in women if sun exposure is minimal.

## FOOD AND NUTRITION

- Pork and pork products are forbidden, including gelatin.
- Alcohol is not used, even in vanilla extract and other preparations.
- Foods such as dates, seafood, honey, sweets, yogurt, milk (goat's milk also), meat, and olive or vegetable oils are encouraged. Beef, chicken, and lamb are commonly used. Couscous, pita bread, rice, millet, and bulgur are frequently included. Eggplant, cucumbers, green peppers, pomegranates, and tomatoes are readily available.
- Typical combination foods include: falafel (grain, fat), hummus (grain, fat), kibbeh (meat, grain, fat), tabouli (vegetable, grain, fat), baba ghanouj (vegetable, fat), pilaf (grain, fat), stuffed grape leaves (meat, grain, fat), and shawarma (meat, grain, fat). Khoresh is a stew with meats (lamb, beef, or veal), poultry, or fish with vegetables; fresh or dried fruits; beans, grains, and even nuts.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- If diet is low in heme iron, anemia may occur. Discuss options if necessary.
- Fasting is not recommended for persons who have diabetes, cancer, or HIV/AIDS. Discuss menu planning for religious occasions.
- Discuss useful dietary changes for managing obesity and diabetes.

## Patient Education

- Discuss periods of fasting if there are undesirable side effects, such as hypotension or fainting.

## OROFACIAL CONDITIONS

## DENTAL DIFFICULTIES AND ORAL DISORDERS

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

Reprinted with permission from: Goodheart HP, MD. *Goodheart's Photoguide of Common Skin Disorders*, 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

## DEFINITIONS AND BACKGROUND

Diet and nutrition affect many oral diseases. Cell turnover is rapid in the tongue and oral mucosa; therefore, the oral cavity is one of the first areas where signs of systemic disease appear. Two oral infectious diseases are diet related: dental caries (tooth decay related to diet composition and frequency), and periodontal disease, associated with malnutrition (Touger-Decker et al, 2003). In dental caries, chronic infectious disease leads to progressive destruction of tooth substances from interactions between bacteria and organic tooth compounds. *Streptococcus mutans* and *Lactobacillus* form acids within 20 seconds to 30 minutes after contact. Erosion of tooth enamel may occur in patients who chronically consume acidic beverages and/or keep such beverages or foods in the mouth for a period of time (e.g., sucking lemons, chewing vitamin C tablets, chewing lemon hard candies). Tooth loss can prevent proper bite and may lessen the ability

to chew foods properly. Dietary advice given when dentures are placed results in increased consumption of fruits and vegetables during stages of change (Moynihan, 2005a).

Health professionals should check the oral and dental health of their patients. Many Americans lack fluoridated water, an effective safeguard against dental cavities. Those who are poor or have no dental insurance are also at risk for caries. Water fluoridation can reduce caries by 20–40% (American Dental Association, 2009).

Some dental problems are age specific. Infants should be monitored for early childhood caries (ECC); dental decay often occurs during the growth spurts of adolescents; and older patients should be monitored for changes in eating habits, inadequate diet, and caries. Elderly persons who wear dentures are more prone to malnutrition (de Oliveria and Frigerio, 2004) and problems with chewing, swallowing, and mouth pain often precede hospitalizations (Bailey et al, 2004).

Poor oral hygiene can increase the likelihood of gingival abnormalities when vitamin C and D intakes have been poor. Some conditions, such as diabetes, can also make individuals prone to dry mouth and dental decay. An increase in water intake, extra care with oral hygiene, chewing sugarless gum, and prevention of periodontal disease are important steps.

With tongue disorders, mastication of food may be affected. The ability to push mashed food with the tongue and anterior hard palate will be affected. Other oral problems may cause pain, problems with chewing, dysphagia, mouth dryness, or infection including aphthous stomatitis, cheilosis, oral cancer, lichen planus, oral herpes, candidiasis, thrush, or xerostomia. Many of these conditions occur because of altered immunity and debility, as in cancer or HIV infection.

Fracture of the lower jaw (mandible) is an injury that requires intermaxillary fixation (wiring). Patients with wired jaws face a whole new lifestyle for up to 6 weeks following surgery. Patients have to eat liquefied meals; proper presurgical patient education is essential.

Proper nutrition is essential for good dental and oral health. Table 2-5 provides a list of the key nutrients needed for healthy oral mucosa and teeth. Vitamins A and C are significant for prevention and treatments of leukoplakias (Scully, 2000; Sheiham et al, 2001). Treatment with beta-carotene or retinoids is often recommended (Lodi et al, 2004). Table 2-6 lists dental problems, treatment, and prevention.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

#### Clinical/History

Height  
Weight  
BMI  
Recent weight changes  
Diet history  
Mouth, gum or tongue lacerations  
Dental caries  
Missing or loose teeth

#### Dentures,

missing,  
loose or  
ill-fitting  
Taste alterations  
Sore or bleeding gums  
High intake of sugars and sticky starches?

#### Lab Work

Alb, transthyretin  
Serum Na<sup>+</sup>, K<sup>+</sup>  
Ca<sup>++</sup>, Mg<sup>++</sup>  
Alk phos  
H & H, serum Fe  
X-rays (mandible)  
Serum folate  
Serum ascorbate and retinol

**TABLE 2-5 Nutrients Needed for Proper Oral Tissue Synthesis and Dental Care**

<b>Protein</b>	Needed for healthy tissue growth and maintenance.	<b>Chromium</b>	Needed for proper glucose metabolism. Controlled intake of carbohydrates helps to maintain healthier gums and overall health status (Moynihan, 2005b).
<b>Vitamin A</b>	Necessary for epithelial tissue and enamel. Beta-carotene may play a role in oral cancer prevention (Lodi et al, 2004).	<b>Copper</b>	Needed for production of blood and nerve fibers.
<b>Vitamin B-complex</b>	Deficiencies show a bright scarlet tongue and stomatitis in niacin deficiency; magenta tongue, glossitis, and angular cheilitis in riboflavin deficiency; smooth tongue in vitamin B <sub>12</sub> deficiency.	<b>Fluoride</b>	Consumption of fluoridated water coupled with a reduction in nonmilk sugar intake is an effective means of caries prevention (American Dietetic Association, 2000; Moynihan, 2005a). Keeps bones healthy. Drinking water should contain 1 ppm; toothpaste, mouth rinses, and topical treatments also help.
<b>Folate</b>	Needed for a healthy blood supply.	<b>Iron</b>	Helps produce red blood cells; promotes resistance to disease; improves health of the teeth, skin, and bones. Maintains energy.
<b>Vitamin C</b>	Enables connective tissue cells to elaborate intercellular substances. Deficiency can lead to easy bleeding or swelling of gums and gingivitis. Forms collagen; helps to heal wounds and bleeding gums.	<b>Magnesium</b>	Helps in bone development. Enhances use of vitamin C. Deficiency may lead to calcium resorption.
<b>Vitamin K</b>	Aids with calcium absorption in bone; adequate blood clotting; helps in healing.	<b>Potassium</b>	Needed for muscle contraction and proper nerve function.
<b>Vitamin D</b>	Protects against chronic inflammation of the gums, which can lead to gingivitis or periodontal disease (Dietrich et al, 2004). Necessary for dentin, bony tissue synthesis; mineralization; and jawbone sufficiency.	<b>Zinc</b>	Regulates the inflammatory process; aids in wound healing. Deficiencies can lead to poor healing, susceptibility to infection, loss of taste, and altered metabolism.
<b>Calcium and phosphorus</b>	Necessary for dentin and bony tissue synthesis. Poor mineralization occurs with deficiency. Maintains jawbone sufficiency.		

**TABLE 2-6 Dental Problems, Treatment, and Prevention**

Symptoms	Likely Cause	Treatment	Prevention
<i>Bad Breath</i>			
Odor from mouth; bad, metallic taste; coated tongue	Food caught around and between teeth; infection in gums; improper brushing; sinusitis; digestive problems, such as preulcerative conditions; diabetes	Practice good oral hygiene, including rinsing with mouthwash; brush tongue often; see dentist to evaluate throat, sinuses, tongue, and possible gum infection, and professionally clean teeth and gums; review diet	Regular dental visits; flossing, brushing, and rinsing; good nutrition
<i>Broken Tooth or Filling</i>			
Tooth feels sharp; tooth sensitivity to temperature and pressure	Accidental trauma; decay; weak tooth from grinding or improper bite	Do not irritate; place piece of soft dental wax from drugstore over cracked or fractured tooth; see a dentist immediately	Regular dental checkups to discover possible weak teeth, decay, or large, unstable fillings
<i>Canker Sores</i>			
Painful red circular area that develops on the tongue, gums, lips, or cheeks; in certain phases, sores have a yellow or white center area; sore to touch; sensitivity to spicy, salty foods	Bacterial or viral infection; trauma from denture in mouth; stress	Use over-the-counter remedies recommended by the dentist; coat lesions after meals; see dentist to make sure there is no infection or for additional medication if pain persists; the dentist will evaluate dentures for weight-bearing points to be certain the problem does not exist there	Avoid irritating the area; avoid spicy, acidic foods while mouth is sore
<i>Dental Abscess (swelling around tooth or cheek)</i>			
Pain, throbbing in gum or tooth; swelling; sensitive bite; loose teeth; sensitivity to heat	Tooth decay; initial eruption of tooth through the gums or fractured tooth; tooth nerve damage	Rinse with salt water solution; use mouthwash; avoid eating on or near tooth; see dentist immediately; may require antibiotics or root canal treatment to prevent spread of infection	Regular dental checkups; good oral hygiene; brushing, flossing, and rinsing
<i>Discolored Teeth</i>			
Teeth have unsightly and discolored appearance; single tooth begins to turn yellow or gray	Surface stain from certain foods, such as tea and coffee; internal staining from tooth nerve damage or from rheumatic fever; stains from tetracycline	Improve oral hygiene; brush frequently; diminish coffee or tea intake; rinse with peroxide; consult dentist to check nerve in darkened tooth; consider supervised tooth bleaching/whitening	Good oral hygiene; avoid foods and liquids that can stain teeth, such as tea and coffee
<i>Gum Disease</i>			
Gum pain; nonthrobbing ache; swelling; gum bleeding; blood in saliva when brushing; metallic taste	Food debris between teeth; tartar beneath gums; infection; poor bite may worsen this condition	Improve oral hygiene by brushing often and flossing; rinse with mouthwash; consult dentist to evaluate extent of condition; treatment by removing plaque and tartar may require surgery and/or bite adjustment	Good oral hygiene; regular dental checkups and cleanings
<i>Red Inflamed Gums</i>			
Color of gums around teeth progresses from pink to red with swelling or puffiness; dry mouth; snoring	Mouth breathing; some medications, such as antihistamines, blood pressure medications, and antidepressants, decrease salivary flow	Use oral salivary rinses and toothpastes for dry mouth; improve oral hygiene; consult dentist because this condition can lead to tooth decay, advanced gum disease, or other mouth infections	Ask physician if medications can be changed; consult dentist about obtaining oral rinses and a snoreguard

(continued)

**TABLE 2-6 Dental Problems, Treatment, and Prevention (continued)**

Symptoms	Likely Cause	Treatment	Prevention
<i>Loose Teeth</i>			
Teeth move; spongy feel to bite; teeth sensitive or even painful when chewing	Gum disease; tooth grinding; orthodontic appliances too tight; cyst, tumor, abscess, or trauma to teeth	See dentist as soon as possible to determine cause; practice good oral hygiene; be aware of tooth grinding or clenching and use appliance to prevent grinding	Regular dental visits; good oral hygiene; have your dentist evaluate your bite; use a bite appliance if your dentist advises
<i>Lumps Under Jaw or Neck Muscle</i>			
Neck sore to touch or movement; swelling in neck; sore throat; difficulty swallowing	Cold/flu; tooth abscess or infection; tumor	Treat cold/flu symptoms; limit neck movement; check temperature; take pain relievers such as aspirin; see a dentist if symptoms persist to evaluate the extent of swelling and infection	Regular dental checkups; patients should pay special attention to any growth or changes in the head or neck
<i>Toothache (tooth pain on biting or chewing)</i>			
Tooth pain related to temperature change or touch or from chewing or biting; dark brown spots on teeth may indicate new decay	Bacterial acids; large filling broken out of tooth; tooth grinding	Rinse mouth often with vanilla extract to soothe discomfort; avoid chewing on tooth; see a dentist as soon as possible to determine cause and further treatment	Regular dental visits for prevention; the sooner examined, the better the chance of success
<i>Tooth Sensitivity to Temperature Change</i>			
Breathing outside in cold air causes pain; waking up with toothache; pain when eating/drinking cold things	Inflamed gums; gum recession that exposes root surfaces; tooth decay; teeth clenching or grinding that has worn away tooth enamel	Use desensitizing toothpaste on a daily basis; use a soft bristle brush; avoid temperature differences; consult dentist for appropriate treatment	Good oral hygiene; apply fluoride gel; use desensitizing toothpaste; avoid food temperature differences; avoid hard bristle toothbrushes; become aware of and avoid tooth grinding or squeezing teeth together; have fillings bonded to seal areas of sensitivity; dentist may recommend a biteguard for grinding

Adapted from Rhode Island Dental Association, 200 Centerville Road, Warwick, RI 02886; Phone: (401) 732-6833. Web site accessed March 28, 2009, at <http://www.ridental.com/dentalproblems.cfm>. Used with permission.

## INTERVENTION

### OBJECTIVES

#### Broken or Wired Jaw

- Provide adequate nourishment to allow healing while reducing jaw movement.
- Decrease complications such as fever, nausea, and vomiting.
- Prevent excessive weight loss; up to 10% is common.
- Maintain a patent airway.

#### Dental Caries

- Alter dietary habits; deprive bacteria of substrate; reduce acid by keeping pH at 7.0.
- Maintain frequent fluoride contact with tooth surfaces as directed by a dental professional.

#### Early Childhood Caries (ECC)

- ECC is a preventable dental disease in which enamel erodes, and tooth surfaces are permanently damaged from long exposure to liquid carbohydrate sources.

- Education is the biggest factor. Children with significant risk factors for caries (e.g., inadequate home dental care, poor oral hygiene, a mother with a high number of cavities, a high sugar intake, enamel defects, premature birth, special health care needs, low socioeconomic status) should be referred to a dentist (Douglass et al, 2004).

#### Edentulism

- Provide proper consistency to allow the patient to eat.
- Monitor for deficiencies in fiber, vitamins A and C if whole grains, fruits, and vegetables are not consumed (Touger-Decker, 2004).

#### Mouth Ulcers or Pain

- Lessen mouth soreness to increase dietary intake; mouth sprays may be available to lessen pain while eating.
- Promote healing for a return to normal eating patterns.
- Prevent weight loss or other consequences.

#### Tongue Disorders

- Provide adequate nourishment despite acute or chronic disability.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Chewing Difficulty**

**Assessment Data (sources of info):** Food records and intake calculations; dental evaluation for loose dentures; weight changes.

**Nutrition Diagnosis:** Chewing difficulty related to inability to chew foods from poor dentition as evidenced by weight loss of 2 lb in 14 days and ill-fitting dentures.

**Interventions: Food and Nutrient Delivery**

ND 1.2 Modify current diet to puree diet until otherwise noted from Dentist/MD.

ND 3.1.1 Continue with shakes BID to enhance energy intake.

Recommend dental referral for dentures.

**Monitoring and Evaluation:** Intake records, reduction in chewing problems, improved weight after fitting of new dentures.

**Inadequate Energy Intake—Early Childhood Caries**

**Assessment Data (sources of info):** Food records (high intake of juice, sweetened beverages throughout the day from the bottle); intake calculations; dental evaluation for ECC; weight loss from inability to chew solids and refusal to drink from a cup.

**Nutrition Diagnosis:** Inadequate energy intake (NI-1.4) related to inability to chew foods as evidenced by early childhood dental caries with poor weight gain.

**Interventions**

**Goals:** Wean from bottle completely. Increase solid food intake and decrease fluids, especially sweetened fluids. Follow a weight gain of at least 0.6 oz/wk, 2.7 oz/mo, or 1 lb/6 mo. Educate parents on importance of healthy oral hygiene and not allowing child to carry liquids around during day or fall asleep with liquids.

**Food and Nutrient Delivery:** ND-1.1 Provide general/healthful diet, provide information on weaning from the bottle, educate on importance of oral hygiene, increase intake of water, decrease intake of juice to a maximum of 4 oz/d diluted with water, eliminate other sweet drinks, alter diet to reduce need to chew (puree, mash, or chop foods).

**Nutrition Education:** E-1.2 Provide information on weaning, calorie boosters, importance of oral hygiene, limiting sweetened beverages. DDS to perform oral surgery for removal of dental caries to decrease pain and increase intake of solid foods for weight gain. RD to continue to monitor weight gain and food intake.

**Counseling:** C-2.5 Counsel patient's mother and father on supporting each other through weaning and the importance of good oral hygiene.

**Coordination of Care:** RC-1.3 Collaborate with MD and DDS on patient's care through oral surgery and monitoring weight status.

**Monitoring and Evaluation:** Intake records, reduction in chewing problems, improved weight, and health status.

**Tube Feeding**

- Children on tube feedings often have dental problems; attend to oral hygiene more carefully than for those fed orally.
- Adults will require special attention to oral hygiene and mouth care while on tube feedings.

**Xerostomia**

- Dry mouth may be more severe after radiation therapy than with other causes, such as diabetes.
- Artificial saliva agents may be useful for some. Reduced saliva affects patient perception of swallowing ability and changes dietary choices (Logemann et al, 2003).
- Good oral hygiene may prevent dental decay.

**FOOD AND NUTRITION****Broken or Wired Jaw**

- A diet of pureed or strained foods and liquids of high protein/calorie content are necessary. Use high-energy supplemental beverages (perhaps 2 kcal/mL). Double-strength milk may also be used to keep protein intake at a high level.
- Take adequate amounts of vitamin C for healing.
- Monitor food temperatures carefully, as extremes may not be tolerated.
- Six to eight meals are needed.
- Follow meals with salt water rinse.

**Dental Caries**

- Decrease sucrose and cooked or sticky starches, as well as the frequency of snacking and duration of exposure time. *Streptococcus mutans* is a common bacterial culprit; others include *Lactobacillus casei* and *Streptococcus sanguis* (Touger-Decker, 2004).
- Use a balanced diet, avoid eating sweets or starches with meals.
- Fluoride exposure should be adequate, including from water supplies.
- The sequence of eating foods, the combination of foods, the form of foods and beverages consumed, and nutrient composition of foods/beverages must be evaluated and altered accordingly (Touger-Decker, 2004).

**Early Childhood Caries (ECC)**

The following are guidelines for prevention (American Academy of Pediatric Dentistry, 2005–2006; Clarke et al, 2006; Wagner, 2006):

- Do not allow a child to fall asleep with a bottle containing milk, formula, fruit juices, or other sweet liquids. Never let a child walk around with a bottle in his/her mouth. Never put an infant or child to bed with a bottle that is filled with sugar-containing beverages, including fruit juice or Kool-Aid.
- Comfort a child who wants a bottle between regular feedings or during naps with a bottle filled with cool water.
- Always make sure a child's pacifier is clean, and never dip a pacifier in a sweet liquid.
- Introduce children to a cup as they approach 1 year of age. Children should stop drinking from a bottle soon after their first birthday.
- Notify the parent of any unusual red or swollen areas in a child's mouth or any dark spot on a child's tooth so that the parent can consult the child's dentist.
- Maintain good oral hygiene.
- Monitor for iron deficiency anemia, which is common (Clarke et al, 2006).

**Edentulism**

- A chopped, ground, strained, or pureed diet should be followed as required. Use the least restricted diet and progress as tolerated.
- Identify potential solutions such as obtaining new dentures or repairing current dentures.

**Mouth Ulcers or Pain**

- Foods low in acid and spices should be consumed; avoid citrus juices, vinegar and other similar foods.
- Supplement the diet with vitamin C, protein, and calories to speed healing.
- Small, frequent meals and oral supplements may be beneficial to prevent weight loss.
- Moist or blenderized foods with additional liquid are helpful.
- Soft, cold foods such as canned fruits, ice cream, popsicles, yogurt, cottage cheese, or cold pasta dishes may be used.
- Use of a straw may be helpful.
- Cut or grind meats or vegetables.
- Extra butter, mild sauces, and gravies may be needed.
- Follow meals by brushing teeth to reduce possibility of dental caries.

**Tongue Disorders**

- If the patient is unable to chew, tube feeding should be considered (Fig. 2-3).
- Liquids may be added to the diet as tolerated. Many foods are tolerated if liquefied and blenderized.

**Tube Feeding**

- Good oral hygiene and mouth care will be needed, even if a patient is not fed by mouth. Tube feeding should include all key nutrients to meet patient needs; see Section 17.

**Xerostomia**

- Moisten foods, adding water or milk when possible. Use sauces or gravies if needed.
- Avoid excessive spices.
- Avoid excessively chewy foods such as steak, crumbly foods such as crackers or cake, dry foods such as chips, or sticky foods such as peanut butter (Touger-Decker, 2004).

**Common Drugs Used and Potential Side Effects**

- Luride is a fluoride supplement for children to strengthen teeth against tooth decay. Avoid use with calcium or dairy products because it may form a nonabsorbable product.
- For patients with cancer, various therapies affect the mouth and gums. Monitor closely.
- Oral side effects of drugs interfere with functioning and increase risks for infection, pain, and possible tooth loss (Spolarich, 2000).

**Herbs, Botanicals, and Supplements**

- Herbs and botanicals may be used; identify and monitor side effects.

- Counsel about use of herbal teas, especially unsuitable products such as comfrey tea.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- If needed for oral or dental problems, blended foods and/or tube feedings should be prepared. Sometimes, using a bulb syringe to feed may be useful.
- Provide creative ideas for the seasoning and flavoring of foods. Discuss acceptable restaurant options for persons who are at home.
- Ensure that fluoride is provided in some way by the diet, water supply, or dental office.
- Read milk labels to ensure vitamin D fortification.
- Dental status is an especially important part of assessment and care for the elderly (Sahyoun et al, 2003; Sheiham et al, 2001).
- Integrating dietary counseling into the dental setting warrants further investigation (Moynihan, 2005a).

**To Prevent Caries**

- Encourage good habits in oral hygiene and diet: detergent foods (raw fruits and vegetables) should be recommended rather than sticky or impactant foods (soft cookies, bread, sticky sweets, dried fruits). Cariostatic foods should be encouraged, such as cheese, raw fruits and vegetables, peanuts, and cocoa.
- Avoid cariogenic foods such as dried fruits, candy, cookies, pies, cakes, ice cream, canned fruit, soft drinks, fruit drinks, lemonade, gelatin desserts, snack crackers, pretzels or chips, and muffins. Brush teeth or eat cheese after meals and sugary snacks to normalize pH.
- Regular use of fluoride daily can help reduce the incidence of root caries (Richards, 2009).

**Patient Education—Food Safety**

- When traveling, avoid ice made from tap water. Airline water may not be free from contamination.
- Use of bottled water is recommended for brushing teeth in countries where water is not safe.

## PERIODONTAL DISEASE AND GINGIVITIS

### NUTRITIONAL ACUITY RANKING: LEVEL 1–2

## DEFINITIONS AND BACKGROUND

*Gingivitis* involves minor inflammatory changes in the gums; it may be acute or chronic, local or generalized. Vitamins C and D may reduce gingivitis (Dietrich et al, 2005). *Acute necrotizing ulcerative gingivitis* (Vincent's disease or trench mouth) is an acute ulceration affecting marginal gingiva with inflamed or necrotic interdental papillae. The onset is abrupt and painful with slight fever, malaise, excess salivation, and bad breath. It can be caused by systemic disease.

Tissues that support teeth in the jaws are collectively known as the periodontium (gums, alveolar bone, periodontal membrane). Any abnormality that leads to a visible change or loss of integrity of any component of the supporting tissue is a periodontal disease. Periodontal disease is a painless, chronic inflammatory disease that most commonly manifests as *pyorrhea alveolaris*. It involves a gross breakdown of supporting tissues with progressive loosening and loss of teeth inflammatory disease initiated by oral microbial biofilm (Van Dyke, 2008). It is a major cause of tooth loss in adults.

*Periodontoclasia* involves destruction of tissues around the teeth. A poor diet and inadequate dental hygiene can cause destruction of the jawbone. Osteoporosis and inflammation-associated bone degradation in periodontitis have a common pathogenesis (Serhan, 2004). Periodontal disease is evident approximately 10 years before osteoporosis.

Periodontal disease can start in the second decade; wisdom teeth are a breeding ground for bacteria that cause problems. Children and teens are also at risk if their oral and dental health needs are not addressed (Cummins, 2006). Nutrient deficiencies are prevalent and smokers are especially vulnerable to vitamin C deficiency (Nishida et al, 2000). Immune-enhancing nutrients for good oral health include protein, zinc, vitamins C and E, calcium, and the B-complex vitamins.

In the United States, periodontal disease affects a large portion of the population. At risk in particular are pregnant women, women after menopause, obese individuals, diabetics, alcoholics, smokers, persons with AIDS or rheumatoid arthritis, persons with respiratory ailments, and persons on medications including heart medicines, antidepressants,

and antihistamines. Periodontal disease may precede bacterial pneumonia, so treatment is important. Evidence-based periodontology includes antimicrobial therapy, regenerative periodontal surgery, periodontal plastic surgery, bone regeneration surgery and implant treatment, and advanced soft tissue management at implant sites (Tonetti, 2000).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

Clinical/History	Sore mouth	Ca <sup>++</sup> , Mg <sup>++</sup>
Height	Overall	Serum ascorbic acid
Weight	nutritional status	H & H, serum Fe
BMI	History of smoking, diabetes, other chronic diseases	Alb, transthyretin
Diet history		CRP
Gums—color, friability, receding		
Oral examination for tooth mobility, calculus	Lab Work	
	Serum glucose	
	Serum Na <sup>+</sup> , K <sup>+</sup>	

## INTERVENTION

### OBJECTIVES

- Reduce inflammation and promote healing.
- Correct poor nutritional habits that can lead to chronic subclinical deficiencies in levels of vitamins A, C, D, amino acids, riboflavin, folacin, zinc, and calcium.
- Prevent further decline in status of bones and gums. Protect the jawbone with adequate calcium and vitamin D (Hildebolt et al, 2004), especially in postmenopausal women.
- Review medications and consider alternatives to those causing dry mouth or other problems.
- Pregnant women with this condition are at risk for preterm birth and other adverse obstetric outcomes, such as preeclampsia and low birth weight; they should be closely monitored with prenatal medical and dental care.

## FOOD AND NUTRITION

- Ensure adequate intake of calcium, protein, zinc, phosphorus, vitamin C, fluoride, and vitamin A. A multivitamin-mineral supplement and vitamin-D fortified milk should be used.
- Use high-detergent foods (firm, fresh fruits and raw vegetables or those that are lightly cooked). Include cranberries, blueberries, green tea, and other foods rich in antioxidants and polyphenols (Kushiyama et al, 2009).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Oral Food and Beverage Intake—Periodontal Disease

**Assessment Data (sources of info):** Food records and intake calculations; dental evaluation.

**Nutrition Diagnosis:** Inadequate oral food and beverage intake related to sore and inflamed gums as evidenced by diet history revealing low use of antioxidant foods and vitamin C from fruits and vegetables; weight loss of 5# in past month; and diagnosis of periodontal disease.

**Intervention:** Education about the role of diet and oral hygiene in periodontal disease. Recommend nutrient and dietary changes to improve quality of food intake, reduce inflammation, and promote healing.

**Monitoring and Evaluation:** Intake records, rate of healing of gum disease.

- Control timing and frequency of meals and snacks to reduce exposure of susceptible gum tissue and teeth to the acids that form plaque. Control blood glucose in diabetes.
- Promote a diet containing foods naturally rich in antioxidants and omega-3 polyunsaturated fatty acids (DHA, EPA), and low in refined carbohydrates (Chapple, 2009).

### Common Drugs Used and Potential Side Effects

- Sodium bicarbonate may be used as a mouthwash. Patients with high BP should not swallow this wash.
- Peridex is an oral rinse to control bleeding gums. Taste changes may occur with its use.
- Triclosan-containing dentifrices may slow periodontal disease progression (Niederman, 2004).
- Antibiotic treatment of periodontitis includes amoxicillin/clavulanic acid, metronidazole, and clindamycin.
- Nonsteroidal anti-inflammatory agents may be used, such as Ibuprofen.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals may be used; identify and monitor side effects. Counsel about use of herbal teas, especially those containing toxic substances.
- For gingivitis, bloodroot, Echinacea, purslane, chamomile, licorice, and sage have been recommended but not confirmed for efficacy.
- A “Connective Tissue Nutrient Formula” that contains vitamins A, C, and D, glucosamine sulfate, magnesium, oligoproanthocyanidins, copper, zinc, manganese, boron, silicon, and calcium may be prescribed to enhance the integrity of key connective tissue elements.
- Naturopathic physicians may prescribe *Panax ginseng*, *Withania somnifera*, and *Eleutherococcus senticosus* to reverse the impact of bacterial and psychosocial stressors.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage a proper diet, especially sources of omega-3 fatty acids, calcium and vitamins C and D.

- Recommend meticulous oral hygiene and regular dental examinations to maintain dental hygiene. Brush often and floss after eating sticky foods such as candy, sticky buns, and fruit rolls. Drink lots of water.
- Encourage pregnant women and persons with dentures, diabetes, cancer, HIV/AIDS, rheumatoid arthritis, or leukemia to pay special attention to oral hygiene.
- Encourage intake of polyphenols and antioxidant-rich foods, including green tea (Kushiyama et al, 2009).

### Patient Education—Food Safety

- Periodontitis involves host-mediated inflammation, with modulation of inflammation at a cellular and molecular level. Avoidance of infection with added inflammatory response will be needed, especially related to food handling and sanitation.

## TEMPOROMANDIBULAR JOINT DYSFUNCTION

### NUTRITIONAL ACUITY RANKING: LEVEL 1

### DEFINITIONS AND BACKGROUND

Temporomandibular joint (TMJ) disorders result from local or systemic causes, such as rheumatoid or osteoarthritis and connective tissue disorders. The TMJ is a diarthrodial joint with moving elements (mandible) and fixed elements (tem-

poral bone). With this dysfunction, overuse or abuse of any part of normal action affects the mastication process. Patients with TMJ disorder pain dysfunction have toothaches, facial pains, and food-intake problems. The National Institute of Dental and Craniofacial Research (2009) indicates that over 10 million people in the United States suffer from TMJ

problems at any given time. Osteoarthritis and internal derangement may coexist in the same joint in about 33% of cases; pathological tissue changes should be examined in patients with TMJ (Dimitroulos, 2005).

Women between the ages of 30 and 60 years account for 75% of all cases. Mandibular deviation may occur from repetitive overloading (stress or habit such as gum chewing, grinding), from functional masseter muscle coordination problems, or from incorrect occlusion (as with missing teeth). Structural problems are treated by surgery (e.g., fusion can be treated by removing the area of fused bone and replacing it with silicon rubber). Sometimes an artificial joint is the answer; but surgery is recommended for only a few patients. Undue muscle tension causes most TMJ, with some other problems stemming from inadequate bite (as from a high filling or a malocclusion). People with TMJ benefit from a visit to their dentist or ear, nose, and throat specialist.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

<b>Clinical/History</b>	Mouth/jaw pain or clicking noise	Ca <sup>++</sup> , Mg <sup>++</sup> H & H, serum Fe
Height	Headaches	Chol, Trig
Weight	Shoulder or neck pain	Alb
BMI		CRP
Diet history		
Stiff neck, face, or shoulders		
Locking of affected joint	<b>Lab Work</b>	
Trismus	Gluc	
Gum status	Serum Na <sup>+</sup> , K <sup>+</sup>	

## INTERVENTION

### OBJECTIVES

- Reduce repetitive overloading by use of a splint or by breaking bad habits such as grinding (bruxism).
- Reduce stress with relaxation techniques. Relieve pain and muscle spasms.
- Prevent or correct malnutrition or weight loss.
- Ensure adequate intake of soft, nonchewy sources of fiber.
- Reduce any existing inflammation and prevent complications such as mitral valve prolapse.

## FOOD AND NUTRITION

- Use a normal diet with soft foods to prevent pain while chewing.
- Cut food into small, bite-sized pieces. Avoid chewy foods such as caramel, nuts, toffee, chewy candies, and gummy bread and rolls.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Chewing Problems

**Assessment Data:** Food records and intake calculations; dental evaluation; pain when chewing.

**Nutrition Diagnosis:** Chewing problems related to TMJ and pain when eating as evidenced by diet history

**Intervention:** Education about soft foods and liquids of high nutrient density. Recommend individualized dietary changes to improve intake and prevent weight loss.

**Monitoring and Evaluation:** Intake records, reduction in TMJ pain, improved intake from nutrient-dense foods.

- Avoid opening mouth widely, as for large and thick sandwiches. Grate vegetables (e.g., carrots) to reduce need for chewing.
- Use adequate sources of vitamin C for adequate gingival health.
- Suggest foods rich in antioxidants, such as green tea, to promote health.

## Common Drugs Used and Potential Side Effects

- Pain medicines may be needed when the condition is active. Monitor side effects for the specific drugs used.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals may be used; identify and monitor side effects. Counsel about use of herbal teas, especially avoiding toxic ingredients.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of dental care in maintaining adequate health.
- Monitor for any tooth or gum soreness; advise the dentist as necessary. Regular oral hygiene must be continued despite mouth pain.
- Physical therapy may be needed to correct functioning of muscles and joints.
- Nail biting, gum chewing, use of teeth to cut thread, or similar habits should be stopped.
- Smoking is often a cause of bruxism, and programs to stop smoking should be considered if needed.

## Patient Education—Food Safety

- Use general safe food handling measures.

## SELF-FEEDING PROBLEMS: VISION, COORDINATION, CHEWING, HEARING LOSS

# SELF-FEEDING PROBLEMS: VISION, COORDINATION, CHEWING, HEARING LOSS

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2 (VARIES BY SEVERITY)

### DEFINITIONS AND BACKGROUND

Self-feeding ability, one of the activities of daily living (ADLs), can be limited by low vision or blindness, lack of coordination, and chewing problems. Where appropriate, these factors are mentioned in other sections. Dysphagia is a fourth problem, described in Section 7. Assessment for vision changes, self-feeding difficulty, hearing, continence, gait and balance, and cognition can reveal a great deal about an individual's ability to function independently (Rao et al, 2004).

**Low vision or blindness** can affect any age; children with developmental disabilities and older persons may have cataracts or macular degeneration. The World Health Organization defines “low vision” as visual acuity between 20/70 and 20/400 with the best possible correction, or a visual field of 20 degrees or less. “Blindness” is defined as a visual acuity worse than 20/400 with the best possible correction. Someone with a visual acuity of 20/70 can see at 20 feet what someone with normal sight can see at 70 feet. Someone with a visual acuity of 20/400 can see at 20 feet what someone with normal sight can see at 400 feet. Normal visual field is about 160–170 degrees horizontally. Age-related macular degeneration and cataract are the leading causes of visual impairment and blindness in the United States; both diseases increase dramatically after age 60.

**Age-related macular degeneration (AMD)** is a vascular condition that damages the retina and affects 25–30 million people worldwide. The Age-Related Eye Disease Study (AREDS), sponsored by the National Eye Institute, found that taking high levels of antioxidants and zinc can reduce the risk of developing advanced AMD by about 25%. The specific daily amounts are 500 mg vitamin C; 400 IU vitamin E; 15 mg beta-carotene; 80 mg zinc oxide; and 2 mg copper as cupric oxide to prevent copper deficiency anemia. Protective foods include nuts, fish (Miljanovic et al, 2005; Seddon et al, 2003) lycopene, lutein and zeaxanthin. Lutein and zeaxanthin are carotenoids that have a role in filtering destructive blue light as photosensitive antioxidants. Smokers should not take beta-carotene supplements (Age-Related Eye Disease Research Group, 2001). In addition to the AREDS supplement, a lower dietary glycemic index (dGI) with higher intakes of DHA and EPA reduces progression to advanced

AMD (Chiu et al, 2009). Diets high in saturated fat, animal fat, linoleic acid, and trans-fatty acids promote higher risk of AMD (Seddon et al, 2003). Abdominal obesity, smoking, and diets high in glycemic index should be avoided. Women tend to have a higher risk than men.

**Cataract** causes clouding in the crystalline lens of the eye, causing opacity and less passage of light. Blindness occurs if not treated. Regular intake of antioxidant foods, including rich sources of vitamins A, C, E and selenium, can be protective.

**Diabetic retinopathy** is a major cause of vision loss. All individuals who have diabetes should have a dilated eye exam annually. Diabetic retinopathy affects as many as 80% of individuals who have had diabetes for 10 years or longer. Careful control of blood glucose and hypertension are important measures to protect the small vessels of the eye. Treatment often involves laser surgery.

**Glaucoma** also has nutritional implications. Risk factors for chronic glaucoma include age over 40; a family history of glaucoma, diabetes, myopia; or being African American. Acute glaucoma may occur in persons with a family history of acute glaucoma, older age, presbyopia, or use of systemic anticholinergic medications. Prostaglandins regulate inner eye pressure; glaucoma may be related to a higher intake ratio of omega-3 fatty acids to omega-6 fatty acids (Kang et al, 2004). Soybean, safflower, and sunflower oils may be protective.

**Hemianopia** yields loss in half of the field of vision; quadrantanopia affects a quarter of the visual field. Vision loss may range from slight to severe. Patients may need guidance about their meals, as they may not see the full plate or tray of food. Vision restoration therapy and the brain's ability to repair itself have made advances for these patients.

**Coordination problems** may occur at any age. Conditions that can cause coordination problems include Alzheimer's disease, alcohol abuse, attention deficit disorder, brain cancer, chorea, Down syndrome, encephalitis, fetal alcohol syndrome, advanced HIV infection, hydrocephaly, multiple sclerosis, Parkinson's disease, Rett syndrome, stroke, and Wilson's disease. Hand-eye coordination is needed for self-feeding, and when this is not working properly, assistance is needed. Other problems affecting meal intake may include falling forward, feet not touching the floor, leaning to one

side, poor balance while sitting, and poor neck control. Sometimes, it is possible to adjust table height, offer pillows or other positioning equipment, offer a footstool, or adjust pedals on a wheelchair. It is recommended to work with an occupational therapist for the proper types of adjustments to allow for better mealtime food intake.

**Chewing problems** may cause inability to consume enough food or foods of varying texture. Total edentulism without dentures may contribute to deterioration in health. Without chewing, there is less production of saliva and food is not properly mixed before swallowing. **Dry mouth (xerostomia)**, from a variety of causes, may interfere with chewing and swallowing; it should be corrected where possible.

**Hearing loss**, while not always affecting food intake, may be related to underlying cardiovascular disease, hypertension, or diabetes. Cochlear vulnerability from microvascular changes may occur (Agrawal et al, 2009). Hearing loss is more common than previously believed and preventive measures, such as lifestyle changes, may be needed as early as adolescence (Helzner et al, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

#### Genetic Markers

#### Clinical/History

Height	Blindness, cataracts, AMD	Needs feeding assistance
Weight		
BMI	Hemianopia, low vision	Needs adaptive feeding equipment
Recent weight changes	Chewing problems	
Diet history	Dysphagia (see Section 7)	
Mouth or tongue lacerations	Signs of dehydration or edema	
Sore or bleeding gums	Coordination problems	
Missing or loose teeth, edentulism	Dry mouth (xerostomia)	
Dentures, especially poorly fitting		

#### Lab Work

Gluc  
Alb, transthyretin  
Serum Na<sup>+</sup>, K<sup>+</sup>  
Ca<sup>++</sup>, Mg<sup>++</sup>  
I & O  
H & H, serum Fe  
X-rays (such as mandible)

## INTERVENTION

### OBJECTIVES

- Promote independence in self-feeding, when possible.
- Address all nutritional deficiencies and complications individually. Select nutrient-dense foods.
- Promote overall wellness and health.
- Increase interest in eating. Increase pleasure associated with mealtimes.
- Prevent malnutrition and weight loss.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Self-Feeding Problems—Low Vision

**Assessment Data:** Food records and intake calculations; vision and self-feeding problems.

**Nutrition Diagnosis:** Self-feeding difficulty related to blindness and no adaptive equipment as evidenced by limited intake at meals and long period required for eating.

**Intervention:** Education about adaptive equipment with careful orientation to items served at meals. Reading menu choices aloud. Refer to Occupational Therapy for proper equipment, techniques for cueing, positioning at mealtime, and encouragement tips.

Counsel about dietary changes to improve intake and prevent weight loss, such as finger foods and easy to handle foods.

**Monitoring and Evaluation:** Intake records showing better intake when using adaptive equipment; weight records; improved quality of life with greater independent functioning at mealtimes.

- Decrease instances in which constipation, anorexia, or other problems affect nutritional status.
- Educate the caregiver about adaptive equipment, utensils, and special food modifications. Patients with hemianopia may require special training to be able to see and eat all of the meals served to them.

## FOOD AND NUTRITION

### Low Vision, Blindness, AMD, Cataracts

- Provide special plate guards, utensils, double handles, and compartmentalized plates with foods placed in similar locations at each meal. Place all foods within 18" reach at mealtime. Explain placement of foods. Open packets if needed.
- Work with occupational therapist (OT) or family to practice kitchen safety and to determine ability to be independent at mealtimes. Allow sufficient time to complete meals; refrigerate or reheat items as needed.
- Create a feeling of usefulness by delegating appropriate tasks related to mealtime, such as drying dishes and assisting with simple meal tasks that are safe for the individual.
- Support companionship during meals, especially if problems occur or if anything else is needed.
- Use straws for beverages unless there is dysphagia.
- Include a balance of fatty acids (omega 3 and omega 6). Use rich sources of DGA and EPA, such as salmon, sardines, herring, tuna, or a fish oil supplement as needed. Use more oils such as olive and canola. Linoleic acid from vegetable oils reduces the positive effects and should be used less often.
- For a diet lower in dGI, include whole grains, soybeans and lentils more often and exclude desserts, candy, sweetened beverages, potatoes and white bread.
- Include more lycopene from pink grapefruit, tomato sauce, tomato juice, and watermelon. Lutein and zeaxanthin are found in broccoli, spinach, other leafy greens, egg yolk. Antioxidant-rich foods that include good sources of

**TABLE 2-7 Nutrients for Healthy Vision<sup>a</sup>**

Protein and Amino Acids	Protein undernutrition is associated with increased risk of cataract. Low protein intake may induce deficiencies of specific amino acids that are needed to maintain the health of the lens, or other nutritional deficiencies, particularly niacin, thiamin, and riboflavin (Delcourt et al, 2005).
Vitamin A, Lutein and Zeaxanthin	Vitamin A is needed for healthy cornea and conjunctiva. Many studies have shown that lutein and zeaxanthin reduce the risk of chronic eye diseases, including age-related macular degeneration and cataracts. Cataract and AMD patients tend to be deficient in vitamin A and the carotenes, lutein, and zeaxanthin (Head, 2001; Krinsky et al, 2003; Seddon et al, 2003). Lutein and zeaxanthin are found in green leafy vegetables (kale, collards, spinach, turnip greens, broccoli) as well as eggs, yellow corn, peas, tangerine, and orange bell peppers. Eggland's Best eggs contain 185 mg of lutein. Lutein is facilitated with ascorbic acid supplementation (Tanumihardjo et al, 2005).
Thiamin	For normal retinal and optic nerve functioning. Protective against cataracts (Jacques et al, 2005).
Riboflavin	For corneal vascularization. Protective against cataracts (Jacques et al, 2005). Riboflavin appears to play an essential role as a precursor to flavin adenine dinucleotide (FAD), a cofactor for glutathione reductase activity (Head, 2001).
Niacin	For healthy vision. Avoid excesses, which can cause nicotinic acid maculopathy (Spirn et al, 2003).
Folate	A strong protective influence on cortical cataract from use of folate or vitamin B <sub>12</sub> supplements is a recent finding (Kuzniarz et al, 2001).
Vitamin B <sub>6</sub>	For healthy conjunctiva. Untreated homocystinuria is known to cause ocular changes; vitamin B <sub>6</sub> can help to lower homocysteine levels.
Vitamin B <sub>12</sub>	For retinal and nerve fibers. Protective against cataract (Kuzniarz et al, 2001). Found only in animal foods such as meat and milk.
Vitamin C	For healthy conjunctiva and vitreous humor. Long-term use of adequate vitamin C may delay or prevent early age-related lens opacity (Ferrigno et al, 2005; Valero et al, 2002). Orange and grapefruit juices, cantaloupe, oranges, green peppers, tomato juice, broccoli, kiwifruit, and strawberries are good sources. Vitamin C (ascorbic acid) is an antioxidant that lowers the risk of developing cataracts, and when taken in combination with other essential nutrients, can slow the progression of age-related macular degeneration and visual acuity loss (American Optometric Association, 2009).
Vitamin D	Helps prevent cancer, heart disease, diabetes, and age-related macular degeneration; it is the most potent steroid hormone in the human body, and is the only vitamin formed with the help of sunlight (American Optometric Association, 2009).
Vitamin E	Important for antioxidant properties. Protects the eyes from free radical damage and may slow the onset of cataracts. Long-term use of supplements may be beneficial (Jacques et al, 2005). Vitamin E is found in almonds, peanuts, peanut butter, sunflower seeds, safflower oil, margarines, fortified cereals, sweet potatoes, and creamy salad dressings.
Omega-3 Fatty Acids	Omega-3 fatty acids and fish are protective against AMD (Cho et al, 2001). Eating fish (sardines, salmon, herring, tuna, fortified eggs) weekly and cutting back on saturated fatty acids are important (Smith et al, 2000). Infants need a supply of DHA for up to a year for healthy visual development (Hoffman et al, 2004). Avoid use of large doses of alpha linolenic acid.
Omega-6 Fatty Acids	Omega-6 fatty acids in soybean, safflower, and sunflower oils may be protective against glaucoma (Kang et al, 2004) but not against cataracts. High doses of canola, flaxseed, and soybean oils may actually increase the risk of cataracts (Jacques et al, 2005).
Selenium	Pathophysiological mechanisms of cataract formation include deficient glutathione levels contributing to a faulty antioxidant defense system within the lens of the eye; nutrients that increase glutathione levels and activity include selenium (Head, 2001; Flohe, 2005).
Sodium	Sodium-restricted diets may protect against cataracts (Cumming et al, 2000).
Zinc	For healthy retina, choroid, and optic nerve. Found in beef, chicken, oysters, mixed nuts, and milk. Zinc is an essential trace mineral, bringing vitamin A from the liver to the retina in order to produce melanin for a protective pigment in the eyes (American Optometric Association, 2009). Zinc is highly concentrated in the eye.

American Optometric Association. Web site accessed March 29, 2009, at <http://www.aoa.org/x11813.xml>.

<sup>a</sup>Long-term use of multivitamin, B group, and vitamin A supplements is associated with reduced prevalence of either nuclear or cortical cataract (Kuzniarz et al, 2001).

vitamins C and E and zinc should also be consumed daily. Snacking on nuts is an excellent choice.

### Coordination Problems

- Self-feeding requires the ability to suck, to sit with head and neck balanced, to bring hand to mouth, to grasp cup and utensil, to drink from a cup, to take food from a spoon, to bite, to chew, and to swallow. Each person should be assessed individually to determine which, if any, aspects of coordination have been affected by his or her condition. Adjust self-feeding accordingly.
- Use clothing protectors at mealtime to maintain dignity.

- Assist with feeding if needed; use adaptive feeding equipment as needed (such as weighted utensils, large-handled cups, larger or smaller silverware than standard). Adjust table or chair height.
- Place all foods within 18" reach at mealtime.

### Chewing Problems

- Dentures should fit well and be adjusted or replaced as needed, such as after weight loss.
- Decrease texture as necessary; use a mechanical soft, pureed, or liquid diet. Season as desired for individual taste. Try to progress in textures if possible because chewing

is important for saliva production and for proper digestion of foods.

- Liquid or blenderized foods may be beneficial. If needed, use a tube feeding.
- For some persons, a straw may be helpful; for others, it is not. Speech therapists can assess this ability.
- Protein foods such as tofu, cottage cheese, peanut butter, eggs, cheese, and milk products can be used when meats or nuts cannot be chewed.
- If fresh fruits and vegetables cannot be consumed, use cooked or canned sources and juices. Use pureed foods when needed. If whole grain breads and cereals are not tolerated, use cooked cereals. Avoid rice or foods with small particles in dysphagia (see Section 7).

### Hearing Loss

- Researchers and international scientists have found a gene that causes deafness in humans: *LRTOMT*.
- Alter diets as needed if diabetes, cardiovascular disease, or hypertension are present. A controlled carbohydrate diet, therapeutic lifestyle diet (low saturated fat), or the DASH diet may be appropriate.

### Common Drugs Used and Potential Side Effects

- For glaucoma, a combination of medications is used to reduce elevated intraocular pressure and prevent damage to the optic nerve. Some may cause dry mouth or fatigue; monitor individually.
- For AMD, Chol-lowering medications (statins) may be protective. Clinical trials are in order.

### Herbs, Botanicals, and Supplements

- Nutrients and botanicals that may prevent cataracts include folic acid, melatonin, and bilberry (Head, 2001). Flavonoids, particularly quercetin, and ginkgo biloba may increase circulation to the optic nerve (Head, 2001). Curcumin is also under study.
- Lutein and zeaxanthin, in whole food or supplemental form, have an impact on retinal function with the potential to preserve vision and prevent degeneration in AMD; further research is needed to determine an effective dose (Carpentier et al, 2009).
- Herbs and botanicals may be used; identify and monitor side effects. For glaucoma, oregano, jaborandi, kaffir potato, and pansy have been recommended but not confirmed as effective. For cataract, rosemary, catnip, and capers have not been found to be effective.

Counsel about use of herbal teas to avoid intake of toxic substances.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the importance of using the various therapies and medications.
- Discuss the role of nutrition in health, weight control, recovery and repair processes.

- For healthy eyes, nutrition plays an essential role; see Table 2-7. Consume 10 mg of lutein weekly, the equivalent of one cup of cooked spinach four times a week. Orange juice is a good choice for vitamin C. The DASH diet is a good plan.
- Provide instruction regarding simplified meal planning and preparation. Refer to agencies such as Meals-on-Wheels if needed.
- Discuss the tips appropriate for the individual (texture, finger foods, ease of placement at meals).

### Patient Education—Food Safety

- Discuss simple hand washing or use of hand sanitizers before meals.

## SKIN CONDITIONS, PRESSURE ULCERS, AND VITAMIN DEFICIENCIES

# SKIN DISORDERS

### NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: Goodheart HP. *Goodheart's Photguide of Common Skin Disorders*. 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

## DEFINITIONS AND BACKGROUND

Human skin is the largest, independent peripheral endocrine organ of the body (Zouboulis, 2000). Skin is affected by both internal and external influences, which may lead to photo aging, inflammation, immune dysfunction, imbalanced epidermal homeostasis, and other disorders (Boelsma et al, 2001). The skin often reflects internal problems such as GI disturbances, alcoholism, or general malnutrition.

Nutritional factors impact hydration status, sebum production, elasticity, and skin cancer (Greenwald, 2001). A

low-fat diet and foods rich in vitamin D and carotenoids may protect against some forms of skin cancer and actinic keratoses (Millen et al, 2004).

Many carotenoids found in nature are also found in the human body. Lutein and zeaxanthin are present in the skin and have shown significant efficacy against ultraviolet light-induced skin damage (Roberts et al, 2009). Retinoids have vitamin A biological activity; they have benefits for skin diseases and reversal of photo aging. Supplementation with vitamins, carotenoids, and polyunsaturated fatty acids has been shown to provide protection against ultraviolet light; however, sunscreen is still important (Boelsma et al, 2001).

Enzymes of the cytochrome P450 (P450 or CYP) family are drug-metabolizing enzymes that are induced in skin in response to xenobiotic exposure; they also play important roles in metabolism of fatty acids, eicosanoids, sterols, steroids, vitamins A and D (Ahmad and Mukhtar, 2004). In psoriasis, for example, many CYP enzymes are elevated; some relationship with celiac disease has been noted.

**Acne** affects many young people and may cause psychological distress. Iodine can aggravate acne; milk and dairy products contain a high level of iodine, but more studies are needed (Arbesman, 2005). Changes in diet are not the primary solution. Benzoyl peroxide is efficacious in mild-to-moderate acne, whereas adapalene and tretinoin are better for greater severity. Green tea polyphenols have anti-inflammatory effects, both taken internally and in topical creams.

**Atopic dermatitis (AD), or eczema**, causes itchy, inflamed skin. It usually affects the insides of the elbows, backs of the knees, and the face, but can cover much of the body.

AD often affects people who either suffer from asthma and/or hay fever or have family members who do (the “atopic triad”). AD flares when the person is exposed to trigger factors, such as dry skin, irritants, allergens, emotional stress, heat and sweating, and infections; avoiding triggers is the key. Because essential fatty acids (EFAs) form an important component of cell membranes, are eicosanoid precursors, and are required for both the structure and function of every cell, EFAs may benefit persons who have AD or psoriasis (Das, 1999).

**Dermatitis herpetiformis** (DH or Duhring’s disease) is related to celiac disease (Karpati, 2004). There is the presence of villous atrophy and endomysial antibodies (EMAs) as markers (Kumar et al, 2001). A gluten-restricted diet is needed.

**Epidermolysis bullosa** is a hereditary condition in which blistering of the skin occurs with even slight trauma. It affects two of every 100,000 live births, occurring in both sexes and all ethnic groups. Nail dystrophy can occur, with rough, thickened, or absent fingernails or toenails. There may be blisters and problems with the soft tissue inside the mouth; protein–energy malnutrition, stunting, anemia, vitamin and mineral deficiencies are common. Treatment involves careful skin and wound care, and prevention of infections.

**Nickel dermatitis** affects 8–15% of women and 1% of men. Sensitization to nickel is often associated with ear piercing (Garner, 2004). In severe cases, reduce exposure to nickel from foods (Antico and Soana, 1999), and other sources.

**Nummular eczematous dermatitis** occurs with a rash; etiology is unknown. The rash is coin shaped and worsens in very hot or cold weather. Wool, soaps, frequent bathing (more than once a day), detergents, and rough clothing may be irritants. No special diet is needed unless food allergies are identified.

**Psoriasis** has patches of scaly red skin that burn, itch, or bleed. Calcitriol and vitamin D analogs are useful, along with controlled exposure to sunlight (Lehmann et al, 2004; May et al, 2004). Omega-3 fatty acids (specifically EPA) with

a drug regimen of etretinate and topical corticosteroids may improve symptoms. Enbrel (etanercept), a tumor necrosis factor alpha (TNF $\alpha$ ) inhibitor, relieves the clinical symptoms and may also clear up related depression and fatigue. There may be a relationship with celiac disease; if tests are positive, a gluten-free lifestyle will be needed.

**Rosacea** is a disorder of the central portion of the facial skin with onset in the third decade and peak in the fourth or fifth decade. A chronic and progressive condition of flare-ups and remissions, rosacea can be disfiguring if left untreated. Rosacea resembles other dermatological conditions, especially acne vulgaris. It affects one in 20 people, or 13 million people in the United States. Members of the same family tend to be affected; fair-skinned individuals of Northern and Eastern European descent (English, Scottish, Welsh, or Scandinavian) are most commonly affected (Litt, 1997). Green tea extract in creams may have benefits.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Single genes control mediators such as enzymes, neuroendocrine transmitters, and cytokines that promote rosacea and probably other skin disorders.

Clinical/History	Lab Work	Thyroid-stimulating hormone (TSH), T4 level
Height	Alb (decreased in exfoliative dermatitis)	H & H, serum Fe
Weight	Transthyretin	Gluc
BMI	Serum zinc	Chol, Trig
Growth pattern in children	Serum histamine (may be elevated)	Serum Na <sup>+</sup> , K <sup>+</sup>
Diet history	Skin tests for allergies	Ca <sup>++</sup> , Mg <sup>++</sup>
Family history of skin disorders, allergies	Anti-tTG, AGA, and/or EMA tests (for celiac)	Serum carotene
Psoriasis?		Retinol-binding protein (RBP)
Rashes, blisters, pustules?		CRP
Dermatitis?		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Psoriasis

**Assessment Data:** Food records and intake calculations; many skin rashes, with psoriasis diagnosed 15 years ago.

**Nutrition Diagnosis:** Inadequate vitamin and fatty acid intake related to chronic history of psoriasis and poor diet as evidenced by diet history revealing high intake of beer, low intake of vitamin D and omega 3 fatty acids, and low serum vitamin D.

**Intervention:** Education about careful exposure to sunshine and use of vitamin D-fortified foods, fatty fish such as salmon and mackerel. Counsel about dietary changes to improve intake of omega-3 fatty acids and vitamin D<sub>3</sub>. Advise cutting beer intake down or out. Coordinate care with physician to evaluate for celiac disease.

**Monitoring and Evaluation:** If positive for celiac, discuss gluten-free lifestyle. Intake records showing better food intake and lower intake of beer; improved quality of life with fewer outbreaks of psoriasis.

## INTERVENTION

### OBJECTIVES

- Reduce inflammation, redness, or edema where present. Prevent further exacerbations of the condition.
- Apply nutritional principles according to the particular condition (such as vitamin D, omega-3 fatty acids, carotenoids, zinc).
- Identify any offending foods; omit from the diet any food allergens or intolerances, such as gluten.

## FOOD AND NUTRITION

- **Acne.** Encourage intake of adequate zinc, carotenoids, and vitamin A foods. This condition is hormone dependent. It is less common in non-Western societies, so a high-fat diet that is low in fruit and vegetable intake should be avoided (Cordain et al, 2002). Drinking green tea can be highly recommended.
- **Acrodermatitis enteropathica.** Supplement with zinc because absorption is often impaired. Use protein of high biological value. Decrease excess fiber, if necessary, to normalize bowel function.
- **Atopic dermatitis.** Eczema is a general term for any type of dermatitis; AD is the most severe and chronic form. AD is a disease that causes itchy, inflamed skin. It typically affects the insides of the elbows, backs of the knees, and the face, but can cover most of the body. Diet therapies do not work well; do not automatically eliminate important foods such as milk and wheat. A trial without salicylates (berries and dried fruits), aspirin, penicillin, food molds, some herbs and spices, and FD&C yellow 5 may be useful. Infants may have hypersensitivity to milk, egg albumin, wheat, or linoleic acid but tend to outgrow it. Control energy excess in obese infants. Avoid herbal products, such as chamomile tea, for which allergy is possible. Green tea is safe and may be recommended.
- **Dermatitis herpetiformis.** A gluten-free diet is quite successful in treating this condition; see Section 7.
- **Epidermolysis bullosa (EB).** A balanced diet that includes extra protein, calories, and a multivitamin–mineral supplement will be useful. Highlight the nutrients that are beneficial, including omega-3 fatty acids, vitamin A, and zinc. Dysphagia is common, and may even lead to esophageal strictures. Anemia, contractures, gastroesophageal reflux (GERD), or scarring of the tongue may occur. Gastrostomy feeding may be needed.
- **Nickel dermatitis.** Avoid canned foods, such as tuna fish, tomatoes, corn, spinach, and other canned vegetables. Do not cook with stainless steel utensils. Chocolate, nuts, and beans may have slightly higher naturally occurring nickel than other foods; avoid large quantities (Christensen et al, 1999).
- **Psoriasis.** Psoriasis may precede arthritis by months or years; both are inflammatory processes. Because of their antiproliferative effects, calcitriol and other vitamin D analogs are highly efficient in the treatment of psoriasis (Lehmann et al, 2004; May et al, 2004). The therapeutic effect of UVB light therapy may be related to its skin synthesis of calcitriol. If celiac sensitive, omit gluten from diet, beverages such as beer, and medications.
- **Rosacea.** Alcoholic beverages (especially red wine), spicy foods, hot beverages, some fruits and vegetables, marinated meats, and dairy products may trigger flare-ups; avoid as needed. Limit use of all forms of pepper, paprika, chili powder, and curry. Substitute with cumin, oregano, sage, thyme, marjoram, turmeric, cinnamon, basil, and milder spices. Recommend drinking green tea.

## Common Drugs Used and Potential Side Effects

When using cortisone ointments, use just a little and massage in well. Application once daily does as much good as using it more often. The potential for long-term use to suppress the adrenal gland exists (Matsuda et al, 2000; Woo and McKenna, 2003).

### Acne

- Isotretinoin (Accutane) may be used for acne. Watch for a decrease in high-density lipoprotein (HDL) and an increase in TG. An increase in depression or suicide attempts seem to be related. Avoid taking with vitamin A supplements. Dry mouth can occur. Do not use during pregnancy.
- Retin A (retinoic acid) is useful for moderate cases of acne; side effects are mild.
- Tetracycline should not be taken within 2 hours of use of milk products or calcium supplements. Excesses of vitamin A can cause headaches or hypertension. Use more riboflavin, vitamin C, and calcium in the diet. Protein and iron malabsorption may result from prolonged use. Diarrhea is the major GI effect. Minocycline causes less GI distress and does not affect calcium metabolism as dramatically. Antibiotics are used for their anti-inflammatory effect.

### Atopic Dermatitis

- Topical cortisone (steroid) creams, such as Aclovate, usually have a mild effect on the nutritional status of the patient. Stronger brands or dosages may act like oral steroids and can suppress the adrenal system if taken for prolonged periods.

### Epidermolysis bullosa

- Wound care products are used for tissue regeneration. Fluid replacement and protein loss may be associated with blistering.

### Psoriasis

- Calcitriol and other vitamin D analogs are often highly effective. Topical products such as tazarotene (Tazorac) and calcipotriene, a form of vitamin D, have been available for years.
- Enbrel (etanercept), Humira (adalimumab), or Remicade (infliximab) are used for severe chronic plaque psoriasis. TNF inhibitors such as efalizumab (Raptiva) yield less-frequent itching and better quality of life (Ricardo et al, 2004).

### Rosacea

- Antibiotic creams such as metronidazole (MetroCream) and azelaic acid (Finacea) are commonly prescribed. Tetracycline may also be prescribed; avoid taking within an hour of dairy or calcium-related supplements.
- Taking an antihistamine about 2 hours before a meal may counter the effects of histamine.
- Aspirin may reduce the effects of niacin-containing foods in sufferers affected by the flushing effect of these foods. Monitor multivitamin supplements and intakes carefully.

## Herbs, Botanicals, and Supplements

- Counsel about use of herbal teas, especially related to potentially toxic ingredients. Herbs and botanicals may be used; identify and monitor side effects.
- For **acne**, salicylic acid helps break down blackheads and whiteheads and helps cut down the shedding of cells lining the hair follicles. Tea tree oil topical solutions may be beneficial for **acne** because of anti-inflammatory effects (Koh et al, 2002; Liao, 2001). Ointment containing tea leaf extract is effective for impetigo, acne, and methicillin-resistant *Staphylococcus aureus*; results equal conventional treatments (Martin and Ernst, 2003).
- For prevention of **AD**, Chinese herbs, dietary restrictions, homeopathy, house dust mite reduction, massage therapy, hypnotherapy, evening primrose oil, emollients, topical coal tar, and topical doxepin are not proven effective (Hoare et al, 2000). Extracts of arnica (*Arnica montana*), chamomile (*Chamomilla recutita*), tansy (*Tanacetum vulgare*), and feverfew (*Tanacetum parthenium*) may cause allergic reactions. Calendula is often recommended but not proven effective.
- For **psoriasis**: bishop's weed, avocado, licorice, red pepper, Brazil nut, and purslane are not confirmed. Red clover is sometimes used for dermatitis or psoriasis; avoid use with warfarin or hormone replacement therapy.
- For **scabies**: evening primrose, onion, neem, and mountain mint have been proposed. No confirming studies are available.
- For **sunburn**: eggplant, plantain, and calendula have been proposed. Topical aloe is used for sunburn and mild burns; it causes GI cramping and hypokalemia if ingested.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage the patient to read food, medication, and supplement labels. A symptom and food diary may be quite useful to identify any relationship between diet, allergies, and skin flare-ups.
- Encourage adequate fluid intake. Hydration of the skin is important. Drinking green tea can be highly recommended.
- Help the patient modify his or her diet as specifically indicated by the condition.
- Discuss the roles of nutrients in skin care. Sunscreens may prevent vitamin D from penetrating the skin, especially formulas with higher protective factors. Therefore, if dietary intakes are low in vitamin D, a supplement may be needed. Protein, vitamin A, and zinc are also important nutrients for healthy skin; describe good sources.
- Discuss the effect of EFAs on membrane function and how to include them in the diet. Omega-3 fatty acids reduce inflammation for some skin conditions. Eskimo skin care products, containing natural stable fish oil, is quite beneficial for improving skin elasticity (Segger et al, 2008). Otherwise, avoid topical products, except as recommended by the doctor.

- Flavones in medicinal plants, some vegetables and spices, have natural anti-oxidant with cytoprotective properties. Carrots, peppers, celery, olive oil, peppermint, rosemary and thyme contain natural levels of luteolin; more research is needed to identify its usefulness in medicine.

## Patient Education—Food Safety

- The usual food safety habits are needed for good skin health. With open sores or exudative lesions on hands, a bandaid might be needed when preparing or serving food.

## PRESSURE ULCERS

### NUTRITIONAL ACUITY RANKING: LEVEL 2–3 (STAGES 1–2), LEVEL 4 (STAGES 3–4)

A = stage 1 B = stage 2 C = stage 3 D = stage 4

Adapted from: Nettina, Sandra M., MSN, RN, CS, ANP, *The Lippincott Manual of Nursing Practice*, 7th ed. Lippincott, Williams & Wilkins, 2001.

### DEFINITIONS AND BACKGROUND

Pressure, friction, or shear and a lack of oxygen and nutrition to an affected area are associated with the development of pressure ulcers over bony or cartilaginous prominences (hip, sacrum, elbow, heels, back of the head). Pressure ulcers are common among patients with protein-energy malnutrition in HIV infection, pulmonary and cardiac cachexia, rheumatological cachexia, cancers, renal diseases, and among bedridden or paralyzed patients. With immobility, loss of lean body mass in muscle and skin, and lowered immunity, the risk of pressure ulcers increases by 74% (Harris and Fraser, 2004).

Many patients with pressure ulcers are below their usual body weight, have a low transthyretin level, and are not taking in enough nutrition to meet their needs (Guenter et al, 2000). Poor nutritional status and decreased oxygen perfusion are predictors of pressure ulcers; nutritional status and length of stay are predictors of ulcer severity in institutions

(Williams et al, 2000). Patients with malnutrition are at risk for many complications, including incidence, progression, and severity of pressure ulcers. Risk factors should be assessed frequently: unintentional weight loss, incontinence, immobility, poor circulation (as in diabetes, peripheral vascular disease, or anemia), infection, prolonged pressure, multiple medications, serum albumin <3.4 g/dL, reduced functional ability, poor oral intake (<50% of meals over 3 days or longer), chewing or swallowing problems, and Chol levels below 160 mg/dL.

The mini-nutritional assessment (MNA) is a useful tool, with better results than using albumin levels or visceral proteins alone (Langkamp-Henken et al, 2005). Causes of malnutrition that should be carefully monitored include (Harris and Fraser, 2004): decreased appetite, requirement of assistance with meal intake, impaired cognition and/or communication, poor positioning, frequent acute illnesses with GI losses, medications that decrease appetite or increase nutrient losses, polypharmacy, decreased thirst response, decreased ability to concentrate urine, intentional fluid restriction because of fear of incontinence, fear of choking with dysphagia, isolation or depression, monotony of diet, and higher nutrient requirements. Reversible protein-energy malnutrition should be treated. A “MEALS ON WHEELS” mnemonic helps in identifying individuals at risk (Morley and Thomas, 2004): **M**edications—**E**mootional problems—**A**norexia/alcoholism—**L**ate-life paranoia—**S**wallowing disorders—**O**ral problems—**N**osocomial infections—**W**andering/other dementia behaviors—**H**yperthyroidism or hypercalcemia—**E**nteric problems—**E**ating problems—**L**ow-salt, low-Chol diets—**S**tones (cholelithiasis).

Wound healing is complex and has three distinct phases. In each phase of wound healing, energy and macronutrients are required. Studies have established specific roles for nutrients including arginine; vitamins A, B, and C; selenium, manganese, zinc, and copper (Mathus-Vliegen, 2004). Administration of nutrition is an important part of wound healing.

Medicare costs attributable to pressure ulcer treatment are over \$2 billion annually. The cost of caring for these preventable pressure ulcers is over \$60,000 per patient (Edlich et al, 2004) and affects 10% of hospital admissions (Harris and Fraser, 2004). Pain, amputations, and osteomyelitis may result; mortality is often secondary to sepsis (Brem et al, 2003). In most cases, it is difficult to determine whether a pressure ulcer led to the terminal event, or whether the process of dying (decreased cardiac output, severe catabolic state) led to an unpreventable pressure ulcer (Braden, 1996).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

#### Clinical/History

Height  
Weight  
Weight changes  
BMI  
BP  
Diet history  
Number, size and stage of ulcer(s)—see Table 2-8  
Exudate, infection or sepsis, fever

Pain  
Abnormal motor coordination  
Changes in appetite, anorexia, indigestion  
Nausea/vomiting  
Diarrhea, bowel incontinence

Urinary tract infections or incontinence  
Recent or frequent surgeries  
Prognostic and Nutritional Index (PINI)

Braden scale: intense or prolonged pressure (activity, mobility, sensory perception) and tissue tolerance for pressure (nutrition, moisture, friction, and shear); scores range from 6 to 23, lower scores suggest higher risk

Norton scale: physical condition, mental status, activity, mobility, and incontinence; rating >16 suggests high risk

#### Lab Work

Gluc  
C-reactive protein  
Serum Chol  
BUN, Creat  
Serum Na<sup>+</sup>, K<sup>+</sup>  
Ca<sup>++</sup>, Mg<sup>++</sup>

H & H, serum Fe, serum ferritin  
Alb, transthyretin, RBP (usually decreased)  
N balance, transferrin  
Total lymphocyte count (TLC)  
Protine or INR  
Serum zinc  
Serum B<sub>12</sub>

**TABLE 2-8 Skin Changes with Aging and Pressure Ulcer Stages**

Skin Change	Consequences
Thinning of epidermis	Increased vulnerability to trauma and skin tears
Decreased epidermal proliferation	Slower production of new skin cells
Atrophy of dermis	Underlying tissue more vulnerable to injury; decreased wound contraction
Decreased vascularity of dermis	Easy bruising and injury; decreased wound capillary growth
Compromised vascular response	Impaired immune and inflammatory responses
Fragility	Easy bruising and tearing
Suspected deep tissue injury	Purple or maroon localized area of discolored intact skin or blood-filled blister due to damage of underlying soft tissue from pressure and/or shear. The area may be preceded by tissue that is painful, firm, mushy, boggy, warmer or cooler as compared to adjacent tissue
<i>Staging*</i>	
<b>Stage I</b>	Intact skin with nonblanchable redness of a localized area usually over a bony prominence. Darkly pigmented skin may not have visible blanching; its color may differ from the surrounding area. The area may be painful, firm, soft, warmer or cooler as compared to adjacent tissue. Stage I may be difficult to detect in individuals with dark skin tones. May indicate “at risk” persons (a heralding sign of risk)
<b>Stage II</b>	Partial thickness loss of dermis presenting as a shallow open ulcer with a red pink wound bed, without slough. May also present as an intact or open/ruptured serum-filled blister. Presents as a shiny or dry shallow ulcer without slough or bruising. This stage should not be used to describe skin tears, tape burns, perineal dermatitis, maceration or excoriation. Bruising indicates suspected deep tissue injury
<b>Stage III</b>	Full thickness tissue loss. Subcutaneous fat may be visible but bone, tendon or muscle are not exposed. Slough may be present but does not obscure the depth of tissue loss. May include undermining and tunneling The depth of a stage III pressure ulcer varies by anatomical location. The bridge of the nose, ear, occiput and malleolus do not have subcutaneous tissue and stage III ulcers can be shallow. In contrast, areas of significant adiposity can develop extremely deep stage III pressure ulcers. Bone/tendon is not visible or directly palpable
<b>Stage IV</b>	Full thickness tissue loss with exposed bone, tendon or muscle. Slough or eschar may be present on some parts of the wound bed. Often include undermining and tunneling. The depth of a stage IV pressure ulcer varies by anatomical location. The bridge of the nose, ear, occiput and malleolus do not have subcutaneous tissue and these ulcers can be shallow. Stage IV ulcers can extend into muscle and/or supporting structures (e.g., fascia, tendon or joint capsule) making osteomyelitis possible. Exposed bone/tendon is visible or directly palpable
<b>Unstageable</b>	Full thickness tissue loss in which the base of the ulcer is covered by slough (yellow, tan, gray, green or brown) and/or eschar (tan, brown or black) in the wound bed. Until enough slough and/or eschar is removed to expose the base of the wound, the true depth, and therefore stage, cannot be determined. Stable (dry, adherent, intact without erythema or fluctuance) eschar on the heels serves as “the body’s natural (biological) cover” and should not be removed

\*Adapted from: National Pressure Ulcer Advisory Panel, 2007 staging. Web site accessed April 1, 2009, at <http://www.npuap.org/>.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Pressure Ulcer

**Assessment Data:** Food intake records, weight records, need for enteral nutrition or feeding assistance, pressure ulcer team reports, other nutritional evaluations and risk measures. Check that Nursing is turning and repositioning every 2 hours and offering fluids.

**Nutrition Diagnosis:** Inadequate protein intake related to poor appetite and intake as evidenced by new stage 2 and stage 4 sacral pressure ulcers this past month with intake records showing limited protein consumption from milk, eggs, cheese and entrees; poor nutritional lab values (H & H, transthyretin) and elevated CRP.

**Intervention:** Education of patient, staff, or family members about the role of nutrition in wound healing. Counseling about acceptable sources of protein and enhancing menu items with protein powders or liquid supplements. Encourage use of oral supplements with medication passes; adequate fluid intake calculated as 30 mL/kg. Careful calculation of fluid, protein, and energy requirements according to stage of ulcers; recalculate as needed if healing does not occur. Micronutrient provision with vitamin–mineral supplement meeting 100% DRIs and RDA levels for zinc, copper, vitamins A and C.

**Monitoring and Evaluation:** Healing of pressure ulcers by 14 days after initiation of treatment; improved intake of protein foods to meet higher needs. Greater understanding by patient, family, or staff about the importance of nutrient-dense foods or formulas. Intake and output records indicating sufficient protein and energy intake. Labs improving for H & H, albumin, CRP.

## INTERVENTION

## OBJECTIVES

- Restore to a healthy nutritional status. Correct protein-energy malnutrition; this is of paramount importance.
- Monitor risk assessments. Nutrition risks evaluate the person's usual food intake pattern; intake of 3–5 days can be useful.
- Improve low-grade infections, fever, diarrhea, and vomiting. Support the patient's immune system to prevent sepsis.
- Heal the pressure ulcer(s) and prevent further tissue breakdown. Assess healing using an appropriate scale, such as the PUSH scale from the National Pressure Ulcer Advisory Panel at <http://www.npuap.org/PDF/push3.pdf>.

## FOOD AND NUTRITION

- Provide a high-quality protein diet (Mathus-Vliegen, 2004). The guidelines for the treatment of pressure ulcers (2006) recommend 1.0–1.5 g protein/kg body weight. A deep ulcer or multiple sites may require 1.5–2 g/kg. It may be necessary to add protein powders to beverages, casseroles, tube feedings, and liquid supplements to get the adequate amount. Intake of protein greater than 2 g/kg of body weight may not be metabolized to increase protein synthesis.
- Recommended calorie levels for wound healing vary from 25 to 35 kcal/kg body weight; use lower levels for obese patients and higher levels for underweight patients.

Whether or not pressure ulcers are preventable is controversial, but removing nutritional deficits is essential (Thomas, 2006).

- Provide small, frequent feedings if oral intake is poor, four to six times daily.
- Supplement diet with a general multivitamin–mineral supplement to supply adequate B vitamins, vitamin A, vitamin C, zinc, and copper; excesses are wasteful, do not necessarily speed the healing process, and may harm the immune system.
- A concentrated, fortified, collagen protein hydrolysate supplement may be of benefit to residents of long-term care facilities who have pressure ulcers (Lee et al, 2006).
- Feed by tube if necessary. With a large sacral pressure ulcer, central parenteral nutrition (CPN) may be the only way to feed if bowel incontinence is present; avoid. EFA deficiencies by including at least 2% of calories from lipid.
- Follow the algorithm given on page 117.

## Common Drugs Used and Potential Side Effects

- Monitor the drug profile for potential side effects, especially for depletion of serum proteins or blood-forming nutrients. Drugs that can affect skin include antibacterials, antihypertensives, analgesics, tricyclic antidepressants, antihistamines, antineoplastic agents, antipsychotic agents, corticosteroids, diuretics, and hypoglycemic agents. Antibiotics may be needed in bacterial sepsis.
- Recommend, if needed, an appetite stimulant. Unintentional weight loss may be corrected by using dronabinol or cannabinoids (Marinol); megestrol acetate (Megace); oxymetholone.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals may be used; identify and monitor side effects and potential drug interactions.
- Counsel about use of herbal teas, especially regarding ingredients that may be toxic or ineffective.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Instruct nursing personnel and patient's family about the importance of adequate nutrition for healing of tissues.
- Discuss importance of maintaining healthy, intact skin. Skin should be kept clean and dry; avoid massage over bony prominences.
- Provide information about high-protein diets, and appropriate calorie and fluid levels.
- Where possible, improve ambulation and circulation to all tissues. Physical activity can help improve appetite.
- Discuss the role of nutrition in wound healing: collagen and fibroblasts require protein, zinc, and vitamin C for proper formation; adequate vitamins A and K, B-complex vitamins for healthy nerves and muscles.
- Discuss degree of assistance needed at mealtimes and provide ideas for self-help devices to increase overall intake (wet cloth under plate, curved flatware, two-handled cup, other adaptive equipment if needed).

## INTERDISCIPLINARY NUTRITION CARE PLAN

### Pressure Ulcer

**Client Name:** \_\_\_\_\_ **#:** \_\_\_\_\_ **Initiated by:** \_\_\_\_\_ **Date:** \_\_\_\_\_

#### SCREEN

Nutrition Screen diagnosis: Pressure Ulcer

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### ASSESS (Check any/all)

- ☐ Multiple pressure ulcers
- ☐ Stage III or IV pressure ulcer
- ☐ Receiving enteral or parenteral nutrition support

#### Weight/BMI

- ☐ Weight change >3 lb/wk, >5%/mo, or >10%/6 mo
- ☐ BMI <20
- ☐ BMI >27

#### Infection (UTI, URI)

#### Poor Oral Intake Symptoms

- ☐ Complex diet order
- ☐ Nausea/vomiting
- ☐ Poor appetite/early satiety
- ☐ Problems chewing/swallowing
- ☐ Depression/anxiety
- ☐ GI distress

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### GOALS (Check any/all):

- ☐ Maintain or improve nutritional status in \_\_\_\_ (goal time).
  - ☐ Correct causes of involuntary weight loss where possible in \_\_\_\_ (goal time).
  - ☐ Maintain or improve hydration status to prevent dehydration in \_\_\_\_ (goal time).
- Weight ☐ maintained, or ☐ loss / ☐ gain of \_\_\_\_ lb in \_\_\_\_ (goal time).
- ☐ Support pressure ulcer healing in \_\_\_\_ (goal time).

#### MODERATE RISK INTERVENTIONS (Check any/all)

- ☐ Power packing your diet provided and explained
- ☐ Food record provided and explained
- ☐ Fluid intake encouraged
- ☐ Wound care explained
- Obtain Dr. orders as needed:**
  - ☐ RD chart consult
  - ☐ Monitor weight q: \_\_\_\_\_
  - ☐ Multiple vitamin/mineral supplement
  - ☐ BID/TID supplements
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### HIGH-RISK INTERVENTIONS (Check any/all)

- ☐ Power packing your diet provided and explained
- ☐ Food record provided and explained
- ☐ Fluid intake stressed

#### Obtain Dr. orders as needed:

- ☐ RD referral for home visit(s)
- ☐ Monitor weight q: \_\_\_\_\_
- ☐ Monitor I & O q: \_\_\_\_\_
- ☐ Multiple vitamin/mineral supplement
- ☐ BID/TID supplements
- ☐ Tube feeding

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### ASSESS RESPONSE (Check any/all)

- ☐ Weight change not appropriate per goal
- ☐ Dehydration
- ☐ Development of Stage III or IV pressure ulcer
- ☐ Development of multiple pressure ulcers
- ☐ Onset of new infection
- ☐ Exhibiting poor oral intake symptoms
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES ACHIEVED

- ☐ Pressure ulcers improved
- ☐ Weight Maintained or improved
- ☐ Hydration status maintained or improved
- ☐ Development of multiple pressure ulcers
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Risk Screen in \_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### ASSESS RESPONSE (Check any/all)

- ☐ Stage III or IV pressure ulcer
- ☐ Multiple pressure ulcers
- ☐ Weight change not appropriate per goal
- ☐ Infection worsened
- ☐ Continued dehydration
- ☐ Continued Poor Oral Intake Symptoms
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES ACHIEVED

- ☐ Pressure ulcers improved
- ☐ Weight Maintained or improved
- ☐ Hydration status maintained or improved
- ☐ Development of multiple pressure ulcers
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Risk Screen in \_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES NOT ACHIEVED

Reassess/evaluate need for EN/PN (refer to Tube Feeding Nutrition Care Plan). Document on Nutrition Variance Tracking form.

### Patient Education—Food Safety

- Hand washing will be important for patients, caretakers, and nurses before and after meals.

## VITAMIN DEFICIENCIES

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Rubin E MD and Farber JL MD. *Pathology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 1999.

### DEFINITIONS AND BACKGROUND

Vitamins are a part of a healthy diet. If a person eats a variety of foods, deficiency is less likely. However, people who follow restricted diets may not get enough of one or more particular nutrients. Deficiencies may be primary (self-induced by inadequate diet) or secondary to disease process. They are especially common in alcoholics, people who live alone and eat poorly, and among those who follow restrictive food fads. Vegetarians are also susceptible, especially for vitamin B<sub>12</sub> deficiency. Appendix A provides greater detail about the vitamins, their sources, toxicities, and deficiencies. Table 2-9 summarizes concerns and physical signs of deficiency.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

#### Clinical/History

Height  
Weight  
BMI  
Diet history  
Neurological, hepatic or renal changes

Physical signs of malnutrition (see Table 2-9 and Appendix A)

#### Lab Work

Vitamin A—serum retinol <0.35 mmol/L

Vitamin C—plasma concentrations <0.2 mg/dL  
Vitamin D—25-OHD values <25 nmol/L  
Vitamin E—plasma alpha-tocopherol <18 μmol/g

**TABLE 2-9 Vitamin Deficiency Summary**

Vitamin	Issues	Physical Signs
<b>Vitamin A</b>	Common in children. Night blindness and eye changes are often early signs. Many infections (such as measles) may cause deficiency. Vitamin A helps form and maintain healthy teeth, mucous membranes, skeletal and soft tissues, and skin. Retinol generates the pigments in the retina. Vitamin A promotes good vision (especially in dim light) and is required for healthy reproduction and lactation. Because beta-carotene is a precursor for vitamin A and because so many carotenoids play a role in maintaining good health, deficiencies of these phytochemicals may play an even larger role in maintaining vitamin A adequacy in the body.	Night blindness, Bitot's spots, xerophthalmia, follicular hyperkeratosis Reduced growth, changes in epithelial tissue, failure of tooth enamel and/or degeneration, loss of taste and smell.
<b>Thiamin</b>	Common in alcoholics, patients with heart failure, and persons with poor-quality diets. Thiamin helps convert carbohydrate (CHO) into energy; a high-CHO diet can deplete thiamin. It is also important for proper functioning of the heart, nervous system, and muscles.	Impairment of cardiovascular, nervous, and gastrointestinal systems.
<b>Niacin and riboflavin</b>	Often in conjunction with other B-complex vitamin deficiencies. Riboflavin (B <sub>2</sub> ) is important for growth, red cell production, and releasing energy from carbohydrates. Niacin assists in the functioning of the digestive system, skin, and nerves; it is important in the conversion of food to energy. A deficient diet or failure of the body to absorb niacin or tryptophan can cause signs of deficiency or pellagra. It is common in certain parts of the world where people consume large quantities of corn and is characterized by dermatitis, diarrhea, and schizophrenia-like dementia. It sometimes develops after gastrointestinal diseases or among alcoholics.	Niacin: Symmetrical, pigmented rash on areas exposed to sunlight, bright red tongue, Dermatitis, diarrhea, depression, and (sometimes) death (the 4 Ds). Riboflavin: Sore throat, hyperemia, edema of pharyngeal and oral mucous membranes, cheilosis, angular stomatitis, glossitis, seborrheic dermatitis, and normochromic, normocytic anemia. Magenta tongue.
<b>Vitamin B<sub>6</sub></b>	Can occur after surgery or as a result of poor diet. Vitamin B <sub>6</sub> deficiency has role in cardiac disorders (atrial fibrillation, hyperhomocysteinemia) and inflammation (Friso et al, 2004) and in dopamine release in the brain. Because vitamin B <sub>6</sub> plays a role in the synthesis of antibodies and red blood cells, a healthy immune system and circulatory system depend on it. The higher the protein intake, the more need there is for vitamin B <sub>6</sub> ; a high protein–low CHO diet may deplete vitamin B <sub>6</sub> .	Seborrheic dermatitis, stomatitis, cheilosis, glossitis, confusion, depression. Convulsions or intractable seizures in infants and young children (Gospe, 2006); anemias; nerve and skin disorders.
<b>Folic acid</b>	May result in a megaloblastic anemia; supplementation is needed (see Section 12). Folic acid acts as a coenzyme with vitamins C and B <sub>12</sub> in the metabolism and synthesis of proteins. It is needed to make red blood cells, to synthesize DNA, and to support tissue growth and cell function. There are roles for folic acid in disease prevention (e.g., neural tube defects, cancers, heart disease).	Depapillation of the tongue, rarely. Pregnancy-induced anemias; neural tube defects (Tamura and Picciano, 2006). Cardiovascular disease with elevated homocysteine levels.
<b>Vitamin B<sub>12</sub></b>	May also result in megaloblastic anemia (see Section 12 on anemias). Peripheral neuropathy and a positive Schilling test are needed to indicate B <sub>12</sub> deficiency. Folic acid supplementation may mask a B <sub>12</sub> deficiency; both should be given.	Tingling and numbness in extremities, diminished vibratory and position sense, motor disturbances including gait disturbances. Pernicious anemia and other anemias; poor vision; some psychiatric symptoms.
<b>Pantothenic acid and biotin</b>	Not common. Pantothenic acid is essential for metabolism and in the synthesis of hormones and cholesterol. Biotin is essential for metabolism of proteins and carbohydrate and the synthesis of hormones and cholesterol.	<i>Pantothenic acid</i> : No visible physical signs of note. <i>Biotin</i> : Inflammation of the lips and skin.
<b>Choline</b>	May occur in long-term TPN use without lipid replacement. Plays a role in preventing neural tube defects along with folic acid.	No visible physical signs of note. Liver damage and altered DNA function.
<b>Vitamin C</b>	Occurs overtly with scurvy after 3 months without intake from inadequate consumption of fresh fruits and vegetables. Hypovitaminosis C can occur in the elderly and the homeless, among those who live alone or have psychiatric diseases, and in those who follow food fads. It is more common than realized in the general population. Long-term deficiency can be a concern for people with cancer or cataracts.	Follicular hyperkeratosis, petechiae, ecchymosis, coiled hairs, inflamed and bleeding gums, perifollicular hemorrhages, joint effusions, arthralgia, delayed wound healing. Weakness, myalgia, vascular purpura, loss of teeth. Biological signs include anemia, hypocholesterolemia, and hypoalbuminemia.

(continued)

TABLE 2-9 Vitamin Deficiency Summary (*continued*)

Vitamin	Issues	Physical Signs
<b>Vitamin D</b>	Insufficiency is a low threshold value for plasma 25-OHD (50 nmol/L). Secondary hyperparathyroidism, increased bone turnover, bone mineral loss, and seasonal variations in plasma PTH can occur with insufficiency. Deficiency is defined as 25-OHD values below 25 nmol/L; common among community-dwelling elderly who live in higher latitudes and among institutionalized elderly and patients with hip fractures. Vitamin D is produced in the skin by exposure to the sun and is found in fortified milk and other foods. For individuals who are not getting enough vitamin D in the diet, supplements may be helpful. The average adult under 50 needs 200 IU of vitamin D a day; 1 cup of vitamin D-fortified milk provides 50 IU of vitamin D (Surgeon General's Report, 2004). Recent studies suggest a role for vitamin D in autoimmune disorders, including multiple sclerosis (Mark and Carson, 2006); ovarian cancer (Zhang et al, 2006); type 1 diabetes or hypertension (Holick, 2006).	Widening at ends of long bones, rachitic rosary in children, rickets. Abnormal bone growth and repair; osteomalacia in adults; muscle spasms. Decreased immunity (Villamor, 2006).
<b>Vitamin E</b>	It is an antioxidant, protects body tissue from the damage of oxidation, helps form red blood cells, and supports the use of vitamin K. Abetalipoproteinemia is the most severe deficiency and occurs mainly in premature and sick children. Fat malabsorption occurs in deficiency, especially in children.	Rupture of red blood cells; nerve damage.
<b>Vitamin K</b>	Rare except in intestinal problems and short gut syndromes because intestinal bacteria in the healthy gut can make vitamin K. Healthy bones require sufficient vitamin K.	Poor wound healing or blood clotting. Osteopenia (Duggan et al, 2004).

Vitamin K— elevated prothrombin time, altered INR	Vitamin B <sub>6</sub> — plasma pyridoxal 5'phosphate <20 nmol/L	Choline— plasma choline and phosphatidyl- choline con- centrations fall when humans are fed a choline- deficient diet, but otherwise there are no definitive tests; abnor- mal liver function tests may occur
Thiamin— erythrocyte transketolase activity >1.20 μg/mL/h; AST is often decreased	Vitamin B <sub>12</sub> — serum concentra- tion <180 pmol/L; elevated tHcy	
Riboflavin— erythrocyte glutathione reductase >1.2 IU/mg hemoglobin	Folic acid— serum con- centration <7 nmol/L; red cell folate <315 nmol/L	
Niacin—N- methyl- nicotinamide excretion <5.8 μmol/d		

poor intakes of vitamin A (Cox et al, 2006). Vitamin D deficiency can lead to increased incidence of hip fracture (Cauley et al, 2008).

## FOOD AND NUTRITION

- **Vitamin A deficiency.** Use a diet including foods high in vitamin A and carotene: carrots, sweet potatoes, squash, apricots, collards, broccoli, cabbage, dark leafy greens, liver, kidney, cream, butter, and egg yolk.
- **B-Complex vitamins:**
- **Thiamin deficiency** (beri-beri). Use a diet including foods high in thiamin: pork, whole grains, enriched

## SAMPLE NUTRITION CARE PROCESS STEPS

### Vitamin A Deficiency

**Assessment Data:** Food intake records, physical signs of deficiency, frequent bouts of infectious illnesses.

**Nutrition Diagnosis:** Inadequate vitamin A intake related to poor appetite and intake as evidenced by prolonged recovery after measles, recent onset of night blindness, serum retinol <0.35 mmol/L, complaints of lethargy and frequent illnesses.

**Intervention:** Education of patient, staff, or family members about the role of vitamin A for healthy immunity and vision. Counseling about good sources of vitamin A and carotenoids. Micronutrient provision meeting 100% DRI for vitamin A.

**Monitoring and Evaluation:** Total recovery after measles. Improvement in vision. Labs improving for retinol. Fewer infectious illnesses, colds, flu, etc. Improved quality of life.

## INTERVENTION

### OBJECTIVES

- Replenish the deficient nutrient and restore normal serum levels.
- Prevent or correct signs, symptoms, and effects of nutrient deficiency. For example, reduced immunity and high maternal and child mortality occur in populations with

cereal grains, nuts, potatoes, legumes, green vegetables, fish, meat, fruit, and milk in quantity. A high-protein/high-carbohydrate intake should be included.

- **Riboflavin deficiency.** Use a diet including foods high in riboflavin: milk, eggs, liver, kidney, and heart. Caution against losses resulting from cooking and exposure to sunlight.
- **Niacin deficiency or pellagra.** Use a diet including foods high in niacin and other B vitamins: yeast, milk, meat, peanuts, cereal bran, and wheat germ.
- **Folic acid deficiency.** Use fresh, leafy green vegetables, oranges and orange juice, liver, other organ meats, and dried yeast.
- **Vitamin B<sub>6</sub> deficiency.** Use dried yeast, liver, organ meats, whole-grain cereals, fish, and legumes.
- **Vitamin B<sub>12</sub> deficiency.** Use liver, beef, pork, organ meats, eggs, milk, and dairy products.
- **Biotin deficiency.** Use liver, kidney, egg yolks, yeast, cauliflower, nuts, and legumes.
- **Pantothenic acid deficiency.** Use live yeast and vegetables.
- **Choline.** Include eggs, liver, beef, milk, oatmeal, soybeans, peanuts, and iceberg lettuce.
- **Vitamin C deficiency or scurvy.** Use a diet high in citrus fruits, tomatoes, strawberries, green peppers, cantaloupe, and baked potatoes.
- **Vitamin D deficiency.** Use fortified milk, fish liver oils, and egg yolks. Expose skin to sunlight if possible.
- **Vitamin E deficiency.** Use vegetable oil, wheat germ, leafy vegetables, egg yolks, margarine, and legumes.
- **Vitamin K deficiency.** Use a diet high in leafy vegetables, pork, liver, and vegetable oils.

### Common Drugs Used and Potential Side Effects or Toxicity

Note: The DRI “tolerable upper intake levels” (UL) address the toxic side.

- **Vitamin A.** Absorption of vitamin A depends on bile salts in the intestinal tract. Controlled high doses may be prescribed for a short period of time. Beware of doses greater than the recommended upper limit per day for a long time, especially for children.
- **Thiamin.** A common dose is 5–10 mg/d of thiamin; anorexia and nausea may be common at the beginning of treatment. Intravenous therapy may be better tolerated.
- **Riboflavin.** Achlorhydria may precipitate a deficiency and may preclude successful correction. Alkaline substances destroy riboflavin.
- **Niacin.** Treatment with niacin may cause flushing. Niacinamide is a better choice; 200–400 mg of niacin or niacin equivalents may be used for a short time. Nicotinic acid can cause nausea, vomiting, and diarrhea.
- **Vitamin B<sub>6</sub>.** Pyridoxine hydrochloride is the common content.
- **Pantothenic acid.** Pantholin is a drug that is prescribed as needed.
- **Choline.** Choline hydrochloride salt may be degraded by intestinal bacteria and cause a fishy body odor. This does not occur when lecithin is eaten in the diet.

- **Vitamin C.** Excesses can cause false-positive glucosuria tests. Cevalin or Cevita are drug sources; 50–300 mg/d may be given to correct scurvy. Excesses may have an antihistamine effect or cause diarrhea.
- **Vitamin D.** Calderol, Rocaltrol, Hytakerol, and Calciferol are common drug sources. Be sure to use vitamin D<sub>3</sub> [25-hydroxyvitamin D (25-OHD)] for greater effectiveness.
- **Vitamin E.** Aquasol E has no adverse side effects if used within measured dosage for age and daily requirements.
- **Vitamin K.** Vitamin K is usually injected to correct deficiency rather than using diet alone. Synkayvite, Mephyton, and Konakion are trade names.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals may be used by many individuals; identify and monitor side effects.
- Counsel about use of herbal teas, especially regarding ingredients that may be toxic.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain where sources of the specific nutrient may be found.
- Demonstrate methods of cooking, storage, etc., that prevent losses.
- Help the patient plan a menu incorporating his or her preferences.
- Discuss the use of vitamin and mineral supplements. Although they may be appropriate to correct a deficiency state, they may not be warranted for continuous or long-term use.

## FOOD ALLERGY AND MÉNIÈRE'S SYNDROME

# FOOD ALLERGY AND INTOLERANCES

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3 (SIMPLE); LEVEL 3–4 (COMPLEX)

### DEFINITIONS AND BACKGROUND

It is important to distinguish food allergies from intolerances caused by toxins or drugs and metabolic disorders such as lactase deficiency or celiac disease. People who have a tendency toward allergy may develop sensitivity to new foods at any time. The manifestations of allergy are caused by the release of histamine and serotonin.

Prevalence of food allergies in the United States is about 6 million people; worldwide, they affect 3.5–4% of all individuals (Taylor, 2008). Allergic tendencies are inherited but not necessarily to a specific antigen (i.e., a parent with a genetic predisposition to severe bee sting reactions could have a child with a bee sting allergy, food allergy, or other allergy). Immune deviation and disturbed gut motility occurs in children with multiple food allergies, along with a maternal history of autoimmunity (Latham et al, 2003). It is now recognized that children who have a fever before age 1 are less likely to develop allergies by age 6–7 years, and exposure to pets such as dogs at an early age builds immunity.

The most common symptoms of food allergies affect the GI tract (GIT): diarrhea, nausea, vomiting, cramping, abdominal distention, and pain. GI allergic manifestations can be

classified as immunoglobulin E-mediated; “mixed” GI allergy syndromes, involving some IgE components and some non-IgE or T cell-mediated components; or eosinophilic gastroenteritis (Garcia-Careaga and Kerner, 2005; Lee and Burks, 2009). **GI food allergies** include a spectrum of disorders that result from adverse immunologic responses to dietary antigens, as defined by the National Institute of Allergy and Infectious Diseases (NIAID) in 2010:

- **Immediate GI hypersensitivity** refers to an IgE-mediated FA in which upper GI symptoms may occur within minutes and lower GI symptoms may occur either immediately or with a delay of up to several hours. This is commonly seen as a manifestation of anaphylaxis. Among the GI conditions, acute immediate vomiting is the most common reaction and perhaps the one best documented as immunologic and IgE mediated.
- **Eosinophilic esophagitis (EoE)** involves localized eosinophilic inflammation of the esophagus. While EoE is commonly associated with the presence of food-specific IgE, the precise causal role of FA in its etiology is not well defined. Both IgE- and non-IgE-mediated mechanisms seem to be involved.
- **Eosinophilic gastroenteritis (EG)** also is both IgE- and non-IgE-mediated, and commonly linked to food allergies. EG symptoms vary depending on the portion of the GIT involved and a pathologic infiltration of the GIT by eosinophils that may be quite localized or very widespread.
- **Dietary protein-induced proctitis/proctocolitis** typically presents in infants who seem generally healthy but have visible specks or streaks of blood mixed with mucus in the stool. <sup>5</sup>IgE to specific foods is generally absent.
- **Food protein-induced enterocolitis syndrome (FPIES)** is another non-IgE-mediated disorder presenting in infancy with vomiting and diarrhea severe enough to cause dehydration and shock. Cow's milk and soy protein are the most common causes. It typically manifests in the first few months of life, with severe projectile vomiting, diarrhea, and failure to thrive. A similar

condition has also been reported in adults, most often related to crustacean shellfish ingestion. Children will often outgrow an allergy to milk and soy by age 5 or 6. Recent research suggests that many children tolerate products containing egg or milk if extensively heated (Sicherer and Leung, 2009).

- **Oral allergy syndrome (OAS)**, or pollen-associated FA syndrome, is a form of localized IgE-mediated allergy. Reaction is usually from direct contact with fresh fruits or vegetables, confined to the lips, mouth, and throat. OAS most commonly affects patients who are allergic to pollens. Symptoms include itching of the lips, tongue, roof of the mouth, and throat, with or without swelling, and/or tingling of the lips, tongue, roof of the mouth, and throat. There is a rapid onset of symptoms, but it is rarely progressive. Cross-reactivity occurs between certain pollen and food allergens, such as ragweed allergy with ingestion of bananas or melons; birch pollen allergy with ingestion of raw carrots, celery, potato, apple, hazelnut, or kiwi; or latex-fruit allergy with apples, avocado, banana, bell pepper, cherries, chestnut, kiwi, nectarines, peach, plums, potato and tomato.

Over 170 different foods have been known to produce an allergy or intolerance. Yet, over 90% of food allergies are caused by eight foods: eggs, milk, wheat, soy, fish, shellfish, peanuts, and tree nuts (TNs). Peanut and TN allergies are the leading cause of fatal or near-fatal food allergic reactions, including respiratory arrest and shock (Sicherer, 2003). The greatest danger comes from anaphylaxis, a violent allergic reaction that involves many parts of the body. Signs include itchy lips, tongue, or palate; metallic taste; flushing and itching or urticaria of skin; angioedema and edema of lips and tongue; nausea, vomiting, or diarrhea; tightness in chest or throat; dysphagia; hoarseness; dry cough; shortness of breath or wheezing; rhinorrhea or congestion; bronchospasm; syncope; chest pain; and hypotension.

Food allergy reactions usually occur within 2 hours. Immediate (1 minute–2 hours) or delayed reactions (2–48 hours) may also occur. **Food-induced anaphylaxis** is an IgE-mediated, rapid-onset, potentially life-threatening systemic reaction in which the affected individual may experience cardiovascular shock and/or serious respiratory compromise due to airway obstruction or bronchoconstriction (NIAID, 2010). Anaphylaxis occurs when a person is exposed to an allergen after being sensitized by at least one previous exposure. Peanuts, TNs, shellfish, milk, eggs, and fish are the most problematic. Tropomyosin is the protein that causes allergic reactions in shellfish (Taylor, 2008). Peanut allergy is quite serious, where even miniscule amounts have caused deaths (Lee and Burks, 2009; Scurlock and Burks, 2004).

Histamine mediates anaphylaxis by triggering a cascade of inflammatory mediators (Winbery and Lieberman, 2002). Histamine occurs naturally in foods such as cheese, red wines, spinach, eggplant, and yeast extract; it may elicit a response, including hives, urticaria, GI irritability, nausea, and flushing (Maher, 2002). A nonallergic reaction may occur from eating spoiled (scombroid) fish, which tends to be high in histamine; it may cause a reaction similar to anaphylaxis.

The GIT is highly involved in nutritional, physiological and immunological health. Gut-associated lymphoid tissue (GALT) is developed after birth with bacterial colonization, supporting development of protective IgA. An imbalance in T cells (type th2 greater than type th1) promotes autoimmune disease, Crohn's disease, or gut disease such as NEC (Walker, 2008). Persons with chronic urticaria may have impaired small bowel enterocyte function, with higher sensitivity to histamine-producing foods (Guida et al, 2000). Probiotics are being widely promoted for a role in reducing undesirable GIT responses to pathogens and allergens. In addition, retinoids regulate immunosuppressive factors within the mucosa; this role is just becoming understood (Strober, 2008).

Exercise and aspirin may facilitate allergen absorption from the GI tract (Matsuo et al, 2005). Food-dependent exercise-induced anaphylaxis (FDEIA) is an allergic reaction induced by intense exercise with the ingestion of a causative food (Matsuo et al, 2005). FDEIA is often associated with celery, chicken, shrimp, oyster, peaches, and wheat.

Alcoholic beverages may also contribute to hypersensitivity reactions: flushing syndrome, anaphylactoid reactions of urticaria/angioedema, asthma, food allergy, or exercise-induced anaphylaxis in susceptible subjects (Gonzalez-Quintela et al, 2004). Alcohol may promote development of IgE-mediated hypersensitivity to different allergens; alcohol abuse and even moderate alcohol consumption are associated with increased total serum IgE levels (Gonzalez-Quintela et al, 2004).

The Food Allergen Labeling and Consumer Protection Act (FALCPA) became effective January 1, 2006. Food ingredient labeling is the first line of defense for those with food allergies and their caregivers. Food ingredient labels should be read every time a food is purchased and used. Under FALCPA, food labels are to provide clear, consistent, and reliable ingredient labeling information by including "common English" names of the top eight major food allergens in food labeling. Legislation requires one of two options for food labeling with these common terms. The first is to list the food allergen in parentheses following the required ingredient term; for example, "whey (milk)" or "semolina (wheat)." The second option is to follow the ingredient declaration with a statement such as "contains flounder, pecan, wheat, and soy." In addition, all spices, flavors, and incidental additives that contain or are derived from a major food allergen will be labeled with the name of an allergen under either ingredient labeling option. For example, a flavor that contains an ingredient derived from milk might say "natural butter flavor (milk)."

Genetically modified (GM) foods are the product of biotechnology. Genetic bioengineering may, eventually, be able to reduce the level of allergens in the food supply (Lehrer, 2004), a common concern among members of the public (Celec et al, 2005). For GM foods, possible allergenicity of proteins is evaluated by comparison of their amino acid sequence with that of known allergens and determination of their stability during processing. GM crops that have been grown commercially are regularly evaluated for allergenic properties (Goodman et al, 2005). Overall, biotechnology can enhance the safety, nutritional value, and variety of foods without promoting allergies (American Dietetic Association, 2006).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Both genetics and environment play a role in promoting food-specific IgE responses (Tsai et al, 2009). Major food allergens are water-soluble glycoproteins. In normal individuals, allergens cause an IgA response along with suppressor CD8+ lymphocyte production. Antigen uptake is altered in children with cow's milk allergy; this affects about 3% of children in the U.S. Soy allergy affects about 1% of children. Peanuts have an Ara h 1 component that promotes IgE-mediated mast cell degranulation; tree nuts have similar effects (Khodoun et al, 2009). Gliadin is often found to be a factor in wheat allergy. Latex contains Hev b protein, to which some people are hypersensitive.

Clinical/History	Lab Work	Double-blind
Height	H & H, serum Fe	food
Weight	Serum tryptase	challenge
BMI	(elevated)	Patch tests for
Recent weight changes	Serum histamine	delayed
Food diaries and symptoms history	Allergen microarray test for IgE profiling	hypersensitivity reactions
BP	Radioallergosorbent test (RAST)	CRP
Temperature	Allergen-specific IgE levels:	Alb,
Chronic GI distress, diarrhea	skin prick tests (SPT)	transferrin
Asthma or rhinitis	give 50% false-positives but are very reliable if negative	BUN, Creat
Angioedema, urticaria		
Double-blind food challenge test		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Intake of Unsafe Foods—Food Allergies

**Assessment:** Food diaries, food history, history of previous anaphylaxis and known food allergens.

**Nutrition Diagnosis:** Intake of unsafe food related to knowledge deficit as evidenced by anaphylaxis reaction after consuming peanuts.

**Intervention:** Education and counseling about identified food allergies (peanuts,) food labeling, recipes, and ingredients; evaluation of nutritional adequacy. Teach how to keep a food diary, keeping a chronological record of all foods eaten and any associated adverse symptoms. If needed, implement an elimination diet.

**Monitoring and Evaluation:** Review of food diaries; reports of no further problems with anaphylactic reactions to foods.

an elimination diet to discover the cause. Note that “rotation diets” are not effective and are potentially dangerous.

- Monitor speed of onset of reactions, delayed versus immediate. The onset of delayed reaction may take from several hours to as long as 5 days. An immediate response is more common with raw foods; patient history may include diarrhea, urticaria, dermatitis, rhinitis, and asthma (see Asthma, Section 5). Allergic diarrhea is almost entirely IgE and mast-cell dependent, mediated by platelet-activating factor (PAF) and serotonin (Finkelman, 2007).
- Treatment of GI allergic disorders includes strict dietary elimination of offending food (Garcia-Careaga and Kerner, 2005). Use of protein hydrolysates has not been proven to be necessary (Osborn and Sinn, 2006).
- Breastfeeding should be promoted for primary prevention of allergic infants who are not lactose-intolerant (Garcia-Careaga and Kerner, 2005).
- Treat nutritional deficiencies or ensure adequate supplementation. Children who have multiple food allergies tend to have growth problems. The nutritional consequences of food allergy by various allergens are listed in Table 2-9.

Follow the new guidelines at <http://www.niaid.nih.gov/topics/foodAllergy/clinical/Documents/guidelines.pdf>.

## INTERVENTION

### OBJECTIVES

- Careful clinical history, diagnostic studies, endoscopy, or double-blind food challenge may be needed. Children with AD could have a food allergy that can be diagnosed using a skin prick test and double-blind food challenge. Assist as needed in obtaining information; teach how to keep a food diary to track reactions to food.
- The therapy is avoidance of incriminating foods, plus education to avoid inadvertent exposures. Exclude or avoid the offending allergen. If it is not known, use

### FOOD AND NUTRITION

- The most common allergens in infants are eggs, wheat, milk, and fish. For children, cow's milk, eggs, soy, peanuts, wheat, TNs, and fish are often a problem. For adults, common allergens include shellfish, peanuts, and TNs. Peanuts are implicated in approximately one third of all cases of anaphylaxis.
- After skin testing, a double-blind, placebo-controlled food challenge (DBPCFC) can be useful (Perry et al, 2004). This should only be used under the guidance

of a physician in case there are immediate or severe reactions.

- For an elimination diet, use an unflavored elemental diet as a hypoallergenic base to which other foods are added as test challenges. Foods that seldom cause an allergic reaction include apples, apricots, artichokes, carrots, gelatin, lamb, lettuce, peaches, pears, rice, squash, and turkey; they may be used in this protocol.
- Read labels of foods prepared for the patient. Check all menu items served to patients. See Table 2-10.
- Monitor food preparation methods to exclude possible cross contact with the allergen.
- Monitor nutrient needs specific for the patient's age; evaluate for possible "hidden" ingredients.
- For infants, exclusive breastfeeding is best as it is nonallergenic.
- Lactating mothers may want to omit cow's milk, eggs, fish, and nuts from their own diets. See Table 2-11. Do

not give cow's milk to infants until after they are 1-year old.

- Children should not eat peanuts, nuts, or fish until they are 3-year old. Toddlers should not eat eggs until after 2 years of age.
- Persons with rhinitis may be sensitive to monosodium benzoate in fruit juice, pie filling, pickles, olives, salad dressings, and fruit drinks.

### Common Drugs Used and Potential Side Effects

- Aspirin may trigger skin reactions, which are associated with the inhibition of cyclooxygenase-1 (COX-1) and characterized by overproduction of cysteinyl leukotrienes; these reactions are due to the interference of aspirin-like drugs with arachidonic acid metabolism (Mastalerz, 2005).

**TABLE 2-10 Major Food Allergens and Nutritional Consequences**

<b>Most Common</b>	Nutrients of concern
Milk	Check for deficiencies in protein, riboflavin, calcium, and vitamins A and D.
Eggs	Check for iron from other sources.
Fish and shellfish	Other protein sources will be needed. Niacin, vitamin B <sub>6</sub> , vitamin B <sub>12</sub> , omega-3 fatty acids, phosphorus, and selenium should be available from other foods.
Nuts, tree	Protein, fatty acids, and other nutrients will be needed from other sources in the diet. Often, children outgrow a tree nut allergy.
Peanuts	Protein, fatty acids, and other nutrients will be needed from other sources in the diet.
Soy	Protein and other nutrients may be needed from other sources.
Wheat	Check for sufficiency of B vitamins and iron from other sources.
<b>Less Common</b>	Most frequently tied to adverse reactions that can be confused with food allergy are yellow dye number 5, monosodium glutamate (MSG), and sulfites.
Food additives: Tartrazine (not a true food allergen)	Yellow dye number 5 can cause hives, although rarely. FD&C Yellow No. 5, or tartrazine, is used to color beverages, dessert powders, candy, ice cream, custards, and other foods. The color additive may cause hives in fewer than one out of every 10,000 people. By law, whenever the color is added to foods or taken internally, it must be listed on the label so those who may be sensitive to FD&C Yellow No. 5 can avoid it ( <a href="http://www.cfsan.fda.gov/~dms/qa-top.html">http://www.cfsan.fda.gov/~dms/qa-top.html</a> ).
MSG (not a true food allergen)	Dietary glutamate is a major energy source for the intestines and placenta. The brain is well protected against a flux of glutamate, and it is not toxic. Glutamate is found naturally in foods such as tomatoes and cheeses and is released in protein hydrolysis during stock or soup preparation. It is added to foods in crystalline form as MSG. MSG, which is 14% sodium, is used as a flavor enhancer, known as "umami." Glutamate helps to stimulate the vagus nerve and helps to facilitate digestion and nutrient absorption (Fernstrom and Garattini, 2000). MSG enhances flavor, but when consumed in large amounts, it can cause flushing, sensations of warmth, lightheadedness, headache, facial pressure, and chest tightness; these effects are temporary. These adverse reactions, "Chinese restaurant syndrome," have not been confirmed in double-blind studies (Geha et al, 2000).
Mustard	Mustard allergy is not as uncommon as previously believed (Figueroa et al, 2005). There is a relationship with mugwort pollinosis and plant-derived food allergies. A relationship between this syndrome and food-dependent exercise-induced anaphylaxis has also been reported (Figueroa et al, 2005).
Rice	Certain ethnic groups may have sensitivities to foods that may not be as allergenic for other populations. An example is an Asian person who develops an allergy to rice. Some of this may be dose-related exposure.
Spices	Spices may cause delayed-typed contact allergic or immediate allergic reaction. Sesame seed is a fairly common allergen. Carmine/cochineal is another minor allergen.
Sulfites (not a true food allergen)	Although not an IgE-mediated allergic response, sulfites can produce life-threatening reactions similar to the major food allergens. To help sulfite-sensitive people avoid problems, FDA requires the presence of sulfites in processed foods to be declared on the label and prohibits the use of sulfites on fresh produce intended to be sold or served raw to consumers (FDA Consumer: <a href="http://vm.cfsan.fda.gov/~dms/wh-arg1.html">http://vm.cfsan.fda.gov/~dms/wh-arg1.html</a> ). Foods such as wine, beer, dried fruits and vegetables, maraschino cherries, and dried or frozen potatoes may contain sulfites. No specific nutrient deficits are likely if omitted from the diet.

**TABLE 2-11 Food Processing Concerns**

<b>Manufacturing processes</b>	The food industry has taken steps to address the needs of consumers with food allergies, including changes to manufacturing processes to reduce the potential for cross-contact with major food allergens. Under existing good manufacturing practice (GMP) regulations, reasonable precautions must be taken to prevent cross-contact with major allergenic proteins. In instances when cross-contact cannot be avoided, even when complying, food and ingredient manufacturers use labeling that informs the food allergic consumer of the possible presence of allergens in the food. Food manufacturers label the ingredients in their products in accordance with existing regulatory requirements. The rule is, “no protein, no problem.”
<b>Oils in processing</b>	Most oils used in food processing and for sale to the public contain no protein and are extracted from the oilseed or nut using solvents and then are degummed, refined, bleached, and deodorized. Some oils are mechanically extracted (cold pressed) and left unrefined to purposely maintain the flavor; these oils may contain protein and be allergenic.
<b>Product recalls</b>	Undeclared food allergens have been responsible for many food product recalls during the past decade, and the food industry has made significant investment, effort, and improvements in allergen control during this time (Hefle and Taylor, 2004). More research will be important.

- Cyclosporine, when used, can be steroid sparing; monitor BUN, Creat, and BP (Kaplan, 2004).
- Epinephrine is the synthetic version of naturally occurring adrenaline. It is the first line of defense for anaphylaxis and often requires an emergency room visit. Injectable epinephrine should be carried by those who are prone to allergic reactions to food and other allergens. An Epi-Pen provides a single dose; the Ana-Kit provides two doses.
- Oral antihistamines, such as Benadryl or Atarax or Vistaril, should be taken with food. Dry mouth, constipation, and GI distress are potential side effects.
- H<sub>1</sub>-antihistamines (such as ranitidine, cimetidine) are adjunctive treatment therapy for acute anaphylactoid reactions, but they have a slow onset of action when compared with epinephrine, the medication of choice (Winbery and Lieberman, 2002). They are a mainstay of therapy for urticaria; nonsedating products include fexofenadine, loratadine, and desloratadine (Monroe, 2005).
- Treatment with topical or systemic steroids is used if all dietary measures are unsuccessful (Garcia-Careaga and Kerner, 2005).
- Consumption of omega-3 fatty acids can reduce the severity of asthma symptoms. With fish allergy, use nonfish oil sources.
- Probiotics have possible use for treatment of AD (Vanderhoof, 2008). Other new treatments for AD, urticaria and angioedema include biologics, vitamin D, and skin creams (Sicherer and Leung, 2009).

- Scientists at NIH fed mice a mixture of whole peanut extract (WPE) and a toxin called staphylococcal enterotoxin B (SEB) to simulate the human anaphylactic reaction to peanuts in mice. They are trying to develop a method for desensitizing people who are allergic to peanuts over time.

### Herbs, Botanicals, and Supplements

- The pathway that activates transcription factors can be interrupted by phytochemicals derived from turmeric (curcumin); red pepper (capsaicin); cloves (eugenol); ginger (gingerol); cumin, anise, and fennel (anethol); basil and rosemary (ursolic acid); garlic (diallyl sulfide, S-allylmercaptocysteine, ajoene); and pomegranate (ellagic acid) (Aggarwal and Shishodia, 2004).
- Bee pollen does not prevent allergies. It may, in fact, cause asthma, urticaria, rhinitis, or anaphylaxis after eating plants that cross-react with ragweed, such as sunflowers or dandelion greens.
- Food/plant sensitivities are common (e.g., melon/ragweed, apple/birch, wheat/grasses). Be wary of herbal teas.
- Jewelweed, parsley, stinging nettle, amaranth, ginkgo, chamomile, and feverfew have been proposed for use in allergies or with hives; no long-term studies are needed.
- Sweeteners are not usually allergenic. After reviewing scientific studies, the FDA determined in 1981 that aspartame is safe for use in foods. Persons who have phenylketonuria (PKU) should not use it because it is made from phenylalanine.
- For conditions such as allergic asthma, clinical trials are underway to determine effectiveness of Traditional Chinese Medicines (TCM).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Education on reading ingredient labeling is essential. Ensure extensive nutrition counseling and health education for those who have food allergies to avoid nutrient deficiencies, to limit unnecessary restrictions, and to prevent reactions. Nutrient deficiencies will depend on the food groups involved and omitted.
- Signs of anaphylaxis (hoarseness, throat tightening, difficulty breathing, tingling in hands or feet or scalp, wheezing) should be taken seriously; call 911 immediately.
- Teach about possible cross-reactivity, such as cow's milk with goat's milk, or various types of fin fish.
- Tips to share with individuals who have allergies are found in Table 2-12.

### Patient Education—Food Safety

- Intake of food allergens is actually “intake of unsafe food” in susceptible individuals. With GI disturbances and reactive symptoms, individuals with food allergies may be more sensitive to foodborne illness. Teach good hand washing, food preparation and storage tips.
- Children who have allergies should wear a Medic Alert tag or bracelet.

**TABLE 2-12** Specifics of Food Allergies

<b>Egg</b>	<p>Reactions are usually mild. Flu shots may contain egg albumin. Yolks are often tolerated.</p> <p><b>ALWAYS CONTAINS IT:</b> Eggs, egg whites, dried eggs, egg solids, egg nog, albumin, cake, some candies or creamed foods, cookies, custard, doughnuts, egg rolls, some frostings, hollandaise sauce, some ice creams, lecithin, mayonnaise, meringue, some puddings, pretzels, Simplese sweetener, souffle, waffles.</p> <p><b>MAY CONTAIN IT:</b> Egg may appear as “albumin” in marshmallows, frozen dinners, and dry food mixes. Egg washes are often used on bakery goods to make them look shiny. Eggs are often used in glazes and icings.</p>
<b>Fish and shellfish</b>	<p>Avoid seafood restaurants. Abalone, clams, crab, crawfish, lobster, oysters, scallops, shrimp, cockle (sea urchin), and mussels are the shellfish that should be avoided.</p> <p><b>ALWAYS CONTAINS IT:</b> Fish, shellfish, agar, alginic acid, ammonium alginate, anchovies, calcium alginate, caviar, disodium ionsinate, potassium alginate, propylene glycol alginate sodium alginate, imitation crab or “surimi,” roe.</p> <p><b>MAY CONTAIN IT:</b> Asian sauces, Caesar salad dressing, omega-3 fatty acid capsules or oils; Chinese, Vietnamese, Japanese, Indian, Indonesian, and Thai foods; fried foods, i.e., French fries, chicken nuggets (often cooked in the same oil as fish/shellfish); steak or Worcestershire sauces.</p>
<b>Latex</b>	<p>Natural rubber latex contains more than 35 proteins that may be related to type IgE-mediated allergy (Perkin, 2000). Latex-specific IgE may be responsible. Cross-reactivity has been documented with banana, avocado, kiwi, and European chestnuts; less commonly with potatoes; tomatoes; and peaches, plums, cherries, and other pitted fruits.</p> <p>Individuals with latex allergy also tend to report food allergies, including fish and shellfish (Kim and Hussain, 1999). Children with spina bifida and atopic dermatitis are a high-risk group for latex sensitization. Increasing age, additional sensitization to ubiquitous inhaled allergens, and enhanced total serum IgE values seem to be important variables for latex sensitization and further sensitization to the latex-associated foods (Tucke et al, 1999).</p>
<b>Milk</b>	<p><b>ALWAYS CONTAINS IT:</b> Casein, caseinates, lactalbumins, lactoglobulins, lactose, nougat, rennet, milk, milk solids, nonfat or powdered milks, buttermilk, evaporated milk, condensed milk, yogurt, cream, cream cheese, sour cream, cheese, cheese sauces, cottage cheese, butter, butter fat, curds, whey, white sauces.</p> <p><b>MAY CONTAIN IT:</b> Artificial butter flavor. Caramel color or flavoring, flavorings or seasonings, puddings, custards, sauces, sherbet. It may be necessary to acquire sufficient calcium from greens and broccoli or clams, oysters, shrimp, and salmon if not allergic to fish. Calcium supplementation may also be warranted. Persons with a milk allergy can add vanilla or other flavorings to soy milk. Goat’s milk has less lactalbumin, vitamin D, and folacin than cow’s milk and supplements may be required. Some people may also be allergic to goat’s milk, so caution must be used. Avoid early introduction of cow’s milk in infancy.</p>
<b>Nuts, tree</b>	<p>Tree nuts include almonds, Brazil nuts, cashews, chestnuts, filberts, hazelnuts, hickory nuts, macadamia nuts, pecans, pine nuts, pistachios, and walnuts. Monitor food labels for nut paste, nut oil, and nut extracts. Avoid nut butters also. Read labels for ground or mixed nuts.</p>
<b>Peanut</b>	<p>Peanuts are a type of legume, but a person is more likely to be allergic to tree nuts than to beans, peas, and lentils. Avoid nut butters also; aflatoxins can cause an allergic-like reaction.</p> <p>For the food industry, new inexpensive kits are available to test for presence of peanut proteins in cookies, cereal, ice cream, and milk chocolate. Despite severity and reaction frequency to peanut and tree nut allergy, only 74% of children and 44% of adults in a large study sought evaluation for the allergy, and fewer than half who did were prescribed self-injectable epinephrine (Sicherer et al, 2003). It may be recommended that those children who outgrow their peanut allergy be encouraged to eat peanut frequently and carry epinephrine until they demonstrate true peanut tolerance (Fleischer et al, 2004).</p> <p><b>ALWAYS CONTAINS IT:</b> Peanuts, mixed nuts, peanut butter, peanut oil, peanut flour, ground or mixed nuts, artificial nuts, nougat, many types of candy or cookies, ethnic dishes made with peanut oil, some egg rolls, marzipan.</p> <p><b>MAY CONTAIN IT:</b> Peanut butter may be used to keep egg rolls from falling apart or in chili as a thickener.</p>
<b>Soybean</b>	<p>Some people are also allergic to legumes such as chickpeas, navy beans, kidney beans, black beans, pinto beans, lentils, and peanuts.</p> <p><b>ALWAYS CONTAINS IT:</b> Soybeans, soybean oil, margarines made from soybean oil, soy sauce, soy nuts, soy milk. Reading food labels will be very important.</p> <p><b>COMMON SOURCES:</b> Soy protein, textured vegetable protein, hydrolyzed plant protein, lecithin, miso, soy sauce, Worcestershire sauce, tofu, tempeh, some vegetable broths.</p>
<b>Wheat</b>	<p>Wheat-dependent, exercise-induced anaphylaxis (WDEIA) and baker’s asthma are different clinical forms of wheat allergy (Mittag et al, 2004).</p> <p><b>ALWAYS CONTAINS IT:</b> Whole-wheat or enriched flour, high-gluten flour, high-protein flour, bran, farina, bulgur, durum, wheat malt, wheat starch, modified starch, wheat germ, graham flour, wheat gluten, matzoh/matzoh meal, semolina, bread crumbs, cereal extract, dextrin, malt flavoring, modified starch.</p> <p><b>COMMON SOURCES:</b> Baby food, baked goods, baking mixes, breaded foods, processed meats, pastas, snack foods, soups, breads, cookies, cakes and other baked goods made with wheat flour; crackers, many cereals, some couscous, cracker meal, pasta, gelatinized starch, hydrolyzed vegetable protein, wheat gluten, vegetable gum, vegetable starch.</p>

- Always work with an RD to identify foods and ingredients to avoid, and develop an eating plan to ensure that each child gets all the nutrients needed to grow and develop properly.

# MÉNIÈRE'S SYNDROME (AUTOIMMUNE INNER-EAR DISEASE)

## NUTRITIONAL ACUITY RANKING: LEVEL 1

### DEFINITIONS AND BACKGROUND

Ménière's syndrome is also known as autoimmune inner-ear disease (AIED); it affects the inner ear, causing disturbed fluid flow. Patient may have a history of otitis media, smoking, or allergies. Attacks last from a few hours to several days,

but the vertigo causes disability in many patients. Ménière's disease affects about 1% of the population and presents with episodic vertigo, fluctuating hearing loss, tinnitus and aural fullness (Hamid, 2009).

Sodium restriction and diuretic treatment are early management measures (Devaiah and Ator, 2000; Minor et al, 2004).

Aggressive medical therapy can prevent disease progression and hearing loss. Treatment options are limited and usually targeted toward reducing endolymphatic hydrops (Hamid, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

Clinical/History	Lab Work	
Nausea and vomiting		Electronystagmography, or balance test (ENG)
Known allergies?		Auditory brain-stem response
BP		CT scan or MRI
Height	IgE levels	Serum Na <sup>++</sup> , K <sup>+</sup>
Weight	H & H, serum Fe	I & O
BMI	Alb	
Diet history	Electrocochleography (ECOG)	
Fluctuating hearing loss		
Tinnitus with roaring sensation		
Vertigo, blurred vision		

## INTERVENTION

### OBJECTIVES

- Correct nausea and vomiting; replace any electrolyte losses.
- Avoid or decrease edema and fluid retention, which can aggravate an attack.
- Omit any known food allergens from the diet.

### FOOD AND NUTRITION

- Low-sodium (1000–2000 mg) diet may be useful.
- Use a multivitamin–mineral supplement and foods that are nutrient dense. Calcium and vitamin D strengthen

the bones of the inner ear. Folate, vitamins B<sub>6</sub> and B<sub>12</sub> reduce high levels of tHcy, which can reduce blood flow to the cochlea. Vitamin B<sub>12</sub> also protects the nerves of the ear.

- Provide a diet that is free of known allergens, specific for the individual.
- Some people report feeling better after eliminating caffeine, aspartame, or alcohol.

### Common Drugs Used and Potential Side Effects

- Diuretics are used to reduce edema in the ear. If thiazides are used (such as furosemide, Lasix), monitor for the need for a potassium replacement. Other treatments to lower the pressure within the inner ear include antihistamines, anticholinergics, or steroids.
- Diazepam (Valium) may cause nausea, drowsiness, fatigue, and other effects. Limit caffeine.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals may be used; identify and monitor side effects. Counsel about use of herbal teas, especially regarding toxic substances.
- For *earache*: ephedra, goldenseal, forsythia, gentian, garlic, honeysuckle, and Echinacea are sometimes recommended but have not been proven as effective.
- For *tinnitus*: black cohosh, sesame, goldenseal, and spinach have been suggested; no long-term studies are on record that prove effectiveness. Ginkgo biloba has been approved for tinnitus in Europe but research has proven little effect (Karkos et al, 2007).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss how a balanced diet can affect general health status.
- Discuss sources of sodium and hidden ingredients that could aggravate the condition.
- Relaxation and biofeedback techniques may be useful for enhancing pain tolerance.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Knowledge Deficit

**Assessment:** Food diaries and frequency of intake of high sodium foods, history of previous anaphylaxis or food allergens.

**Nutrition Diagnosis:** Knowledge deficit related to high sodium foods as evidenced by chronic fluid retention in the ear.

**Intervention:** Education and counseling about high sodium foods, food labeling, recipes, and ingredients. Teach how to keep a food diary, keeping records of foods eaten and any adverse symptoms related to Ménière's.

**Monitoring and Evaluation:** Review of food diaries; reports of fewer problems related to Ménière's syndrome.

## FOODBORNE ILLNESS

## FOODBORNE ILLNESS

NUTRITIONAL ACUITY RANKING: LEVEL 1 (PREVENTIVE COUNSELING);  
LEVEL 2 (CORRECTIVE THERAPY)

## DEFINITIONS AND BACKGROUND

True foodborne illness involves GIT insults, infections, or intoxications resulting from contaminated beverages or food. Millions of cases occur annually, but only a few hundred are reported. The Centers for Disease Control and Prevention report that there are millions of cases each year in the United States alone. The most vulnerable are elderly people, pregnant women, immune-compromised people, and children. Bacterial pathogens cause the largest percentage of outbreaks; chemical agents, viruses, and parasites are often implicated. In addition, multistate outbreaks caused by contaminated produce and outbreaks caused by *Escherichia coli* O157:H7 remain a concern. See Table 2-13.

Pathogens often transmitted via food contaminated by infected food handlers are *Salmonella typhi* and other species, *Shigella*, *Staphylococcus aureus*, *Streptococcus pyogenes*, hepatitis A virus, norovirus, *Listeria*, and *E. coli* O157:H7. Personal hygiene is one of the most important steps in food safety. The Centers for Disease Control and Prevention and most health departments require that food handlers and preparers with gastroenteritis **not** work until 2 or 3 days after they feel better. Strict hand washing after using the bathroom and before handling food items is important in preventing contamination. Food handlers who were recently sick can be given different duties in the foodservice operation so that they do not have to handle food.

An outbreak occurs when two or more individuals develop the same symptoms over the same time period. Infants and children younger than age 6, people with chronic illnesses (such as HIV infection or cancer), pregnant women, and elderly individuals are most at risk. For most infections, reported incidence is highest among children aged <4 years (CDC, 2010). Table 2-14 lists the most common foodborne illnesses, their onset and duration.

Nausea, vomiting, diarrhea, abdominal cramping, vision problems, fever, chills, dizziness, and headaches may occur. Some people attribute their symptoms mistakenly to “stomach flu.” The Foodborne Diseases Active Surveillance Network

(FoodNet) of CDC’s Emerging Infections Program conducts active, population-based surveillance in the United States. The incidence of *Vibrio* infection continues to increase while there have been declines in reported incidence of infections caused by *Campylobacter*, *Listeria*, *Salmonella*, Shiga toxin-producing *Escherichia coli* (STEC) O157, *Shigella*, and *Yersinia* have been observed (CDC, 2010).

A recent legislative provision requires school food authorities participating in the National School Lunch Program (NSLP) or the School Breakfast Program (SBP) to develop a school food safety program for the preparation and service of school meals served to children, based on the hazard analysis and critical control point (HACCP) system (Food and Nutrition Services, 2009). Figure 2-11 shows the Food Safety Pyramid of how issues are handled by health departments and the Centers for Disease Control and Prevention (CDC).

ASSESSMENT, MONITORING,  
AND EVALUATION

## CLINICAL INDICATORS

Clinical/History	Nausea Abdominal cramps Blood or parasites in stools? Fever? Timing of symptoms after suspected meal	Signs of dehydration; I & O
Height Weight BMI Usual weight Weight loss/changes during illness Diet history Vomiting Diarrhea		<b>Lab Work</b> Na <sup>+</sup> , K <sup>+</sup> Chloride (Cl <sup>-</sup> ) H & H, serum Fe

## SAMPLE NUTRITION CARE PROCESS STEPS

## Foodborne Illness

**Assessment:** Food diary reveals intake of unsafe food or beverage, altered GI function (diarrhea, nausea, vomiting).

**Nutrition Diagnosis:** Intake of unsafe food related to salmonella as evidenced by onset of multiple episodes of vomiting and foodborne gastroenteritis, diarrhea, and lethargy in past several days.

**Intervention:** Education about rehydration with foods containing sodium, potassium, fluids (such as Gatorade). Counseling about food safety measures, including hand washing, avoidance of cross-contamination, safe food storage.

**Monitoring and Evaluation:** Review of food diaries; fewer problems related to foodborne illness from intake of unsafe food.

**TABLE 2-13 Tips for Educating Individuals about Food Allergies***Shopping in Food Stores*

**DELI:** Ask to have the deli slicer cleaned before preparing the order. Avoid prepared foods because they often share bins and serving utensils. Request that clean gloves to be worn.

**ICE CREAM SHOPS:** Make sure they do not share scoops for different flavors.

**PACKAGED FOODS:** Read labels to detect hidden allergens. Choose foods made in facilities that do not make other problematic products. Re-read labels often as ingredients may change; if unsure, call the manufacturer.

**SALAD BARS:** Be careful with severe allergies because food can drop from one container into another.

*Dining Out*

**AVOID FRIED FOODS,** which often share oil with other problem foods.

**INQUIRE AHEAD** if possible and consult the chef on best menu picks for safe dining.

**USE A PLEASANT BUT ASSERTIVE MANNER** in explaining the situation to wait staff. Let them know that eating even a small amount of a certain food(s) will make you severely ill.

**BE CAREFUL** of sauces and soups. Make sure you know exactly what is in them before eating.

**REGULAR PATRONAGE.** Choose a favorite eatery that accommodates well and visit often.

*At School*

**EDUCATE.** Schools need to educate their entire staff, improve prevention and avoidance measures, make sure epinephrine is readily available and that the staff knows how to administer it, and use consumer agency resources (Munoz-Furlong, 2004). The Food Allergy Network has educational kits targeted at schools to assist in the training of the staff on food allergies.

**MEDIC ALERT.** Students should be encouraged to wear a Medic-Alert bracelet.

**CAFETERIA MEALS.** Food allergy continues to rise in childhood, and careful meal planning is needed.

*At Home*

**KEEP A FOOD DIARY.** Identify all symptoms, timing, and foods eaten.

**READ FOOD LABELS** every time a food is purchased and used.

**FIND RECIPE BOOKS THAT PROVIDE ALTERNATIVES.** Recipe books are available from formula companies, food manufacturers, the Food Allergy and Anaphylaxis Network, and registered dietitians.

**PATIENT OR PARENT EDUCATION.** Patients and parents must stay informed about how to handle allergic reactions (Stone, 2004).

*At the Doctor's Office*

**TESTING.** Cytotoxic testing, sublingual provocative tests, pulse tests, kinesiologic testing, yeast hypersensitivity, and brain allergy theories should be dismissed entirely.

*After Anaphylaxis*

To work with anaphylaxis, remember the "3 Rs": **RECOGNIZE** symptoms; **REACT** quickly; **REVIEW** what happened to prevent it from happening again.

**INTERVENTION****OBJECTIVES**

- Allow the GIT to rest after rehydration; progress diet as tolerated.
- Prepare and store all foods using safe food-handling practices and good personal hygiene. Temperatures should be maintained below 40°F or above 140°F for safe food handling, storage, and holding.
- Teach the importance of hand washing, care of food contact surfaces, and insect or rodent extermination. This is especially important in foodservice operations where members of the public are fed.
- Any person operating a foodservice operation should know and use Hazard Analysis and Critical Control Point (HACCP) procedures to evaluate critical control points where foodborne illness risk is high and use precautions and safeguards (McCluskey, 2004). Careful monitoring is recommended. For the aging population in particular, barriers against the use of HACCP should be minimized (Strohbehn et al, 2004).
- Sanitize all surfaces before food preparation; sanitize after each food item is prepared when using the same surface (e.g., cutting boards and slicers). See Table 2-15 for more safe food practices.

**TABLE 2-14 Symptoms, Sources, and Pathogens That Cause Foodborne Illness**

General Source of Illness	Symptoms	Bacteria
Raw and undercooked meat and poultry	Abdominal pain and cramping, diarrhea, nausea, and vomiting	<i>Campylobacter jejuni</i> , <i>Escherichia coli</i> O157:H7, <i>Listeria monocytogenes</i> , <i>Salmonella</i>
Raw (unpasteurized) milk and dairy products, such as soft cheeses	Nausea and vomiting, fever, abdominal cramps, and diarrhea	<i>L. monocytogenes</i> , <i>Salmonella</i> , <i>Shigella</i> , <i>Staphylococcus aureus</i> , <i>C. jejuni</i>
Fresh or minimally processed produce	Diarrhea, nausea, and vomiting	<i>E. coli</i> O157:H7, <i>L. monocytogenes</i> , <i>Salmonella</i> , <i>Shigella</i> , <i>Yersinia enterocolitica</i> , viruses, and parasites

Specific Illness	Symptoms	Bacteria	Onset and Duration
Meats, milk, vegetables, and fish (diarrhea). Rice products; potato, pasta, and cheese products (vomiting) Consider also: sauces, puddings, soups, salads, casseroles, pastries	Watery diarrhea, abdominal cramping, vomiting	<i>Bacillus cereus</i> Gram-positive, aerobic spore former	6–15 hours after consumption. Duration = 24 hours
Raw and undercooked meat and poultry; raw milk and soft cheeses	Abdominal pain and cramping, diarrhea (often bloody), nausea, and vomiting. Note: 40% of Guillain-Barré syndrome (GBS) cases in the United States are caused by campylobacteriosis	<i>Campylobacter jejuni</i>	2–5 days after exposure. Duration = 2–10 days
Improperly canned goods especially with low acid content—asparagus, green beans, beets, and corn; chopped garlic in oil; chile peppers; improperly handled baked potatoes wrapped in aluminum foil; home-canned or fermented fish. Honey contains spores	Muscle paralysis caused by the bacterial toxin; double vision, inability to swallow, slurred speech and difficulty speaking, and inability to breathe Infants appear lethargic with poor muscle tone, feed poorly, are constipated, and have a weak cry	<i>Clostridium botulinum</i>	18–36 hours after eating contaminated food; can occur as early as 6 hours or as late as 10 days. Duration may be weeks or months
Canned meats, contaminated dried mixes, gravy, stews, refried beans, meat products, and unwashed vegetables	Nausea with vomiting, diarrhea, acute gastroenteritis	<i>Clostridium perfringens</i>	Within 6–24 hours from ingestion; lasting 1 day
Contaminated food from poor handling	Watery stools, diarrhea, nausea, vomiting, slight fever, and stomach cramps; especially in immunocompromised patients	<i>Cryptosporidium parvum</i> (protozoa)	2–10 days after infection
Contaminated water with human sewage may lead to contamination of foods; infected food handlers. More common with travel to other countries	Watery diarrhea, abdominal cramps, low-grade fever, nausea, and malaise. In infants or debilitated elderly persons, electrolyte replacement therapy may be necessary	<i>Escherichia coli</i> ; Enterotoxigenic <i>E. coli</i> (ETEC)	With high infective dose, diarrhea can be induced within 24 hours
Undercooked ground beef and meats; unpasteurized fruit juices such as apple cider; unwashed fruits and vegetables (lettuce, alfalfa sprouts); dry-cured salami, game meat; cheese curds. <i>E. coli</i> O157:H7 can survive in refrigerated acid foods for weeks	Hemorrhagic colitis (painful, bloody diarrhea) The condition may progress to hemolytic anemia, thrombocytopenia, and acute renal failure requiring dialysis and transfusions	<i>E. coli</i> O157:H7; Enterohemorrhagic <i>E. coli</i> (EHEC)	Onset is slow, 3–8 days after ingestion Antibiotics are not used as they can spread the infection Hemolytic uremic syndrome can be fatal, especially in young children

(continued)

**TABLE 2-14 Symptoms, Sources, and Pathogens That Cause Foodborne Illness (continued)**

Specific Illness	Symptoms	Bacteria	Onset and Duration
Processed, ready-to-eat products (undercooked hot dogs, deli or lunchmeat, unpasteurized dairy products). Postpasteurization contamination of soft cheeses, milk, or commercial coleslaw. Cross-contamination between food surfaces	Mild fever, headache, vomiting, and severe illness in pregnancy; sepsis in immunocompromised patients; febrile gastroenteritis in adults; meningococcalitis in infants. May lead to meningitis or septicemia if untreated	<i>Listeria monocytogenes</i> (LM)	Onset is 2–30 days. Can be fatal
Direct contact or droplets from contaminated hands or work surfaces (stool or vomit). Most common on cruise ships	Gastroenteritis with nausea, vomiting, diarrhea; fever with chills; abdominal cramps; headache; muscle aches. Vomiting may be frequent and quite violent, but subsides within a few days. Drink liquids to prevent dehydration	<i>Norovirus</i> Virus cannot multiply outside human body. Once on food, it can be transmitted easily to humans	24–48 hours after ingestion of the virus but may appear as early as 12 hours. Lasts only 1 or 2 days
Raw or undercooked meat, poultry, fish, unpasteurized dairy products; unwashed fruits and raw vegetables (melons and sprouts). Need thorough cooking, hygiene, and sanitation	Diarrhea, fever, and abdominal cramps. Most people recover without treatment. However, elderly, infants, and those with impaired immune systems are more likely to have a severe illness requiring hospitalization and antibiotics	<i>Salmonella typhimurium</i>	12–72 hours after infection. Duration = 4–7 days
Raw or undercooked eggs; eggs in foods such as homemade hollandaise sauce, caesar and other salad dressings, tiramisu, homemade ice cream, homemade mayonnaise, cookie dough, frostings	Nausea and vomiting, fever, abdominal cramps, and diarrhea	<i>Salmonella enteritidis</i>	12–72 hours after infection. Duration = 4–7 days
Milk and dairy products; cold mixed egg, tuna, chicken, potato, and meat salads	Bloody diarrhea, fever, and stomach cramps	<i>Shigella</i> (causes Shigellosis)	24–48 hours after exposure
Meat, pork, eggs, poultry, tuna salad, prepared salads, gravy, stuffing, cream-filled pastries	Nausea, vomiting, retching, abdominal cramping, and prostration	<i>Staphylococcus aureus</i> Cooking does not destroy the toxin. Refrigerate foods immediately after preparation and meal service	Within 1–6 hours; rarely fatal. Duration = 1–2 days
Milk, ice cream, eggs, steamed lobster, ground ham, potato salad, egg salad, custard, rice pudding, shrimp salad Foodstuffs at room temperature for several hours between preparation and consumption	Sore and red throat, pain on swallowing, tonsillitis, high fever, headache, nausea, vomiting, malaise, rash, rhinorrhea Complications are rare and are treated with antibiotics	<i>Streptococcus pyogenes</i> Entrance into the food is the result of poor hygiene, ill food handlers, or the use of unpasteurized milk	Onset = 1–3 days
Raw or undercooked shellfish, especially raw clams and oysters, contaminated with human pathogen	Vomiting, diarrhea; chills, fever, and collapse Can be fatal in immunocompromised individuals	<i>Vibrio vulnificus</i> , <i>V. parahaemolyticus</i> This bacterium is in the same family as cholera. It yields a norovirus	16 hours after eating contaminated food. Duration = 48 hours
Raw or undercooked pork products. Postpasteurization contamination of chocolate milk, reconstituted dry milk, pasteurized milk, and tofu	Fever, abdominal pain, and diarrhea (often bloody) in children In older children and adults, right-sided abdominal pain and fever may be predominant, mimicking appendicitis. Rarely, skin rash, joint pains, and sepsis may occur	<i>Yersinia enterocolitica</i> Occurs most often in young children. Cold storage does not kill the bacteria	1–2 days after exposure. Duration = 1–3 weeks or longer

Adapted from the following Web sites (accessed April 7, 2009):

**TABLE 2-15 Safe Food Handling and Food Safety Guidelines***Food Preparation*

- Clean hands, food contact surfaces, and fruits and vegetables.
- Meat and poultry should not be washed.
- Because bacteria are commonly found on foods such as cantaloupe, cilantro, and imported produce, wash all fresh fruits and vegetables. Scrub the outside of produce such as melons and cucumbers before cutting. Scallions have been linked to hepatitis A outbreak; cook them thoroughly.
- Discard cracked eggs; avoid using products from dented cans.
- Avoid food preparation when sick with viral or bacterial infections; use gloves if needed.
- Sanitize work surfaces and sponges daily with a mild bleach solution (2 teaspoons per quart of water is sufficient). However, if a work surface comes into contact with raw food, it should be sanitized after contact with each food.
- Separate raw, cooked, and ready-to-eat foods while shopping, preparing, and storing foods.
- Sanitize work surfaces after each food. Ideally, keep one board for poultry, another for meats, and another for produce to prevent cross-contamination. Discard cutting boards that are badly damaged.
- Chill (refrigerate) perishable food promptly and defrost foods properly. Thaw meats and poultry in the refrigerator, not at room temperature. If necessary, thaw in a sink with cold running water that allows continuous drainage or thaw quickly in the microwave and use immediately.
- Do not partially cook meat or poultry in advance of final preparation. Bacteria may still grow rampantly.
- Cook foods to a safe temperature to kill micro-organisms. Cook beef to proper internal temperature of 160°F, pork to 165°F, and poultry to 175°F. Cook hamburger to the proper temperature of 165°F; “pink in the middle, cooked too little.” Monitor internal temperatures with an accurate food thermometer placed correctly into the meat or poultry.
- Boil water used for drinking when necessary; hold at boiling temperature for 1 minute.
- Avoid raw or partially cooked eggs, raw or undercooked fish or shellfish, and raw or undercooked meats because of potential foodborne illnesses.
- Avoid raw (unpasteurized) milk or products made from it.
- Avoid serving unpasteurized juices and raw sprouts.

*Holding and Serving Foods*

- Hold and serve foods at 140–165°F during meal service.
- Reheat foods to at least 165°F. Discard leftovers after the first reheating process.
- Keep hot foods above 140°F and cold foods below 40°F.
- Discard cooked foods that are left at room temperature for more than 2 hours.
- Reheat home-canned foods appropriately. In institutional settings, do not allow home-cooked foods at all.
- Only serve certain deli meats and frankfurters that have been heated to steaming hot temperature.
- Keep pet foods and utensils separate from those for human use.
- Use clean plates and separate utensils between raw and cooked foods.
- Cool foods quickly in shallow pans (2–4 inches deep). Temperature should reach 70°F within 2 hours. If food has not cooled to that level, place in the freezer for a short time. Then, wrap lightly and return to refrigerator.

*Other Tips*

- When traveling, avoid tap water and ice made from tap water, uncooked produce such as lettuce, and raw or undercooked seafood.
- Airline water may not be free from contamination. Use of bottled water is recommended. Coffee and tea may not be hot enough to kill all bacteria.
- See Fight BAC guidelines at <http://www.fightbac.org>.

**FOOD AND NUTRITION**

- For patients with extreme diarrhea or vomiting, feed with intravenous glucose (NPO) until progress has been made.
- Oral rehydration therapy may be a useful adjunct treatment in the recovery process.
- Start with bland or soft foods and then progress to a normal diet.
- Prolonged inability to eat orally may require tube feeding.

**Common Drugs Used and Potential Side Effects**

- Hydrochloric acid in the stomach protects against pathogens ingested with food or water. A gastric fluid pH of 1–2 is deleterious to many microbial pathogens. Neutralization of gastric acid by antacids or the inhibition of acid secretion by various drugs can alter stomach pH and may increase the risk of acquiring food- or waterborne illnesses (Smith, 2003).
- Octreotide (Sandostatin) may be used parenterally only. It may alter fat absorption and fat-soluble vitamin absorption.

- Antibiotics such as Puromycin, erythromycin, or a fluoroquinolone may be prescribed.
- For *Salmonella*, ampicillin, gentamicin, trimethoprim/sulfamethoxazole, or ciprofloxacin may be used. New strains of this bacteria have evolved so that they are more resistant to antimicrobial treatment (Foley and Lynne, 2008).
- *V. vulnificus* infection is treated with doxycycline or cef-tazidime.

## Herbs, Botanicals, and Supplements

- Note that herbs and botanicals themselves could be a source of foodborne bacteria and thus exacerbate an existing foodborne infection. If herbs and botanicals are used, identify and monitor for potential contamination and side effects.
- Counsel about use of herbal teas, especially regarding toxic substances.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage safe methods of food handling. More males, African Americans, and adults aged between 30 and 54 years consume raw/undercooked ground beef than any other group; males, Caucasians, Hispanics, and young adults aged between 18 and 29 years often engage in poor hygienic practices (Patil et al, 2004).
- Monitor water supply for unexpected odors or color changes; report to authorities.
- Discuss ways to prevent further episodes of foodborne illness. See Table 2-15.
- Hand washing is important. Wash hands with soap before handling raw foods of animal origin, after handling raw foods of animal origin, and before touching anything else. Prevent cross-contamination in the kitchen. Proper refrigeration and sanitation are also essential.
- Avoid raw milk and cook all meats and poultry thoroughly. Drink only pasteurized milk.
- Bacteria may be found in raw vegetables and fruits. Wash before eating.
- Throw out bulging, leaking, or dented cans and jars that are leaking. Safe home canning tips can be obtained from county extension services or from the U.S. Department of Agriculture.
- Commercial mayonnaise, salad dressings, and sauces appear to be safe due to their content of acetic acid and lesser amounts of citric or lactic acids (Smittle, 2000). Thus, if items are prepared using cold dressings, they stay at proper temperatures longer.
- To prevent parasite infestation (such as *Giardia*), sewage treatment, proper hand washing, and use of bottled water is recommended (Kucik et al, 2004).
- Food handlers need more education to understand their role in food safety, especially non-English speaking staff members (DeBess et al, 2009). Correct hand washing procedures, involvement of both managers and

**TABLE 2-16 Recommended Refrigerator Food Storage**

Food	Time Period
Butter	1–3 months
Cheese, hard	6 months unopened; 3–4 weeks opened
Cheese, soft	1 week
Chicken, turkey	1–2 days
Eggs in shell	3–5 weeks
Eggs, raw	2–4 days
Fish, cooked	3–4 days
Fish, raw	1–2 days
Gravy	1–2 days
Hamburger, raw	1–2 days
Juices, chilled	3 weeks unopened, 7–10 days opened
Luncheon meat	3–5 days opened, 2 weeks in sealed package
Margarine	4–5 months
Milk	1 week
Pizza	3–4 days
Roast or steak	3–5 days (uncooked)
Sausage, raw	1–2 days
Sausage, smoked	1 week
Shellfish, fresh	1–2 days
Soups, stews	3–4 days
Yogurt	1–2 weeks

food handlers, and support from health departments are all important (Pragle et al, 2007). Errors in methods of washing hands, utensils, and preparation surfaces between food preparation tasks are common (Kendall et al, 2004).

- Three key practices are needed for safe food handling: careful hand washing, using thermometers, and proper handling of food surfaces (Pilling et al, 2008). Barriers in the workplace often include time constraints, inconvenience, inadequate training, and insufficient resources (Howells et al, 2008).
- Cancer and immunocompromised patients are especially vulnerable to foodborne illness. Risk-reducing behaviors, better food handling of routine foods, and hand washing should be encouraged (Medeiros et al, 2008).
- Young adults also need education about food safety for themselves and for their future families (Byrd-Bredbenner et al, 2007).
- Low socioeconomic status has been shown to be linked with poorer quality produce and an increased reliance on small retail stores (Koro et al, 2010).
- Biotechnology has developed food crops that are more resistant to pests and have better nutritional value as well as having longer shelf-life for food safety. Some consumers are concerned about the safety of food irradiation, genetically modified foods (GMOs), and potential allergens. Nutrition professionals should reassure the public that GM items are safe to eat.

# Pediatrics: Birth Defects and Genetic and Acquired Disorders

## BACKGROUND AND CONSIDERATIONS

Because good nutrition is essential for achieving growth and development, screening and assessment should be an integral part of health care. Efforts should be made to enhance appetite and intake in children who are not with their families; familiarity is important. Simple nutritional screening tools can help identify children at risk for malnutrition, affecting one fourth to one third of children admitted to a hospital. When there are problems with growth, proper interventions and referrals are important. A checklist of “ABCDE” factors can be used to assure completion of all assessments. Poor health habits, limited access to services, and long-term use of multiple medications are common health risk factors (American Dietetic Association, 2010). See Table 3-1 for assessments and calculations and see Table 3-2 for common pediatric problems. Nationally credentialed dietetics professionals are best able to provide appropriate nutrition information as it pertains to wellness, good health, and quality of life (American Dietetic Association, 2010). In particular, children with developmental disabilities and special health care needs frequently have growth alterations (failure to thrive (FTT), obesity, or growth retardation), metabolic disorders, poor feeding skills, medication–nutrient interactions, or dependence on enteral or parenteral nutrition (PN; American Dietetic Association, 2010). Nutrition services should be provided throughout life in a manner that is interdisciplinary, family-centered, community-based, and culturally competent (American Dietetic Association, 2010).

**TABLE 3-1 Useful Assessments in Pediatrics****Anthropometric**

Use age-, gender-, and disease-specific growth charts from the Centers for Disease Control and Prevention (CDC) with trained personnel and appropriate equipment. *Figure 1 shows how to measure the length of an infant properly.*

**Figure 1.** Measuring an infant. (From Bickley LS, Szilagyi P. *Bates' guide to physical examination and history taking*, 8th ed. Philadelphia: Lippincott Williams & Wilkins, 2003).

- Birth data (Weight, length, head circumference, size, gestational age)
  - Low birthweight  $\leq 2500$  g or 5.5 lb
  - Very low birth weight  $\leq 1500$  g or 3.5 lb
- Growth parameters: *Figure 2 provides the pediatric BMI tables*
  - Current height (ht) and weight (wt)
  - Wt/age  $< 10$ th percentile or  $> 85$ th percentile (overweight) or  $> 95$ % (obese)
  - Ht/age  $< 5$ th percentile
  - Wt/ht  $< 5$ th percentile (underweight or FTT) or  $> 85$ th percentile (overweight)
  - Head circumference  $< 5$ th percentile (under 3 years of age)
- Pubertal staging (Tanner Stages), skeletal maturity staging
- Small for gestational age—need catch up growth to normalize length and weight; may later have CKD or metabolic syndrome as adults
- Unintentional weight loss

**Behavioral—Psychosocial**

- Developmental disorders: mental retardation, learning disorders, motor skills disorder, communication disorders, or PDDs
- Growth and development milestones

**CALCULATED BODY MASS INDEX (BMI) FOR CHILDREN AND ADOLESCENTS**

**Figure 2.** Pediatric BMI tables (*continued*)*(continued)*

**TABLE 3-1 Useful Assessments in Pediatrics (continued)**

- Hunger and satiety; use of food for reward or as pacifier
- Home environment and family economics (access to food)
- Access to interdisciplinary, family-centered, community-based and culturally relevant services (American Dietetic Association, 2004)

*Clinical*

- Altered gastrointestinal function: nausea, vomiting, acute diarrhea, constipation, GERD
- Altered nutrition-related biochemical values—such as serum cholesterol. Total serum cholesterol should be <170 mg/dL in children and teens. If >170–199 mg/dL, take a second total serum cholesterol, and average the two together. If >200 mg/dL, a fasting lipid profile is needed
- Birth defects: some can be diagnosed before birth, using prenatal ultrasound, amniocentesis, and chorionic villus sampling (CVS). Ultrasound can help diagnose structural birth defects, such as spina bifida and heart

or urinary tract defects. Amniocentesis and CVS are used to diagnose chromosomal abnormalities, such as DS

- Chewing and swallowing difficulties (such as from cleft lip or palate, oral lesions)
- Chronic illnesses (cancer, cardiac disease or heart failure, diabetes, elevated lipids, FTT, hypertension, kidney disease, malabsorption, HIV/AIDS, trauma)
- Congenital or chromosomal abnormalities, inborn metabolic disorders
- Digestive and malabsorptive problems from celiac disease, lactose deficiency, or inflammatory bowel disease; sugar intolerance; foul-smelling, bulky stools indicate fat malabsorption
- Food allergies
- Inadequate intake because of depression, pain or dyspnea, poor appetite >3 days
- Increased nutrient demands, as from protein–energy malnutrition, pressure ulcers

(continued)

**TABLE 3-1 Useful Assessments in Pediatrics (continued)**

- Marked weight loss (malabsorption, IBD, hyperthyroidism, or malignancy)
- Medications with nutritional side effects:
  - Antibiotics (energy, protein, minerals; GI problems)
  - Anticonvulsants (vitamins C, K, D, and B-complex, and calcium)
  - Corticosteroids (calcium, phosphorus, glucose levels; weight gain or stunting)
  - Diuretics (potassium, magnesium, calcium, energy; GI problems)
  - Stimulants such as ritalin (energy and protein intake, growth, appetite)
  - Sulfonamides (vitamin C, protein, folate, and iron)
  - Tranquilizers (energy intake; weight gain)
- Inability to consume oral diet:
  - Pediatric tube feeding: prematurity, developmental delays, orofacial defects, CP, anorexia nervosa, cystic fibrosis, metabolic disorders, renal failure, HIV infection, or inflammatory bowel disorders
  - Pediatric TPN: biliary atresia, Hirschsprung's disease with enterocolitis, Crohn's disease, ulcerative colitis, congenital short-bowel, GI ischemia or fistulas, severe burns or trauma, and bowel transplantation. It may be possible to wean from TPN to tube or oral feeding in some conditions; for others, PN may be permanent. Children cannot tolerate fast-ing as long as adults
- Increased nutrient needs for trauma, surgery, recent hospitalizations, acute illnesses, chemotherapy or radiation

*Developmental Disabilities*

- Altered nutritional status, feeding skills, feeding behaviors including positioning
- Use specific screening tools for each physical, motor, sensory, or developmental delays. Use arm span where height is difficult to measure
- In children whose weight is hard to maintain, catch-up growth is important with a focus on protein and kilocalors
- Individualize care: design the desired outcomes, determine necessary resources, and seek regular feedback on progress or obstacles. Personal control, independence, and choice must be considered

*Eating and Feeding Skills*

- Avoidance of easily aspirated foods
- Biting, chewing or swallowing difficulty requiring texture modifications
- Coordination for safe and proper chewing, sucking, swallowing
- Feeding: length of time, feeding method, skill level, persons involved
- Food allergies, multiple or severe
- Food Intake: ability to eat and retain food
- Food preferences, dislikes, and intolerances
- Special formula or supplements, tube feeding or PN

*Genetic and Metabolic Disorders*

- Growth failure, skin rashes, developmental delays, vomiting or diarrhea and other concerns affect nutrition and health status in:
  - Amino acid metabolism: phenylketonuria (PKU); maple syrup urine disease (MSUD); glutaric acidemia type 1 (GA1); argininosuccinic acidemia (ASA); tyrosinemia (TYR); propionic acidemia (PA); isovaleric acidemia (IVA); citrullinemia type 1 (CIT)
  - Carbohydrate metabolism: galactosemia; glycogen storage disease (GSD); galactose-phosphate uridylyltransferase (GALT)
  - Fatty acid metabolism: medium chain acyl dehydrogenase deficiency (MCAD); carnitine uptake deficiency (CUD); very long-chain acyl-CoA dehydrogenase (VLCAD); abetalipoproteinemia (ABL)
- Presently, screening for 29 disorders is recommended for newborns in the United States; many states are doubling or tripling the number of tests offered (Isaacs and Zand, 2007). Newborn screening consists of testing; follow-up of abnormal screening; diagnostic testing; disease management; continuous evaluation and improvement of the system. Clues that suggest a genetic condition or an inherited susceptibility to a common disease include the following:
  - Two or more seemingly unrelated medical conditions (e.g., hearing loss and renal disease, diabetes and muscle disease)
  - A medical condition and dysmorphic features
  - Developmental delay with dysmorphic features and/or physical birth anomalies
  - Developmental delay associated with other medical conditions
  - Progressive mental retardation, loss of developmental milestones
  - Progressive behavioral problems
  - Unexplained hypotonia
  - A movement disorder
  - Unexplained seizures
  - Unexplained ataxia
  - Two or more major birth anomalies
  - Three or more minor birth anomalies
  - One major birth defect with two minor anomalies
  - A cleft palate, or cleft lip with or without cleft palate
  - Unusual birthmarks (particularly if associated with seizures, learning disabilities, or dysmorphic features)
  - Hair anomalies (hirsute, brittle, coarse, kinky, sparse or absent)
  - Congenital or juvenile deafness
  - Congenital or juvenile blindness
  - Cataracts at a young age
  - Primary amenorrhea
  - Ambiguous genitalia

(continued)

**TABLE 3-1 Useful Assessments in Pediatrics (continued)**

Proportionate short stature with dysmorphic features and/or delayed or arrested puberty	<i>A Fetus With</i>
Disproportionate short stature	A major structural anomaly
Premature ovarian failure	Significant growth retardation
Proportionate short stature and primary amenorrhea	Multiple minor anomalies
Males with hypogonadism and/or significant gynecomastia	(Gilchrist, 2002; March of Dimes, 2009)
Congenital absence of the vas deferens	
Oligozoospermia/azoospermia	

**TABLE 1A: Examples of Single Gene Disorders in Adults<sup>a</sup>**

<b>Neurology</b>	<b>Infectious disease</b>
Muscular dystrophy	Immune deficiencies
Spinocerebellar ataxia	<b>Metabolic disorders</b>
Hereditary neuropathy	Hemochromatosis
Dystonia	Lipid disorders
Early onset Alzheimer's disease	Homocysteine
Familial multiple sclerosis	<b>Gastroenterology</b>
Familial amyotrophic lateral sclerosis	Osler-Weber-Rendu disease
Neurofibromatosis	Polyposis
<b>Nephrology</b>	<b>Oncology</b>
Autosomal dominant polycystic kidney disease	<i>BRCA1/2</i>
Hereditary nephritis	Familial adenomatous polyposis and hereditary nonpolyposis colon cancer
Disorders of renal physiology	Familial prostate cancer
<b>Hematology</b>	Multiple endocrine neoplasia
Hemoglobinopathies	Hippel-Lindau disease
Hereditary disorders of hemostasis	Li-Fraumeni syndrome
Hereditary hypercoagulability	<b>Musculoskeletal disorders</b>
<b>Pulmonary disorders</b>	Inherited disorders of connective tissue—
Adult-onset cystic fibrosis	Marfan's, Ehlers-Danlos, osteogenesis imperfecta
Alpha-1-antitrypsin deficiency	<b>Dermatology</b>
<b>Cardiac disorders</b>	Ichthyosis
Conduction abnormalities	Bullous disorders
Cardiomyopathy	

Notes: Inborn metabolic disorders are usually due to defects of single genes that code for enzymes, intended to convert substrates into products.

<sup>a</sup>This is a far from complete list.

**TABLE 3-1 Useful Assessments in Pediatrics (continued)**

*Estimating Daily Energy Requirements (EER) and Total Energy Expenditure (TEE) for Infants and Children  
(Derived from Institute of Medicine, 2002; Lucas, 2004)*

Age (months)	Equation
0–3	$(89 \times \text{Wt} - 100) + 175$
4–6	$(89 \times \text{Wt} - 100) + 56$
7–12	$(89 \times \text{Wt} - 100) + 22$
13–35	$(89 \times \text{Wt} - 100) + 20$
Boys: Age (years)	Equation
3–8	$\text{EER} = 88.5 - 61.9 \times \text{age (y)} + \text{PA} \times (26.7 \times \text{Wt} + 903 \times \text{Ht}) + 20$
9–19	$\text{EER} = 88.5 - 61.9 \times \text{age (y)} + \text{PA} \times (26.7 \times \text{Wt} + 903 \times \text{Ht}) + 25$
3–19, overweight	$\text{TEE} = 114 - 50.9 \times \text{age (y)} + \text{PA} \times (19.5 \times \text{Wt} + 116.4 \times \text{Ht})$
Girls: Age (years)	Equation
3–8	$\text{EER} = 135.3 - 30.8 \times \text{age (y)} + \text{PA} \times (10.0 \times \text{Wt} + 934 \times \text{Ht}) + 20$
9–19	$\text{EER} = 135.3 - 30.8 \times \text{age (y)} + \text{PA} \times (10.0 \times \text{Wt} + 934 \times \text{Ht}) + 25$
3–19, overweight	$\text{TEE} = 389 - 41.2 \times \text{age (y)} + \text{PA} \times (15.0 \times \text{Wt} + 701 \times \text{Ht})$

*Physical Activity (PA) Coefficients for Children Aged 3–19 Years*

Activity Level	Coefficient for Boys Aged 3–19 years	Boys	Coefficient for Girls Aged 3–19 years	Girls
	Normal Wt	Overweight	Normal Wt	Overweight
Sedentary	1.0	1.0	1.0	1.00
Low active	1.13	1.12	1.16	1.18
Active	1.26	1.24	1.31	1.35
Very Active	1.42	1.45	1.56	1.60

*Acceptable Macronutrient Ranges*

Age	Range (% of energy)		
	CHO	Fat	Protein
Full-term infant	35–65	30–55	7–16
1–3 years	45–65	30–40	5–20
4–18 years	45–65	25–35	10–30

# ABETALIPOPROTEINEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

### DEFINITIONS AND BACKGROUND

Abetalipoproteinemia (ABL) is a rare, inherited disease characterized by the inability to make low-density lipoproteins (LDL), very low-density lipoproteins (VLDL), and chylomicrons or to fully absorb dietary fats through the gut. Other names for this condition are Bassen-Kornzweig syndrome, acanthocytosis, or apolipoprotein B deficiency.

Acanthocytosis refers to the altered shape of the normal erythrocyte into one with a few irregularly shaped external projections that are thorny in appearance (Rampoldi et al., 2002; Wong, 2004). Infants present with FTT and fatty and pale stools that are frothy and foul smelling. They may also have a protruding abdomen, developmental delays, slurred speech, and problems with balance and muscle coordination after age 10. Mental deterioration and scoliosis also occur.

Prognosis is related to the progression of neurological and visual problems. Severe forms lead to irreversible neurological disease before age 30 and often to blindness. Progressive ataxic neuropathy and retinopathy are related to oxidative damage resulting from deficiencies of vitamins E and A (Granot and Kohen, 2004). Therefore, vigorous nutritional supplementation is essential (Chardon et al, 2008). Other treatments such as stem-cell therapy and gene product replacement are under evaluation.

Serum apolipoprotein B levels (low or absent)	Fecal fat study: high levels with steatorrhea	Ca <sup>++</sup> , Mg <sup>++</sup> EMG or nerve conduction velocity testing (demyelination of peripheral nerves)
Albumin (Alb)	Serum retinol and vitamin E	
Total Cholesterol (TC)	Serum vitamin K; Pro-time (PT) or international normalized ratio (INR)	Hemoglobin and hematocrit (H & H)
LDL Cholesterol (may be low)	Alkaline phosphorus (for vitamin D status)	
VLDL (may be low)		
Fatty acid profile		
Triglycerides (Trig)		

## INTERVENTION

### OBJECTIVES

- Decrease rapid progression of disorder by giving large doses of fat-soluble vitamin supplements. This may help prevent deterioration of vision and degeneration of the retina (retinitis pigmentosa).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Microsomal triglyceride transfer protein (MTTP or MTP) deficiency

<b>Clinical/History</b>	Retinal degeneration, retinitis pigmentosa	Neurological changes
Height	Low vision or blindness	<b>Lab Work</b>
Weight	Developmental delay?	CBC with abnormal, thorny-shaped cells
Growth chart		
Diet/intake history		
Scoliosis		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Steatorrhea

**Assessment Data:** Food records indicating poor intake; changes in weight; cholesterol levels.

**Nutrition Diagnoses (PES):** Inadequate fat soluble vitamin intake (especially E) related to fat malabsorption in ABL as evidenced by frothy stools four to five times daily, low serum cholesterol level, low serum levels of vitamin E, and abdominal distention.

**Intervention:** Education of parents about the need for fat-soluble vitamin supplementation and for linoleic acid supplementation for condition.

**Monitoring and Evaluation:** Improved lab reports for vitamin E and cholesterol; weight improvement; fewer frothy stools and less abdominal distention.

- Avoid use of long-chain triglycerides; use medium-chain triglycerides (MCT) instead.
- Prevent nutrient deficiency symptoms and conditions, such as FTT; impaired balance; difficulty walking, and other complications. Provide linoleic acid supplementation for essential fatty acids (EFAs).

## FOOD AND NUTRITION

- The diet should contain no more than 5 oz of lean meat, fish, or poultry per day.
- Use skim milk instead of whole milk; reduce fats from other types of dairy products.
- Use MCT oil in food preparation and with gravies, sauces, and other cooked foods. Avoid excesses to prevent liver problems.
- The diet should be supplemented with fat-soluble vitamins A, D, E, and K plus linoleic acid to prevent deficiency. Water-miscible forms will be needed.

## Common Drugs Used and Potential Side Effects

- Large doses of supplemental vitamins A and E may be needed and prescribed by the physician (Chowers et al, 2001).

## Herbs, Botanicals, and Supplements

- Herbs and botanicals are not recommended for this condition because there are no clinical trials proving efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Advise that MCT products should be consumed slowly to avoid side effects such as diarrhea.

- Discuss the need for intake of linoleic acid.
- A multivitamin–mineral supplement will be recommended. Identify food sources of the fat-soluble vitamins and discuss how the disorder prevents use of these vitamins accordingly.
- For persons with low vision, teaching with food models or large pictures may be more beneficial than use of text. Audiotapes may also be developed.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# ATTENTION-DEFICIT DISORDERS

## NUTRITIONAL ACUITY RANKING: LEVEL 1

## DEFINITIONS AND BACKGROUND

Attention-deficit disorder (ADD) and attention-deficit hyperactivity disorder (ADHD) were formerly called “hyperkinesis.” Adults can have symptoms as well and may find relief from certain medications and therapies. ADD is a neurobiological condition characterized by developmentally inappropriate level of attention, concentration, activity, distractibility, and impulsivity; it is more common in males.

ADHD is the most commonly diagnosed behavioral disorder of childhood, affecting an estimated 7% of school-

aged children (Schonwald, 2005). Three types are designated: predominantly hyperactive-impulsive, predominantly inattentive, and combined hyperactive-impulsive and inattentive; most children have the combined form. The Preschool ADHD Treatment Study (PATs) provides guidance for diagnostic considerations and intervention strategies for children between the ages of 3 and 5. Most ADHD is identified by age 6. Children with ADHD with a particular version of a certain gene have thinner brain tissue in the areas of the brain associated with attention, which is usually outgrown.

Glucose is the brain's energy source. In ADD, brain regions that inhibit impulses and control attention actually use less glucose; this decreased activity in the brain leads to inattention. PET scan comparisons between the brain of a normal child and the brain of an ADHD child show a significant difference. Children should be assessed for brain injury or seizure disorders, which may cause inattention and sleep disturbances (Schubert, 2005).

Exposure to lead is neurotoxic. Lead is found in trace amounts in everything from children's costume jewelry to imported candies to soil and drinking water (Nigg et al, 2010). It attaches to sites in the brain's striatum and frontal cortex, causing genes there to turn on or remain inactive, disrupting brain activity, decreasing cognitive control and contributing to hyperactivity and lack of vigilance (Nigg et al, 2010).

Children with ADHD may have low levels of other nutrients. Iron deficiency causes abnormal dopaminergic neurotransmission and may also contribute to ADD (Konofal et al, 2004). Zinc and EFAs (EPA and DHA) may be needed along with pharmacotherapy (DiGirolamo and Ramirez-Zea, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** ADHD often runs in families. Several genes make people more susceptible: SLC6A1, SLC9A9, HES1, ADRB2, HTR1E, DDC, ADRA1 A, DBH, DRD2, BDNF, TPH2, HTR2 A, SLC6A2, PER1, CHRNA4, SNAP25, and COMT but SLC9A9 has the strongest relationship (Lasky-Su et al, 2008). While genes account for 70% of hyperactivity and inattention in children, 30% is environmental (Nigg et al, 2010).

Clinical/History	EEG	Lab Work
Height	Sleep disturbances	Glucose (Gluc)
Weight	Middle ear infections	H & H, serum Fe
Growth chart	with hearing loss	Ferritin levels
Diet/intake history	Learning disabilities	Serum lead (elevated?)
Mental retardation, other developmental delay?	Anxiety or depression	Serum zinc (low?)
Head injury?	Nocturnal enuresis	Alb
Seizures or hx of epilepsy?		Chol
		Liver function tests (LFTs)

## INTERVENTION

## OBJECTIVES

- Prevent nutrient deficiencies if diet is inadequate or with extensive documented food allergies.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Poor Food Choices

**Assessment Data:** Food records indicating poor intake; weight loss and food jags. Low H & H levels.

### Nutrition Diagnoses (PES):

NI 1.4. Inadequate energy intake related to insufficient energy intake from a diet compared to estimated needs as evidenced by weight loss and dietary intake records.

NI 55.1. Inadequate iron intake related to a disordered eating pattern as evidenced by a low Hgb of 10 g/L and low iron food choices.

**Interventions:** Food-nutrient delivery to include iron-rich foods. Educate parents about introducing new iron-rich food items, reducing distractions at mealtime, scheduling of activities to give structure, and the use of small snacks throughout the day to improve overall intake of nutrients and energy. Counseling about the importance of nutrient density in children's diets. Coordinate care with medical team to test and identify other risks, such as high serum lead or low zinc levels.

**Monitoring and Evaluation:** Improved nutrient density in food intake records. Better attention in school, fewer complaints about hyperactivity.

- Address poor intake and appetite, where present. Offer foods that are liked along with one to two new tastes to encourage expanding preferences.
- Correct zinc deficiency and iron deficiency anemia, where indicated.
- Rule out lead poisoning.
- Provide sufficient intake of omega-3 fatty acids and other micronutrients.

## FOOD AND NUTRITION

- The diet should be balanced and sufficient in energy and protein for age and sex. The MyPyramid food guidance system should be the basis for planning; see Section 2.
- Omit any food allergens that have been medically diagnosed and verified (McCann et al, 2007).
- Elimination of sugar is not required; moderation is reasonable. Small, frequent healthy snacks may be beneficial.
- EFA supplementation may be useful (Murphy et al, 2005; Schnoll et al, 2003). Include DHA and EPA in the diet from tuna, mackerel, herring, sardines, and salmon (Ramakrishnan et al, 2009). The use of fortified foods requires some long-term studies (Riediger et al, 2009).
- Offer plenty of whole grains, low-fat dairy, fruits, and vegetables in greater proportion than sugary foods to provide more micronutrients and phytochemicals.
- Discuss good food sources of zinc and iron, especially for children with a limited diet or food jags. They may not eat meats, poultry, fish, eggs, and fortified cereals in sufficient amounts.

## Common Drugs Used and Potential Side Effects

- Stimulants such as Ritalin (methylphenidate) have been used for many years. They may cause weight loss, appetite change, sleep problems or irritability. Newer, long-acting medications will alleviate some of the burden of ADD (Connor and Steingard, 2004). See Table 3-3.
- Nonstimulant Strattera (atomoxetine) is used to increase attention and the ability to focus; long-term use may cause liver damage or suicidal thoughts, so monitor carefully.
- Antiepileptic drugs phenobarbital, gabapentin, and topiramate may alter attention whereas lamotrigine and carbamazepine may have beneficial effects on attention span.
- Mood stabilizers, beta-blockers, or serotonin reuptake inhibitors be used in managing aggression or self-injury. There are many side effects, such as weight gain or loss, elevation of glucose with possible diabetes, gastrointestinal distress; monitor closely.

## Herbs, Botanicals, and Supplements

- Many parents try complementary medicine (CAM) as an alternative to stimulant medicines as the marketing for herbal remedies, elimination diets, and food supplements for ADHD has increased. There are key questions regarding safety and efficacy of these treatments in children (Sawani, 2008). Herbs and botanicals are not recommended for this condition because there are no clinical trials proving efficacy.

**TABLE 3-3 ADHD Medications Approved by U.S. Food and Drug Administration (FDA)<sup>a</sup>**

Trade Name	Generic Name	Approved Age
Adderall	Amphetamine	3 and older
Adderall XR	Amphetamine (extended release)	6 and older
Concerta	Methylphenidate (long acting)	6 and older
Daytrana	Methylphenidate patch	6 and older
Desoxyn	Methamphetamine hydrochloride	6 and older
Dexedrine	Dextroamphetamine	3 and older
Dexrostat	Dextroamphetamine	3 and older
Focalin	Dexmethylphenidate	6 and older
Focalin XR	Dexmethylphenidate (extended release)	6 and older
Metadate ER	Methylphenidate (extended release)	6 and older
Metadate CD	Methylphenidate (extended release)	6 and older
Methylin	Methylphenidate (oral solution and chewable tablets)	6 and older
Ritalin	Methylphenidate	6 and older
Ritalin SR	Methylphenidate (extended release)	6 and older
Ritalin LA	Methylphenidate (long acting)	6 and older
Strattera	Atomoxetine	6 and older
Vyvanse	Lisdexamfetamine dimesylate	6 and older

<sup>a</sup>Not all ADHD medications are approved for use in adults.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Different causes of the symptoms of ADD may include allergies, food intolerances, anxiety, depression, family problems, poor discipline, or acute illnesses. A healthy, balanced diet is important (Marcason, 2005).
- Since glucose is the brain's source of energy, a sufficient intake of carbohydrate is needed. Assure that healthy choices are made from dairy, fruit and vegetable, and bread and cereal items. Reduce intake of sugary sweets, beverages, and snacks as a commonsense approach.
- Identify and remove sources of lead in the environment, especially if serum levels are found to be high.
- EFAs are important; include adequate amounts of fats in the daily diet (Ross et al, 2007).
- Zinc intake also plays an important role (Arnold and DiSilvestro, 2005; DiGirolamo and Ramirez-Zea, 2009).
- Identify and treat nocturnal enuresis, which may be present.
- Children need clear, consistent rules and praise when rules are followed.
- Individual psychotherapy may be quite beneficial. Encourage full participation.
- Children need help to stay organized and follow directions. Use of a schedule is important; organize everyday items; use notebook organizers.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing meals and snacks. Use clean utensils and containers.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

## AUTISM SPECTRUM DISORDER

### NUTRITIONAL ACUITY RANKING: LEVEL 1-2

#### DEFINITIONS AND BACKGROUND

**Autism spectrum disorder (ASD)** begins in childhood as developmental disabilities caused by abnormalities in the brain. Generalized enlargement of gray and white matter cerebral volumes is present at 2 years of age. Increased rate of brain growth occurs in the latter part of the first year of life (Hazlett et al, 2005). The ASDs are part of a broader category of pervasive developmental disorders (PDDs), affecting over 500,000 individuals in the United States.

Autism is a neurodevelopmental condition affecting 1 in 160 children in the United States (West et al, 2009). Children with ASDs have unusual ways of learning, paying attention, or reacting to different sensations. They like to repeat certain behaviors and do not want change in their daily activities. They are hypersensitive to sensory stimuli (tastes, smells, sounds, sights) and withdraw from what is perceived as distressing or painful. People with ASDs have problems with social and communication skills. Up to 40% of persons with an ASD do not speak. Rather than conversing in a dialogue fashion, they may repeat back what has been said (echolalia).

**Autism** is considered to be genetic. Environmental factors with exposure to toxins, infections such as measles, mumps, or rubella, and diet play a role (White, 2003). Mental retardation and seizures of mild-to-moderate intensity can be present, especially in **fragile X syndrome** (found mostly in males). **Rett syndrome** occurs primarily in girls and is evident by repetitive hand movements. In **Asperger's disorder**, speech occurs at the usual time, intelligence is normal or above average, but social skills are stunted and interests are limited or obsessive.

Pica with anemia is common, such as eating paper, string, or dirt. Ritualistic eating behaviors, food limitations, messy eating habits and food jags are common; variety in texture or colors may not be accepted. Foods that could cause choking should be avoided. A quiet environment for eating is best tolerated.

High use of oral antibiotics or higher mercury exposure can aggravate oxidative stress and decrease detoxification capacity, leading to decreased plasma methionine, glutathione, cysteine, SAM, and sulfate (Adams et al, 2007; James et al, 2004). A methylation problem is likely (Deth et al, 2007). Allergies or sensitivities are also relevant. Autistic chil-

dren often have IgA deficiency, decreased natural killer (NK) cell numbers, antibodies against serotonin receptors, and a tumor necrosis factor (TNF) response to casein, gluten, and soy (Schneider, 2007; Vojdani et al, 2008). Mega doses of nutrients are not helpful.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** At least 10 genes and enzymes have been implicated (Campbell, 2006; Muhle et al, 2004; Schneider, 2007): Adenosine Deaminase; Cystathionine-B-Synthase; Catecholamine-O-Methyltransferase (COMT 472G > A); FOXP2, RAY1/ST7, IMMP2 L; GABA(A) receptor; Glutathione-S-transferase (GST M1); MET Receptor Tyrosine Kinase (MET); Methionine Synthase (MS); Methionine Synthase Reductase (MSR); MTHFR C677 T and A1298 C; Paraoxonase (PON1); Reduced folate carrier (RFC 80G > A); Reelin and RELN genes at 7q22-q33; Serotonin transporter gene (5-HTT); Transcobalamin II (TCN2 776G > C); UBE3 A genes.

Clinical/History	MRI or CT scan of the brain	Lactose breath test
Height	Pica	Thyroid studies
Weight	Endoscopy	LFTs Lipid profile
Head circumference	Sleep patterns	RAST or allergy testing
Growth chart	Lab Work	
Diet/intake history	CBC with differential	Alb
Childhood	Gluc	Chol, Trig
Asperger Syndrome Test (CAST), a parental questionnaire	H & H, Serum Fe, Ferritin	Serum lead (with pica)
	Celiac screening panel	C-reactive protein (CRP)

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Intake of Unsafe Foods

**Assessment Data:** Food records indicating intake of gluten; loss of weight; chronic rashes, infections and diarrhea; small bowel biopsy indicating celiac disease.

#### Nutrition Diagnoses (PES):

NI 5.3. Inadequate protein-energy intake related to highly restricted eating behaviors and pickiness as evidenced by parental report of insufficient intake, below 50% for age for weight, growth failure, and frequent lack of interest in food.

NB 3.1. Intake of unsafe foods related to sensitivity to gluten in autistic child as evidenced by biopsy positive for celiac disease, rashes, chronic diarrhea.

**Intervention:** Educate parents about gluten-free diet, food labeling, simple meal preparation. Counseling about use of food diaries and routines; how to include frequent nutrient-dense snacks of desired food items.

**Monitoring and Evaluation:** Improved weight records; fewer loose stools, infections and rashes.

## INTERVENTION

### OBJECTIVES

- Prevent or lessen complications of the disorder, such as feeding problems. Offer consistency in food textures and tastes to prevent sensory overload.
- Evaluate carefully and analyze which nutrients should be replaced in the diet. If the diet has been severely limited, nutritional status may be at risk.
- Correct constipation if fiber intake is low and if symptoms are present.
- Work with other therapies, such as speech therapy or occupational therapy, to determine how to best offer foods of greater texture and variety that can be consumed by the child or offered by the caregiver.
- Monitor food jags, pica, history of choking on foods, and intolerances for varied textures, and adapt meals and menu items accordingly. Goal is to eat foods from all parts of the food pyramid regardless of texture.
- Autism seems to be related to altered immunity (Ashwood et al, 2004). Frequent infections, gastro-intestinal (GI) concerns (including chronic constipation or diarrhea) thyroid problems, and allergies are common and require nutritional management. A high prevalence of non-IgE-mediated food allergies exist in young children with ASDs, with GI symptoms (Jyonouchi, 2008).
- Monitor use of the popular gluten casein-free diet, as more clinical trials are needed to confirm efficacy (Millward et al, 2008).

### FOOD AND NUTRITION

- Offer foods of texture and variety that are desired by the child. Follow a usual pattern and enhance with nutrient-

dense additives in food preparation that will not alter flavor and texture.

- If a multivitamin–mineral supplement is needed, use one that has acceptable taste to the individual.
- Gluten-casein-soy elimination diets have some success, but can also lead to nutrient deficiencies. Use under supervision of a dietitian.
- Offer extra energy if weight is low, a common finding. Assess needs according to activity levels, weight and nutritional status, and medications that are prescribed.
- Since the brain requires omega-3 fatty acids for membrane integrity and to reduce inflammation, it is beneficial to include them in the diet or to use them in supplemental form.
- Some autistic children have disaccharide deficiencies; alter diet accordingly.

## Common Drugs Used and Potential Side Effects

- Only risperidone has Food and Drug Administration approval for the pharmacologic management of autism in children (West et al, 2009).
- Atypical antipsychotic agents, selective-serotonin reuptake inhibitors, stimulants, and *N*-methyl-D-aspartate receptor antagonists may be used off-label to decrease core behaviors and associated symptoms (West et al, 2009). If clonidine, clomipramine, haloperidol, naltrexone, or desipramine is prescribed for behavioral or learning problems, monitor for GI side effects, nausea, and diarrhea. Olanzapine (Zyprexa) may cause weight gain, dry mouth, and constipation. Fluoxetine (Prozac) may cause anorexia or weight loss, GI distress, and diarrhea.
- Medications to control seizures may be needed (Tuchman, 2004).
- D-cycloserine treatment may improve social withdrawal without side effects (Posey et al, 2004).
- Folinic acid, betaine, and methylcobalamin may be needed to normalize metabolic imbalances or to treat cerebral folate deficiency (James et al, 2004; Moretti et al, 2005).

## Herbs, Botanicals, and Supplements

- Over half of children with autism are using CAM (Golnick and Ireland, 2009). Melatonin, sulfation glutathione, amino acids, chelation, probiotics, thyroid supplements, antifungals are common. In one report (Golnick and Ireland, 2009) physicians encouraged multivitamins (49%), EFAs (25%), melatonin (25%), and probiotics (19%) and discouraged withholding immunizations (76%), chelation (61%), anti-infectives (57%), delaying immunizations (55%), and secretin (43%). Evidence-based studies are needed.
- Herbs and botanicals are not recommended for these conditions because clinical trials have not proven efficacy.
- “Improved diet” techniques may include organic foods, which adds expense to the cost of meals.
- Vitamin–mineral mega doses such as vitamin B<sub>6</sub> and magnesium may have been used; discuss the implications and potential risks.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Evaluate for behaviors such as pica; discuss how this may lead to anemia.
- Assist with tips on how to handle picky eating, rigid food behaviors, and nutrient insufficiency. Discuss various ways to include nutrient-dense foods in the diet.
- Discuss the importance of maintaining a quiet environment with few interruptions or distractions.
- Keep language simple and concrete; do not offer abstract text. Pictures and simple words are more effective when working with an older child or teen.
- Artificial colors and preservatives may have a detrimental effect on behavior, especially red and yellow food dyes. Limit their use in the diet.
- Avoid allergens, where documented.
- Support various therapies, such as speech therapy, occupational therapy, use assistive technology and biomedical applications that are evidence-based.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers. Sanitize work surfaces before food preparation.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer. To avoid wasting foods, serve small portions more frequently.

# BILIARY ATRESIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

### DEFINITIONS AND BACKGROUND

Biliary atresia (neonatal hepatitis) is a serious condition, affecting one in 15,000 births. Incidence is highest in the Asian population. Unconjugated hyperbilirubinemia occurs in approximately 60% of normal-term infants and in 80% of

preterm infants; persistence beyond 2 weeks of age demands evaluation (Gubernick et al, 2000).

Complete degeneration or incomplete development of one or more of the bile duct components occurs due to arrested fetal development. CD4(1) lymphocytes and CD56(1) NK cells predominate in the liver of infants with extrahepatic biliary

atresia (Davenport et al, 2001). Lymphocyte-mediated inflammatory damage of the bile ducts plays a role (Shinkai et al, 2006), as does altered *HLA-DR* gene expression in bile ductules (Feng et al, 2004).

Biliary atresia results in persistent jaundice, enlarged spleen, liver damage, portal hypertension, clay-colored stools, dark urine, irritability, and swollen abdomen. The condition becomes evident between 2 and 6 weeks after birth. Treatment involves having a surgical procedure done, the Kasai procedure, which bypasses the ducts to connect the liver to the small intestine. It is more successful if performed early. Complications of the surgery can include liver failure, infections, and sepsis.

If a donor is available, the patient may be a candidate for a liver transplantation. This is the most common disease in childhood that requires liver transplantation. Malnutrition is a critical predictor of mortality and morbidity in children with biliary atresia. Immunosuppressive drugs are then necessary to overcome organ rejection.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** *HLA-DR* gene in bile ductules has been noted, but otherwise not likely inherited.

#### Clinical/History

Birth weight  
Height  
Growth (%)  
Diet/intake history  
Dark urine  
Steatorrhea  
Swollen abdomen; edema  
Jaundice >1 month  
Clay-colored stools

Nuclear hepatoino diacetic acid (HIDA) test

Liver scan or biopsy

#### Lab Work

Alb  
Transthyretin  
H & H  
Alk phos  
Chol  
Trig  
Transferrin

Blood urea nitrogen (BUN)  
Aspartate aminotransferase (AST)  
Alanine aminotransferase (ALT)  
Alpha-1 antitrypsin deficiency  
PT or INR  
Serum zinc  
Serum copper

## INTERVENTION

### OBJECTIVES

#### Preoperatively

- Correct malabsorption and alleviate steatorrhea from decreased bile.
- Correct malnutrition of fat-soluble vitamins and zinc. Prevent rickets, visual disturbances, peripheral neuropathy, and coagulopathies.
- Prevent hemorrhage from high blood pressure (BP) if there is portal hypertension.
- Prepare for surgery or transplantation.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Altered GI Function

**Assessment Data:** Stool and urine tests; abdominal girth; weight changes; poor intake.

**Nutrition Diagnoses (PES):** Altered GI function related to degenerating bile ducts and biliary atresia as evidenced by clay-colored stools, abdominal distention, jaundice, and dark urine.

**Intervention:** Educate parents about the needed surgery and need for protein, fat-soluble vitamins.

**Monitoring and Evaluation:** Improved weight and intake after surgery; reduced abdominal distention and normalized stools and urine color.

#### Postoperatively

- Support proper wound healing by providing all necessary nutrients (e.g., vitamin C, zinc) using appropriate and tolerated feeding method.
- Promote normal growth and development.
- Provide regular nutritional assessments to evaluate progress and improvement or decline.
- Reduce inflammation, which may continue even after surgery (Asakawa et al, 2009).

## FOOD AND NUTRITION

#### Preoperative

- Infants need 1.5–3.0 g protein/kg dry weight to avoid protein catabolism, dependent on enteral versus parenteral source. This translates to 2–2.5 g/kg for PN and 2.5–3 g/kg for enteral nutrition, 1–1.5 g/kg if encephalopathic.
- Identify products enriched with branched-chain amino acids (BCAAs).
- Small, frequent feedings may be useful.
- Use low total fat from the diet. Supplement with oil high in MCTs; add EFAs for age and body size. Pregestimil or Alimentum or other elemental formulas may be needed to decrease fiber and prevent hemorrhage anywhere along the GI tract.
- With edema, limit intake of sodium to 1–2 g/d.
- Supplement with vitamins A, D, E, and K. Intravenous or water-miscible forms can be used.
- Provide antioxidants as serum levels of minerals, such as selenium, zinc, and iron, tend to be low. Avoid use of copper in total parenteral nutrition (TPN) or supplements to prevent toxic build-up.
- Tube feed especially if recurrent or prolonged bleeding from the GI tract occurs. If nasogastric (NG) feeding is not tolerated, a percutaneous gastrostomy (PEG) tube may be used. Failing nutrition should prompt aggressive support (Utterson et al, 2005).

#### Postoperative

- Control sodium, protein, and other nutrients only if necessary based on symptoms such as edema and renal failure. Carefully monitor vitamin and mineral requirements.
- Use of antioxidants will be needed to reduce inflammatory processes (Asakawa et al, 2009).

- For needed catch-up growth, tube feeding may be beneficial. Assure that all key nutrients are included over a long-term basis.

### Common Drugs Used and Potential Side Effects

- Ursodiol (Actigall, Urso) promotes bile flow and may be used after surgery. Side effects are minimal.
- Phenobarbital and cholestyramine are often used to control hyperlipidemia and pruritus. Increase vitamin D, calcium, vitamin B<sub>12</sub> and folate intake. Constipation can result.
- Corticosteroids may be needed to stimulate independent bile flow. Long-term use can deplete stores of calcium and phosphorus; may elevate glucose, cause stunting, or cause weight gain.
- Diuretics may be used; monitor for depletion of potassium, magnesium, calcium, and folate. Anorexia can occur.
- Antibiotics such as Bactrim or Septra may be needed to manage cholangitis, common following the Kasai procedure. Anorexia, nausea, or vomiting may result. Use of acidophilus and probiotic products may alleviate loss of intestinal bacteria.
- Growth hormone (GH) may be useful to promote catch-up growth.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals are not recommended with this condition because the liver is not able to perform its usual role of detoxification.
- Probiotics may be helpful; more studies are needed.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach parents about proper feedings or supplements. Indicate which foods provide antioxidants, including vitamins C and E, selenium.

- If bile flow improves after surgery or transplantation, a regular diet may be used, although continuing use of MCT oil may be better tolerated for awhile.
- Teach that the fat-soluble vitamins A, D, E, and K can be used only when they are bound to fat. It may be important to take supplemental forms.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

## BRONCHOPULMONARY DYSPLASIA

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

Adapted from: Cagle PT, MD. *Color Atlas and Text of Pulmonary Pathology*. Philadelphia: Lippincott Williams & Wilkins, 2005.

### DEFINITIONS AND BACKGROUND

Bronchopulmonary dysplasia (BPD) is a chronic lung disease with abnormal growth of the lungs, often following the respiratory distress syndrome of prematurity. One third to one half of all infants born before the 28th week of gestation develop BPD and inflammatory regulators appear to be involved in the pathogenesis in the fetus (Cohen et al, 2007). Chronic aspiration of GI contents is common; measurement of pepsin is one marker (Farhath et al, 2008). The use of supplemental oxygen, while necessary, may also aggravate the condition (Bancalari and Claure, 2006).

Very low-birth-weight (VLBW) infants with severe respiratory disease need extra nutrients for epithelial cell repair and to support catch-up growth. VLBW infants should be given adequate nutritional attention (e.g., parenteral or enteral nutrition, fluid restriction) from the first day of life to enhance growth and minimize respiratory morbidity (Biniwale and Ehrenkranz, 2006). Respiratory failure, supplemental oxygen use, mechanical ventilation, endotracheal intubation, and congenital heart disease all affect nutritional status (D'Angio and Maniscalco, 2004). Slow growth occurs and feeding problems are common. Long-term chronic care is required.

Infants with BPD benefit from comprehensive nutrition and feeding therapy with adequate energy, parental support and education, and feeding evaluation (Biniwale and Ehrenkranz, 2006). Between 10% and 25% of preterm infants with BPD have malnutrition after 2 years of age, and 30–60% of them will continue to suffer from persistent airway obstruction or asthma (Bott et al, 2004).

Glutamine is the main source for lung energy; inositol is necessary for surfactant synthesis; vitamin E and selenium have antioxidant effects (Bott et al, 2004). Vitamin A provides benefit in these patients (Biniwale and Ehrenkranz, 2006; Spears et al, 2004). Long-chain polyunsaturated fatty acids and surfactant replacement therapy are sometimes used to prevent BPD in susceptible infants (D'Angio and Maniscalco, 2004), but controlled trials are needed to verify efficacy (Biniwale and Ehrenkranz, 2006).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Gene expression of the newborn umbilical cord implicates chromatin remodeling pathways in premature infants with BPD (Cohen et al, 2007).

### Clinical/History

Gestational age	Emesis	Alkaline
Length	Stool pattern	phosphatase
Body mass index (BMI)	Urinary output	(alk phos)
LBW or VLBW	BP	White blood cell
growth charts	Pulmonary	(WBC) count
for height	hypertension	Gluc
and weight		Oxygen saturation levels
Size for	<b>Lab Work</b>	Partial pressure of carbon dioxide (pCO <sub>2</sub> )
gestational age (use intrauterine growth chart if available)	H & H	Partial pressure of oxygen (pO <sub>2</sub> )
Head circumference	Pepsin levels	Ca <sup>++</sup> , Mg <sup>++</sup>
Diet/intake history	pH	Urine-specific gravity
	Chol, Trig	
	K <sup>+</sup> and Cl <sup>-</sup>	
	(tend to be low)	
	Na <sup>+</sup>	
	Alb	

## SAMPLE NUTRITION CARE PROCESS STEPS

### Overfeeding

**Assessment Data:** Weight and growth charts, presence of Gastroesophageal reflux disease (GERD) or vomiting, low serum potassium and chloride.

**Nutrition Diagnoses (PES):** Excessive oral intake of formula in VLBW infant related to respiratory distress and BPD as evidenced by vomiting after most feedings and GERD.

**Intervention:** Educate parents about need for appropriate amounts of formula, feeding tips for discharge to home, appropriate rate of growth and weight change.

**Monitoring and Evaluation:** Weight records, decreased vomiting and episodes of GERD, normalized labs for K<sup>+</sup> and Cl<sup>-</sup> and other labs.

## INTERVENTION

### OBJECTIVES

- Increase energy intake to improve growth and respiratory functioning by correcting nutritional deficits (Lai et al, 2006).
- Correct gastroesophageal reflux. Position an infant carefully if formula fed.
- Avoid parenteral overfeeding, which may lead to PN-associated cholestasis (Robinson and Ehrenkranz, 2008).
- Achieve desirable growth. Infants with BPD tend to have delayed development (Bott et al, 2004). Energy needs are approximately 25–50% above normal. Correct malnutrition and anorexia from respiratory distress and ventilator support.
- Provide optimal protein for linear growth, development, and resistance to infection. Improve lean body mass if depleted.
- Spare protein by providing extra energy from fat and carbohydrate. However, excesses of carbohydrate can increase CO<sub>2</sub> production and prevent extubation; calculate needs carefully.
- Replace lost electrolytes, especially chloride, which may lead to death if uncorrected.
- Prevent EFA deficiency.
- Prevent complications, such as aspiration pneumonia or choking during feeding.
- Fluid restriction may be needed if fluid retention is noted; monitor closely.
- Prevent metabolic bone disease by including sufficient calcium and vitamin D intake.

### FOOD AND NUTRITION

- Energy requirements will be 25% above normal; provide 120–160 kcal/kg to achieve optimal weight.
- Within the first few days of life, TPN or tube feeding may be required. Initially: 70 (PN) or 95 (enteral) kcal/kg, increasing gradually to 130–180 kcal/kg after acuity subsides.

- Protein requirements may be slightly higher than usual. Careful formula management is needed; Trophamine is beneficial (Blau et al, 2007). Initially, use 2.0 g protein/kg, increasing to 2.5–3.5 g/kg.
- Decrease total carbohydrate (CHO) intake if glucose intolerance develops; monitor blood glucose levels.
- Provide at least the normal recommended allowances for antioxidant and other important nutrients. Include vitamins A, D, and E (use water-miscible sources if necessary); provide adequate calcium, phosphorus, and iron if needed. Nutrient or energy-enriched infant formulas may be needed for catch-up growth.
- Fluid intake (may be restricted to <150 cc/kg/d) and sodium levels may need to be restricted if there is pulmonary edema or hypertension.
- With decreased suck and swallowing ability, tube feeding may be better tolerated. Infants can tolerate most formulas. Nocturnal tube feeding may be useful, especially with growth failures. With gastroesophageal reflux (GERD) a gastrostomy feeding tube may be appropriate.
- Increase fat:CHO ratio with respiratory distress. To meet EFA needs, start with 0.5–1 g/kg and progress to 3 g/kg.
- Omega-3 fatty acids, selenium, inositol, vitamins A and E have been suggested for use with infants who have chronic pulmonary insufficiency (Biniwale and Ehrenkranz, 2006; Bott et al, 2004).
- When ready to progress to an oral diet, use of solids may be better tolerated than liquids. If necessary, thicken liquids or formula (e.g., with baby cereal or other thickeners). Use a supine position to avoid aspiration.

### Common Drugs Used and Potential Side Effects

- Exogenous steroid therapy (dexamethasone or methylprednisone) is only used for pulmonary compliance in ventilated premature infants (Grier and Halliday, 2005). This may compromise vitamin A status and restrict bone growth. Sodium retention, anorexia, edema, hypertension, and potassium losses are side effects. Take with food to decrease GI effects. Use more protein and less sodium; enhance potassium if needed.
- Antibiotics are needed during infections; acidophilus and probiotic products may alleviate losses of intestinal bacteria.
- Bronchodilators or caffeine may be used for apnea of prematurity. Anorexia can occur.
- Diuretics may be needed to lessen pulmonary edema. Monitor those that deplete serum potassium, such as furosemide (Lasix). Magnesium, calcium, and folate may be also depleted; appetite may decline.
- Cysteine, N-acetyl cysteine, or cystine may be used in combination with chloride.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for BPD because the lungs are not able to perform their role in oxygenation of cells.
- Use of acidophilus and probiotic products may be useful with chronic antibiotic therapy.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Diet must be re-evaluated periodically to reflect growth and disease process. Assure adequacy of vitamins and related nutrients for lung health (for example, vitamin A).
- Ensure that all foods and beverages are nutrient dense.
- New foods may be introduced gradually; thicken as needed to avoid aspiration.
- Fluid intake should be adequate to meet needs but not excessive.
- Discuss signs of overhydration and dehydration with the parent/caregiver.
- Oral–motor skills may be delayed from long-term ventilator use; discuss how to make adjustments with caregiver.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# CARBOHYDRATE METABOLIC DISORDERS

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### Condition affecting members of a family

### DEFINITIONS AND BACKGROUND

Abnormalities of glucose metabolism are the most common errors of carbohydrate metabolism; causes include both environmental and genetic factors and generally lead to one of the forms of diabetes (see chapter 9). Glucose is transported across cell membranes by active sodium-facilitated transport in the intestinal or renal cells; in all other cells, the GLUT family of glucose transporters are needed (Brown, 2000). Diagnosis of “carbohydrate malabsorption” occurs during infancy or childhood, with hypoglycemia, hepatomegaly, poor physical growth, and deranged biochemical profiles.

**Congenital glucose–galactose malabsorption** (congenital renal glycosuria) is an extremely rare, autosomal recessive trait. Watery, profuse diarrhea occurs from deficiency in the sodium-coupled cotransport of glucose and galactose in the intestinal mucosa. There is no cure, but removal of lactose, sucrose, and glucose lessens symptoms. **Glucose transporter type 1 (Glut1) deficiency syndrome** produces a seizure disorder with low glucose in the cerebrospinal fluid, developmental delay, and acquired microcephaly (Wang et al, 2004). **Glut2 deficiency** produces Fanconi–Bickel syn-

drome, which resembles type I glycogen storage disease (GSD; Brown, 2000).

**Fructose intolerance** results from a defect in the enzyme converting fructose to glucose (1-phosphofructaldolase). It is an autosomal recessive disease, as common as 1 in 20,000 persons in some European countries. Fructose intolerance causes GI discomfort, nausea, malaise, and growth failure. Ingesting fructose causes profound hypoglycemia; if left untreated, progressive liver disease results.

**Galactosemia** (galactose-1-phosphate uridylyltransferase deficiency or GALT deficiency) causes cataracts, hepatomegaly, and mental retardation. It occurs in one of 60,000 births. People with galactosemia are unable to fully metabolize the simple sugar galactose. The enzyme galactokinase may play a role (Holden et al, 2004). High levels of the sugar alcohol, galactitol, may be present. FTT, vomiting or diarrhea, jaundice, liver disease occur after milk ingestion. Bone density may decline over time (Panis et al, 2004). Cataracts, encephalopathy, or death from *E. coli* sepsis may occur (Berry, 2008). In females, serum FSH levels may be elevated and primary ovarian insufficiency (POI) may prevent successful pregnancy (Berry, 2008).

**GSDs** are rare genetic disorders in which glycogen cannot be metabolized to glucose in the liver because of enzyme deficits. Glycogen is the storage form of glucose and is found in the liver and muscles; a small amount is also found in the kidney and intestine. In severe cases of GSD, liver transplantation may be needed. Table 3-4 lists the various types of GSD.

**Sucrose intolerance** occurs rarely as a genetic defect or temporarily after GI flu or irritable bowel distress. Sucrase and maltase deficiency may occur simultaneously, with an osmotic diarrhea.

**Lactose intolerance** is discussed in chapter 7; the autosomal recessive trait deficit is encoded by the lactase gene on chromosome 2 with a frequency of 5% to 90% in humans.

**TABLE 3-4 Signs of Cerebral Palsy**

Struggles with fine motor skills: handling scissors, using crayons, buttoning a shirt, and any other movement that uses fingers and hands.
Struggles with gross motor skills: walking, riding a tricycle, kicking a ball, and other movements using legs and arms.
Trouble sitting upright; it takes a lot of muscle tone to sit up without toppling over.
Shakes a lot or has uncontrollable jerking of her legs, arms, or torso.
Muscles are weak.
Body tremors, drooling, weakened muscles in his face; may lose control of his tongue.
Trouble moving from one position to another.
Trouble sucking.

Source: <http://www.cerebralpalsy.org/what-is-cerebral-palsy/symptoms/>.

## The Pentose Pathway and Glutathione Production

GSH & GSSG: glutathione

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The congenital defects relate to aberrant transporter genes: glucose-galactose malabsorption syndrome, *SGLT1*; glucose transporter 1 deficiency syndrome, *GLUT1*; Fanconi-Bickel syndrome, *GLUT2*; fructose intolerance, *fructose-1-phosphate aldolase*. The GSDs have deficiency in various types of microsomal *glucose-6-phosphatase (G6Pase)* activity.

<b>Clinical/History</b>	Edema	Trig, Chol
Height or length	Demyelinating neuropathy?	(elevated in Von Gierke's disease)
Weight		
BMI		
Growth (%)		
Diet/intake history		
Infections		
Nausea and vomiting		
Jaundice		
Infantile seizures		
Acquired microcephaly		
Development delay or FTT?		
	<b>Lab Work</b>	
	Gluc (decreased in fructosemia)	LFTs: ALT, AST, CK
	HgbA1 c (decreased erythrocyte glucose uptake)	Urinary and serum galactose or fructose
		Acetone Serum
		phosphate
		Serum lactate
		Serum ammonia
		Serum bilirubin
		Uric acid
		Alb

### INTERVENTION

### OBJECTIVES

- Eliminate the offending macronutrient that cannot be digested; adjust the other macronutrients to promote growth and health maintenance. Prevent hypoglycemia, where indicated.
- Read labels carefully.
- Fructose intolerance requires omission of fructose from the diet.
- For galactosemia, correct the diet to prevent physical and mental retardation, cataracts, portal hypertension, and cirrhosis. Vitamin E seems to have positive, protective effects. Read labels carefully; galactose is not always reported. Consider infant formulas containing glucose, without lactose and maltose; lactose-restricted diet products;

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal GI Function

**Assessment Data:** Weight and growth charts, nausea and vomiting, elevated LFTs, and frequent episodes of hypoglycemia.

**Nutrition Diagnoses (PES):** Abnormal GI function related to metabolic disorder and GSD as evidenced by nausea and vomiting.

**Intervention:** Educate parents about frequency and timing for meals and snacks, enhancing energy intake through six to eight small meals daily plus nightly gastrostomy feeding of a complete nutritional supplement with cornstarch, DHA, and special oil.

**Monitoring and Evaluation:** Weight records, growth, tolerance for various food consistencies, less nausea and vomiting.

rice-based milk substitutes; lactose-free products that contain glucose.

- For (Glut1) deficiency syndrome, a higher fat intake is useful. The ketogenic or a modified Atkins diet should be introduced early and continue into adolescence (Ito et al, 2008; Klepper, 2008).
- For the GSDs, maintain glucose homeostasis, prevent hypoglycemia, promote positive nitrogen balance and growth, and correct or prevent fatty liver. Prevent EFA deficiency (Abdel-Ghaffar et al, 2003). Consider carbohydrate-modified products such as cornstarch (as a low-release glucose source).
- Sucrose/maltose intolerance requires omission of sucrose and maltose from the diet.

## FOOD AND NUTRITION

### *Congenital Glucose–Galactose Malabsorption*

- Use a diet free from sucrose, lactose, and glucose. Add fructose to a CHO-free formula incrementally as tolerated.
- Fructose may be used for older children; the other CHO sources should be avoided.

### *Fructosemia*

- Diet must exclude fructose, sucrose, sorbitol, invert sugar, maple syrup, honey, and molasses.
- Read labels carefully. Tube feedings or intravenous solutions may contain sources of fructose.

### *Galactosemia*

- Use a lactose and galactose-free diet—no milk, milk products, soybeans, peaches, lentils, liver, brains, or breads or cereals containing milk or cream cheese. Omit fresh blueberries and honeydew melon; fresh cherries, citrus, mango, red plums, and strawberries are allowed (Stepnick-Gropper et al, 2000).
- For infants, try Isomil or ProSobee, Elecare, Nutramigen, or formulas containing casein hydrolysate.
- Supplement with calcium, vitamin D, vitamin E, and riboflavin. In some disorders, galactose can often be reintroduced later in life.
- Read labels carefully; galactose is not reported on labels. Formulas labeled “low lactose” are *not* good substitutes; they contain lactose in amounts that can seriously harm patients with galactosemia.
- Be careful when using tube feedings or intravenous solutions; they may contain lactose.

### *Glycogen Storage Disorders*

- Increase protein intake to improve muscle strength (Bembi et al, 2003).
- Use small, frequent feedings and, if steroids are used in treatment, a low-sodium diet. Long-term use of steroids can deplete stores of calcium and phosphorus and may elevate glucose, cause stunting, or cause weight gain.
- Avoid lactose and sucrose. Read all product labels.
- Glucose may be used. Concentrated sweets may be restricted unless made with pure glucose syrup.
- Cornstarch is used to prevent hypoglycemia.
- Sometimes, night feedings with additional daytime meals work effectively. Giving 4 tbsp cornstarch in 5 oz of fluid

and 3 oz of juice, carnitine, DHA via gastrostomy (24 mL/h) at night may help the liver to maintain a normal blood glucose level (Isaacs and Zand, 2007).

- A multivitamin–mineral supplement with vitamin C, iron, and calcium may be needed because fruits and milk are limited. As necessary, replete nutrients such as vitamin B<sub>12</sub>, folate, calcium, and iron.

### *Sucrose/Maltose Intolerance*

- Omit sucrose and maltose from the diet.
- For the nongenetic form, gradually add these sugars back into the diet.
- Tube feedings or intravenous solutions may contain sources of sucrose or maltose; read labels.

## Common Drugs Used and Potential Side Effects

- For persons with galactosemia, eliminate drugs containing lactose; supplement with calcium and riboflavin.
- Sucrose and maltose are added to many drugs; check carefully.
- All vitamin–mineral supplements must be free of the nontolerated carbohydrates.
- If liver transplantation is needed, support the immunosuppression with appropriate nutrition interventions. Changes in fluid or sodium or other nutrients may be required.
- In Pompe disease, Myozyme (alglucosidase alfa) may be prescribed.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for these conditions because there are no controlled trials to prove efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain which sources of carbohydrate are allowed specific to the disorder.
- Read labels carefully. Many foods contain milk solids, galactose (e.g., luncheon meats, hot dogs), and other sugars; omit according to the disorder. Contact formula companies regarding product updates.

### *Patient Education—Food Safety*

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# CEREBRAL PALSY

**NUTRITIONAL ACUITY RANKING: LEVEL 3**

Adapted from: Weber J RN, EdD and Kelley J RN, PhD. *Health Assessment in Nursing*, 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

**DEFINITIONS AND BACKGROUND**

Cerebral palsy (CP) results from brain damage to motor centers before, during, or after birth. Human epidemiological data suggest a relationship between CP and cytokines or inflammation (Gaudet and Smith, 2001). One of 500 live births may be affected. Each year, 1200 to 1500 preschool-age

children in the United States are identified as having CP, which causes physical and mental disabilities that are nonprogressive.

Infants may present with early abnormal rolling, stiffness, irritability, and developmental delays (see Table 3-5). Seizures, mental retardation, hyperactive gag reflex, tongue thrust, poor lip closure, inability to chew properly, behavioral problems, visual or auditory problems may occur. Symptoms may be mild or severe, and vary from one person to the next. Skeletal maturation is frequently delayed.

**Spastic** (uncontrolled shaking or difficult, stiff movement) affects about 75%, **athetoid** (involuntary worm-like movement) affects 15%, **ataxic** (impaired coordination and balance) affects about 10%, and many individuals have a **mixed** form of CP. In many individuals, wasting of voluntary muscles contributes to reduced resting energy needs (Hogan, 2004). The potential for malnutrition exists, wherein indirect calorimetry is useful to assure adequacy of intake (Hogan, 2004).

**ASSESSMENT, MONITORING, AND EVALUATION****CLINICAL INDICATORS**

**Genetic Markers:** The condition is not genetic in origin.

Clinical/History	Low 5-minute Apgar score (below 7)	Height or length Weight and growth chart (%)
Low birth weight (LBW)		

Shaking, worm-like, or stiff movements	Self-feeding problems	Serum $\text{Ca}^{++}$ , $\text{Mg}^{++}$
Impaired balance and coordination	Seizures	Transferrin
Skull x-ray	GERD	Alk phos
Chewing problems	Constipation	H & H, serum Fe, ferritin
Diet/intake history	<b>Lab Work</b>	
	Gluc	
	Alb	

## INTERVENTION

### OBJECTIVES

- Alleviate malnutrition resulting from the patient's inability to close lips, suck, bite, chew, or swallow.
- Promote independence through use of adaptive feeding devices. Eye-hand coordination is often lacking, and grasp may not be strong.
- Assess appropriate energy and nutrient needs. When adequately nourished, children and adolescents with CP appear more tranquil and require decreased feeding time (Hogan, 2004). Promote mealtimes in a quiet, unhurried environment.

**TABLE 3-5 Medications for Congenital Heart Disease**

Generic Name	Brand Name	Concerns
Acebutol	Sectral	GI distress or nausea
Atenolol	Tenormin	GI distress or nausea
Azathioprine	Imuran	
Baby aspirin	Bayer	
Captopril	Capoten	GI distress or nausea
Cisapride	Propulsid	
Digoxin	Lanoxin	
Enalapril	Vasotec	
Furosemide	Lasix	GI distress or nausea; potassium, magnesium, calcium, and folate may be depleted
Hydrochlorothiazide	Hydrodiuril	GI distress or nausea; potassium, magnesium, calcium, and folate may be depleted
Lisinopril	Zestril	
Metoprolol	Lopressor	
Prednisone	Deltasone	Depletes calcium and phosphorus; may elevate glucose, cause stunting, or cause weight gain.
Propranolol	Inderal	
Spironolactone	Aldactone	
Warfarin	Coumadin	Need steady intake of vitamin K; no big fluctuations

## SAMPLE NUTRITION CARE PROCESS STEPS

### Difficulty with Feeding Self and Soy Allergy

**Assessment Data:** Weight and growth charts, medical history of aspiration, difficulty consuming adequate intake orally or by tube, soy allergy.

**Nutrition Diagnosis (PES):** NB 2.6. Self-feeding difficulty related to inability to bite properly and use utensils in CP as evidenced by weight loss of 4 lb in 6 months, current BMI of 13, ht and wt percentiles both <5%, history of aspiration when tube fed, allergy to soy.

#### Interventions:

Food and Nutrient Delivery

ND 1.2. Increase caloric intake through bolus feeding.

ND 1.3. Provide high-calorie, high protein formula free of soy.

Nutrition Education.

E 1.1. Discuss importance of nutrition and foods child is able to tolerate.

Counseling

C 2. RD to counsel mother and home nurse on importance of enhancing high calorie foods as necessary to prevent weight and muscle loss.

Care Management

RC 1.3. RD to collaborate with MD and home nurse for highest quality of care for patient, RD to collaborate with formula company to find high calorie high protein formula that is soy-free.

**Monitoring and Evaluation:** Weight records, improved intake of sufficient energy and protein to rebuild muscle mass and improve in growth percentiles; improved BMI for age.

- Correct nutritional deficits, altered growth rate, developmental delays, or retardation.
- Prevent or correct constipation, aspiration pneumonia, gastroesophageal reflux, pressure ulcers.

## FOOD AND NUTRITION

- Energy requirements of children and adolescents will vary depending on functional capacity, degree of mobility, severity of disease, and level of altered metabolism (Hogan, 2004). Reduce energy intake for spastic patients or those with severely limited activity, 11 kcal/cm for ages 5–11. For moderately active patients, use 14 kcal/cm for ages 5–11. Increase energy intake (up to 45 kcal/kg) to accommodate for added movements of the athetoid patient over age 18.
- Breast milk is recommended for infants with CP (Vohr et al, 2006).
- Feeding gastrostomy tubes are a reasonable alternative for severe feeding and swallowing problems and poor weight gain (Rogers, 2004; Sullivan et al, 2004). Night feedings may allow more normal daytime routines. Daytime bolus feedings of high-calorie, high-protein formulas at scheduled times may also be needed to provide adequate nutrition in some cases.

- For chewing problems, eliminate coarse, stringy foods. Puree foods as needed.
- With frequent vomiting, assess actual intake; anti-emetic medications may be needed.
- For constant dribbling, add cereal or yogurt to fluids. Replace fluids, thickened if needed.
- For constipation, use laxative or high-fiber foods such as bran in the diet. Provide extra fluids. In younger children, too much fiber can displace intake of adequate nutrition.
- Supplement with a general multivitamin–mineral supplement, especially for B-complex vitamins, calcium, and vitamin D (Henderson et al, 2005).
- For pressure ulcers or skin breakdown from minimal positioning of the body, ensure adequate protein, vitamins C and A, and zinc. Work with caregivers to turn and reposition every 2 hours.

### Common Drugs Used and Potential Side Effects

- Dantrolene (Dantrium) inhibits the release of calcium in muscle and skeletal tissue, preventing muscle cramping and spasms. Diarrhea, changes in BP, weight loss, and constipation may all occur.
- Klonopin (clonazepam) is a benzodiazepine used to slow down the central nervous system (CNS) for treatment of spasticity. Side effects may include constipation or diarrhea, dizziness, drowsiness, clumsiness, unsteadiness, a “hangover” effect, headache, nausea, and vomiting.
- Antibiotics such as baclofen may cause or aggravate diarrhea. Use of acidophilus and probiotic products may alleviate loss of intestinal bacteria.
- Laxatives may often be needed; monitor fiber and fluid needs. Milk of magnesia can be used safely in a pediatric dosage. Avoid using laxatives containing mineral oil.
- Anticonvulsants may increase risk of osteomalacia. Nutrient deficiencies are common: vitamins D, B<sub>6</sub>, B<sub>12</sub>, and K, folate, calcium, and biotin are often insufficient and should be replaced.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used; there are no controlled trials to prove efficacy.
- Probiotics may be used to alleviate loss of intestinal bacteria. Encourage natural sources such as yogurt or acidophilus milk, if tolerated.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Remind older patients to keep lips closed to avoid losing food from their mouths as they try to chew.
- Fortify the diet with dry or evaporated milk, wheat germ, and other nutrient enhancers when intake is inadequate.

- Allow extra time for feedings. Use of adaptive feeding equipment may be beneficial. Provide special training as needed for a specific feeding procedure (e.g., a premie nipple for poor suck).
- Help parent or caretaker with problems related to dental caries, drugs, constipation, pica, or weight.
- Exercise can be beneficial, such as recreational sports, yoga, and hippotherapy.
- Tube feeding may be needed. Ensure proper positioning to avoid aspiration or GERD.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# CLEFT LIP AND PALATE (OROFACIAL CLEFTS)

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Rubin E MD and Farber JL MD. *Pathology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 1999.

### DEFINITIONS AND BACKGROUND

Cleft lip and palate are congenital malformations occurring during the embryonic period of development. They result in a fissure in the lip and roof of the mouth, which may be unilateral or bilateral. Incidence is approximately one in 700 births in Caucasians, or about 5000 births annually in the United States. Infants with cleft palate are often smaller in size and weight than other infants.

Periconceptional folate and folic acid intake prevents orofacial clefts (OFC; Krapels et al, 2004). Other nutrients also play a role, and many mothers who eat poorly risk having a baby with OFC. Sufficient preconceptual intake of macronutrients and key micronutrients may decrease OFC risk (Krapels et al, 2006; Mitchell et al, 2003). There is also a risk from inadequate zinc intake (Tamura et al, 2005).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Interferon regulatory factor 6 (IRF6) gene may be related.

#### Clinical/History

Length (height)  
Growth (%)  
Weight  
Weight changes  
Diet/intake history  
Head circumference

Cleft type (unilateral or bilateral; complete or incomplete)  
Otitis media (OM) or other infections

Chewing difficulty

#### Lab Work

Gluc  
Alb  
H & H  
Serum Ca<sup>++</sup>,  
Mg<sup>++</sup>

## INTERVENTION

### OBJECTIVES

- Cleft palate is more of a problem than cleft lip. Compensate for the patient's inability to suck because of the air space between the mouth and nose.
- Prevent choking, air swallowing, coughing, and fatigue as much as possible.
- Encourage breastfeeding where possible to protect against OM (Aniansson et al, 2002).
- Supply the child with energy to heal and to grow; offer tips for meal planning and resources because feeding will be a challenge (Redford-Badwal et al, 2003).
- For surgery, allow extra energy and protein for healing; use a multivitamin supplement. Before surgery, a custom retainer device may be placed in the mouth and is intended to gradually pull the edges of the cleft closer to achieve better lip repair. The device also aids in the feeding process.

### FOOD AND NUTRITION

- Provide a normal diet in accordance with the patient's age and dietary recommendations. Monitor diet carefully

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inability to Bite or Chew

**Assessment Data:** Weight and growth charts, difficulty chewing and biting into foods.

**Nutrition Diagnoses (PES):** NC 1.2. Biting/chewing difficulty related to craniofacial malformations as evidenced by prolonged feeding time and decreased intake.

**Intervention:** Educate parents about texture changes, timing for meals, enhancing energy intake through high calorie foods and supplements, oral health and hygiene.

**Monitoring and Evaluation:** Weight records, growth, tolerance for various food consistencies.

because mother may have had a poor diet during pre-conceptual period and pregnancy.

- For infant feeding, use a medicine dropper or plastic bottle with a soft nipple and enlarged hole. The use of a squeezable, collapsible bottle with a longer nipple and a large crosscut opening, which allows parents to control the flow of milk, can help. Release formula or milk a little at a time, in coordination with the infant's chewing movements. Burp infant frequently to release swallowed air. Feed the infant in an upright position to prevent aspiration.
- When the infant is 4–6 months of age, begin to add solids in the diet. Pureed baby foods can be used, or the infant can be spoon fed with milk used to dilute the baby foods. Feed solids from a spoon and avoid use of a bottle or commercial syringe feeder, unless prescribed for unique circumstances.
- Avoid fruit peelings, nuts, peanut butter, leafy vegetables, heavy cream dishes, popcorn, grapes, biscuits, cookies, and chewing gum as they may get lodged in the palate. Avoid spicy, acidic foods if they cause irritation.

### Common Drugs Used and Potential Side Effects

- No specific medicines are used for cleft lip and palate; surgery is the primary treatment. After surgery, there may be a need for antibiotics if infection sets in.
- Women who are taking valproate, lithium, carbamazepine and other bipolar disorder medicines should discontinue use during pregnancy to reduce risk for cleft lip or palate.
- If genetic testing indicates an MTHFR allele, L-methylfolate (such as in Deplin) may be prescribed.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals are not required for cleft lip or palate.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain how to feed the infant with a special nipple as needed.
- Solids may be started at 4–6 months. Using thickened baby food or pureed items as tolerated.
- Supplement the diet with vitamin C if citrus juices are not taken well.
- Have the parents use only small amounts of liquid when they are feeding an infant. To prevent choking, slow swallowing should be encouraged and proper positioning should be taught.
- Discuss the impact of surgery and how to promote effective healing by using a nutrient-dense diet with

adequate amounts of protein, energy, vitamins A and C, and zinc.

- Because of the types of problems that may occur (teeth in the area of the cleft may be missing or improperly positioned, affecting biting and chewing ability; speech difficulties; frequent colds, sore throats, OM, tonsillitis), assistance from a variety of therapists and professionals is needed. The dietitian can assist with nutrition and feeding-related issues. Nutrient density and texture assessments should be ongoing.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants; this will decrease the risk of botulism.

# CONGENITAL HEART DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Gold DH, MD, and Weingeist TA, MD, PhD. *Color Atlas of the Eye in Systemic Disease*. Baltimore: Lippincott Williams & Wilkins, 2001.

### DEFINITIONS AND BACKGROUND

Congenital heart disease is the most common birth defect in the United States, with an estimated incidence of approximately 12–14 of 1000 live births per year (Owens and Musa, 2009). Usually, some developmental defect occurred between weeks 5 and 8 of pregnancy (e.g., from rubella). An increased risk for malnutrition, growth failure, or pulmonary hypertension occurs.

Energy expenditure is significantly elevated and feeding difficulties are common. Increased levels of ghrelin and other factors may lead to growth retardation and FTT. Supplementary oxygen is often needed, especially during feeding; the child will not grow if oxygen is inadequate.

Surgical repair may be delayed to allow weight gain. Surgery is performed when a patient reaches an ideal weight and age, or if FTT precludes further waiting. The neonate undergoing cardiopulmonary bypass surgery experiences profound metabolic response to stress and has less metabolic reserves for wound healing and growth (Owens and Musa, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Some congenital heart defects are related to an abnormality of an infant's chromosomes (5–6%), single-gene defects (3–5%), or environmental factors (2%) while the majority are multifactorial. Down syndrome (DS), Williams syndrome, trisomy

13 or trisomy 18 are examples of conditions that are often linked with congenital heart disease (Children's Hospital Boston, 2009).

#### Clinical/History

Height  
Weight  
Head circumference  
Growth pattern

#### Lab Work

Gluc  
Urinary Osm  
Na<sup>+</sup>, K<sup>+</sup>  
BUN, creatinine (Creat)

Chol  
Trig  
Serum folate, B<sub>12</sub>  
H & H, serum Fe or ferritin  
O<sub>2</sub>, CO<sub>2</sub>  
Serum zinc

## INTERVENTION

### OBJECTIVES

- Support normal growth and weight gains; growth failure is common, especially with associated heart failure. An 8–16 oz gain in one month might be acceptable.
- Improve oral intake. Poor sucking may occur in infants, but it is possible to breastfeed with education and support of the mother (Barbas and Kelleher, 2004).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### High Energy Requirements

**Assessment Data:** Weight and growth charts, need for ventilator support, fluid requirements, estimated needs to increase rate of growth.

#### Nutrition Diagnoses (PES):

NI 1.2. Increased energy expenditure related to breathing and inadequate weight gain as evidenced by low oxygen saturation levels, inadequate rate of growth, <5% weight for height and age.

NC 1.3. Breastfeeding difficulty related to poor sucking ability as evidenced by observation of mother during attempts to breastfeed, with infant unable to latch on and sustain intake longer than a few seconds.

**Intervention:** Assist mother with breastfeeding tips and explain how to use supplemental formulas if needed to support growth of infant. Educate mother/parents about increasing nutrient density, frequency of meals or snacks, types of formula needed when required, allowing extra feeding time due to dyspnea.

**Monitoring and Evaluation:** Weight records and improved growth rate allowing child to have heart surgery.

- Lessen fatigue associated with mealtimes. Assure adequate oxygen replacement, especially during feeding.
- Meet energy needs from increased metabolic rate and the need for catch-up growth, without creating excessive cardiac burden or excessive renal solute overload.
- Improve appetite, which can be decreased from the medications.
- Promote good oral hygiene to prevent infections.

## FOOD AND NUTRITION

- Determine and provide calories as needed for age (e.g., 100 kcal/kg in second year of life). See Table 3-1. Most formulas contain 67 kcal/dL or 20 kcal/oz. Severe FTT cases may need an extra 30–60 kcal/kg/d over usual; follow standard mixing recommendations for formula concentration and add modular products to reach a desired level. For infants, a formula up to 90–100 kcal/dL can be used while carefully monitoring adequacy of fluid ingestion.
- Energy should contain approximately 10% protein (avoid overloading), 35–50% fat as vegetable oils (known to be readily absorbed), and 40–55% CHO.
- Sodium intake should be approximately 6–8 mEq daily, dependent on diuretic use and cardiopulmonary status.
- Continuous 24-hour tube feeding may be useful. PEG tube feeding can be a useful adjunctive therapy, especially using formulas with a lower mineral to protein ratio (e.g., partially demineralized whey).

## Common Drugs Used and Potential Side Effects

- Diuretics are often prescribed. Other drugs are specific to the individual patient's requirements; see Table 3-6. Give medicines before feedings to be sure they have been taken.
- With Nesiritide, used to cause diuresis; hypotension may result (Feingold and Law, 2004).
- Infective endocarditis (IE) among children with *Staphylococcus aureus* bacteremia may require treatment with antibiotics; use of probiotic products may alleviate loss of intestinal bacteria.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used because there are no controlled trials to prove efficacy.
- With prolonged use of antibiotic therapy, probiotic products may be useful. Encourage intake of yogurt, acidophilus milk, and related products.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of nutrition in achieving adequate growth and controlling heart disease.
- Discuss growth patterns and goals.

**TABLE 3-6 Normal Growth Rates for Height and Weight in Children**

Age	Growth in Length or Height (mm/d) <sup>a</sup>	Growth in Length or Height (inches/yr)
0–6 months	1.06 declining to 0.77	7–10
6–12 months	0.47	6–7
1–2 years	0.35 declining to 0.30	4–5
2–3 years	—	3–4
3–4 years	—	2–3
4–10 years	—	2

Age	Daily Growth in Weight (oz/d) <sup>a</sup>	Growth in Weight
0–4 months	1.0 declining to 0.61	1½ lb/mo
4–10 months	0.61 declining to 0.47	1 lb/mo
10–24 months	0.47 declining to 0.25	½ lb/mo
2–8 years	—	3–4 lb/y

### Formula for Measurement Conversion

One pound = 0.455 kg OR 2.2 lb = 1 kg

One inch = 2.54 cm

Multiply each inch by 2.54 to come up with length in centimeters

Multiply each pound by .455 to come up with weight in kilograms or take the pounds and divide by 2.2

<sup>a</sup>See Russell-Silver Syndrome Growth Charts, based on the Centers for Disease Control and Prevention's federally authorized growth charts, <http://www.magicfoundation.org>.

- Provide support for breastfeeding mothers who wish to continue as long as possible.
- Discuss the role of nutrition in oral health and overall immunity.
- Women who wish to become pregnant should be sure they are immunized against rubella, which can cause congenital heart disease.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# CYSTINOSIS AND FANCONI'S SYNDROME

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Tasman W, Jaeger E. *The Wills Eye Hospital Atlas of Clinical Ophthalmology*, 2nd ed. Lippincott Williams & Wilkins, 2001.

### DEFINITIONS AND BACKGROUND

In cystinosis, crystals of cystine are deposited throughout the body. If left untreated, the disease may lead to kidney failure. Toxic accumulations of copper in the brain and kidney account for neurological symptoms. Cystinosis may be inherited or acquired, such as by lead poisoning. Manifestations are also seen in hereditary fructose intolerance. Myopathy leads to restrictive lung disease in adults who have not received long-term cystine depletion. Whether or not oral cystamine therapy can prevent this complication remains to be determined (Anikster et al, 2001).

**Infantile nephropathic cystinosis**, the most severe form, is a lysosomal membrane transport defect. FTT, rickets, metabolic acidosis, unexplained glucosuria of renal tubular origin, loss of color in the retina of the eyes, and severe photophobia can appear as early as 3–18 months of age. In **intermediate cystinosis**, kidney and eye symptoms become apparent during the teenage years or early adulthood. Polyuria, growth retardation, rickets, acidosis, and vomiting are present. In **benign**

**or adult cystinosis**, crystalline cystine accumulates primarily in the cornea of the eyes and adults may present with acidosis, hypokalemia, polyuria, or osteomalacia.

**Fanconi's syndrome**, a generalized tubular dysfunction, can be either acquired or inherited. The hereditary form may accompany Wilson's disease, galactosemia or glycogen storage diseases. Nephrotoxic drugs, such as use of some chemotherapy agents, streptozocin, antiretrovirals, valproate, or outdated tetracycline, may cause the acquired form (Knorr et al, 2004). Vitamin D deficiency, myeloma, amyloidosis, and heavy metal intoxication may also be triggers. Regardless of origin, Fanconi's syndrome results in multiple organ damage, with profound renal damage. Excessive urination (polyuria), excessive thirst (polydipsia), and severe hypokalemia occur. Renal transplantation may be needed.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The affected gene in the inherited form is *CTNS*, located on chromosome 17, which codes for cystinosin.

#### Clinical/History

Birth weight (infant or child)

Present weight  
Length or Height

Growth (%), head circumference

Abnormal sensitivity to light (photophobia)

Loss of color in the retina

Rickets  
Dehydration  
Dysphagia  
Patchy brown skin

Diet/intake history  
Polydipsia, polyuria

#### Lab Work

Gluc  
Ca<sup>++</sup>, Mg<sup>++</sup>  
Aminoaciduria

Serum phosphorous (decreased)	K <sup>+</sup> (decreased)	I & O
Phosphaturia	CO <sub>2</sub>	Uric acid (decreased)
Aminoaciduria	Alb	BUN, Creat
Na <sup>+</sup>	H & H	Ceruloplasmin
	Serum Fe	WBCs
	Serum vitamin D	

## INTERVENTION

### OBJECTIVES

- Remove the offending nephrotoxin in the acquired forms.
- Prevent bone demineralization and kidney failure. Correct hypokalemia, hypophosphatemia, and vitamin D insufficiency.
- Manage swallowing dysfunction.
- Support growth, which tends to be stunted in children.
- Prevent or delay corneal damage.
- Provide sufficient volumes of fluid and supplemental nutrients.
- Prepare for renal transplantation if needed. Postoperatively, promote wound healing and prevent graft rejection.

### FOOD AND NUTRITION

- Use a diet low in cystine, with protein-free diet, PFD1 or PFD2 from Mead Johnson.
- Provide sufficient fluid intake. Input and output should be checked by standards for age.
- Supplement with vitamin D<sub>3</sub> (cannot convert 25-dihydroxycholecalciferol); give phosphate and calcium as appropriate. Bicarbonate is also needed.
- Provide sufficient sodium and potassium replacements.
- Alter consistency (liquids, solids) as needed.
- Prepare for wound healing with sufficient vitamins A, C, zinc, protein, and energy.

### Common Drugs Used and Potential Side Effects

- Sodium bicarbonate or citrate should be used to correct acidosis. Take separately from iron supplements. Edema can occur.

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### Inadequate Vitamin and Mineral Intakes

**Assessment Data:** Weight and growth charts, lab reports showing losses of K<sup>+</sup> and phosphorus in the urine, evidence of rickets (bowed legs).

**Nutrition Diagnoses (PES):** Inadequate mineral intake (potassium and phosphorus) related to excessive urinary losses from cystinosis as evidenced by urine tests, insufficient vitamin D metabolism and rickets.

**Intervention:** Educate parents about sources of vitamin D, potassium and phosphorus from medications and diet.

**Monitoring and Evaluation:** Weight records, growth, labs for potassium, phosphorus, and vitamin D.

- K depletion may require replacement therapy with a K-containing salt.
- Cysteamine (Cystagon), administered orally, halts glomerular destruction and decreases cystine content in cells. It mitigates morbidity and death (Gahl et al, 2007).
- Long-term GH treatment can be safe and effective; it should be started early in the course of the disease (Wuhl et al, 2001).

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for this condition because there are no controlled trials to prove efficacy.
- Use of Chinese herbs may be problematic, causing some forms of cystinosis in susceptible individuals. Discourage use.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Emphasize the importance of correcting fluid and electrolyte imbalances.
- Discuss any necessary changes in consistency to assist with dysphagia.
- Discuss diet for managing renal failure if necessary.
- If transplantation is needed, discuss guidelines for managing side effects such as graft–host resistance.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# DOWN SYNDROME

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

DS is a congenital defect in which patients carry an altered chromosome; trisomy patients have an extra chromosome 21. Children with DS have short stature, decreased muscle tone, constipation, intestinal defects, weight changes, and mental retardation. There is a higher risk for congenital heart disease, gum disease, celiac disease, Hirschsprung's disease, hypothyroidism, leukemia, respiratory problems, and gastroesophageal reflux. Incidence of the syndrome is often related to maternal age.

Chronic oxidative stress is a consideration; antioxidants, such as selenium, vitamins C and E, are important to include. Research also suggests that folate has a relationship. Women of childbearing age should consume 400 mg folic acid daily through food sources and/or supplementation. (Czeizel and Puho, 2005).

Compared with other individuals, those with DS may have lower levels of vitamin A, thiamin, folate, vitamin B<sub>12</sub>, vitamin C, magnesium, manganese, selenium, zinc, carnitine, carnosine, and choline; excesses of copper, cysteine, phenylalanine (Phe), and superoxide dismutase are sometimes encountered (Thiel and Fowkes, 2004). Disorders of metabolism involving vitamin B<sub>6</sub>, vitamin D, calcium, and tryptophan may play a role (Thiel and Fowkes, 2004).

The use of chromosome engineering to generate trisomic mouse models and large-scale studies of genotype–phenotype relationships in patients will contribute to the future under-

standing of DS (Wiseman et al, 2009). First-trimester screening is generally recommended.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** DS is caused by trisomy of chromosome 21 (Hsa21). There are other alleles that may have an impact.

#### Clinical/History

Length or height  
Birth weight  
Present weight  
BMI  
Diet/intake history  
Head circumference  
DS growth chart  
Growth (%)

Hyperextensibility of joints  
History of prematurity?  
Large tongue, eye slant  
Endocardial defects  
Developmental delay  
Small nose with flat bridge  
Pica

Skin prick test

#### Lab Work

Gluc  
Uric acid (increased)  
Plasma zinc  
Chol, Trig  
Na<sup>+</sup>, K<sup>+</sup>  
Ca<sup>++</sup>, Mg<sup>++</sup>  
I & O  
Serum folate

## SAMPLE NUTRITION CARE PROCESS STEPS

**Overweight**

**Assessment Data:** Weight and growth charts, BMI >normal range.

**Nutrition Diagnoses (PES):** NC 3.3. Overweight related to inadequate energy expenditure in DS as evidenced by BMI >28, limited activity levels, and frequent consumption of high fat foods and snacks.

**Intervention:** Discuss differing growth patterns from usual which may lead to excessive weight gain. Discuss optimal nutrition goals and physical activity, encouraging plenty of daily activity. Review foods to avoid because of risks for choking.

**Monitoring and Evaluation:** Weight records, growth and improved BMI levels, tolerance for various foods and consistencies.

## INTERVENTION

## OBJECTIVES

- Provide adequate energy and nutrients for growth. Short stature is not caused by nutritional deficiencies; use appropriate DS growth charts.
- Monitor introduction of solid food, which may be delayed. Fruits and vegetables may not be consumed in adequate amounts.
- To avoid lowered intake of vitamins and minerals, treat obesity in children with DS with a balanced diet plus vitamin and mineral supplements; no energy restriction; and an increase in physical activity.
- Assist with feeding problems; tongue thrust and poor suck are common.
- Reduce emotional problems that lead to overeating. Overfeeding should be avoided. Use proper positioning.
- Manage constipation, diarrhea, gluten enteropathy, urinary tract infections (UTIs), gum and periodontal diseases, which are common. Prevent osteoporosis and bone disease.

## FOOD AND NUTRITION

- Supply adequate amounts of energy for age; for children aged 5–11 years, use 14.3 kcal/cm for girls and 16.1 kcal/cm for boys (Lucas, 2004, p. 41).
- Use protein according to age-dependent dietary reference intakes.
- Use a gluten-free diet if celiac disease is present (Hill et al, 2005).
- Monitor pica, overeating, and idiosyncrasies.
- Provide supplemental sources of folate, vitamin A, vitamin E, zinc, iron, and calcium if intake of fruits, vegetables, meats, dairy products, or whole grains is limited.
- Provide feeding assistance if needed. Tube feed if the patient is unable to eat orally; gradually wean to solids when possible.
- Provide extra fluid for drooling, diarrhea, or spillage.
- Encourage complex carbohydrates, prune juice, etc., if constipation is a problem.

## Common Drugs Used and Potential Side Effects

- Aricept may have some benefit in individuals with DS. Nausea or diarrhea are sometimes side effects.
- For MTHFR alleles, products such as L-methylfolate (Deplin) may be given.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used; because there are no controlled trials to prove efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain feeding techniques that may be beneficial. Discuss use of self-feeding utensils if needed.
- Help control energy intake and physical activity for appropriate levels.
- Never rush mealtime. Encourage socialization.
- Discuss how growth patterns differ from usual; FTT (Krugman and Dubowitz, 2003) or excessive weight gain may result as the child grows older.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature >2 hours.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

## FAILURE TO THRIVE

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

FTT is a diagnostic term used to describe infants and children who fail to grow and develop at a normal rate; it indicates protein, energy, vitamin, and mineral insufficiency. In many pediatric centers, one third of the referred children are malnourished. FTT is a complex problem that can be caused by many medical or social factors; without treatment, chronic illnesses or death may ensue.

Prompt diagnosis and intervention are important for preventing malnutrition and developmental delays. Careful attention must be paid to growth charts and medical histories (Krugman and Dubowitz, 2003). Food refusal, poor feeding, vomiting, gagging, irritability, and FTT are commonly found in both infantile feeding disorders (IFD) and common treatable medical conditions (Levy et al, 2009).

Weight is the most reliable marker for FTT. According to the American Academy of Pediatrics (2004), FTT is established when weight (or weight/height) is less than 2 standard deviations below the mean for sex and age and/or the weight curve has dropped more than 2 percentile lines on the National Center for Health Statistics growth charts after a previously stable pattern. Other indices include a small head circumference, muscular wasting, apathy, weight loss, or poor weight gain. Learning failure (e.g., slow to talk, behavior problems) can occur. Infants with DS, intrauterine growth retardation (IUGR), or premature birth follow different growth patterns than usual; monitor carefully to evaluate for FTT (Krugman and Dubowitz, 2003). About 25% of normal infants will shift to a lower growth percentile in the first 2 years of life and then remain at that percentile; this is not FTT (Krugman and Dubowitz, 2003).

**Primary FTT** originates from social/environmental deficits, inadequate feeding procedures, or caretaker behaviors. Adolescent mothers may need a lot of support and education. Proximity and touch are especially disturbed in feeding disorders (i.e., mothers provide less touch that supports growth), and children demonstrate signs of touch aversion (Feldman et al, 2004). Early interventions by trained home visitors may promote a more nurturing environment and reduce developmental delays.

**Secondary FTT** originates from some disease states (e.g., cancer, allergies, chronic infections, cystic fibrosis, cleft lip or palate, DS, or other physical or mental disability). Growth failure plus fever of unknown origin and anemia in older children or teens may suggest the onset of Crohn's disease; evaluation is recommended. About half of the causes of FTT

are organic; the other 50% are from inorganic causes. The American Dietetic Association suggests at least five medical nutrition therapy visits for infants and children with FTT.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Genes causing FTT would be related to the specific condition, such as a congenital heart defect, spina bifida, DS, cystic fibrosis.

Clinical/History	Diet and intake history	Infections, parasites?
Height	Feeding schedule and timing	Frequent UTIs
Very low birth weight?	Food allergy, especially milk allergy	Maternal depression?
Apgar scores	GERD	<b>Lab Work</b>
Premature or small for gestational age (SGA)?	Medical history	H & H
Current or goal weights	Breastfed or bottle fed?	Serum Fe, ferritin
Growth grid	Solid food introduction pattern	Anemia (iron, sickle cell, other)
Percent height for age (actual height/expected height)	Diarrhea or vomiting?	Alb
Head circumference; microcephaly?	Constipation	Gluc
Skinfold thickness	Dehydration	Chol, Trig
	Inadequate access to food?	BUN
		Thyroid function tests
		I & O
		Sweat test

#### INTERVENTION

#### OBJECTIVES

- All children with FTT need additional calories for catch-up growth at about 150% of the energy requirement for

## SAMPLE NUTRITION CARE PROCESS STEPS

## FTT

**Assessment Data:** Weight and growth charts, medical conditions causing excessive energy expenditure or requirements, feeding methods used for the child, available financial resources to buy food or formula, access to safe and sufficient food supply.

**Nutrition Diagnoses (PES):** NI 2.1. Inadequate oral food/beverage intake related to minimal intake of formula and age-appropriate foods as evidenced by drop in more than 2 percentile lines on the National Center for Health Statistics growth chart after having achieved a previously stable pattern and medical Dx of FTT.

**Interventions:**

Food and Nutrition Delivery:

ND 5.7. Feeding environment to support growth in 12-month-olds.

ND 1.2. To follow increased caloric intake and frequent snacks.

Nutrition Education:

E 2.2. RD to provide nutrition counseling to support weight gain in patient and teach mother and caretaker how to properly feed according to infant's nutritional needs. Discuss adequate timing for feeding child. Educate and teach mother about appropriate feeding behaviors and practices for 12-month-olds.

Counseling:

C 2. Counsel mother/caretaker on how to provide nutritional needs for patient and environment to support those need. Goal is to achieve daily gains of weight, 30 g/d.

Coordination of Care:

RC 1.3. RD to collaborate with MD; RD will refer patient for in-home assessment and follow-through. Correct environmental causes of FTT. Refer to WIC or SNAP (food stamps) programs to help with financial challenges and food insecurity.

**Monitoring and Evaluation:** Weight records, growth, tolerance for various foods or formulas, financial access to food.

their expected, not actual, weight (Krugman and Dubowitz, 2003). Use calculations for determining needs from the most current *Pediatric Manual of Clinical Dietetics*.

- Identify and correct etiologies such as decreased energy intake, increased nutrient losses, increased metabolic demands. Determine if malnutrition is primary (from faulty feeding patterns or dietary inadequacy) or secondary (from disease process interfering with intake).
- Teach the parent or caretaker how to properly feed and how to determine needs. Advise parents to support nurturing during feeding.
- Provide the most optimal nutrition compatible with a normal growth pattern. Achieve daily gains of 30 g for young infants; extra may be desirable for catch-up. Nutrient-enriched formulas are probably not necessary (Henderson et al, 2007).
- Provide a schedule of feeding for infant's age to support catch-up growth and improved brain development (Powers et al, 2008). See Table 3-7 for more details.

## FOOD AND NUTRITION

- Conduct a thorough nutrition assessment and acquire actual intake records when possible. Evaluate the child's nutritional history and growth in comparison with the percentiles of other same-age children. If special growth charts are needed, use those instead (as for DS). Discuss findings with parent or caretaker.
- Calculate energy and protein needs carefully. While not easy to do, indirect calorimetry may be needed.
- Check recommended intakes for all nutrients. Provide adequate zinc and vitamin B<sub>6</sub>, as determined by the infant's age; 120–130% is a common practice.
- Monitor growth (weight) weekly; feeding behaviors.
- If the infant is dehydrated, provide adequate amounts of fluids. However, FTT can be aggravated by excessive consumption of fruit juice and sweetened beverages (often 12–30 oz daily) which may replace other nutrient-dense foods. Limit to 4–6 oz daily until overall diet quality and growth rate have improved.
- Provide meals and snacks at scheduled times; support a comfortable social and emotional environment. Family meals and allowing children to be a part of meal preparation are also important.
- If FTT children are strictly vegan, monitor for vitamins B<sub>12</sub>, D, B<sub>6</sub>, iron, zinc, and calcium deficiencies.
- Tube feeding may be useful as a supplemental or alternative feeding method; nightly feeding is an effective recommendation if it can be managed by the caregiver.

## Common Drugs Used and Potential Side Effects

- Evaluate medications given for any reason to determine if some or all affect nutritional intake. Adjust diet as needed.
- Endogenous cannabinoids or other appetite enhancers are being studied for their safety and effectiveness in FTT.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for FTT; there are no controlled trials to prove efficacy.
- Probiotics are useful for their live micro-organisms with a health benefit for GI disorders, cancer, infant allergies, FTT, and infections (Brown and Valiere, 2004).
- Zinc supplementation may be needed during catch-up growth in malnourished children (Castillo-Duran and Weisstaub, 2003). Avoid prolonged or excessive doses.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Describe appropriate nutritional intake according to age and any predisposing medical conditions.
- Encourage the use of appropriate growth charts at home to monitor success. Develop a progress chart for developmental milestones. Growth spurts follow sustained weight gains; monitor growth frequently.

**TABLE 3-7 Grading and Treatment for Hirschsprung's-Associated Enterocolitis**

Grade	Clinical Symptoms		
I	Mild explosive diarrhea, mild or moderate abdominal distention; no systemic manifestations		
II	Moderate explosive diarrhea, moderate-to-severe abdominal distention; mild systemic symptoms		
III	Severe explosive diarrhea, marked abdominal distention, and shock or impending shock		
<b>Fiber enhancement</b>			
Breakfast	Whole wheat waffles with fresh fruit. Cereal choices: oatmeal, Frosted Mini Wheats, Kashi Mighty Bites, Raisin Bran, Wheat Chex. Whole wheat bagel, or whole wheat English muffin with chunky peanut butter. Bran muffins. Dried fruit to increase fiber content. Add fresh fruit		
Lunch or dinner	Vegetable soup with whole wheat crackers. Whole wheat sandwich with leaf lettuce, tomato, meat of choice. Whole wheat macaroni and cheese with peas. Whole wheat spaghetti with sautéed zucchini and tomatoes in sauce. Fresh fruit. Whole wheat pizza with sauce, cheese, and vegetable toppings (green, red, yellow or orange peppers, mushrooms, tomatoes, olives). For tacos, use whole wheat tortillas, add vegetables (tomatoes, lettuce, olives, avocado). Brown rice, whole wheat pasta, legumes, beans; add a vegetable as a side. Green, red, yellow or orange peppers and cucumber slices with vegetable dip. Sliced pears, peaches, strawberries, or cantaloupe with fruit dip. Celery, 2 Tbsp peanut butter, raisins. Whole grain crackers		
<b>Fiber supplements:</b>			
Name	Active Ingredient	Serving Size	Amount of Fiber
Metamucil wafers	Psyllium 50% soluble	2 wafers	6 g
Metamucil powder	Psyllium 65% soluble	1 tbsp	3 g
Ground flax seed	45% insoluble, 55% soluble	1 tbsp	3 g
Benefiber	Wheat dextrin, 100% soluble	2 tbsp	3 g
Citrucil	Methocellulose, 100% soluble	1 scoop or 4 caplets	2 g
Pectin	100% soluble	1.75 oz package	4.3 g

**Sources:**

- American Dietetic Association. *Fiber facts: soluble fiber and heart disease*. Chicago: American Dietetic Association, 2007.
- Children's Hospital of Boston. Accessed April 27, 2009, at <http://www.childrenshospital.org/az/Site2116/mainpageS2116P0.html>.
- Li BW, Andrews KW, Pehrsson PR. Individual sugars, soluble, and insoluble dietary fiber contents of 70 high consumption foods. *J Food Comp Anal*. 15:715–723, 2002.

- Offer simple, specific instructions when needed, such as mechanics of breastfeeding and typical intakes for children of same age. If formula is used, improper mixing of formula is common; help correct any misunderstandings.
- Discuss nutrient density (e.g., milk vs. sweetened carbonated beverages; whole fruit vs. juice).
- Explain proper use of over-the-counter vitamin–mineral supplements, age-appropriate for the child.
- Address any harmful or unusual dietary beliefs (Feld and Hyams, 2004).
- Practical suggestions should be offered regarding nurturing and emotional support for the child. Parenting classes may be beneficial.
- Coordinate referral to child welfare services where neglect is suspected (Block et al, 2005). Refer to WIC programs, La Leche League, SNAP (food stamps) whenever appropriate.
- Follow-up should be provided at outpatient clinics or by home visits.

**Patient Education—Food Safety**

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.

- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants; this will decrease the potential risk of botulism.

## FATTY ACID OXIDATION DISORDERS

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

Fatty acid oxidation disorders disrupt mitochondrial energy generation and ketone production (Isaacs and Zand, 2007). Muscle protein breaks down and may lead to death if the heart muscle is involved. The fatty acid disorders with dietary implications include medium-chain acyl-CoA dehydrogenase deficiency (MCAD), long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency, and very long chain acyl-CoA dehydrogenase deficiency (Isaacs and Zand, 2007).

MCAD is caused by the lack of an enzyme required to convert fat to energy. Children with MCAD cannot use MCTs to make energy, so the body begins to malfunction when they fast (i.e., they have no more long-chain dietary fats available from the diet). MCAD occurs in approximately one in every 10,000 live births. MCAD occurs mostly among Caucasians of Northern European background. Symptoms typically begin in infancy or early childhood, often with simple lethargy. While some affected individuals have no symptoms at birth, disorders such as hypoglycemia, seizures, coma, brain damage, or cardiac arrest can occur very quickly with illness. If not detected and treated appropriately, MCAD can result in death. About 1 in 100 sudden infant death syndrome (SIDS) deaths are probably a result of undiagnosed MCAD (Nennstiel-Ratzel et al, 2005).

Early detection allows treatment and a normal life expectancy. Medical nutrition therapy to lower dietary fats does not decrease toxic metabolites because the body can make triglycerides from carbohydrates, proteins, or fats (Isaacs and Zand, 2007). The appropriate fatty acids must be omitted.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** MCAD involves medium-chain acyl-coenzyme A (CoA) dehydrogenase deficiency; adenosine replaces guanosine at position 985 of the MCAD gene.

#### Clinical/History

Length (height)  
Birth weight  
Present weight  
Growth (%)  
Diet/intake history

Seizures?  
Retardation?

#### Lab Work

Gluc  
Alb  
Chol

Trig  
Lipid Panel  
H & H  
Serum Fe

### INTERVENTION

#### OBJECTIVES

- Avoid periods of fasting, day and night (Roe and Ding, 2001). Use IV glucose when food cannot be tolerated, such as with colds or flu.
- Customize protocol for the individual. LCHAD requires a severe dietary restriction of long-chain fats, to the lowest level that can deliver the EFAs and fat-soluble vitamins (Isaacs and Zand, 2007). MCT can be used in LCHAD but not in MCAD.
- Provide EFAs.

#### FOOD AND NUTRITION

- Restrict periods of fasting by offering small, frequent feedings (Oey et al, 2005).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Intake of Types of Fats

**Assessment Data:** Weight and growth charts.

**Nutrition Diagnoses (PES):** Excessive intake of medium chain fatty acids related to MCAD deficiency as evidenced by signs of lethargy and elevated levels of triglycerides.

**Intervention:** Educate parents about avoiding sources of MCT; document in medical record about formulas to avoid.

**Monitoring and Evaluation:** Weight records, growth, improvement in lipid levels, reduced lethargy, normal mental development for age.

- A diet with avoidance of the specific, problematic fatty acids will be needed. For example, do not use enteral formulas that contain MCTs in MCAD.
- The diets will be higher in carbohydrates and fat-free protein foods.
- Supplement linoleic and  $\alpha$ -linolenic acids; monitor by laboratory measurements of fatty acids.
- Supplemental carnitine has been recommended.
- Waking the child at least once during the night, or feeding by gastrostomy or NG tube overnight, is required for most of the fatty acid oxidation disorders (Isaacs and Zand, 2007).
- Monitor weight and growth closely to prevent obesity, but do not skip meals or feedings.

### Common Drugs Used and Potential Side Effects

No specific drugs are used. Dietary alterations are the management.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for MCADD because there are no controlled trials to prove efficacy for any related problems.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Educate about the dangers of fasting, including periods during illness.
- Share information about frequent feedings and how to avoid the designated fatty acids from supplemental products, formulas, etc.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

## FETAL ALCOHOL SYNDROME

### NUTRITIONAL ACUITY RANKING: LEVEL 1–2

Adapted from: Sadler T, PhD. *Langman's Medical Embryology*, 9th ed. Image Bank. Baltimore: Lippincott Williams & Wilkins, 2003.

### DEFINITIONS AND BACKGROUND

Generally noted shortly after birth, fetal alcohol syndrome (FAS) is a syndrome in infants with developmental delay, ocular anomalies, LBW, tremors, short stature, retarded intellect, seizures, and microcephaly. There is a continuum of FAS recognized as fetal alcohol spectrum disorders (FASD).

FAS is the third leading cause of mental retardation in the United States; it is the most preventable (Centers for Disease Control and Prevention, 2004).

No level of alcohol consumption during pregnancy is safe (Centers for Disease Control and Prevention, 2004). Exposure to alcohol during brain development can permanently alter the physiology of the hippocampal formation, thus promoting epileptic activity and depression (Bonthius et al, 2001). Disrupted cholesterol homeostasis may contribute

to neurotoxicity; the developing brain requires cholesterol for proper cell proliferation (Guizzetti and Costa, 2005). Approximately 10% of pregnant women use alcohol and 2% engage in binge drinking or frequent use of alcohol (Centers for Disease Control and Prevention, 2004).

Acetaldehyde damages RNA (Eriksson, 2001; Wang et al, 2009). The steady concurrent use of tobacco and alcohol by young women emphasizes the need for enhanced efforts to reduce initial tobacco and alcohol use by young people. Women who report abuse of tobacco or alcohol should be evaluated for abuse of both substances, and interventions should address abuse of both substances, especially to prevent FAS (Ebrahim et al, 2000).

Early risk assessment is needed, though it may be difficult to find and treat children who have FASD. Using the combination of weight and head circumference below the 10th percentile at birth is useful for identifying children at substantial risk for growth and developmental delays (Weiss et al, 2004). Children with FAS may have more social and medical needs. They often have more facial dysmorphism, growth deficiency, central nervous system dysfunction, muscular problems, hospitalizations for OM, pneumonia, dehydration, and anemia (Kvigne et al, 2004).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** FAS is considered to be environmental.

Clinical/History	Head circumference (<10th percentile)	Lab Work
Birth weight	Seizures	Alb
Current weight (often below 10th percentile)	Physical growth delay	Na <sup>+</sup> , K <sup>+</sup>
Length	Functional deficits (motor, social, memory, etc.).	Gluc
Growth (%)		H & H
Diet/intake history		Serum Fe
		Ca <sup>++</sup> , Mg <sup>++</sup>
		Serum folate

## INTERVENTION

### OBJECTIVES

- Promote effective family coping skills and effective parental bonding.
- Prevent additional retardation or developmental delays, blindness, other complications.
- Improve intake and nutritional status.
- Prevent or correct vomiting, cardiac symptoms, other problems.
- Encourage normal growth patterns; prevent FTT.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Energy Intake

**Assessment Data:** Weight and growth charts, head circumference below 10% tile.

**Nutrition Diagnoses (PES):** Inadequate energy intake related to increased energy demands from FAS as evidenced by microcephaly (head circumference below 10% tile) and slow growth rate for age.

**Intervention:** Educate parents about enhancing energy intake through nutrient-dense foods and supplements.

**Monitoring and Evaluation:** Weight records, growth, head circumference more closely normal for age.

## FOOD AND NUTRITION

- Provide a diet appropriate for age and status. Ensure adequate protein and energy for catch-up growth.
- If necessary, provide tube feeding or TPN while hospitalized. Some infants may require additional nutrition support in the home setting to promote better growth and development.

## Common Drugs Used and Potential Side Effects

- Anticonvulsants may be needed to correct seizures. Monitor for depletion of vitamins C, D, B<sub>6</sub>, B<sub>12</sub>, and K, folic acid, and calcium.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for FAS because there are no controlled trials to prove efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss appropriate feeding techniques for age of infant.
- Discuss importance of diet in aiding normal growth and development.
- Encourage mother's participation in alcohol rehabilitation if needed. Discuss her future plans for additional pregnancies and encourage counseling to avoid continued alcohol intake during that time.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.

- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants; this will decrease potential risk of botulism.

## HIRSCHSPRUNG'S DISEASE (CONGENITAL MEGACOLON)

### NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

Hirschsprung's disease (HD) is characterized by the absence of ganglion cells and the presence of hypertrophic

nerve trunks in the distal bowel. HD is also known as jejunal ganglionic or congenital megacolon. Its incidence is 1 in 5000 live births. HD may reoccur in other babies born to the same family with a child with HD (Stewart and von Allmen, 2003).

As a congenital malformation, HD interferes with normal mass peristalsis and functional obstruction. Normally, ganglia stimulate the gut and allow peristalsis to occur. In HD, the ganglia are missing, and segments of bowel become obstructed. This creates abdominal distention, failure to pass meconium stool, vomiting, and constipation. If diagnosed when older, growth failure may be a presenting sign.

Surgical removal may be required to alleviate bowel obstruction, followed by a temporary colostomy. Complications after a definitive pull-through procedure for HD include stricture formation, enterocolitis, and occasionally, wound infection (Finck et al, 2001). Often, removal of the affected area and reconnection of the colon occurs at age 6 months or older.

Over the long term, one in five patients will have continued constipation, occasional soiling, and incontinence, and one in 10 patients may have severe problems. A special type of enterocolitis, HD-associated enterocolitis (HAE), may also be a concern (Nofech-Mozes et al, 2004). The condition can be life threatening, and signs include hypoalbuminemia, diarrhea and vomiting, and anorexia and weight loss. See Table 3-8.

**TABLE 3-8 Glycogen Storage Diseases (GSDs): Deficiency of a Glycogen Synthase That Normally Converts Glycogen to Glucose**

Disease	Description
GSD1: glucose-6 phosphatase deficiency (G6PD), von Gierke disease	Slow or stunted growth, enlarged liver, delayed or absent pubertal development, gout, kidney failure, and a poor ability to withstand fasting due to low blood sugar occur. Patients with this condition are prone to frequent infections, hemolytic anemia, and inflammatory bowel disease. Brain damage can result from low glucose availability (Melis et al, 2004). Early death was common. Portacaval shunt may be considered in patients with height for age <3rd percentile (Corbeel et al, 2000).
GSD 2: alpha-glucosidase deficiency, Pompe disease	Onset in infancy is the most severe; most patients present with hypotonia and cardiomyopathy. Recombinant human GAA (rhGAA) can be tested for enzyme replacement (Raben et al, 2005).
GSD 3: debrancher enzyme deficiency, Cori disease or Forbes disease	There may be low bone density and a high risk for osteoporosis (Cabrera-Abreu et al, 2004).
GSD4: brancher enzyme deficiency, Andersen disease	Glycogen branching enzyme (GBE) deficiency results in the accumulation of an amylopectin-like polysaccharide and presents with liver disease, progressing to cirrhosis (Bruno et al, 2004).
GSD5: muscle glucagon phosphorylase deficiency, McArdle disease	X-linked liver glycogenosis (XLG) is one of the most common forms; onset is often in adults. Low levels of phosphorylase result in abnormal storage of glycogen in muscle tissue, muscle pain, cramping, stiffness, and poor exercise tolerance. Avoid strenuous exercise.
GSD6: liver phosphorylase deficiency, Hers disease	Gross hepatomegaly and hypoglycemia occur with reduced liver phosphorylase activity.
GSD7: muscle phosphofructokinase deficiency, Tarui disease	This syndrome presents often with exertional myopathy and hemolytic syndrome.
GSD9 a: liver glycogen phosphorylase kinase deficiency	Growth retardation, abdominal distention, and hepatomegaly may be present (Schippers et al, 2003). Liver transplantation results in normal fasting glucose production and normal glucose and insulin concentrations.
GSD9b: $\beta$ -subunit phosphorylase kinase Fanconi-Bickel syndrome	Hepatorenal glycogenosis is abnormal.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** HD develops before a child is born but is not thought to be genetic.

#### Clinical/History

Birth weight  
Length  
Present weight  
FTT?  
Growth (slow)  
Diet/intake history  
Failure to pass meconium after birth (newborn)  
Watery diarrhea (newborn)

#### Constipation

Temperature (fever?)  
Vomiting  
Abdominal distention  
Rectal bleeding?  
Dehydration; I & O  
Abdominal x-ray  
Barium enema  
Malabsorption  
Enterocolitis?

#### Lab Work

H & H  
Serum Fe, ferritin  
Alb  
 $\text{Na}^+$ ,  $\text{K}^+$   
 $\text{Ca}^{++}$ ,  $\text{Mg}^{++}$   
Gluc  
LFTs

## INTERVENTION

### OBJECTIVES

- Provide adequate nutrition for the patient's age and development. Growth may be inhibited.
- Replace electrolytes and fluids, especially with diarrhea and enterocolitis.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Altered GI Function

**Assessment Data:** Weight and growth charts, constipation and stool records.

#### Nutrition Diagnoses (PES):

NC 1.4. Altered GI function related to megacolon as evidenced by current complaints of constipation.

NB 1.7. Undesirable food choices related to lack of fruit and vegetable intake and increase in cookies and crackers in diet.

**Intervention:** Educate parents about high fiber foods and increased use of fruits, vegetables, whole grains and fluids.

**Monitoring and Evaluation:** Weight records, decreased symptoms of constipation, improved stooling pattern.

- Compensate for poor absorption of nutrients; water-miscible forms of fat-soluble vitamins may be needed.
- Prevent complications after surgery, especially constipation, incontinence, or enterocolitis.

## FOOD AND NUTRITION

- Use a high-energy/high-protein diet. Enteral products, oral supplements, or TPN can be used.
- Monitor serum electrolytes, especially potassium, if laxatives are used. Encourage a diet high in fiber and fluid to wean off medication if possible.
- Provide fluids adequate for the patient's age, hydration status, and extra fluid requirements.
- Use a laxative diet (Cincinnati Children's, 2009); see Table 3-8.
- Provide TPN if large sections of the bowel are removed. Advance infant feedings as tolerated using human milk or preterm or standard infant formulas, and then gradually progress to soft/bland foods.
- Monitor calcium, magnesium, and other nutrients if long-term TPN is needed.

## Common Drugs Used and Potential Side Effects

- Antibiotics may be needed if perforation has occurred or when there is enterocolitis. Monitor for side effects.
- In constipation, laxatives can deplete numerous nutrient reserves; monitor carefully. Encourage a diet high in fiber and fluid to wean off medication if possible.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for megacolon because there are no controlled trials to prove efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach patient about sources of protein, energy, potassium, and other key nutrients from diet.

- Discuss wound healing or colostomy procedures after surgery.
- For constipation and bowel incontinence, a high-fiber diet may be useful; discuss signs and symptoms of obstruction to report immediately to a doctor. Initial suggestion: age plus 10, example 4 years + 10 = 14 g/d.
- Extra fluids will be needed with high-fiber intake.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# HIV INFECTION, PEDIATRIC

## NUTRITIONAL ACUITY RANKING: LEVEL 4

## DEFINITIONS AND BACKGROUND

There are unique considerations related to HIV infection in infants, children, and adolescents. With the use of highly active antiretroviral therapy (HAART), there is minimal mother-to-child transmission of HIV infection in

developed countries (i.e., 1–2% only) (King et al, 2004; Newell and Thorne, 2004). In developed nations, HIV infection is more of a chronic disease, with extensive medications, costs, and side effects to consider. A high proportion of HIV-infected individuals are African or African American.

Developing nations still have a battle to address. Infants who are breastfed by HIV-infected mothers have the risk of acquiring the infection. In addition, HIV-infected mothers may transmit opportunistic pathogens to their infants. FTT and protein–calorie malnutrition are common. Every child with HIV infection should be assessed at baseline and every 4–6 months thereafter to determine risk of nutritional compromise. Severity or degree of nutritional risk is measured with anthropometric, biochemical, dietary intake, and medical data. Salivary gland disease is a common finding related to HIV infection; gland enlargement or xerostomia may present, and the reduction in saliva must be addressed (Pinto and DeRossi, 2004).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** HIV infection is not genetic but is transmitted prenatally by the infected mother, or by contaminated needles or blood transfusions.

Clinical/History	Head circumfer- ence (infants)	Lab Work
Height	Stunting	H & H
Weight	FTT	Serum Fe
Weight for height,	Mid-arm	Alb
BMI	muscle	Na <sup>+</sup> , K <sup>+</sup>
Growth	circumference	Ca <sup>++</sup> , Mg <sup>++</sup>
percentile and pattern	(MAMC)	Gluc
Diet/intake	Opportunistic	Immunological status
history;	infections	CD4+ T-cell counts
energy intake		Vitamin A level

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Energy Intake

**Assessment Data:** Weight and growth charts, frequent infections.

**Nutrition Diagnoses (PES):** Inadequate energy intake related insufficient intake, diarrheal losses, and high metabolic demand of HIV as evidenced by weight loss and frequent opportunistic infections.

**Intervention:** Educate parent/caregiver about use of tolerated high calorie foods and supplements.

**Monitoring and Evaluation:** Weight records, growth, tolerance of formulas or supplemental products.

## INTERVENTION

### OBJECTIVES

- Maternal factors, including Vitamin A level and CD4+ T-cell counts during pregnancy, as well as infant viral load and CD4+ T-cell counts in the first several months of life, can help identify those infants at risk for rapid disease progression who may benefit from early aggressive therapy.
- Achieve a normal growth pattern; allow for catch-up growth and monitor growth patterns closely.
- Prevent opportunistic infections by improving or maintaining immune status with good nutrition.
- Alleviate wasting syndrome, diarrhea, malabsorption, enteric infections, malnutrition, and immune deficiency. Preserve lean body mass.
- Follow the CDC evidence-based guidelines (CDC, 2009):
  1. Emphasize the important role of effective antiretroviral therapy in augmenting immune function
  2. Support diagnosis and management of immune reconstitution inflammatory syndrome, a condition in which the immune system begins to recover, but then responds aggressively to a previously acquired opportunistic infection
  3. Prevent Hepatitis B and C, *Mycobacterium tuberculosis* infection, malaria
  4. Manage drug–drug interactions and drug–nutrient interactions

### FOOD AND NUTRITION

- Use a high-protein diet. Enteral products, oral supplements, and frequent snacks should be used if required. Protein needs may be 1.5–2 times the usual for age and gender.
- Energy needs may vary from 50% to 200% of the usual requirements. Children with severe encephalopathy may be bed bound and require fewer total calories.
- Assure adequacy of fluid intake, especially with many medications to be taken each day.
- A multivitamin supplement is needed to provide at least 100% of the daily needs. Poor absorption may be a problem for vitamins A, C, B<sub>6</sub>, and B<sub>12</sub>, folate, iron, selenium, and zinc. Calcium is needed to prevent loss of bone mass (O'Brien et al, 2001).
- Naturally occurring antioxidants are safe when consumed in normal amounts. For example, include nuts for vitamin E and selenium and citrus fruits for vitamin C. Be aware of excesses from pills and other supplemental forms because excesses can deplete immunity. Mega doses are up to 10 times the RDA (American Academy of Pediatrics, 2004) and have not proven to be of benefit.
- Aggressive nutritional support is critical. Nocturnal, continuous feedings may be useful.

### Common Drugs Used and Potential Side Effects

- Few HIV medicines are produced in pediatric formulations. Those drugs available as syrups have limitations,

such as short shelf-life, objectionable taste, difficult measuring of correct doses, and expense. For a list of FDA-approved medications used in HIV infection, see Section 15.

- HIV-infected mothers may transmit opportunistic pathogens to their infants. There may be antibiotics or antiviral agents prescribed that should be closely monitored for nutritional and GI side effects. Adherence to complex antiretroviral (HAART) therapy requires addressing developmental, psychosocial, and family factors (Mellins et al, 2004). Early treatment saves lives.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for HIV; there are no clinical trials proving efficacy.
- HIV-infected individuals may be attracted to the many possible supplements on the market. Carefully review all items and discuss their viability or potential for harm.
- Use of acidophilus and probiotic products may alleviate loss of intestinal bacteria.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- There will be a need for medication management, a nutrient-dense diet, doctor visits, and other intervention and therapies. Provide support to the child and family or caregivers.
- Encourage formula feeding for mothers who has HIV infection.
- Discuss HIV infection prevention strategies, especially with noninfected teens. Researchers are working on a vaccine for HIV prevention.
- Children should receive all of their usual vaccinations to prevent other illnesses or complications.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.

- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard beverages and foods that left at room temperature for 2+ hours.
- Avoid honey in the diets of infants to decrease the risk of botulism.

# HOMOCYSTEINURIA

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### DEFINITIONS AND BACKGROUND

The significance of homocysteine (Hcy) in human disease was unknown until 1962, when cases of homocystinuria were correlated with vascular disease (McCully, 2007). Hcy is usually converted to cysteine and partly remethylated to methionine with the help of vitamin B<sub>12</sub> and folate.

Homocystinuria (HCU) is a rare, autosomal recessive metabolic disorder of amino acid metabolism. In HCU type I from deficiency of cystathionine-beta-synthase (which requires vitamin B<sub>6</sub> for activation). Hcy accumulates in the blood, methionine builds up, cysteine decreases, mental retardation and eye changes can occur from a lack of glutathione production (Ramakrishnan et al, 2006). In types II, III, and IV, methionine is decreased and no mental retardation occurs; here, treatment involves folate, vitamin B<sub>12</sub> and avoiding excess of methionine (Ramakrishnan et al, 2006). Newborn screening is recommended (Refsum, Fredriksen et al, 2004).

**HCU due to deficiency of CBS** is inherited as an autosomal recessive trait. Human CBS is an S-adenosylmethionine-regulated enzyme that plays a key role in the metabolism of Hcy. HCU type 1 occurs in 1 in 200,000 births worldwide, with stronger prevalence in Ireland, Norway, and Qatar. Untreated, it leads to mental retardation, seizures, altered

growth, hepatic disease, osteoporosis, thromboses, glaucoma, cataracts, and strokes. Individuals with HCU may be unusually tall in stature, with long arms and legs; this growth is directly mediated by Hcy.

**Deranged vitamin B<sub>6</sub> metabolism or low levels of reductase enzyme** may also cause HCU. A single biochemical test is not available; abnormal urinary tHcy response after methionine loading is the most sensitive test (Guttormsen et al, 2001). Urinary excretion of Hcy occurs but is unusual.

**5,10-Methylene-tetrahydrofolate reductase deficiency (MTHFR)** affects many enzyme systems. It can present with mental retardation, microcephaly, gait disturbance, psychiatric disturbances, seizures, abnormal EEG, and limb weakness. Therapy usually involves administration of folinic acid to enhance enzyme activity; 5-methyl-tetrahydrofolate to replace the missing end product; extra betaine, hydroxycobalamin, carnitine, and riboflavin to assist with related enzymatic actions.

For some patients, medications can reduce the excretion of Hcy in the urine, increase body weight, and improve mental function. Methionine may be given to correct low serum levels, and pyridoxine may lower serum Hcy levels if needed. If individuals do not respond to combinations of these drugs, supportive care is offered to reduce symptoms.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutations in the cystathionine beta-synthase (CBS) on chromosome 21 are most common. Methylene-tetrahydrofolate reductase (MTHFR), 5-methyltetrahydrofolate-homocysteine methyltransferase (MTR), and 5-methyltetrahydrofolate-homocysteine methyltransferase reductase (MTRR) genes cause HCU less frequently. Patients with a cobalamin C (CblC) defect have combined methylmalonic aciduria and HCU (Heil et al, 2007).

Clinical/History	Osteopenia or osterporosis (DEXA)	Urinary tHcy after methionine load
Birth weight	Marfan syndrome (long limbs, tall stature)	Serum folate
Present weight		Macrocytic anemia?
Length		MTHFR activity
Growth (%); FTT?		Serum B <sub>12</sub>
Scoliosis		Serum B <sub>6</sub>
Diet/intake history	<b>Lab Work</b>	Serum Ca <sup>++</sup> , Mg <sup>++</sup>
Nearsightedness	ALT, AST	
Lens dislocation	Gluc	
Blood clots in veins	Plasma methionine (fluctuates)	
Mental retardation	Plasma cysteine	
Cognitive changes or psychiatric problems	Serum Hcy (elevated)	
	Urinary methylmalonic acid	

## INTERVENTION

### OBJECTIVES

- Prevent mental retardation, growth delays, fractures, lens changes. Fractures occur because of defective collagen formation. A lens may become dislocated in CBS deficiency.
- Prevent cardiovascular complications (arterial and venous thrombosis, stroke, hypertension). Note: Dramatic decline in cardiovascular mortality in the United States since 1950 may be attributable in part to voluntary fortification of the food supply with vitamin B<sub>6</sub> and folic acid (McCully, 2007). Supplement with essential nutrients. Low folic acid intake aggravate the symptoms.
- In **Type I HCU**, reduce methionine in the diet to prevent accumulation of Hcy.
- **Metabolic disorders of cobalamin** will require intramuscular vitamin B<sub>12</sub>.
- **Alterations of the MTHFR alleles** may require use of L-methylfolate.

### FOOD AND NUTRITION

- Increase fluid intake.
- **HCU type I** is treated with supplementation of vitamin B<sub>6</sub> and cystine (to supply sulfur). If nonresponsive to B<sub>6</sub>, use a low-methionine diet with a supplement of cystine. Reduce intake of methionine from meat, poultry, fish, and eggs. Soy products (e.g., Isomil, ProSobee, Soyalec) can be used. XMET Maxamaid (SHS North America), Hominex 1 for infants or Hominex 2 for children (Ross Laboratories), or Product HOM 1 or HOM 2 (Mead Johnson) is also useful.
- **For cobalamin metabolic disorders:** Intramuscular vitamin B<sub>12</sub> is needed; dietary or supplemental vitamin B<sub>12</sub> is not effective.
- **For MTHFR:** Methylated folic acid, Vitamins B<sub>6</sub> and B<sub>12</sub>, riboflavin, choline, and betaine are useful supplements.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Intake of Bioactive Substances

**Assessment Data:** Weight and growth chart showing long limbs, tall stature for age, lab tests showing HCU and low serum levels of vitamins B<sub>6</sub>, B<sub>12</sub>, and folate, myopia and hx of thrombotic clots in legs.

**Nutrition Diagnoses (PES):** Inadequate intake of bioactive substances related to genetic defect as evidenced by HCU and low serum levels of B<sub>6</sub>, B<sub>12</sub>, and folate.

**Intervention:** Educate parents about dietary enhancements for foods rich in B<sub>6</sub>, B<sub>12</sub>, and folate. Counseling about appropriate drug therapy and desirable nutritional outcomes.

**Monitoring and Evaluation:** Weight and growth records showing slower increments in added height; improved serum levels of vitamins; decreased or minimal Hcy in the urine.

### Common Drugs Used and Potential Side Effects

- Dipyrindamole may be used to decrease thrombosis.
- Pyridoxine therapy (vitamin B<sub>6</sub>) for longer than 1 month is useful for some forms. The doctor may prescribe 100–500 mg or higher.
- Folic acid and vitamin B<sub>12</sub> should be supplied in a methylated form if needed. For example, Cerefolin (Pan Am Labs) contains methylated folate and B<sub>12</sub> plus N-acetylcysteine; Deplin contains 7.5 mg L-methylfolate.
- Choline and betaine may be useful (Alfthan et al, 2004; Busby et al, 2005).

### Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for HCU because there are no controlled trials to prove efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Emphasize the importance of controlling diet, snacks, using proper forms of supplemental nutrients.
- Discuss good food sources of folic acid and other B-complex vitamins. Therapy with folic acid, vitamin B<sub>6</sub>, l-carnitine, and intramuscular vitamin B<sub>12</sub> often results in improvement of symptoms (Heil et al, 2007).
- Newborn screening of tHcy is useful to detect vitamin B<sub>12</sub> deficiency or HCU (Refsum et al, 2004).
- Because of increased incidence of osteoporosis, high serum Hcy levels interfere with collagen cross-linking (McLean et al, 2004). Controlling serum Hcy is important for bone health.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# LARGE FOR GESTATIONAL AGE INFANT (INFANT MACROSOMIA)

## NUTRITIONAL ACUITY RANKING: LEVEL 1–3

### DEFINITIONS AND BACKGROUND

Infants whose weight is more than the 90th percentile for gestational age are classified as large for gestational age (LGA). Birth weight is high (3300–4000 g) at 40 weeks. Obesity and gestational diabetes increase the risk of an LGA delivery (Ehrenberg et al, 2004). LGA infants may also be born to mothers who are multiparous.

Macrosomia in newborns raises the risk for birth-related problems (Samaras et al, 2004). Problems may include hypoglycemia, respiratory distress, aspiration pneumonia, bronchial paralysis, or facial paralysis. LGA neonates usually have higher body fat and lower lean body mass than appropriate for gestational age (AGA) infants. Cord plasma adiponectin and leptin levels are very high in LGA infants; adiponectin is involved in regulating fetal growth (Tsai et al, 2004).

After birth, rapid adaptation is necessary for infants to be able to maintain independent glucose homeostasis; this process is compromised in LGA infants (Beardsall et al, 2008). Controlling maternal weight gain remains an important goal for successful pregnancy outcome. High birth weight may eventually promote impaired glucose tolerance, diabetes, obesity, or cancer (Samaras et al, 2004).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mitochondrial RNA deletions may be involved, but no specific gene has been identified.

Clinical/History	Neonatal	Lab Work
Head circumference	Behavior Assessment	Serum Gluc; hypo-glycemia?
Length	Scale (motor maturity, autonomic stability, and withdrawal)	Elevated serum insulin
Birth weight more than the 90th percentile for gestational age	Respirations	Chol, Trig
Neonatal Growth Assessment Scores	pCO <sub>2</sub> , pO <sub>2</sub> levels	Alb
	BP	Hemoglobin
	Diet/intake history	Hct (elevated)?
	I & O	Hyperbilirubinemia?
		Urinary acetone

## INTERVENTION

### OBJECTIVES

- Allow adequate growth rate and development.
- Prevent rapid phase of hypoglycemia.
- Maintain energy intake at a desired level while allowing adequate growth in the infant. Prevent obesity and its consequences for the infant as much as possible.
- Monitor serum lipids or bilirubin as deemed necessary.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal Nutritional Labs

**Assessment Data:** Abnormal labs for blood glucose, insulin, bilirubin, hematocrit in LGA infant.

**Nutrition Diagnoses (PES):** Abnormal nutritional lab values related to macrosomia as evidenced by neonatal hyperinsulinism after termination of maternal glucose at birth.

#### Interventions:

Prophylactic IV infusion of 10% dextrose in water until early frequent feedings can be established.

Educate mother about monitoring for signs of hypoglycemia, hyperbilirubinemia.

#### Monitoring and Evaluation:

Blood glucose levels should be closely monitored by bedside testing.

Evaluate over first few weeks for blood glucose control and normalization of serum insulin, bilirubin, hematocrit.

## FOOD AND NUTRITION

- Feed the infant often, as indicated by infant's appetite and goal weight pattern. Control total glucose intake if infant shows signs of hyperglycemia.
- Alter intake of fat as determined by lipid profile.
- Maintain a sufficient level of protein if energy needs to be restricted from CHO or fat.

### Common Drugs Used and Potential Side Effects

- Insulin may be necessary to control hyperglycemia. Beware of any excesses of insulin, which could aggravate hypoglycemia.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for LGA infants because there are no controlled trials to prove efficacy for any related problems.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss normal growth patterns as appropriate for the infant, reviewed in concert with the pediatrician. Signs of hyperglycemia and hypoglycemia should be discussed.
- Review risks inherent in another pregnancy, especially if the mother has diabetes. Counseling may be beneficial.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# LEUKODYSTROPHIES

## NUTRITIONAL ACUITY RANKING: LEVEL 1

### DEFINITIONS AND BACKGROUND

Leukodystrophies (peroxisome biogenesis disorders) are genetic disorders that affect the myelin sheath. While the genetic defect and biochemical abnormalities have been defined, there is a wide range of phenotypic expression (Moser et al, 2005). Neonatal adrenoleukodystrophy and infantile Refsum's disease are mild phenotypes. The most severe form is Zellweger's syndrome, which may be fatal and is characterized by an enlarged liver, high serum levels of iron and copper, and visual changes. Noninvasive and presymptomatic diagnosis and prenatal diagnosis are available; family screening and genetic counseling are important (Moser et al, 2005).

**X-linked adrenoleukodystrophy (X-ALD)** is one of the autosomal recessive disorders with an enzymatic defect in very long-chain fatty acid (VLCFA) oxidation, which is usually abundant in sphingomyelin. Ultimately, the myelin sheath surrounding the nerves is destroyed, causing demyelination and neurological problems. Adrenal gland malfunction causes Addison's disease (adrenal insufficiency). Accumulation of saturated VLCFA, especially hexacosanoate (C26:0), occurs because there is a missing or defective protein (ALD protein) to process that fatty acid. The incidence of X-ALD is estimated to be one in 17,000 in all ethnic groups (Moser et al, 2005).

Onset of X-ALD is usually in childhood, with a rapid, progressive demyelination, hypotonia, and psychomotor retardation. However, at least half of patients with X-ALD are adults with somewhat milder manifestations, and women who are carriers may become symptomatic (Moser et al, 2005). X-ALD is often misdiagnosed as ADHD in boys and as multiple sclerosis in men and women (Moser et al, 2005).

Prognosis is poor and death may occur up to a decade after onset.

The observation that dietary fatty acids affect membrane composition has led to the use of modified diets in these conditions. Lorenzo's oil is a mixture of oleic and erucic (rapeseed, or canola) oils, which reduces the production of VLCFA. Early oral administration helps infants and children with the neonatal form (Suzuki, 2001). In addition, the omega-3 fatty acid, DHA, is present in large amounts in infant brains but is often absent in infant formulas. Therefore, intake of omega-3 fatty acids is now recommended. Gene therapy of endogenous hematopoietic stem cells, pharmacological upregulation of other genes encoding proteins involved in peroxisomal beta-oxidation, reduction of oxidative stress, and possibly lovastatin are under study (Semmler et al, 2008).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Most of the leukodystrophies are genetic. X-linked adrenoleukodystrophy (X-ALD) is caused by defects of the ABCD1 gene on chromosome Xq28. See website <http://www.ulf.org/types/types.html> for details about the 34 known types.

<b>Clinical/History</b>	Poor sucking; feeding problems	Alb Chol Trig Plasma sphingomyelin H & H Pipelicolic acid testing
Height		
Weight		
Growth chart		
Diet/intake history		
Bronzing of skin (Addison's disease)		
Cataracts or glaucoma?		
	<b>Lab Work</b>	
	Plasma phosphatidylcholine	
	Fatty acid profile; VLCFA (elevated?)	

### INTERVENTION

### OBJECTIVES

- Decrease rapid progression of demyelination of CNS by offering sufficient fatty acids (DHA). Overall, maintain total VLCFA levels while altering fatty acid sources.
- Prevent or lessen complications of the disorder, including adrenal dysfunction.
- Support the physical therapy by maintaining strength with an adequate diet.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Self-Feeding Difficulty

**Assessment Data:** Abnormal weight and growth, difficulty with self-feeding.

**Nutrition Diagnoses (PES):** Self-feeding difficulty related to low vision and limited mobility.

**Intervention:** Educate parents about DHA and appropriate fat ratios. Counsel about tips for self-feeding, including special adaptive equipment.

**Monitoring and Evaluation:** Weight records, growth, slower disease progression.

## FOOD AND NUTRITION

- Increase endogenous VLCFA synthesis of monounsaturated fatty acids by restricting exogenous (dietary) VLCFA (C26:0) to less than 3 mg and by increasing oleic acid (C18:1). The typical American diet yields 35–40% total energy from fat with 12–40 mg C26:0 daily.
- Offer a low- to very low-fat diet, with supplementation of oleic and erucic acids (Lorenzo's oil), plus DHA (Deon et al, 2008). Include sources of omega-3 fatty acids, such as salmon, tuna, or mackerel, for older children and adults. Use good food sources of vitamins C, E, selenium, zinc for antioxidant properties.
- Lorenzo's oil is similar to olive oil (87% C18:1, 4.8% linoleic acid) but lacks measurable fatty acids with a chain length greater than C20. It can be used in cooking, as a supplement in juice, as an oil for salad dressings, or in food preparation instead of margarine, butter, mayonnaise, or shortening.
- If the patient requires tube feeding, a formula can be developed that contains nonfat milk, specialty oils, corn syrup or sugar, and a vitamin–mineral supplement.

## Common Drugs Used and Potential Side Effects

- Hormone-replacement therapy is necessary in all patients with adrenal insufficiency (Semmler et al, 2008). Long-term prednisone and spironolactone may cause hyperglycemia and osteoporosis.
- Use of lovastatin is being tested.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for this condition because there are no clinical trials proving efficacy.

- Studies suggest that vitamin E, selenium, and carnitine (antioxidants) should be considered.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The whole family can support the diet; it can be adapted for everyone. Discuss cooking methods using Lorenzo's oil.
- Restaurant dining can be a problem and special meals may have to be developed for travel.
- If nausea occurs, the oil can be taken in an emulsion.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# LOW BIRTH WEIGHT OR PREMATURITY

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### DEFINITIONS AND BACKGROUND

Every newborn is classified as one of the following: premature (<37 weeks of gestation), full-term (37–42 weeks of gestation), or postterm (>42 weeks of gestation). **Prematurity** is generally correlated with LBW. **LBW** infants may be small for date, have IUGR, or have dysmaturity. LBW infants weigh less than 2500 g or 5.5 lb (<10th percentile for gestational age) at birth. VLBW infants (<1300–1500 g) are especially prone to nutritional deficits. Infants who weigh 1000 g are called “micropreemies.”

Low weight or BMI at conception or delivery, as well as poor weight gain during pregnancy, are associated with LBW, prematurity, and maternal delivery complications (Ehrenberg et al, 2003).

In the United States, infants born to mothers younger than 20 or older than 35 years are more likely to be preterm than infants born to mothers 20–35 years old (March of Dimes, 2009). Teens should be counseled to delay pregnancy until they are adults.

LBW infants have higher risk of mortality, morbidity, and poor growth. Typical problems of the LBW or premature infant include hypoglycemia, hypothermia, jaundice, dry skin, decreased subcutaneous fat, and anemia. Admission to neonatal intensive care units (NICUs) is common, especially for respiratory distress.

Adequate nutrition support almost immediately after birth is important to prevent growth restriction.

Undernutrition at critical stages of development (especially protein) produces long-term short stature, organ growth failure, neuronal deficits of number and dendritic connections, later behavioral and cognitive outcomes (Hay, 2008). Without nutrition starting immediately after birth, the infant enters a catabolic condition, which limits normal development and growth (Hay, 2008). During the first months after discharge, VLBW babies need to have nutrition support to help promote early catch-up growth and mineralization. Careful and frequent monitoring of growth patterns is needed to prevent developmental delays.

Premature breast milk has higher electrolyte, protein, and MCT levels than mature breast milk. Breastfeeding in

the NICU is very beneficial and has long-term benefits for the child (Vohr et al, 2006). Feeding “on demand” is best (Crosson and Pickler, 2004). Preterm infants have lower energy expenditure when they are fed breast milk than when they are fed formula (Lubeztsky et al, 2003). Early feeding increases intestinal lactase activity, which is a marker of intestinal maturity and may influence clinical outcomes. Nearly all studies have shown that minimal enteral feeding approaches (e.g., “trophic feeds”) promote the capacity to feed enterally (Hay, 2008).

Omega-3 fatty acids are important for healthy infants (Fewtrell et al, 2004). Maternal dietary intake of DHA is important. The brain, retina, and neural tissues are rich in DHA and arachidonic acid (ARA). Table 3-9 lists the nutritional deficits found in premature or LBW infants.

Milk has distinct advantages over formulas in avoiding necrotizing enterocolitis (NEC); minimal enteral feeding regimens produce less NEC than more aggressive enteral feeding (Hay, 2008). Caution must also be used in feeding as overfeeding has the potential to produce adipose tissue, or obesity, which then leads to insulin resistance, glucose intolerance, and diabetes (Hay, 2008).

Supplementation for premature infants remains controversial. Glutamine does not decrease sepsis (Poindexter et al, 2004), whereas selenium supplementation does (Darlow and Austin, 2003). Overall, the American Dietetic Association recommends at least five medical nutrition therapy visits for high-risk, premature infants.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** There are no specific markers that predict LBW.

<b>Clinical/History</b>	Apgar scores I & O Hypotension? Infection? Respiratory distress? Retinopathy of prematurity (ROP)?	Alb Ca <sup>++</sup> , Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup> Transthyretin ALT, AST Serum folic acid and vitamin B <sub>12</sub> Serum phosphorus Lecithin to sphingomyelin ratio (L:S ratio) Bilirubin
Birth weight

Temperature (often decreased)		
Sucking reflex		
	<b>Lab Work</b>	
	Gluc H & H; No. of RBCs Anemia?	

**TABLE 3-9 Nutritional Deficits in the Premature or Low Birth Weight Infant**

Problem	Implication
Immaturity at the cellular level	Altered biochemical needs
Underdeveloped digestive/absorptive abilities	Malabsorption
Essential fatty acid deficiency	Slowed growth, renal and lung changes, fatty liver, impaired water balance, RBC fragility, and dermatitis
Delayed oral neuromuscular development and small gastric capacity	Limited ability to consume adequate amounts of nutrients
Marginal nutrient stores at birth	Fat, glycogen, and minerals such as calcium and phosphorus
Slow growth	Higher metabolic demands
Poor nutritional intake of the mother	Deficiencies such as folate

**INTERVENTION****OBJECTIVES**

- Begin feedings of distilled water or colostrum as soon as possible for infants without respiratory distress. Early feeding (3–5 days after birth) tends to allow babies to mature faster; they have fewer days of intolerance, a shorter hospital length of stay, and earlier tolerance of full feedings.
- Encourage the mother to breastfeed as long as possible. Taurine is an especially important nutrient in breastmilk (Verner et al, 2007). If tube feeding is needed, mother can express milk to be given to the infant; it can also be supplemented to meet special needs. Supplement with EFAs and DHA. Assure adequate intake of folate and vitamin B<sub>12</sub> to prevent anemias.
- Provide glucose as soon after birth as possible; adjust according to frequent measurements of plasma glucose to achieve and maintain concentrations >45 mg/dL but <120 mg/dL to avoid hypoglycemia, and hyperglycemia respectively (Hay, 2008).

**SAMPLE NUTRITION CARE PROCESS STEPS****Inadequate Protein-Energy Intake**

**Assessment Data:** Low birth weight, inadequate growth, poor feeding skills.

**Nutrition Diagnoses (PES):** Inadequate intake of protein and energy related to prolonged feeding time and difficulty latching-on, as evidenced by premature birth, underweight (<3 percentile) and irritability after feeding.

**Intervention:** Educate staff and parents about nutritional requirements and appropriate formula choice if mother has discontinued breastfeeding.

**Monitoring and Evaluation:** Weight records, catch-up growth, tolerance of formula feedings, less irritability after feeding.

- When possible, use enteral feedings instead of parenteral to reduce onset of cholestasis and osteopenia.
- Gradually increase energy and protein to meet the needs of rapid growth. For protein, ensure a proper whey to casein ratio.
- With parenteral feeding, include amino acids in proper amounts, especially cysteine, taurine (Wharton et al, 2004), tyrosine, glycine, and arginine (Wu et al, 2004). Intravenous TrophAmine can be used. Be sure selenium is provided (Darlow and Austin, 2003).
- Promote catch-up growth and development. While long-term effects such as metabolic syndrome occur among LBW or premature infants later in life, effective nutrition support is needed (Greer, 2007).
- Prevent illness, rickets, respiratory distress, hypoglycemia or hyperglycemia, NEC, infections, obstructive jaundice, and tyrosinemia.

**FOOD AND NUTRITION**

- While in the radiant warmer, provide water at 60–80 mL/kg body weight/d; gradually increase to 150 mL/kg. Add electrolytes (sodium, potassium, and chloride) on at least the second day.
- Day 1: Breastfeed or give glucose at 6–8 mg/kg/min. Advance by no more than 20 mL/kg daily.
- Progress to special formulas such as Similac Special Care 24 or Enfamil Premature Formula (24 kcal/oz) to yield 120–150 mL/kg up to 180–200 mL/kg/d. NeoSure or Enficare are helpful for transition to home (22 kcal/oz with added Ca<sup>++</sup> and phosphorus).
- Within 7 days, the diet should provide 120–150 kcal/kg BW daily; carbohydrate should be 40–45% total kcal (10–30 g/kg). Protein should be age specific.
- Tube feeding initiation: Start at 10–15 mL/hr at one quarter strength. Progress as tolerated to desired rate. Specialty products have been developed for VLBW infants, such as Mead Johnson's Enfamil Human Milk Fortifier (Berseth et al, 2004). See Table 3-10 for estimated energy and macronutrient calculations.
- Use TPN if not feeding by day 3; glucose infusion rate is 15 mg/kg/min. TPN needs are similar to enteral needs. Crystalline amino acid infusions promote positive nitrogen balance by use of 1 g/kg/d as soon as possible. Use up to 3 g/kg/d of lipid infused continuously or early enteral feeding to prevent cholestatic liver disease. Monitor for carnitine deficiency. See Table 3-11 for recommended vitamin and mineral intakes.
- There may be subtle and delayed hunger cues from the infant. If poor sucking or swallowing instincts exist, the infant may need gavage feeding. Feed every 2 hours or use continuous drip feeding and change to bolus feedings when full strength is tolerated. If infant weighs 1000–1750 g, feed more vigorously; if infant weighs 1750 g or more, feed as a normal-term infant.
- The micronutrient needs of a stable, preterm LBW infant may be as follows: high levels of calcium 120–230 mg/kg; vitamin E (water soluble), 6.0–12.0 mg/kg; 2.5 mg iron/100 kcal in formula (necessary only if stores are depleted); vitamin D, 400 IU/d; folic acid, 25–50 µg/kg; sodium to avoid hyponatremia, 2–3 mEq/kg; vitamin C,

**TABLE 3-10 Nutrient Needs of Preterm Infants**

	Under 2.5 kg body weight	Over 2.5 kg body weight
Daily basal needs	60–80 kcal/kg	40–70 kcal/kg
+ Fecal losses	10–20 kcal/kg	10–20 kcal/kg
+ Growth (tissue synthesis, energy stores)	10 kcal/kg	10 kcal/kg
Total energy needs <sup>a</sup>	110–130 kcal/kg enteral	100–120 kcal/kg enteral
Parenteral needs (no fecal losses, no thermogenic effect of food)	90–110 kcal/kg	80–100 kcal/kg
Protein	3.5–4.0 g/kg enteral	3.6–4.0 g/kg enteral
Amino acids	2–3 g/kg parenteral	3.2–3.5 g/kg parenteral
Lipid	0.5 g/kg for essential fatty acids	0.5 g/kg for essential fatty acids
Fluid	80 mL/kg; increase 10–20 mL/kg daily to 120–160 mL/kg	60 mL/kg; increase 10–20 mL/kg daily to 120–150 mL/kg

<sup>a</sup>Add extra kilocalories for fever (7% per 1-degree elevation); cardiac failure; sepsis; failure to thrive; major surgery; BPD.

Iodide	1 µg/kg	1 µg/kg
Manganese	1 µg/kg	1 µg/kg
Molybdenum	0.25 µg/kg	0.25 µg/kg
Selenium	1.5–2 µg/kg	2 µg/kg
Zinc	400 µg/kg	50–250 µg/kg

Needs are estimated for use with a solution of 2.5 g/dL of amino acids infused at 120–150 mL/kg/dL.

Derived from: Hay WW Jr. Strategies for feeding the preterm infant. *Neonatology*. 94:245, 2008, and Mirtollo, et al. Safe practices for parenteral nutrition. *J Parenter Enteral Nutr*. 28:39S, 2004.

18–24 mg/kg; and phosphorus, 60–140 mg/kg. Monitor need for vitamins A and B<sub>12</sub>, magnesium, zinc, selenium, and copper. Other nutrients should be provided according to DRI tables for the newborn.

- Total fat should be 5–7 g/kg to meet half of energy needs without excess carbohydrate. Soybean oil provides EFAs (1–2% kcals as EFA) in the form of linoleic acid. Exogenous carnitine may be needed to take EFAs into the mitochondria. Inositol may be needed in respiratory distress.

#### Common Drugs Used and Potential Side Effects

- With hyperkalemia and hyperglycemia, continuous intravenous insulin is needed.
- Sometimes, supplemental thyroid hormone or iodide may be prescribed.
- Other medications may be used for underlying disease states. Monitor for side effects.
- Use caution with vitamin supplements. Early vitamin supplementation may promote increased asthma, especially in black children (Milner et al, 2004).

#### Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for LBW or premature infants because there may be allergic or asthmatic reactions.
- Glutamine supplementation does not seem to alleviate NEC.

#### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach the caretaker or parent about increased nutrient needs of LBW or premature infant. Special formulas have

80 kcal/dL (usual is 67 kcal/dL) and have MCT, extra protein, calcium, phosphorus, and sodium.

- Emphasize progression of infant feeding for an adequate growth pattern and weight. Catch-up is common by 2–3 years of age in this population. VLBW infants experience catch-up growth and attain predicted genetic height during adolescence (Anderson, 2008).
- Emphasize the importance of nutrient density for growth (e.g., zinc, vitamin B<sub>6</sub>, and vitamin E).
- Do not overfeed; excess nonprotein energy is stored as fat regardless of its source (fat or carbohydrate). High-energy or MCT intake in otherwise healthy, growing preterm infants should be avoided (Romero et al, 2004).
- Monitor for the tendency to aspirate, for lactose intolerance, and for other problems. Feed slowly to avoid NEC.
- The child may benefit from the WIC program if available.
- Follow-up clinic or home visits are recommended. Offer tips such as using small, frequent feedings; using a quiet, calm environment for feeding; supporting the jaw; and trying special feeding equipment if needed (angle-neck bottle).

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any formula, beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey because of the potential risk of botulism.

## MAPLE SYRUP URINE DISEASE

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

#### DEFINITIONS AND BACKGROUND

Maple syrup urine disease (MSUD) results from an autosomal recessive trait, causing an inborn error of metabolism of the BCAAs leucine, isoleucine, valine. Byproduct ketoacids become elevated and may cause life-threatening cerebral edema and dysmyelination (Riazi et al, 2004). The elevated BCAAs (leucinoses) cause an infant or child with MSUD to become symptomatic. Neurotransmitter deficiencies related to BCAA accumulation, and energy deprivation through

Krebs cycle disruption from ketoacid accumulation, are mechanisms (Zinnanti et al, 2009).

In the United States, MSUD occurs in one in 225,000 births. The Mennonite population from eastern Pennsylvania has a high percentage of births with this disorder. MSUD also occurs in other populations throughout the world. Onset occurs in children between the ages of 1 and 8 years.

Symptoms in an infant include poor sucking reflex, anorexia, FTT, listlessness, irritability, and a characteristic odor (sweet, burnt maple syrup odor of the urine and sweat).

**TABLE 3-12 Types and Nutrition Interventions for Maple Syrup Urine Disease (MSUD)**

Type	Nutrition Intervention
Classic MSUD	Most common. Little or no enzyme activity (usually <2% of normal). Protein from branched-chain amino acids (BCAAs) must be severely restricted.
Intermediate MSUD	Higher level of enzyme activity (approximately 3–8% of normal). Tolerance for leucine is slightly better. Management is the same as for the classic form.
Intermittent MSUD	Milder form; greater enzyme activity (8–15% of normal). Few symptoms until 12–24 months of age, often in response to an illness or larger protein intake. During episodes of illness or fasting, the BCAA levels elevate, the characteristic odor becomes evident, and the child can go into a metabolic crisis.
Thiamin-responsive MSUD	Rare form. Giving large doses of thiamin to the thiamin-responsive child will increase the enzyme activity. Moderate protein restriction is needed.

Derived from: data available at <http://www.msud-support.org/overv.htm>, accessed January 2, 2005.

Afflicted infants have a high-pitched cry and may alternate between being limp or rigid. Without treatment, symptoms progress rapidly to seizures, coma, and death (Schonberger et al, 2004). With earlier diagnosis and treatment, there is a lower risk of peripheral neuropathy.

Nutrition therapy is lifelong. Supplemental isoleucine and valine are usually required (Chuang and Shih, 2001). The amino acid mixture contributes 30–40% of total energy, leaving 60–70% from food (Isaacs and Zand, 2007). Note that thiamin is the coenzyme for BCAAs and should be made available. There are four classifications for the types of MSUD: classic, intermediate, intermittent, and thiamin-responsive; these refer to the amount and type of enzyme activity present. See Table 3-12.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The branched-chain alpha-keto acid dehydrogenase (BCKD) is missing.

#### Clinical/History

Perspiration with maple odor  
Grand mal seizures?  
Hypertonicity  
Cerebral edema?

#### Lab Work

Plasma leucine, isoleucine, valine (therapeutic range of 100–300  $\mu\text{mol/L}$ )

Plasma L-alloisoleucine 0.5 $\mu\text{mol/L}$ (most specific and most sensitive for MSUD)	Urinary excretion of ketoacids Urine odor of burnt maple syrup Alb	Globulin Uric acid (increased?) H & H Serum Fe Serum osmolality
---	--	---

## INTERVENTION

### OBJECTIVES

- Prevent endogenous protein catabolism (Morton et al, 2002).
- Prevent toxic concentrations of BCAAs (Riazi et al, 2004) by using an appropriate medical formula, special intravenous feeding, or low-BCAA diet. Monitor serum levels of leucine frequently to determine current status.
- Support normal growth and development with adequate protein synthesis and prevention of essential amino acid deficiencies. Overcome any difficulty with feeding related to poor sucking reflex.
- Control intake of BCAAs for life. As the child grows, add BCAAs individually in a controlled manner.
- Maintain normal serum osmolality (Morton et al, 2002).
- In emergencies, hemodialysis is sometimes necessary (Hmiel et al, 2004).

## FOOD AND NUTRITION

- Restrict intake of BCAAs in the diet to 45–62 mg/d (Riazi et al, 2004). Use Mead Johnson's MSUD powder or Ross Laboratories' Maxamaid MSUD. Use the latter with PFD1 or PFD2 (Mead Johnson) because it contains no cholesterol or fat.
- When BCAA levels are high (during illness or fasting), it may be necessary to use a specific IV solution that allows the excess leucine, valine, and isoleucine to be used for protein synthesis in the body, thereby rapidly decreasing the elevated levels.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Protein Intake

**Assessment Data:** Weight and growth charts, elevated serum leucine.

**Nutrition Diagnoses (PES):** Excessive protein intake related to MSUD and genetic inability to metabolize large amounts of dietary BCAAs as evidenced by high serum leucine and elevated urinary keto-acids.

**Intervention:** Educate parents about appropriate formula to manage MSUD. Counsel about appropriate formula and food sources of leucine and needed supplements, including thiamin.

**Monitoring and Evaluation:** Weight records, growth, improved appetite, improved serum and urinary lab test results.

- Provide adequate energy intake from CHO and fat to spare amino acids for building tissue, etc.
- Use small amounts of milk in the diet to support growth. Cow's milk contains 350 mg of leucine, 228 mg of isoleucine, and 245 mg of valine per 100 mL.
- Avoid eggs, meat, nuts, and other dairy products. Gelatin, a form of protein low in BCAAs, may be used in the diet.
- If hemodialysis is needed, monitor fluid, protein, and electrolytes carefully.

### Common Drugs Used and Potential Side Effects

- Sometimes insulin or a similar agent is given to speed up the utilization of excess BCAAs.
- The doctor may prescribe large doses of thiamin for children who are thiamin-responsive.
- Avoid use of aspirin with MSUD; individuals with this condition are more prone to Reye's syndrome.
- Norleucine is being tested as a possible treatment for emergency management of MSUD crises.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for MSUD because there are no controlled trials to prove efficacy.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Educate caregiver and patient that the diet must be maintained for life.
- Discuss the diet's total energy and protein intake that are appropriate for the patient's age and stage of development.
- Illness or infection can cause elevations of BCAAs. This can lead to vomiting, diarrhea, irritability, sleepiness, unusual breathing, staggering, hallucinations, and slurred speech. This is an emergency and must be treated immediately.
- With knowledge of the pathophysiology of MSUD and understanding of what to do for cerebral edema, fluid and electrolyte management, nutrition, and psychosocial issues, a full life is possible (Robinson and Drumm, 2001).

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# NECROTIZING ENTEROCOLITIS

## NUTRITIONAL ACUITY RANKING: LEVEL 4

Adapted from: Ronald L. Eisenberg, *an Atlas of Differential Diagnosis*, 4th ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

### DEFINITIONS AND BACKGROUND

NEC involves ischemia of the intestinal tract and invasion of the mucosa with enteric pathogens. This is a common GI problem in preterm and SGA infants with tissue injury and inflammation, congenital heart disease, or with Hirschsprung's disease. Symptoms and signs include a distended abdomen, lethargy, respiratory distress, pallor, hyperbilirubinemia, vomiting, diarrhea, grossly bloody stools, and sepsis.

NEC is the leading cause of short bowel syndrome in infancy; it is a medical emergency. NEC affects about 1–8% of all admissions to NICUs. Thrombocytopenia within the first 3 days after a diagnosis of NEC suggests a higher likelihood of bowel gangrene, morbidity, and mortality (Kenton et al, 2005). Neonatal endotoxemia and release of proinflammatory cytokines are important contributors to NEC; gut barrier failure plays an important role in adverse outcomes (Sharma et al, 2007).

If feeding intolerance is significant, it is beneficial to use breast milk rather than formula. Milk has distinct advantages over formulas; minimal enteral feeding regimens produce less NEC than more aggressive enteral feeding (Hay, 2008). There is no conclusive evidence about the use of special formulas that include glutamine or arginine. Preventive strategies include amino acid or polyunsaturated fatty acid administration (Reber and Nankervis, 2004).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** NEC is not genetic in origin.

<b>Clinical/History</b>	Weight/birth weight	Diet/intake history
	Height/length	

Head circumference	<b>Lab Work</b>	Pro time (prolonged), INR
Vomiting	CBC; elevated WBCs	Guaiac test for blood in stools
Diarrhea?	Thrombocytopenia (low platelet count)	Na <sup>+</sup> (decreased)
Distended abdomen	Neutropenia	K <sup>+</sup> (increased)
Lethargy	Hemoglobin (decreased)	Platelets (decreased)
Respiratory distress	Hct (altered?)	Gluc
Pallor	Abdominal x-rays	Lactic acidosis
Hyperbilirubinemia		pO <sub>2</sub> , pCO <sub>2</sub>
Grossly bloody stools		
Sepsis		

### INTERVENTION

### OBJECTIVES

- TPN is needed for 14–21 days while the intestine heals.
- Prevent or correct dehydration, hypoglycemia, and electrolyte imbalances.
- Correct diarrhea and further malnutrition.
- Prepare patient for bowel surgery, for wound healing, and for the possibility of ostomy feeding if surgery becomes necessary, as for perforation or after peritonitis.
- Because breastfeeding is more protective than formula feeding, promote maternal breastfeeding or use of donor milk after TPN (Updegrave, 2004).

### FOOD AND NUTRITION

- Acute: No oral feedings; use IVs to support circulation. TPN as appropriate with periods of extensive intestinal inflammation and peritonitis.
- Recovery: Use two times RDA of protein; 25% more kilocalories than normal for age; frequent feedings. Where possible, offer donor milk if mother cannot breastfeed.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Increased Energy Expenditure

**Assessment Data:** Weight loss, sepsis, diarrhea and vomiting, fever, stooling pattern.

**Nutrition Diagnoses (PES):** Increased energy expenditure related to NEC with losses from diarrhea and vomiting as evidenced by fever, bloody stools, distended abdomen, and altered lab values.

**Intervention:** Provide support for use of breastmilk, where possible.

**Monitoring and Evaluation:** Weight stabilization or gains in growth, cessation of bloody stools and diarrhea or vomiting, resolution of fever and sepsis, lab values returning to normal.

- Some partially elemental formulas are available, such as Pregestimil or Nutramigen, or more elemental nutrients may be required if the digestive tract has not recovered fully. Among infants between 1000 and 2000 g at birth, giving feedings at 30 mL/kg/d seems to be a safe practice and is faster than using 20 mL/kg/d (Caple et al, 2004).
- Ensure adequate iron, copper, and zinc. Iron-fortified products may reduce the need for blood transfusions in VLBW infants (Berseth et al, 2004). Copper seems to protect against TPN-related liver damage from intrauterine growth deficits (Zambrano et al, 2004).
- Occasionally, a colostomy or ileostomy must be performed, and tube feeding may be needed.

### Common Drugs Used and Potential Side Effects

- Aggressive treatment of hyperglycemia may be needed, as with insulin (Hall et al, 2004). Monitor for side effects.
- Systemic antibiotics are started, usually a  $\beta$ -lactam antibiotic and an aminoglycoside. Some outbreaks may be infectious.

### Herbs, Botanicals, and Supplements

- Studies suggest use of probiotics (Henry and Moss, 2004). A systematic Cochrane review promotes enteral feeding of probiotics in preterm infants >1000 g at birth but not for smaller infants (Alfaleh and Bassler, 2008). *Lactobacillus acidophilus* and *Bifidus infantis* may be beneficial.
- Herbs and botanicals should not be used for NEC.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Promote breastfeeding or use of donor milk.
- When formula is used, assure that the parent/caretaker understands the differences between ready-to-feed and concentrated formula related to, hypertonicity of the solution.
- If surgery and short-gut is the resolution, long-term TPN may be needed.
- Careful monitoring of growth is important. Besides bowel sequelae, VLBW infants who survive NEC are at risk for impairment of growth and neurodevelopment (Yeh et al, 2004).
- Monitor weight and stool changes; advise physician when necessary.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer. Powdered infant formulas are not sterile and may contain pathogenic bacteria; milk products are also media for bacterial proliferation (Agostoni et al, 2004).
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# NEURAL TUBE DEFECTS: SPINA BIFIDA AND MELOMENINGOCELE

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Reprinted with permission from: Pillitteri A. *Maternal and Child Health Nursing*, 4th ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

The neural tube folds and closes during the third and fourth weeks of pregnancy to form the brain and spinal cord (Li et al, 2006). Neural tube defects (NTDs) are serious birth defects of the spine (spina bifida) and brain (anencephaly), affecting approximately 3000 pregnancies each year in the United States. Women at risk for having a baby with NTDs are of English/Irish ancestry or Hispanic ancestry, may have diabetes mellitus, are obese, have poor dietary habits, or take medications that are folate antagonists.

The natural folates are chemically unstable and poorly bioavailable in contrast to the chemical form, folic acid (Scott, 2009). Periconceptional consumption of folic acid (400 mg daily) reduces the occurrence of NTDs by 50–70% (Centers for Disease Control and Prevention, 2004; Hamner et al, 2009). No more than one fifth of women take supplements effectively, largely due to the fact that over half of pregnancies are unplanned (Scott, 2009).

A remarkable successes of epidemiology was the demonstration in the late twentieth century that spina bifida and anencephaly are caused primarily by folate deficiency (Oakley, 2009). The genetic MTHFR polymorphisms may cause congenital folate malabsorption, severe MTHFR deficiency, and formiminotransferase deficiency (Whitehead, 2006). In these cases, diets deficient in folate *do not* influence the incidence or severity of NTDs; folic acid and methionine cycle genes for SNP genotyping alter the effects of diet (Boyles et al, 2006).

Low levels of betaine-tHcy methyltransferase (BHMT) and choline may be associated with NTDs (Boyles et al, 2006; Innis et al, 2007; Shaw et al, 2004). Betaine (trimethylglycine) is formed from choline, or from the diet (seafood, wheat germ, bran, and spinach). Risks may be greater when vitamin B<sub>12</sub> status is low (van der Linden et al, 2006). Because results vary from one population to another, studies are needed to clarify how different populations respond to betaine and choline from diet or supplements.

**Spina bifida** includes any congenital defect involving insufficient closure of the spine (usually laminae of the vertebrae). Most defects occur in the lower lumbar or sacral areas of the back (the lowest areas of the back) because this area is the last part of the spine to close. **Spina bifida occulta** involves the bones of the spine not closing completely while the spinal cord and meninges remain in place; skin covers the defect. **Spina bifida cystica** is more severe. **Anencephaly** forms when the brain does not close; the baby lacks parts of the brain, skull, or scalp, may be deaf, blind, and usually will not thrive.

In **meningoceles**, the meninges (the membranes covering the spinal cord) protrude through the vertebral defect but the spinal cord remains in place. Clubfoot, dislocated hip, scoliosis, and other musculoskeletal deformities may also be present. **Myelomeningocele (MMC)** is one of the most severe forms of birth defects of the brain and spinal cord. MMC accounts for about 75% of all cases of spina bifida, affecting 1 of every 800 infants. Pregnant women may show a positive alpha-fetoprotein level during prenatal testing in a triple screen. The spinal canal is incomplete. This causes decreased or lack of function of body areas controlled at or below the defect. Partial or complete paralysis of the legs, partial or complete lack of sensation, loss of bowel or bladder control, meningitis, hydrocephalus, and hip dislocation may also be present. Sometimes, surgery for the tethered cord or to repair the hydrocephalus improves quality of life. MMC patients are usually wheelchair bound, wear braces, or use crutches. Obesity can increase likelihood of pressure ulcers or make ambulation and surgery more difficult.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Folate status is a significant determinant of NTD risk; genetic variation, folate nutriture, and specific metabolic, and/or genomic pathways are involved (Beaudlin and Stover, 2007). Women who have a methylenetetrahydrofolate reductase (MTHFR) allele tend to have a higher risk for giving birth to an infant with an NTD. Hispanic and Latina women,

women from the United Kingdom and Italy may have this allele and should be tested before pregnancy.

<b>Clinical/History</b>	Spinal x-rays or computed tomography (CT) scan	H & H Serum Fe Chol Na <sup>+</sup> , K <sup>+</sup> Ca <sup>++</sup> , Mg <sup>++</sup> Serum folic acid MTHFR allele? Hcy Serum B <sub>12</sub> , Methylmalonic acid
Height, weight	Diarrhea or Constipation	
Birth weight/length	Incontinence	
Growth percentile	Skin integrity	
Weight changes	Hydrocephaly	
Diet/intake history (folate, choline, B <sub>12</sub> , betaine)	<b>Lab Work</b>	
Temperature	Gluc	
I & O	Alb,	
Vertebral defect	transferrin	

## INTERVENTION

### OBJECTIVES

- Manage feeding problems, which are common. Assure proper positioning for all feedings.
- Achieve and maintain ideal BMI for age. There are decreased energy needs because of short stature and limited mobility. Obesity is common.
- Reduce impact of the defect. Promote any and all possible ambulation or activity.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Folic Acid Intake

**Assessment Data:** Prenatal weight gain, dietary records, and nutrient analysis, MTHFR allele.

**Nutrition Diagnoses (PES):** NI 54.2. Inadequate vitamin (folic acid) intake related to diet history and increased needs during pregnancy as evidenced by diet recall with folate intake much lower than needs in pregnancy (600 mcg) and prior birth of an infant with NTD.

#### Interventions:

Food and Nutrient Delivery:

ND 1.3. Add natural sources of folate to diet—orange juice, carrots, green vegetables.

ND 1.3. Eat fortified cereal at breakfast and whole grains such as oatmeal, brown rice.

ND 3.2. Recommend folic acid supplement of 400 µg/d.

Education: Rich folate sources from food; importance of taking a daily multivitamin supplement.

Counseling: Investigate need for L-methylfolate during pregnancy related to genetic allele.

**Monitoring and Evaluation:** Weight and health records. Prenatal care and intake of supplemental folic acid. Note of willingness to comply with recommendations.

- Correct infections; prevent or correct sepsis and pressure ulcers.
- Correct nutrient deficiencies.
- Alter diet to prevent or correct constipation, obesity, and UTIs.
- Increase independence and self-care potentials.
- Preserve brain function as far as possible.
- Correct swallowing problems (from Arnold–Chiari malformation of the brain).
- Initiate treatment or surgical intervention as appropriate.

## FOOD AND NUTRITION

- Individualize diet for proper nutrition to achieve a desirable weight and monitor carefully.
- Decrease energy to control weight. Use special growth charts. The standard CDC charts will be irrelevant. For children under age 8 who are minimally active, use 9–11 kcal/cm or 50% fewer calories than recommended for child of a similar age (Lucas, 2004, p. 41). For older teens or adults, 7 kcal/cm may be needed for weight loss; generally, needs are about 50% of normal.
- Provide adequate protein, folic acid, B-complex vitamins, choline, betaine, zinc, and other nutrients for age.
- Low-calorie snacks may be the only between-meal snacks allowed.
- Provide adequate nutrients for wound healing if surgery has been performed. For healing of any pressure ulcers, adequate zinc, vitamins A and C, and protein are required.
- For females of childbearing age, pay attention to folic acid, choline, vitamin B<sub>12</sub>, betaine intakes. A multivitamin with minerals should be recommended for those who lack variety in their diets.
- Ensure adequate fiber intake and fluid to prevent or correct problems with diarrhea or constipation.
- Individuals with spina bifida are often allergic to latex; they may require a diet that limits use of apples, avocado, banana, bell pepper, cherries, chestnut, kiwi, nectarines, peach, plums, potato, and tomato.

## Common Drugs Used and Potential Side Effects

- Antibiotics may be required if the patient develops sepsis. Use of acidophilus and probiotic products may alleviate loss of intestinal bacteria.
- Avoid zinc and iron with parenteral administration in sepsis; these are bacterial nutrients.
- Botulinum-A toxin injections have been used in cases of neurogenic detrusor overactivity to manage some bladder incontinence (Leippold et al, 2003). Otherwise, medications for managing urinary incontinence may be used; monitor for side effects.
- Medications prescribed may affect the utilization of folate: anticonvulsant medications (e.g., phenytoin), metformin, sulfasalazine, triamterene, and methotrexate. Other medications deplete important nutrients prenatally, such as antibiotics, antihypertensives, cathartics, corticosteroids, stimulants, sulfonamides, and tranquilizers. Vitamin and mineral supplements are needed to compensate for the specific nutrient alteration.

- Sulfonamides may crystallize vitamin C in the bladder; extra vitamin C, protein, iron, and folate may be needed.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used because there are no controlled trials to prove efficacy for any related problems.
- Use of low-calorie cranberry juice may help reduce UTIs.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Behavior modification, low-calorie food and snack preparation, rewards, and activity/exercise factors should be reviewed with the parent/caretaker. Food lists with green “go” foods, red “stop” foods, and yellow “caution” foods have been used with success in weight management.
- Discuss potential medical conditions, such as fractures, seizures, lazy eye, early puberty, and latex allergy. Bone health and allergies can be managed with some nutritional interventions.
- Family counseling may be needed in preparation for future pregnancies. Referral to a local chapter of the March of Dimes may be beneficial.
- Even with food fortification, women of childbearing age should be advised to take a folic acid–containing supplement on a daily basis (Schuaibi et al, 2008). Choline, betaine, and B<sub>12</sub> should be included as well.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# OBESITY, CHILDHOOD

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4 (COUNSELING)

Asset provided by Anatomical Chart Co.

## DEFINITIONS AND BACKGROUND

The prevalence of overweight is increasing for children and adolescents in the United States. “At risk for overweight” is defined by the sex- and age-specific  $\geq 85$ th percentile cutoff points of the CDC growth charts or of BMI for age; overweight or obese is defined as  $\geq 95$ th percentile of growth charts or BMI for age. BMI increases during the first year of life and then decreases; it begins to rise again at 6–6.5 years of age. BMI tables are not useful before age 2; they are a screening tool and do not reflect body composition well. While BMI tables have limitations, they are considered a reasonable place to begin; an increase in BMI of three to four units is a reason to investigate further.

The preferred weight gain pattern in childhood is as follows: infant doubles birth weight by 6 months and triples birth weight at 12 months. Tripling birth weight before 1 year is associated with increased risk of obesity. In year 2, gain is 8–10 lb (3.5–4.5 kg); in year 3, gain is 4.5–6.5 lb (2–3 kg); annually thereafter, the gain is about 4.5–6.5 lb (2–3 kg). Until 6 years of age, the number of fat cells increases (hyperplasia). After 6 years of age, the size of fat cells increases (hypertrophy). Hormones play a role. Leptin, insulin, and adiponectin regulate lipid metabolism.

**TABLE 3-13 Complications of Childhood Obesity**

Psychosocial	Poor self-esteem
	Anxiety
	Depression
	Eating disorders
	Social isolation
	Lower educational attainment
Neurologic	Pseudotumor cerebri
Endocrine	Insulin resistance
	Type 2 diabetes
	Precocious puberty
	Polycystic ovaries (girls)
	Hypogonadism (boys)
Cardiovascular	Dyslipidemia
	Hypertension
	Coagulopathy
	Chronic inflammation
	Endothelial dysfunction
Pulmonary	Sleep apnea
	Asthma
	Exercise intolerance
Gastrointestinal	Gastroesophageal reflux
	Steatohepatitis
	Gallstones
	Constipation
Renal	Glomerulosclerosis
Musculoskeletal	Slipped capital femoral epiphysis
	Blount's disease <sup>a</sup>
	Forearm fracture
	Back pain
	Flat feet

<sup>a</sup>Blount's disease is a growth disorder of the tibia that causes the lower leg to angle inward (tibia vara).

Obesity is an epidemic. Rates of unhealthy body weight among children and adolescents have tripled since the 1980s. Three critical periods for prevention of adult obesity are: ages 5–7 years, adolescence, and pregnancy. Interaction between genes in the fetus and maternal overnutrition or undernutrition are relevant; obese women should attempt healthy weight loss before they become pregnant (American Dietetic Association, 2009). Women should then be encouraged to breastfeed.

After birth, overfeeding for catch-up growth in a premature or underweight child can contribute to obesity; weight gain proceeds at a rate that is too fast for linear growth. Overnutrition, resulting from high birth weight or gestational diabetes, is associated with subsequent fatness in the child. Many adult-onset disorders are showing up in obese children; see Table 3-13.

Research suggests that phthalates from soft plastics disrupt endocrine glands and affect hormones that regulate bodily functions; long-term exposure may contribute to obesity. In addition to genetics and environment, social factors in childhood also strongly influence adult obesity. Parents should provide children with access to nutrient-dense foods and beverages and high-fiber foods; reduce children's access to high-calorie, nutrient-poor beverages and foods both at home and at restaurants; avoid excessive food restriction; do not use food as a reward; and encourage children to eat breakfast on a daily basis (Ritchie et al, 2005). A Lifestyle Behavior Checklist may be used to identify problems that parents have in managing the behavior of their children and their confidence in doing so (West and Sanders, 2009). Management of preadolescent obesity seems to be most successful when it is started during preschool years.

Counseling must distinguish between “simple obesity” and severe or “morbid” obesity in the child, as well as the comorbidities. Major attitudinal changes are often needed in parents or caretakers when a child has reached the severe/morbid phase. Table 3-14 offers tips for weight loss plans.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Twin studies have shown that 40–70% of the variation in BMI is inherited. The genetics of obesity is a work in progress; see Web site <http://obesitygene.pbrc.edu/>. Research suggests an association between the FTO, MC3R, seven other genes, and overweight.

Clinical/History	Height	weight into adulthood
Maternal gestational diabetes	Present weight	BMI $\geq 95\%$ = overweight with need for in-depth assessment
Gestational age at birth	Weight hx	
Birth length, birth weight	Diet/intake history	
	BMI 85–94% = at risk of continuing over-	

**TABLE 3-14 When to Initiate Weight Loss Diets in Children**

Children aged 2–7 years	BMI: 85th to 94th percentiles; BMI greater than the 95th percentile with no complications	Maintain weight
	BMI is above the 95th percentile with mild complications (mild hypertension, dyslipidemia, insulin resistance)	Gradual weight loss is recommended
	Patients with acute complications such as pseudotumor cerebri, sleep apnea, obesity hypoventilation syndrome, or orthopedic problems	Refer to a pediatric obesity center
Children 7 years of age and older	BMIs between the 85th and 94th percentiles with no complications	Maintain weight
	If the BMI is between the 85th and 94th percentiles with mild complications or the BMI is equal to or above the 95th percentile	Gradual weight loss is recommended

## INTERVENTION

### OBJECTIVES

Health Recommendations (American Academy of Pediatrics, 2009)

- Identify and track patients at risk by virtue of family history, birth weight, or socioeconomic, ethnic, cultural, or environmental factors. Calculate and plot BMI annually in all children and adolescents; use change in BMI to identify rate of excessive weight gain relative to linear growth. Develop a weight maintenance or weight loss plan that is individualized for the child.
- Encourage parents and caregivers to promote healthy eating patterns by offering nutritious snacks, such as vegetables and fruits, low-fat dairy foods, and whole grains; encouraging children's autonomy in self-regulation of food intake and setting appropriate limits on choices; and modeling healthy food choices.
- Routinely promote physical activity, including unstructured play at home, in school, in child care settings, and throughout the community. Limit television, computer, and video time to a maximum of 2 h/d.
- Recognize and monitor for risk factors such as hypertension, dyslipidemia, hyperinsulinemia, impaired glucose tolerance, metabolic syndrome, early puberty, liver disease, eating disorders, skin infections, food allergies, asthma, and sleep apnea.

- Discuss tips that are easily handled by the dietetics professional; refer complex cases to a behavioral specialist. Discourage the use of sweets and foods to reward behavior. Avoid the “clean plate” theory, but be wary about withholding food, which can have the opposite effect.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Overweight

**Assessment Data:** Weight and growth charts, physical activity pattern showing sedentary lifestyle and minimal activity (no recess, outside activity swing use set only), BMI >85 percentile for age.

**Nutrition Diagnoses (PES):** Excessive energy intake (N1–1.5 or N1–2.2) related to low physical activity level and intake of high calorie snacks as evidenced by diet and activity records.

### Interventions:

Food-nutrient delivery:

ND 1.1. General healthful diet; establishing regular meal patterns (three meals a day with two snacks) that follow healthy plate tool, incorporating fiber into the diet (more whole grains, more fruits and vegetables), increasing to about 26 g/d.

ND 1.3. Specific foods and beverages (healthy snacks and low-calorie beverages).

Education:

E 1. Initial/brief nutrition education on label reading, portion sizes of food, and fiber intake. Educate parents about how to increase activity levels with games, dancing, outside play, and healthier, lower calorie snacks and beverages.

Counseling:

C 2. Nutritional-related cognitive behavioral therapy using motivational interviewing to determine what parents and patient want to change and are willing to work on regarding high fat/sugary foods in the home, frequent fast food meals, and inadequate fiber intake.

Coordination of care

RC 1. Referral to an agency or dietitian who conducts grocery store tours to help choose foods more wisely.

**Monitoring and Evaluation:** Weight records, growth chart showing improved height for weight (below 85 percentile BMI) for age.

- Help the child “find” the right body for him or her. Encourage self-recognition of hunger cues (e.g., stop eating when feeling “full”).

### Advocacy Objectives

- Help parents, teachers, coaches, and others who influence youth to discuss health habits, not body build, as part of their efforts to control overweight and obesity.
- Enlist policy makers from local, state, and national organizations and schools to support a healthful lifestyle for all children, including a proper diet and adequate opportunity for a regular physical activity.
- Encourage organizations that are responsible for health care and health care financing to provide coverage for effective obesity prevention and treatment strategies.
- Encourage public and private sources to direct funding toward research on effective strategies to prevent overweight and obesity and to maximize limited family and community resources.
- Support social marketing that promotes healthful food choices and increased physical activity.

## FOOD AND NUTRITION

- Support needs for the child according to age and sex of the child: protein at 10–35%, fat at 25–40%, and CHO at 45–65% (Institute of Medicine, 2002). Plan a diet with basal calories plus activity, and likelihood of growth spurts.
- Weight loss is typically recommended for children over age 7 or for younger children who have related health concerns; slow and steady—anywhere from 1 lb/wk to 1 lb/mo (Mayo Clinic, 2009).
- For family teaching, discuss easy behavioral changes. Place less emphasis on a specific calorie level than on portion sizes that are child-appropriate. Use MyPyramid for kids.
- Emphasize low-fat, low-cholesterol foods with elevated cholesterol. Use plant stanols and sterols in the diet.
- Reduce the energy intake by reducing the energy density of foods, increasing fresh fruits and nonstarchy vegetables low-calorie versions of products. Decrease the use of sweets as snack foods or dessert. Decrease the use of fatty or fried foods.
- Include sources of iron, B-complex vitamins, vitamin C, and protein, if needed to correct anemias.
- Limit milk to a reasonable daily amount for the age. Be sure others foods are consumed in addition to milk. Use low-fat or skim milk after 2 years of age.
- Limit juice to 6 oz for young children. Limit sugar-sweetened beverages in general.
- Added sugars in foods/beverages should comprise <25% of total calories consumed.
- Control between-meal snacks; offer fresh fruit or vegetables, plain crackers, pretzels, plain popcorn, cooked egg slices, unsweetened fruit or vegetable juices, and low-fat cheese cubes. Age-appropriate snacks are important; avoid popcorn and other foods that may cause choking in young children.
- Give small helpings at meals; allow more small helpings until “full.” Discuss “hunger cues” and “satiety cues.”
- Ensure that the family has adequate fluoridated water, as dental caries are common.

## Common Drugs Used and Potential Side Effects

- Discourage the use of drugs for weight loss; no diet medicines are safe for children younger than 16 years. Sibutramine added to a comprehensive behavioral program for teens can induce significant weight loss.
- Antidepressants are sometimes prescribed for childhood depression, which is common. Side effects such as changes in metabolism and appetite can contribute to obesity in some children. Both childhood depression and anxiety are associated with increased BMI percentiles; childhood psychopathology is an important factor that should be carefully monitored (Rofey et al, 2009).

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for childhood obesity; there are no controlled trials to prove efficacy or safety.
- Physicians may ask dietitians to discuss herbs, botanicals, life cycle, and disease-specific and obesity guidance with their patients.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Responsibilities should be shared. Parents are responsible for a proper emotional setting and for what is offered; the child is responsible for what and how much is eaten (Satter, 2009). Emphasis becomes *supporting each child's normal growth* (Satter, 2009). See Table 3-15 for more tips.
- Intervention should start early and focus on the family, not just the child. Educate parents about the dangers of medical complications.
- Discuss age-appropriate portions and snacks. Many parents innocently overfeed their children; show them child-sized plates and utensils with sample portion sizes.
- Try to alter intake of one “problem food” per visit (regular soda or sugar-sweetened fruit punch). Diluting juice, substituting lower calorie beverages, and calculating number of calories saved can be quite effective. Reading labels is a useful teaching tool.
- Tailor treatment and prevention efforts for each person. Interactive interventions and self-monitoring are keys to success for many individuals (Lombard et al, 2009). Internet-based coaching sessions may be quite helpful as they can be tailored to the individual's needs and concerns (Block et al, 2008).
- Integrate culturally appropriate approaches and strategies. Bilingual professionals might help with developing culturally sensitive programming.
- Encourage regular family meals whenever possible; limit unplanned or habitual snacking. Between meals, ice water can be offered as a special treat instead of sweetened beverages. Good role modeling by parents is essential. Maintain the child's self-image through positive reinforcement.
- Discuss the relationship of food, weight, and energy balance. Metabolic rates are low while watching television. When working with families to prevent and treat childhood

**TABLE 3-15** Components of Successful Weight Loss for Children

Component	Comment
Reasonable weight loss goal	Initially, a rate of 1 lb per month if <95th or >85th percentile with comorbidity, based on age.
Dietary management	Guide family choices rather than dictating; encourage child to eat when hungry and to eat slowly. Encourage family meals. Avoid using food as reward or withholding as punishment. Drink plenty of water and limit sugar-sweetened beverages. Plan healthy snacks. Aim for five servings of fruits and vegetables each day. Promote healthy breakfast each day. Consume milk with dinner instead of soft drinks.
Physical activity	Begin according to child's fitness level, with ultimate goal of 60 minutes of moderate activity daily.
Behavior modification	Teach self-monitoring, nutritional education, control of cues, modification of eating habits, physical activity, attitude change, reinforcements, and rewards.
Family involvement	Review family activity and television viewing patterns; involve parents in nutrition counseling.

Adapted from: Mullen MC, Shield J. *Childhood and adolescent overweight: the health professional's guide to identification, treatment and prevention*. Chicago, IL: American Dietetic Association, 2004.

weight problems, one should attend to children's time spent with screen media, the frequency of family meal-times, and parents' perceptions of neighborhood safety for children's outdoor play (Gable et al, 2007). Limit television and nonproductive computer time to <2 hours daily (American Academy of Pediatrics, 2009). Encourage activity, such as jogging, ball games, swimming, bike riding, and school-based physical activities, since many children who enter adolescence overweight will become overweight or obese adults. Dance videos are easy to do at home, especially for children who are self-conscious.

- Discourage potentially dangerous weight-control schemes or practices.
- A system for "traffic light" foods can be used for younger children: green for "go" foods, yellow for "caution" foods, and red for "stop" foods.
- Parents who practice restrained eating with their children tend to be overly indulgent later (fast/feast); the result is chronic anxiety. Eating can become very controlled, inconsistent, and emotional. Highlight nonfood-related achievements; avoid nagging about diet or food.
- In extreme obesity, bariatric surgery may be needed. Improved quality of life generally occurs for teens (Murray, 2008). However, there are profound implications and risks that differ from adults; they may have greater weight regain and may be noncompliant with treatment after surgery (Levitsky et al, 2009). Research on nonsurgical treatments is on-going.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing meals.
- Before using tap water as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard beverage or food that has been left at room temperature for 2+ hours.

## OTITIS MEDIA

### NUTRITIONAL ACUITY RANKING: LEVEL 1

### DEFINITIONS AND BACKGROUND

Acute OM (acute middle ear infection) occurs when there is a bacterial or viral infection of the fluid of the middle ear that leads to production of pus, excess fluid, or even bleeding in the middle ear. The Eustachian tube becomes clogged. Tubes of the ear of a child are shorter and less slanted than in adults, allowing bacteria and viruses to find their way into the middle ear more easily. Pressure from fluids associated with OM may cause the eardrum to rupture.

Ear infections often occur along with respiratory infections (such as *H. influenza*) or with blocked sinuses and Eustachian tubes caused by allergies. OM with effusions (OME) can lead to significant hearing loss in children if not properly treated. Recent illness of any type and lowered immunity; crowded or unsanitary living conditions; genetic factors; cold climate and high altitude; and bottle feeding of infants (can allow fluid to pool in the throat near the Eustachian tube) may be etiologies. LBW infants may be prone to repeated ear infections.

Breast milk is more protective than formula feeding (Ip et al, 2007). Breast milk contains lactoferrin and a number of other anti-inflammatory factors (Hanson, 2007). The prevalence of early-onset and repeated OM continues to increase among preschool children; an increase in prevalence of allergic conditions is a concern (Auinger et al, 2003).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Susceptibility to infections may run in families.

#### Clinical/History

Height  
Birth length  
Birth weight  
Present weight  
Diet/intake history  
Family history of asthma, allergies

#### I & O

Fever?  
Irritability, fussiness?  
Exposure to cigarette smoking?  
Audiometry

#### Lab Work

H & H  
Serum Fe  
Chol, Trig  
Gluc  
Alb  
Na<sup>+</sup>, K<sup>+</sup>  
Serum IgE and allergy testing

### INTERVENTION

### OBJECTIVES

- Promote breastfeeding of newborns, especially for 6 months or longer.
- If formula fed, babies should be positioned in a semi-upright position so that the milk will flow downward into the baby's stomach and not wash up and into the baby's nasal passages and up through the Eustachian tubes. Always position the infant's head higher than the stomach.
- In older children, monitor nutrient density of the diet to maintain a healthy immune system. Inclusion of more fruit and a children's multivitamin–mineral supplement may be needed for poor eaters or during food jags.
- Prevent chronic suppurative OM and hearing loss.

### FOOD AND NUTRITION

- Determine the recommended allowances for the child's age group: kilocal, protein, and other nutrients. Plan a reasonable menu pattern accordingly.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Intake of Unsafe Foods

**Assessment Data:** Diet and intake history, recent lab testing indicating allergy to milk and eggs, frequent ear infections, notation that infant was not breastfed after 3 weeks of age.

**Nutrition Diagnoses (PES):** Intake of unsafe foods related to recent identification of specific food allergies (milk, eggs) as evidenced by six ear infections in past 2 years.

**Intervention:** Educate parents about foods that are to eat/prepare; food labeling; choices at restaurants, schools. Counsel about adapting recipes and holiday meals that suit the family.

**Monitoring and Evaluation:** Alleviation of responses to food allergens, improvement or elimination of food allergy reactions at home, at school, and out at restaurants. Improved nutritional quality of life as observed by parent(s).

- Highlight foods that include sufficient levels of iron, vitamins A, D<sub>3</sub>, and C, and zinc to support a healthy immune system to fight further infections. Studies are under way to determine if antioxidant-rich foods make any difference in healing.
- If child has food allergies, discuss options for maintaining a healthy diet, especially if large food group categories must be eliminated.

## Common Drugs Used and Potential Side Effects

- Antibiotics such as penicillin are often prescribed for bacterial infections; side effects may include rash, vomiting, and diarrhea. Viral infections have to run their course.
- Vaccines may be available for some of the bacterial agents that cause OM.

## Herbs, Botanicals, and Supplements

- Xylitol may have anti-adhesive factors for reducing infections, but no commonly available products have been tested.

- Probiotics in foods such as yogurt can help to replenish the gut and support healthy immunity.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain to parents that overfeeding can aggravate asthma, which is often triggered by bouts of OM. If needed, teach principles for managing food allergies and asthma.
- Toddlers should not be taking a bottle to bed.
- Discuss the role of nutrition and immunity.
- Chronic recurrence should be addressed with an ear-nose-throat specialist to prevent hearing loss and speech delay.
- Smoking around the child should be discontinued (Kuiper et al, 2007).
- Use of pacifiers, cow's milk allergy, environmental smoke or mold, and other issues may be problematic. More clinical trials are needed to determine the best advice.

## PHENYLKETONURIA

## NUTRITIONAL ACUITY RANKING: LEVEL 4

## DEFINITIONS AND BACKGROUND

Phenylketonuria (PKU) is a rare, inherited condition that occurs in one in 10,000 births. Phenylalanine (Phe) is not metabolized to tyrosine because of a mutation in Phe hydroxylase. Infants are tested for this disorder after birth and after the first feeding and again if levels of Phe are above given cutoff levels ( $\geq 6$  mg/dL). If very strict diets are

followed early and continually, normal development and life span are possible. Children with PKU who follow their special diet for life have fewer intellectual and neurological deficits; do not discontinue at any age. Refer to a metabolic dietitian or special programs at the state level.

Desirable serum Phe levels are below 10 mg/dL; higher levels are associated with declining IQ. There is international consensus that patients with Phe levels  $< 360 \mu\text{M}$  on a

free diet do not need Phe-lowering dietary treatment, whereas patients with levels  $>600 \mu\text{M}$  do. In general, however, “diet for life” is the rule, especially for women with PKU who are considering pregnancy.

Tyrosine is an essential amino acid in patients with PKU because of the limited Phe converted to tyrosine. Treatment with large neutral amino acid supplements may help to correct low or deficient blood concentrations of both tyrosine and tryptophan, which are precursors for dopamine and serotonin (Koch et al, 2003). Individuals who follow diets low in natural proteins should be advised to take selenium and iron supplements (Acosta et al, 2004).

Serum lipids are usually under good control because of the vegetarian-type diet needed for PKU (Schulpis et al, 2003). However, micronutrient status of folic acid and vitamins B<sub>6</sub> and B<sub>12</sub> can be low, and there may be a risk for coronary artery disease.

Tetrahydrobiopterin (BH4) is the natural cofactor that fuels the activity of the phenylalanine hydroxylase (PAH) enzyme. When BH4 is given orally to some people with PKU, the activity of mutated PAH improves; this is “BH4-responsive PKU” in which lowering of Phe by 30% has been seen (Michals-Matalon, 2008; Michals-Matalon et al, 2007). This gives an exciting new treatment for PKU for those who are responsive.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutation in the phenylalanine hydroxylase (PAH) gene.

<b>Clinical/History</b>	Dry skin or dermatitis	Plasma Phe
Birth weight	Blonder hair	Urinary Phe
Present weight	than siblings	Plasma tyrosine
Growth (%)	Electroencephalograms	H & H, serum Fe, ferritin
Diet/intake history	oagrams (EEGs)	Serum pyridoxine, vitamin B <sub>12</sub> , folic acid
Developmental delay	Seizures	Serum carnitine (may be low)
Retardation?	<b>Lab Work</b>	Serum zinc and selenium
Musty odor in urine and sweat	Response to dose of 10 mg/kg BH4	
Length/height		

## INTERVENTION

### OBJECTIVES

- Prevent toxic buildup of abnormal metabolites to prevent mental retardation, and to promote normal intellectual and social development.
- Establish the child's daily requirement for Phe, protein, and energy according to age. The appropriate Phe intake

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inappropriate Intake of Types of Amino Acids

**Assessment Data:** Diet intake records, serum lab values of Phe, previous education on appropriate diet for PKU management; negative response to BH4 administration.

**Nutrition Diagnosis:** Inappropriate intake of amino acids related to low comprehension of nutrition care plan as evidenced by serum Phe level of 12 mg/dL, where  $>8 \text{ mg/dL}$  indicates loss of dietary control in PKU.

**Intervention:** Counseling on Phe in diet, use of special formulas and products, referral to State Health Department for resources and financial support, referral to child health clinics.

**Monitoring and Evaluation:** Serum Phe reports, changes in mental health status and alertness.

for age is as follows: infants 0–3 months, 60–90 mg/kg; infants 4–6 months, 40 mg/kg; infants 7–9 months, 35 mg/kg; infants 10–12 months, 30 mg/kg; children 1–2 years, 25 mg/kg; and children 2+ years, 20 mg/kg of body weight.

- Provide a diet aiding growth and development with a high energy to protein ratio to spare protein.
- Introduce solids and textures at usual ages; encourage self-feeding when it is possible for the infant.
- Establish a positive attitude toward the modified diet for parents, caretakers, and the child.
- Monitor for deficiency in nutrients, such as DHA, vitamin B<sub>12</sub>, folic acid, selenium, and iron.

## FOOD AND NUTRITION

- Use a diet low in Phe. Use special milk substitutes made from casein hydrolysate, corn oil, corn syrup, tapioca starch, minerals, and vitamins: Phenyl-free, or Maxamaid XP. Phenyl-free does not provide total nutritional needs. Phlexy-10 is available from SHS North America.
- Initially, the infant's tolerance must be assessed individually, and progress in treatment must develop accordingly. A small amount of milk and 85–100% from specialty formula are used to meet the infant's needs. Subtract Phe requirement in formula from total needs (the difference is that which is provided by solid foods).
- Glycomacropeptide (GMP), an intact protein formed from cheese whey, contains minimal Phe and can be supplemented with limiting AAs as a safe and highly acceptable alternative to synthetic AAs as the primary protein source in PKU (van Calcar et al, 2009). It is now recognized that the phenylalanine:tyrosine ratio affects executive function in PKU, so care must be taken to plan the diet properly (Sharman et al, 2009).
- Determine if serum iron, vitamin B<sub>12</sub>, folic acid, selenium, or other nutrient levels are low and enhance diet or use a multivitamin–mineral supplement as needed.
- Introduce solids and textures at the appropriate ages. Omit meat, fish, poultry, bread, milk, cheese, legumes, and peanut butter from the diet of older children. Try

using low-protein bread, pasta, crackers, cookies, and muffin mixes.

- To add calories, try jam, jelly, sugar, honey, molasses, syrups, cornstarch, and oils that are Phe-free. Flavors can be added to the formula to continue its use as a beverage.
- Fish oil supplements may be used to replace the DHA missing from a standard Phe-free diet; this helps improve neurologic development and fine motor coordination (Beblo, 2007). The exact amount of DHA needed is not known (Koletzko et al, 2009).

### Common Drugs Used and Potential Side Effects

- Kuvan (phenoptin) contains sapropterin dihydrochloride, a synthetic dihydrochloride salt of naturally occurring tetrahydrobiopterin (BH4). Individuals with PKU should be tested to determine if they could benefit from taking this medication (Michals-Matalon, 2008; Trefz et al, 2009).

### Herbs, Botanicals, and Supplements

- Herbs and botanical products are not recommended for use in PKU.
- Fish oil supplements may be beneficial (Koletzko et al, 2009; Beblo, 2007).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Because initial acceptance of formula may be poor due to its strong taste, the mother should be careful not to express her own distaste. Recommend appropriate recipes and cookbooks.
- Monitor the calculation of Phe in the diet. Avoid items sweetened with aspartame (NutraSweet), including diet sodas.
- School challenges vary, but the diet provides good control for most cases (Filiano, 2006). Attention deficit disorder can present as the child grows older.
- Self-management should begin by 7–8 years of age, at least for formula preparation. By 12 years of age, the child should begin calculating his or her own intake of Phe from foods.
- Women who have PKU tend to give birth to children with microcephaly, mental retardation, congenital heart defects, and IUGR. Metabolic control by the end of the first trimester is, therefore, important as a goal. Treatment at any time during pregnancy may reduce the severity of

delayed development. Referral to a metabolic dietitian is highly recommended.

### Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# PRADER-WILLI SYNDROME

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

Prader-Willi Food Pyramid <http://www.pwsausa.org/syndrome/foodpyramid.htm>.

### DEFINITIONS AND BACKGROUND

Prader-Willi syndrome (PWS) is a disorder caused by DNA abnormalities of chromosome 15. Major characteristics are infant hypotonia, hypogonadism, mental retardation (average IQ is around 70), small hands and feet, atypical facial features, and obesity because of insatiable appetite in early childhood. Short stature is part of the syndrome and is not nutritional in origin.

The incidence of PWS is 1 in 10,000–16,000 births in the United States. Onset occurs at birth, but symptoms begin by 1–4 years of age. PWS infants often present with absence of crying, poor suck, lethargy, and floppy muscle tone (hypotonia). Motor development is delayed. Hyperphagia results in marked obesity with high risk of metabolic and cardiovascular complications (Schmidt et al, 2008). Lifelong morbidities include osteoporosis, type 2 diabetes, respiratory disorders, and cardiorespiratory failure related to obesity and hypotonia (Allen and Carrel, 2004). Sexual development is incomplete; most PWS individuals are infertile.

Ghrelin levels are high in PWS (DelParigi et al, 2002). It is produced mostly by the stomach but also by the pituitary, hypothalamus, GI tract, lung, heart, pancreas, kidney, and testis. Ghrelin stimulates GH secretion, appetite and food intake, fat mass deposition, and weight gain gastric motility and acid secretion; exerts cardiovascular and anti-inflammatory effects; modulates cell proliferation; and influences endocrine and exocrine pancreatic secretion, as well as glucose and lipid metabolism.

Early dietary treatment starting at the second year of life and continued until the age of 10 years is effective in avoiding excessive weight gain in patients with PWS, but results in shorter stature; GH may be useful (Eiholzer and Whitman, 2004; Schmidt et al, 2008). Individuals with PWS are not able to control their food sneaking, stealing, and gorging behaviors. Because they are difficult to manage, approximately 75% of PWS patients live in group homes. Distinction of behavioral problems from psychiatric illness is important as well (Goldstone et al, 2008).

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** The OCA2 gene is associated with PWS in the long arm of chromosome 15 (region 15q11–q13). In 99% of cases of PWS, the child has two chromosome regions that are both maternally inherited; DNA from the father is missing for chromosome 15 (Isaacs and Zang, 2007).

Clinical/History	FTT, then rapid weight gain between 1 and 6 years of age	BMI Slow mental development Almond shaped eyes
Height		
Birth weight		

Irregular areas of skin (bands, stripes, or lines)	Down-turned mouth	Hyperghrelinemia
Small head, hands, feet	Hyperphagia	Gluc, Glucose tolerance test (GTT)
Sleep apnea	Light hair, eyes	
Asthma?	<b>Lab Work</b>	Alb
Hypotonia, floppy limbs	DNA-based diagnostic testing of chromosome 15	BP
		Chol, Trig
		LFTs pCO <sub>2</sub> , pO <sub>2</sub>
		H & H
		Serum Fe

## INTERVENTION

### OBJECTIVES

- Reduce excess weight. Monitor weight weekly.
- In preschool children, prevent obesity.
- Maintain recommended dietary intakes for all nutrients, especially protein to promote growth and development.
- Provide feeding assistance if needed.
- Prevent complications including CHD, hypertension, diabetes, sleep apnea, dental problems, and pneumonia. Correct serum lipid levels if elevated.
- Minimize unusual food-seeking behaviors such as eating food from the trash or eating inappropriate or unpalatable food combinations. Correct pica and related nutritional deficits, especially iron.
- Promote an exercise program.

## SAMPLE NUTRITION DIAGNOSES

### PWS

**Assessment Data:** Diet, weight, and physical activity histories.

**Nutrition Diagnosis:** Obesity related to excessive nutrient intake as evidenced by BMI of 35 and nutrition history indicating consumption of 2900 kcal/d and sneaking of foods between meals.

#### Interventions:

Food and Nutrient Delivery:

ND 1.3. Use of the Prader-Willi food pyramid to plan meals.

ND 5.7. Adjust availability and locations of foods kept in the house to minimize food sneaking.

Education:

E 2.5. Teach portions based on the PW food pyramid. Give examples of meals and snacks based on total servings from food groups; provide examples of age-appropriate physical activities.

Counseling:

Appropriate nutrient intake, enhancing physical activity, and keeping logs. Use of “Go-Caution-No” foods in color-coded “stop-light” system.

**Monitoring and Evaluation:** Have patient return in 1 month to assess weight, diet, and activity logs.

## FOOD AND NUTRITION

- Often, these children start with FTT and then become obese by age six; identify where the child is on this continuum. Gavage feeding may be needed for infants.
- Use 10–11 kcal/cm of height to maintain weight; 8.5 kcal/cm for slow weight loss (Lucas, 2004, p. 41). For older teens, reduce the total calorie level to 7–8 kcal/cm for weight loss, or 10–14 kcal/cm to maintain. Patients’ needs are about 60% of those without PWS.
- Ensure that the diet provides adequate protein and nutrients with RDAs for age.

## Common Drugs Used and Potential Side Effects

- Weight loss products have not proven to be useful in this population. Drugs may react differently and are, therefore, not recommended.
- GH may be used to correct short stature and hormone replacement therapy may be used to improve signs of osteopenia or osteoporosis (Allen and Carrel, 2004; Schmidt et al, 2008).
- Ghrelin antagonists are being developed. Ghrelin peaks are related to habitual meal patterns and tend to rise in anticipation of eating rather than eliciting feeding (Frecka and Mattes, 2008).

## Herbs, Botanicals, and Supplements

- Persons with PWS may be more sensitive; small doses of herbs and drugs may cause a greater reaction than in other people (see <http://www.pwsausa.org/syndrome/herbal.htm>). Therefore, herbs and botanicals should not be used.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss feeding practices plus activity factors. Encourage daily activity.
- Behavior modification is an important part of treatment. Help the patient lose weight with specific behavior modification techniques; teach the green/yellow/red (go/caution/stop) method for food choices.
- Record keeping and calorie counting are useful. Control of excess intake is the main goal; locked refrigerators or cupboards may be needed.
- An interdisciplinary approach is useful (Eiholzer and Whitman, 2004). There is a need to reduce guilt and depression; self-monitoring is the eventual goal.

# RICKETS

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Becker KL, Bilezikian JP, Brenner WJ, et al. *Principles and Practice of Endocrinology and Metabolism*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 2001.

## DEFINITIONS AND BACKGROUND

Rickets is generally caused by failure of osteoid to calcify during periods of growth. Vitamin D<sub>3</sub> (cholecalciferol) is formed in the skin from cholesterol with stimulation from ultraviolet-B light. Calcitriol is a steroid hormone that has impact on over 1000 genes in the human body (Edlich et al, 2009). Vitamin D insufficiency and deficiency during pregnancy may lead to lower maternal weight gain, disturbed skeletal home-

ostasis in the infant with reduced bone mineralization, rickets, and fractures (Pawley and Bishop, 2004). Less often, a deficiency of calcium or phosphorus may contribute to rickets. In adults, the condition is known as osteomalacia.

Because sunlight is important to skin production of vitamin D, where exposure is limited, deficiency is likely. Prevention and treatment of vitamin D deficiency is accomplished by regulated sun exposure as well as vitamin D supplementation (Edlich et al, 2009). Natural vitamin D levels, those found in humans living in a sun-rich environment, are between 40 and 70 ng/mL (Cannell and Hollis, 2008).

Rickets can be seen in 30–70% of premature, LBW and VLBW infants; it is also seen in breastfed children from multiple births, and infants with darker skin pigmentation living at higher latitudes. An increased number of children have rickets because more African American women are breastfeeding, fewer infants receive vitamin D supplements, and mothers and children are exposed to less sunlight.

Rickets may also occur in fat malabsorption syndrome, steatorrhea, anticonvulsant use, renal failure, or biliary cirrhosis. One detrimental consequence of untreated vitamin D-rickets is dilated cardiomyopathy (Brown et al, 2009). It is, therefore, important to identify and treat vitamin D deficiency.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** X-linked hypophosphatemic rickets (XLH) is related to the PHEX gene and is the most common cause of vitamin D-resistant rickets.

Clinical/History	Decreased linear growth	Metabolic acidosis
Height	Steady growth	DEXA scan for bone density
Weight	Muscle spasm	Wrist radiographs
Growth (%)	Chvostek's sign (facial spasm)	
Diet/intake history		

Radiographs for	Lab Work	Hypophosphatemia?
fractures	25(OH) D levels:	Serum Ca <sup>++</sup>
Leg bowing, inability to walk or stand	sufficient ≥30 ng/mL;	(often low)
Seizures or irritability	deficient ≤20 ng/mL	Parathyroid hormone (elevated)
	Urinary Ca <sup>++</sup> (elevated)	Mg <sup>++</sup> , Na <sup>+</sup> , K <sup>+</sup>
	Alk phos (increased)	

## INTERVENTION

### OBJECTIVES

- Correct body mineral status; prevent further problems and deformity. Vitamin D participates in mineral homeostasis, regulation of gene expression, and cell differentiation. Complement drug therapy with adequate diet.
- Prevent or correct hypocalcemia, dental caries, bone fractures.
- Promote growth; short stature can result if not treated early enough.

### FOOD AND NUTRITION

- Use vitamin D–fortified milk if there are no milk allergies or lactose intolerance. Use calcium-containing foods such as cheeses, yogurt, fortified juice and ice cream, if fluid milk is not tolerated.
- Consuming vitamin D–fortified foods improves 25(OH)D concentrations. Fatty ocean fish are better sources than most other foods; hence, cod liver oil used to be given to children in past generations.
- If diet is inadequate in the specific nutrients, ensure intake of a supplement appropriate for age and sex. Avoid excesses of phytate from high fiber diets.
- Follow guidelines for sensible sun exposure and supplemental vitamin D; 800–1000 IU/d is reasonable

(Holick, 2008). The skin forms vitamin D using 5-dihydroxycholesterol, then hydroxylating in the liver to vitamin D<sub>2</sub> (calcidiol, or 25-hydroxycholecalciferol), which circulates in the plasma. The active form is hydroxylated in the kidney into cholecalciferol (calcitriol or 1,25-dihydroxycholecalciferol). Note that a healthy liver and kidney must be available to make the active form.

## Common Drugs Used and Potential Side Effects

- A large dose of vitamin D is given upon a rickets diagnosis; 2000–7000 IU vitamin D per day should be sufficient (Cannell and Hollis, 2008).
- With steatorrhea, check serum levels of vitamin D and calcium and supplement appropriately.
- Rickets may occur secondary to prolonged antacid, anti-convulsant, or furosemide (Lasix) use; a vitamin D supplement will be needed.

## Herbs, Botanicals, and Supplements

- Sunlight, artificial ultraviolet B (UVB) radiation, and vitamin D<sub>3</sub> supplementation are sources of vitamin D (Cannell and Hollis, 2008).
- Long-term harm from higher doses of vitamin D is not clear (Cranney et al, 2008). No more than the UL should be taken.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss needed alterations of the diet in conjunction with drug therapy.
- Good posture and positioning are important aspects of treatment.
- The recommended intakes for vitamin may not be enough, especially for dark-skinned children and those who live in northern latitudes (Misra et al, 2008; Ward et al, 2007). Discuss the role of sunlight in vitamin D metabolism.
- Infants who are given vegan diets may have low intakes of vitamin D.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Vitamin Intake

**Assessment Data:** Low serum 25(OH) D<sub>3</sub>, intake history for young child, X-rays.

**Nutrition Diagnoses (PES):** Inadequate vitamin D intake related to low intake of fortified foods including dairy products as evidenced by low serum levels, X-ray showing bowed legs and rickets.

**Intervention:** Educate mother about use of vitamin D<sub>3</sub> in fortified foods including milk and cereals daily. Discuss good sources of supporting nutrients (calcium, etc.).

**Monitoring and Evaluation:** X-rays, serum 25(OH) D<sub>3</sub>, food diary and intake records showing improved intake of vitamins and minerals.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# SMALL FOR GESTATIONAL AGE INFANT AND INTRAUTERINE GROWTH RETARDATION

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

Infants whose weight is less than 10th percentile for gestational age are “small for gestational age” (SGA). Each year, about 40,000 infants born in the United States are SGA; they are at risk for preterm delivery, perinatal asphyxia, meconium aspiration, and hypoglycemia (Zaw et al, 2003). Another name for SGA infants is intrauterine growth restriction (IUGR). There is usually a wide range in weight gain after birth in SGA infants.

Nongenetic causes may retard intrauterine growth but are not often apparent before 32–34 weeks of gestation. Growth retardation due to nongenetic factors may cause malnutrition while sparing growth of the brain and long bones. Some other genetic disorders and congenital infections result in total growth retardation, in which height, weight, and head circumference are equally affected.

IUGR results from placental insufficiency. This insufficiency can result from maternal diseases (hyperemesis, preeclampsia, primary hypertension, renal disease, or diabetes); from infections such as cytomegalovirus, rubella virus,

or *Toxoplasma gondii*; or if the mother is a narcotic or cocaine addict or heavy user of alcohol or tobacco (Dodds et al, 2006) (Table 3-16).

The fetus needs glucose, amino acids, and oxygen to grow normally. If IUGR was caused by chronic placental malnutrition, SGA infants may demonstrate remarkable catch-up growth within the first 2–3 years after delivery, if provided with adequate nutrition. The rates of catch-up growth vary according to many factors including birth weight, gestational age, parental size, adequacy of intrauterine growth, neurological impairment, clinical course, and nutrition (Carver, 2005). Insulin-like growth factor has a critical role in mediating fetal and postnatal growth (Randhawa and Cohen, 2005).

Common complications in SGA infants include hypoglycemia, perinatal asphyxia, meconium aspiration, polycythemia, respiratory distress syndrome, and NEC (Dodds et al, 2006). Prognosis is quite serious for infants who have perinatal asphyxia or congenital conditions.

**TABLE 3-16 Risk Factors for Developing IUGR in Pregnancy**

Pregnancies that have any of the following conditions may be at a greater risk for developing IUGR:

- Maternal weight of less than 100 lb
- Poor nutrition during pregnancy
- Birth defects or chromosomal abnormalities
- Use of drugs, cigarettes, and/or alcohol
- Pregnancy induced hypertension (PIH)
- Placental abnormalities
- Umbilical cord abnormalities
- Multiple pregnancy
- Gestational diabetes in the mother
- Low levels of amniotic fluid or oligohydramnios

Source: American Pregnancy Web site at <http://www.americanpregnancy.org/pregnancycomplications/iugr.htm>, accessed May 10, 2009.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** SGA is not a genetically oriented condition.

#### Clinical/History

Prenatal ultrasound  
Length, Weight  
Growth (<10 percentile)  
Decreased linear growth

## SAMPLE NUTRITION CARE PROCESS STEPS

**Malnutrition**

**Assessment Data:** Weight and growth charts, showing <10 percentile for gestational age.

**Nutrition Diagnoses (PES):** Malnutrition related to intrauterine growth retardation as evidenced by weight/length percentile at 9% and SGA birth.

**Intervention:** Educate mother about breastfeeding versus formula feeding, the need for gradual catch-up growth without overfeeding, and supporting healthy immunity.

**Monitoring and Evaluation:** Weight records, catch-up growth rate, health status (fewer infections, illnesses over time).

## INTERVENTION

## OBJECTIVES

- Correct body mineral status; prevent further problems and deformity.
- Complement any necessary drug therapy with adequate diet. Monitor carefully for side effects.
- Identify and treat underlying congenital problems.
- Promote catch-up growth, since short stature can result if not treated early enough. Compensatory catch-up growth may continue into adolescence and adulthood (Carver, 2005). If too rapid in the first 6 months, children may be obese at age 3 (Taveras et al, 2009).
- Prevent or correct hypoglycemia, perinatal morbidity, and other complications.
- Prevent long-term consequences, such as hypertension, insulin resistance and metabolic syndrome, type 2 diabetes mellitus, cardiovascular disease, short stature, and polycystic ovary syndrome (van Weissenbruch et al, 2005).

## FOOD AND NUTRITION

- Promote exclusive breastfeeding whenever possible to promote cognitive development. At least 6 months is needed.
- While nutrient-enriched formulas that provide 22 kcal/oz are often prescribed for VLBW preterm infants after hospital discharge, for promoting greater rates of catch-up growth and increases in head circumference, studies are not as clear in SGA infants (Carver, 2005).
- Use a balanced diet appropriate for older children. Include reasonable snacks with high-quality nutritional value.
- If diet is inadequate in the specific nutrients, ensure intake of a sufficient level of vitamin D, calcium, and phosphorus for age and sex.

## Common Drugs Used and Potential Side Effects

- GH therapy for improving height in these children has been approved by the FDA; it promotes growth acceleration and normalization of height during childhood. High doses can affect carbohydrate metabolism and cause hyperglycemia.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used in children.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help families adjust to special requirements for their child. The child may have diabetes and other chronic consequences from being born SGA.
- Children born SGA without postnatal catch-up are shorter and have higher weight than children of similar age, height, and sex. In addition, insufficient nutrition during the first 3 years of life is correlated with poor neurodevelopmental outcomes (Belfort et al, 2008). Discuss the importance of good nutrition in infancy.
- Prepare for future pregnancies by discussing the need to avoid alcohol and tobacco.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

## For More Information

- Intrauterine Growth Retardation

# TYROSINEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

Hereditary tyrosinemia type I (HTI), a severe disease affecting primarily the liver, is caused by a deficiency of fumarylacetoacetate hydrolase (FAH). Tyrosine, Phe, and methionine build up. The condition is acute, often causing death within the first year of life. Type I needs to be treated with diet for life and is a much more severe disease than other types. This condition results in liver failure or severe nodular cirrhosis with renal tubular involvement. This form is common in Quebec, Canada; it affects 1 in 100,000 individuals.

Tyrosine accumulation can be aggravated by vitamin C deficiency, a high-protein diet, or liver immaturity. Prenatal diagnosis is possible and can be performed by measuring succinyl acetone in the amniotic fluid or FAH in amniotic fluid cells, allowing for genetic counseling. Liver transplantation may be needed.

Type II tyrosinemia is caused by a deficiency of the enzyme tyrosine aminotransferase (TAT) and affects the eyes with excessive tearing and photophobia; eye pain and redness; painful skin lesions on the palms and soles; and intellectual disability. Type III is caused by a deficiency of the enzyme 4-hydroxyphenylpyruvate dioxygenase (HPD) that presents with seizures, intermittent ataxia, and intellectual disorders.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Deficiency of FAH, the last enzyme of tyrosine catabolism, leads to accumulation of the toxic substrate fumarylacetoacetate (FAA) in hepatocytes and renal proximal tubular cells (Jacobs, 2006). Mutations in the HPD and TAT genes cause types I and II. The gene is mapped to band 15q23–q25. About 30 distinct mutations have been reported for Type I.

<b>Clinical/History</b>	Rancid butter-like odor (type I)	FAH (very low?)
Birth weight, present weight	FTT	Plasma Phe
Growth (%)	Irritability	Methionine
Diet/intake history	Jaundice	H & H
Abdominal distention	Diarrhea, bloody stools	Serum Fe
Hyperpigmentation	Annual CT or MRI of liver	Plasma tyrosine
Dermatitis		LFTs (elevated)
“Cabbage-like” odor		Bilirubin (elevated)
	<b>Lab Work</b>	Phosphate
	Urinary succinyl acetoacetate levels (high)	Gluc (low?)
		Alb (often low)
		Nitisinone level

### INTERVENTION

### OBJECTIVES

- Restrict Phe and tyrosine from the diet to promote normal growth and intellectual development.
- Provide adequate vitamin C for conversion processes.
- Prevent severe liver, kidney and neurological, damage, or rickets (Jacobs, 2006).

### FOOD AND NUTRITION

- Initially, feed a Phe/tyrosine hydrolysate to infants, with small amounts of milk added to provide the minimum requirements of tyrosine and Phe. Mead Johnson product TYROS and 3200-AB; Ross product Maxamaid XPHEN, TYR; or TYROMEX-1 or TYREX from SHS can be used.
- If blood methionine levels are elevated, try PFD1 or PFD2 (Mead Johnson). Use carbohydrate supplements, vitamins, and minerals.
- Low-tyrosine/Phe diet limits foods such as cow's milk and regular formula; avoid meat, eggs and cheese. Regular flour, dried beans, nuts and peanut butter must also be limited. Focus on fruits and vegetables and the special formula.
- Supplement with vitamins C and D appropriate to the patient's age.

### Common Drugs Used and Potential Side Effects

- Nitisinone (Orfadin) reduces the toxic effects of tyrosine in the body when used along with the dietary restrictions (Santra et al, 2008). Fortunately, with this medication,

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal GI Function

**Assessment Data:** Altered LFTs, anorexia, irritability, cabbage-like body odor, bloody diarrhea.

**Nutrition Diagnoses (PES):** Altered GI function related to missing FAH enzyme as evidenced by bloody diarrhea, poor appetite, altered LFTs.

**Intervention:** Educate parents about the special formula and diet for managing tyrosinemia. Refer to genetic counselor if they wish to have more children.

**Monitoring and Evaluation:** Normal weight and growth, LFTs, normal intellectual development after following the diet and taking the medicine. No sign of rickets.

liver transplantation may not be necessary and hepatic carcinoma may be delayed.

- Antibiotics may be needed to correct infections. Use of acidophilus and probiotic products may alleviate loss of intestinal bacteria.
- Vitamin D may be needed if the child has rickets.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for tyrosinemia because there are no controlled trials to prove efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Provide sources of tyrosine and Phe in the diet determined appropriately for age and body size.
- Adjust intake of energy and nutrients according to the patient's age.
- Discuss desirable intake of protein (avoid excesses) and encourage adequate intake of vitamin C to meet recommended levels.
- Genetic counseling is advised for the family members (Scott, 2006).

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

# UREA CYCLE DISORDERS

## NUTRITIONAL ACUITY RANKING: LEVEL 2–4

## DEFINITIONS AND BACKGROUND

As a group, urea cycle disorders occur in one in 25,000 newborns. Table 3-17 describes the urea cycle disorders and their treatment. Ornithine transcarbamylase (OTC) deficiency is the most common disorder. Statewide newborn screening does not always include these conditions, but screening is important if there is any family history of these disorders.

The urea cycle disorders are manifested most often in the newborn between ages 1 and 5 days, when they are often initially thought to be septic. With later onset, patients have partial enzyme deficiencies and are recognized after a clinical episode months or years later. When they present in childhood, adolescence, and adulthood, there may be FTT, persistent vomiting, developmental delay, behavioral changes, hyperammonemia, irritability, somnolence, seizures, and coma; if not treated rapidly, they may cause irreversible neuronal damage. Diagnosis of urea cycle disorder should be considered in any child or adult with unexplained neurological and psychiatric disorders with anorexia, unexplained coma with cerebral edema, and respiratory alkalosis. Some cases of SIDS may be related to urea cycle disorders.

The hyperammonemia that occurs is a deadly neurotoxin. Chronic hyperammonemia results in increased L-tryptophan metabolites including serotonin. Ammonia levels above 60  $\mu\text{mol/L}$  lead to anorexia, irritability, lethargy, vomiting, somnolence, disorientation, asterixis, cerebral edema, coma, and death (Cohn and Roth, 2004).

Diet is one of the main treatments of these disorders; protein intake should be adjusted according to the metabolic disorder, its severity, the patient's age, growth rate, and preferences (Wilcken, 2004). Poor appetite, nutritional problems, and chronic catabolism are common and difficult to treat (Wilcken, 2004).

Any patient on a low-protein diet should be monitored clinically, with appropriate laboratory tests and an emergency plan; hemodialysis may be needed. Most patients, except those with arginase deficiency, will need supplements of arginine, but the value of other supplements, including citrate and carnitine, is unclear (Wilcken, 2004). Gene therapy and liver transplantation are treatments that show promise.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Deficiencies of CPSI, ASS, ASL, NAGS, and ARG are inherited in an autosomal recessive manner. OTC deficiency is inherited in an X-linked manner. All are genetic diseases associated with lack of a protein or enzyme activity in the urea cycle.

**TABLE 3-17 Urea Cycle Disorders (UCD)**

UCD	Enzyme Deficiency	Symptoms/Comments	Treatment
Type I hyperammonemia	Carbamoylphosphate synthetase I (CPS I)	Within 24–72 hours after birth, infant becomes lethargic, needs stimulation to feed, vomiting, increasing lethargy, hypothermia and hyperventilation; without measurement of serum ammonia levels and appropriate intervention, infant will die	Arginine that activates <i>N</i> -acetylglutamate synthetase
<i>N</i> -acetylglutamate synthetase deficiency	<i>N</i> -acetylglutamate synthetase (NAGS)	Severe hyperammonemia, deep coma, acidosis, recurrent diarrhea, ataxia, hypoglycemia, hyperornithinemia	Carbamoyl glutamate to activate CPS I
Type 2 hyperammonemia	Ornithine transcarbamylase (OTC)	Most commonly occurring UCD, only X-linked UCD, ammonia and amino acids elevated in serum, increased serum orotic acid due to mitochondrial carbamoylphosphate entering cytosol and being incorporated into pyrimidine nucleotides, which leads to excess production and consequently excess catabolic products	High-carbohydrate, low-protein diet, ammonia detoxification with sodium phenylacetate or sodium benzoate
Classic citrullinemia	Argininosuccinate synthetase (ASS)	Episodic hyperammonemia, vomiting, lethargy, ataxia, seizures, eventual coma	Arginine administration to enhance citrulline excretion; also sodium benzoate for ammonia detoxification
Argininosuccinic aciduria	Argininosuccinate lyase (argininosuccinase) (ASL)	Episodic symptoms similar to classic citrullinemia, elevated plasma and cerebral spinal fluid argininosuccinate	Arginine and sodium benzoate
Hyperargininemia	Arginase	Rare UCD, progressive spastic quadriplegia and mental retardation, ammonia and arginine high in cerebral spinal fluid and serum arginine, lysine, and ornithine high in urine	Diet of essential amino acids excluding arginine, low-protein diet

Adapted from: <http://themedicalbiochemistrypage.org/nitrogen-metabolism.html#clinical>.

<b>Clinical/History</b>	Developmental delay	month of age; 35–50 µg/dL in older children and adults
Birth weight, present weight	<b>Lab Work</b>	
Growth (%)	Plasma amino acid levels (specific to disorder)	Phos Gluc Alb
Diet/intake history		H & H
FTT	Hyperammonemia: 150 µg/dL in neonates; 70 µg/dL in infants to one	Blood gases Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup> Ketonuria
Vomiting		
Irritability		
Somnolence		
Lethargy, seizures or coma		

## INTERVENTION

### OBJECTIVES

- Restrict total protein from the diet to minimize endogenous ammonia production and protein catabolism. Limit one or more essential amino acids while providing adequate energy and nutrients (Trahms, 2008).
- Promote anabolism with normal growth and development for age; use energy from nonprotein sources in amounts to spare protein for other purposes.
- Normalize blood ammonia levels and reduce the effects of hyperammonemia to prevent neuronal damage. Elevated levels of ammonia can come from either muscle breakdown or diet; determine which process is the problem.
- Administer desired substrates of the urea cycles. If necessary, support dialysis if blood ammonia levels are three to four times above normal.

### FOOD AND NUTRITION

- Use a protein-controlled diet (often 1.0–1.5 g/kg daily) with use of special amino acid formulas developed specifically

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### Altered Nutrition-Related Lab Values

**Assessment Data:** Weight and growth charts showing FTT, anorexia, elevated serum ammonia.

**Nutrition Diagnoses (PES):** Altered nutrition-related labs related to hyperammonemia in urea cycle disorder as evidenced by anorexia, lethargy and sleepiness, FTT with weight/height at 3 percentile.

**Intervention:** Educate parents about low protein formula, enhancing energy intake through high calorie foods and supplements containing calcium.

**Monitoring and Evaluation:** Weight records, growth, improved appetite and intake, reduced serum ammonia levels, greater alertness.

for urea cycle disorders. These formulas provide approximately 50% of the daily dietary protein allowance; some patients may require individual BCAA supplementation.

- Pharmaceutical grade (not over-the-counter) L-citrulline (for OTC and CPS deficiency) or L-arginine free base (ASA and citrullinemia) is also required. These are not to be used in arginase deficiency.
- Add extra energy sources if needed to support growth and development. Weight gain is the best measure of success in infants and children. Metabolic nutritionists routinely prescribe calorie modules such as Prophree, Polycose and ModuCal. If dehydration occurs, intravenous fluids and glucose may be needed.
- Multiple vitamins and calcium supplements are recommended.

## Common Drugs Used and Potential Side Effects

- Protein restriction is used in conjunction with medications to remove ammonia from the blood. Medications are given by way of tube feedings, either via gastrostomy tube or NG tube. To provide alternative route for ammonia, what is given depends on where the defect in the urea cycle has occurred.
- Arginine is often supplemented (400–700 mg/d), except for arginine deficiency (Trahms, 2008). For argininosuccinate synthetase and argininosuccinate lyase deficiencies, 0.4–0.7 g arginine/kg/d is given; 0.17 g/kg/d of citrulline is given for carbamyl phosphate synthetase deficiency.
- Sodium phenylbutyrate (Buphenyl) is used to normalize serum ammonia by diverting nitrogen to alternative paths for excretion (Scaglia et al, 2004). It is administered three to four times daily to keep ammonia under control.

## Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for urea cycle disorders because there are no controlled trials to prove efficacy.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Provide sources of all essential amino acids in the diet, determined appropriately for age and body size. There are tables available for these purposes (Trahms, 2008).
- Adjust intake of energy and nutrients according to the patient's age.
- Comprehensive newborn screening is recommended for families who have had the birth of one or more children with these disorders.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.

- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.
- Do not use honey in the diets of infants to decrease potential risk of botulism.

## WILSON'S DISEASE (HEPATOLENTICULAR DEGENERATION)

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Gold DH, MD, and Weingeist TA, MD, PhD. *Color Atlas of the Eye in Systemic Disease*. Baltimore: Lippincott Williams & Wilkins, 2001.

#### DEFINITIONS AND BACKGROUND

The major physiological role of copper is to serve as a cofactor to a number of key metabolic enzymes. Copper is a trace element essential for normal cell homeostasis, promoting iron absorption for hemoglobin synthesis and for formation of bone and myelin sheath. In hepatic tissues, 90% of the copper in the copper-albumin complex is converted to ceruloplasmin. Wilson's disease is a rare inborn disease related to copper storage (Merle et al, 2007). Tissue deposition occurs instead of formation of ceruloplasmin in Wilson's disease.

An autosomal recessive disorder, Wilson's disease results in hepatolenticular degeneration, cirrhosis, neurologic damage, damage to the kidney, brain, and cornea. Onset occurs at birth, but symptoms may appear from 5 to 40 years of age. The disease may lead to neurodegeneration and behavior abnor-

malities. Three types of neurological symptoms can occur: dystonic syndrome (dystonic postures and choreoathetosis); ataxic syndrome (postural and intentional tremor and ataxia of the limbs); and parkinsonian syndrome (hypokinesia, rigidity, and resting tremor). Shortened attention span, slurring of speech, and depression are early symptoms. Individuals who present with neuropsychiatric problems are often identified later in life and have poorer outcomes than those with hepatic symptoms (Merle et al, 2007).

A low-copper diet is seldom essential but implemented when other therapies are unsuccessful (e.g., copper-chelating agents). Other dietary treatments under study include the use of increased histidine, specific polyunsaturated fatty acids, low soy, and other plans. If not diagnosed until onset of fulminant liver failure, the patient will die by age 30. Liver transplantation is the best treatment. New ideas regarding the clinical management of this disorder will emerge with elucidation of the cellular basis of the disease (Fink and Schilsky, 2007).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Wilson disease involves two abnormal copies of the *ATP7B* gene, one from each parent. The alteration is on chromosome 13.

Clinical/History	Kayser-Fleischer ring (gold or gray-brown opacity of peripheral cornea)	Enlarged liver Swallowing difficulty Drooling? Easy bruising Jaundice?
Height		
Weight		
BMI		

Fixed pseudo-smile	<b>Lab Work</b>	Bilirubin (>300 $\mu\text{mol/L}$ )
Postural tremor of arms	Ceruloplasmin (often low)	Alk phos, low (<600 IU/L)
Rigidity	Serum Cu (abnormal)	Serum zinc
Abrupt personality change	Liver copper levels	Alb
Splenomegaly, esophageal varices?	Urinary Cu	H & H
Hepatitis or cirrhosis?	ALT, AST [low transaminases (100–500 IU/L)]	BUN, Creat
		Serum P
		PT or INR

## INTERVENTION

### OBJECTIVES

- Keep optimal balance of copper in patient.
- Decrease serum copper levels, generally with drug chelation. Enhance urinary excretion of excesses.
- Prevent or reverse damage to body tissues and liver.
- Watch caloric intake to prevent obesity.
- Monitor changes in gag reflex or dysphagia.
- Provide sufficient zinc to chelate excess copper under doctor's supervision.
- Prepare for transplantation where possible.
- Prevent or correct bone demineralization (Selimoglu et al, 2008).

### FOOD AND NUTRITION

- A normal diet provides 2–5 mg/d of copper. To lower copper in the diet (to 1–2 mg), use limited amounts of liver, kidney, shellfish, nuts, raisins and other dried fruits, dried legumes, brain, oysters, mushrooms, chocolate, poultry, and whole-grain cereals.
- A lacto-ovo-vegetarian diet may be useful to increase content of fiber and phytates; copper is less available in vegetarian diets.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Excessive Mineral Intake

**Assessment Data:** Neurological symptoms, altered LFTs, changes in the eye, low ceruloplasmin and elevated serum copper.

**Nutrition Diagnoses (PES):** Excessive mineral (copper) intake related to Wilson's disease and disordered copper metabolism as evidenced by altered labs for copper and ceruloplasmin.

**Intervention:** Educate parents about the role of copper in the body, and how zinc interacts; discuss the medication effects and the need for possible transplantation.

**Monitoring and Evaluation:** Improved neurological symptoms and lab values posttransplantation.

- Control energy intake, food textures, and other nutrients if necessary.
- Increase fluid intake but avoid alcoholic beverages.
- Increase zinc from meat, poultry, fish, eggs, and milk if deemed appropriate for the patient.
- Assure adequate intake of calcium, vitamins D and K for bone health (Selimoglu et al, 2008).

## Common Drugs Used and Potential Side Effects

- Zinc acetate may be used to chelate copper with fewer side effects than D-penicillamine. Doses of 75–150 mg are often prescribed. Oral zinc is a suitable alternative to penicillamine as long-term maintenance therapy.
- D-penicillamine (Cuprimine or Depen), a copper-chelating agent, should be taken orally before meals. A vitamin B<sub>6</sub> supplement is needed with this drug; usually a dose of 25 mg.
- Laxatives or stool softeners may be needed. Encourage a diet high in fiber and fluid to wean off medication if possible.
- Corticosteroids and immunosuppressive therapy are used for autoimmune hepatitis. Side effects can be significant, including hyperglycemia, osteopenia, and nutrient depletion.
- Tetrathiomolybdate is being tested for use in Wilson's disease (Brewer et al, 2006).

## Herbs, Botanicals, and Supplements

- A neurological disorder has been noted after taking Chinese herbs; it is best to avoid them in Wilson's disease (Wang and Yang, 2003).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach the patient about the copper and zinc content of foods. Explain that breast milk has higher copper levels than cow's milk to those individuals who need to know.
- Help the patient with feeding at mealtimes, if poor muscular control is demonstrated.
- Discuss effective coping mechanisms, community resources, and genetic counseling.
- Discuss the importance of maintaining prescribed drug therapy, which is essential for life.

## Patient Education—Food Safety

- Hand washing with soap and hot water is recommended before preparing formula or meals. Use clean utensils and containers for mixing formula.
- Before using tap water for formula preparation or to give as a beverage, let cold tap water run for 2 minutes to remove any lead that may be in the pipes.
- Follow the 2-hour rule: discard any beverage or food that has been left at room temperature for 2 hours or longer.

- Do not use honey in the diets of infants to decrease potential risk of botulism.

# Neuro-psychiatric Conditions

## CHIEF ASSESSMENT FACTORS

- Blunting of Emotions, Apathy, Egocentricity
- Bowel or Bladder Dysfunction
- Confusion, Memory Loss; Disorientation Regarding Place and Time
- Depression, Anxiety
- Disturbed Taste, Smell, Changes in Vision
- Dizziness, Vertigo, Drowsiness
- Dysphagia; Coughing or Choking While Eating/Swallowing
- Easy Aspiration of Food into Lungs
- Extremities: Coldness, Stiffness, Limited Movement, Discoloration, Pain
- Hallucinations, Tremors; Tics, Spasms, Ataxia
- Headaches, Pain
- Impulse Control Disorder
- Loss of Consciousness, Seizures
- Marked Disturbance in Eating Behaviors, Pica
- Mood Swings, Behavioral Changes, Psychotic Delusions
- Nervousness, Irritability
- Numbness, Paralysis, Sensory Pain
- Poor or Weaker Judgment; Difficulty Performing Familiar Tasks
- Problems with Abstract Thinking, Personality Changes
- Status of Food in Oral Cavity
- Stress (may speed up aging process because of protein kinase C)
- Weakness

## OVERVIEW OF NEUROLOGICAL AND PSYCHIATRIC DISORDERS

The central nervous system (CNS) consists of the brain and spinal cord. The brain has three main sections: the cerebrum, the cerebellum, and the brainstem. The normal adult brain weighs 3 lb; it grows steadily until 20 years of age and then loses weight for the rest of life. Gray matter consists of CNS tissue rich in neuronal cell bodies, their dendrites, axons, and glial cells; it includes the cerebral cortex, the central spinal cord, the cerebellar cortex, and the hippocampal cortex. White matter refers to large axon tracts in the brain and spinal cord involved with the cerebral hemispheres, the cerebellum, and the hippocampus. Figure 4-1 shows the brain and the spinal cord.

This chapter provides an overview of neurological and psychiatric disorders that have nutritional implications. A few disorders are found in other relevant sections; autism in Section 3, dysphagia in Section 7, anesthesia in Section 14. The primary neurological disorders are separated from psychiatric disorders. The newest edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM)* is due in 2012; the American Psychiatric Association (APA) and NIMH worked together to expand the scientific basis for psychiatric diagnosis and classification.

Figure 4-1

The brain and the gut work synergistically with each other and with other organs. Table 4-1 lists functions of the brain. Table 4-2 lists the cranial nerves and highlights those that affect chewing and swallowing. Nutrition influences the genetic onset and consequences of many chronic diseases.

TABLE 4-1 Brain Parts and Their Functions

Parts	Relevant Nerves	Functions
<b>FOREBRAIN</b>		
Cerebrum—temporal lobe	8th cranial nerve	Controls hearing, expressive language, music and rhythm. Contains the hippocampus. Diseases that affect this area include Alzheimer's disease, depression, and mania
Cerebrum—frontal lobe		Controls personality, mood, behavior, reasoning, emotional control, and cognition. Diseases affecting this area include Alzheimer's disease, depression, mania, and Huntington's disease
Cerebrum—parietal lobe		Comprehension of written language and oral speech; sensory stimulation such as pain, touch, smell, hearing, and heat; body position. Alzheimer's disease affects this area; epilepsy and stroke may also impact this area
Cerebrum—occipital lobe	2nd cranial nerve	Vision
Thalamus		Relays sensory information to the cerebral cortex
Hypothalamus		Lies beneath the thalamus. Secretes corticotropin-releasing hormone, affects metabolism by its influence on pituitary gland. Secretes vasopressin, which regulates sleep and wake cycles
Limbic system	System of nerve pathways	<b>Amygdala</b> affects depression <b>Hippocampus</b> may affect mania, depression, and Alzheimer's. Located inside the temporal lobe (humans have two hippocampi, one in each side of the brain). Part of the limbic system. Plays a part in memory, learning, and navigation
<b>MIDBRAIN</b>	3rd cranial nerve	Site between hindbrain and forebrain. Controls oculomotor nerve; eye movement. Affected in Parkinson's disease and some strokes
<b>HINDBRAIN</b>		
<b>CEREBELLUM</b>	3rd–5th cranial nerves	Found at bottom rear of the head. Posture and balance; voluntary movements such as sitting, standing, and walking. Directing attention and measuring time; other motor and cognitive functions. Stroke often affects this area
Pons	4th–7th cranial nerves	Connects brainstem with cerebellum. Receives information from visual areas to control eye and body movements. Controls patterns of sleep and arousal; coordination of muscular movements; helps maintain equilibrium. Affects sleep disorders
Medulla oblongata	8th–12th cranial nerves	Hearing, balance, some taste, some swallowing. Movement of the tongue. Involuntary functions such as heartbeat, circulation, muscle tone, and breathing. Stroke often affects this area
<b>SPINAL CORD</b>		Sends and receives messages to and from brain and body parts

**TABLE 4-2** Cranial Nerves and Those Specifically Affecting Mastication and Swallowing

	Nerve	Function	Affected Part of Body
I	Olfactory	Smell	Olfactory bulbs
II	Optic	Vision	Retina
III	Oculomotor	Eyeball movement Lens accommodation	Four eyeball muscles and one eyelid muscle
	Oculomotor	Pupil constriction	
IV	Trochlear	Eyeball movement	Superior oblique muscles
V	Trigeminal <sup>a</sup>	Sensations General sensory from tongue Proprioception	Face, scalp, teeth, lips, eyeballs, nose and throat lining Anterior two thirds of tongue Jaw muscles for mastication
	Trigeminal	Chewing	Muscles of mastication
VI	Abducens	Eyeball movement	Lateral rectus muscle
VII	Facial <sup>a</sup>	Taste Proprioception	Anterior two thirds of tongue Face and scalp
	Facial	Facial expressions	Muscles of the face
	Facial	Salivation and lacrimation	Salivary and lacrimal glands via submandibular and pterygopalatine ganglia
VIII	Vestibulocochlear	Balance Hearing	Vestibular apparatus of internal ear Cochlear of internal ear
IX	Glossopharyngeal <sup>a</sup>	Taste Proprioception for swallowing Blood pressure receptors	Posterior two thirds of tongue Throat muscles Carotid sinuses
	Glossopharyngeal	Swallowing and gag reflex Tear production	Throat muscles Lacrimal glands
	Glossopharyngeal	Saliva production	Parotid glands
X	Vagus	Chemoreceptors Pain receptors Sensations Taste	Blood oxygen concentration, aortic bodies Respiratory and digestive tracts External ear, larynx, and pharynx Tongue
	Vagus	Heart rate and stroke volume Peristalsis Air flow Speech and swallowing	Pacemaker and ventricular muscles Smooth muscles of digestive tract Smooth muscles in bronchial tubes Muscles of larynx and pharynx
XI	Spinal Accessory	Head rotation	Trapezius and sternocleidomastoid muscles
XII	Hypoglossal <sup>a</sup>	Speech and swallowing	Tongue and throat muscles

Adapted from: [http://www.teaching-biomed.man.ac.uk/resources/wwwcal/cranial\\_nerves/page2.asp](http://www.teaching-biomed.man.ac.uk/resources/wwwcal/cranial_nerves/page2.asp), accessed January 16, 2005.

<sup>a</sup>Cranial nerves affecting chewing and swallowing.

One individual may have up to 500,000 single nucleotide polymorphisms (Ferguson, 2007). A steady stream of neurotransmitters is needed for good mental and neurological health, yet they are subject to dietary manipulation. Increases or decreases in dietary precursors of serotonin, dopamine, norepinephrine, and acetylcholine affect nerve functioning. Brain levels of tryptophan, tyrosine, or choline control the rates at which neurons synthesize serotonin, dopamine, or acetylcholine, respectively (Wurtman, 2008). “Brain foods” can be suggested to prevent or treat many stress-related mental disorders (Takeda, 2004).

Heritable abnormalities include major depressive disorder (MDD), attention deficit hyperactivity disorder (ADHD), bulimia nervosa (BN), dysthymic disorder, fibromyalgia, generalized anxiety disorder, irritable bowel syndrome, migraine, obsessive-compulsive disorder, panic disorder, posttraumatic stress disorder, premenstrual dysphoric disorder, and social phobia (Hudson et al, 2003). The biological link between

psychiatric and metabolic disorders is now clear (Bazar et al, 2006). Insulin resistance, diabetes, hypertension, metabolic syndrome, obesity, attention-deficit disorders, depression, psychosis, sleep apnea, inflammation, autism, and schizophrenia (SCZ) operate through common pathways; treatments used for one may prove beneficial for others (Bazar et al, 2006). Melatonin (MT), for example, is a powerful antioxidant that protects mitochondrial DNA; it easily crosses blood-brain barrier and has a role in ADHD, Alzheimer’s disease (AD), autism, Parkinson’s disease, seasonal affective disorder (SAD), and bipolar disorders (BDs).

Lipids are also essential for brain and neuron functioning. Lipid peroxidation is the outcome of free radical-mediated injury to the brain, where it directly damages membranes and generates oxidized products. Brain lipid peroxidation is a therapeutic target early in Alzheimer’s and Huntington’s diseases (Montine et al, 2004; Wu and Meydani, 2004). Brain P-450 enzymes catalyze the formation

of neurosteroids and eicosanoids and they metabolize substrates such as vitamins A and D, cholesterol, and bile acids (Liu et al, 2004).

Nutrient intake has long-range effects. Deficiencies of vitamins B<sub>12</sub>, folic acid, B<sub>6</sub>, C, or E, iron, or zinc mimic the effects of radiation on the body by damaging DNA through strand breaks and oxidative lesions; deficient iron or biotin causes mitochondrial decay and oxidant leakage, leading to accelerated aging and neural decay (Ames, 2004).

Micronutrient scarcity during periods of human evolution has altered DNA and promoted some of our modern, late-onset diseases (Ames, 2006). Dietetic professionals should consider the complexities of neuropsychiatric conditions as well as the influence of diet on both reproductive and adult health.

A multidisciplinary approach is most effective. Psychotherapy addresses the will to change, responsibility for self, and search for meaning and identity. Psychiatrists focus on the medical and chemical management of prescribed drugs. Social workers assist with family and relationship issues. Dietitians focus on overall health status, medical issues, prescribed medicines, alternative therapies, and appropriate nutritional treatments. Assessment must include careful review of medical and treatment histories. Interventions must apply a positive approach, prevention of malnutrition, use of the team con-

cept, restoration of feeding abilities, and improved nutritional quality of life. Table 4-3 lists important disorders; Table 4-4 lists neurotransmitters and their nutritional relevance; and Table 4-5 describes nutrients and substances important for brain health.

**TABLE 4-3 Disorders of Mental Health (DSM-IV)**

Mental Health Disorders	Explanation or Relevance to Nutrition
Acute stress disorder	Development of anxiety and dissociative and other symptoms within 1 month following exposure to an extremely traumatic event; other symptoms include re-experiencing the event and avoidance of trauma-related stimuli.
Adjustment disorder	Maladaptive reaction to identifiable stressful life events.
Amnesic disorder	Mental disorder characterized by acquired impairment in the ability to learn and recall new information, sometimes accompanied by inability to recall previously learned information, and not coupled to dementia or delirium.
Anxiety disorders	A group of mental disorders in which anxiety and avoidance behavior predominate, including panic disorders, agoraphobia, specific phobia, social phobia, obsessive-compulsive disorder, posttraumatic stress disorder, acute stress disorder, generalized anxiety disorder, and substance abuse anxiety disorder.
Attention-deficit disorder	Mental disorder characterized by inattention (such as distractibility, forgetfulness, not finishing tasks, and not appearing to listen), by hyperactivity and impulsivity (such as fidgeting and squirming, difficulty in remaining seated, excessive running or climbing, feelings of restlessness, difficulty awaiting one's turn, interrupting others, and excessive talking). See Section 3 for details.
Autistic disorder	Severe pervasive developmental disorder with onset usually before 3 years of age and a biological basis related to neurological or neurophysiological factors. Characterized by qualitative impairment in reciprocal social interaction (e.g., lack of awareness of the existence of feelings in others, failure to seek comfort at times of distress, lack of imitation), in verbal and nonverbal communication, and in capacity for symbolic play. Restricted and unusual repertoire of activities and interests.
Binge eating disorder	An eating disorder characterized by repeated episodes of binge eating, as in bulimia nervosa, but not followed by inappropriate compensatory behavior such as purging, fasting, or excessive exercise.
Bipolar disorders	Mood disorders characterized by a history of manic, mixed, or hypomanic episodes, usually with concurrent or previous history of one or more major depressive episodes.
Body dysmorphic disorder	A mental disorder in which a normal-appearing person is either preoccupied with some imagined defect in appearance or is overly concerned about some very slight physical anomaly.
Catatonic disorder	Catatonia due to the physiological effects of a general medical condition and neither better accounted for by another mental disorder nor occurring exclusively during delirium.
Childhood disintegrative disorder	Pervasive developmental disorder characterized by marked regression in a variety of skills, including language skills, social skills or adaptive behavior, play, bowel or bladder control, and motor skills, after at least 2, but less than 10, years of apparently normal development.

(continued)

**TABLE 4-3 Disorders of Mental Health (DSM-IV) (continued)**

Mental Health Disorders	Explanation or Relevance to Nutrition
Circadian rhythm sleep disorder	Lack of synchrony between the schedule of sleeping and waking required by the external environment and that of a person's own circadian rhythm.
Conduct disorder	A type of disruptive behavior disorder of childhood and adolescence characterized by a persistent pattern of conduct in which rights of others or age-appropriate societal norms or rules are violated. Misconduct includes aggression toward people or animals, destruction of property, deceitfulness, theft, and serious violations of rules.
Conversion disorder	Mental disorder with loss or alteration of voluntary motor or sensory functioning suggesting physical illness (such as seizures, paralysis, dyskinesia, anesthesia, blindness, or aphonia) having no demonstrable physiological basis.
Delusional disorder	Mental disorder marked by well-organized, logically consistent delusions but lacking other psychotic symptoms. Most functioning is not markedly impaired, the criteria for schizophrenia have never been satisfied, and symptoms of a major mood disorder have been present only briefly if at all.
Depersonalization disorder	Dissociative disorder characterized by one or more severe episodes of depersonalization (feelings of unreality and strangeness in one's perception of the self or one's body image) not due to another mental disorder, such as schizophrenia. The perception of reality remains intact; patients are aware of their incapacitation. Episodes are usually accompanied by dizziness, anxiety, fears of going insane, and derealization.
Depressive disorders	Mood disorders in which depression is unaccompanied by manic or hypomanic episodes.
Disruptive behavior	Group of mental disorders of children and adolescents consisting of behavior that violates social norms, is disruptive, distressing others more than it does the person with the disorder.
Dissociative disorders	Mental disorders characterized by sudden, temporary alterations in identity, memory, or consciousness, segregating normally integrated memories or parts of the personality from the dominant identity of the individual.
Dissociative identity disorder	Multiple personality disorder; characterized by the existence in an individual of two or more distinct personalities, each having unique memories, characteristic behavior, and social relationships.
Dysthymic disorder	Mood disorder characterized by depressed feeling (sad, blue, low), by loss of interest or pleasure in one's usual activities, and by at least some of the following: altered appetite, disturbed sleep patterns, lack of energy, low self-esteem, poor concentration or decision-making skills, and feelings of hopelessness. Symptoms have persisted for more than 2 years but are not severe enough to meet the criteria for major depressive disorder.
Eating disorder	Any of several disorders (anorexia nervosa, bulimia nervosa, pica, and rumination disorder) in which abnormal feeding habits are associated with psychological factors.
Factitious disorder	Repeated, intentional simulation of physical or psychological signs and symptoms of illness for no apparent purpose other than obtaining treatment.
Generalized anxiety disorder	Excessive, uncontrollable anxiety and worry about two or more life circumstances, for 6 months or longer, accompanied by some combination of restlessness, fatigue, muscle tension, irritability, disturbed concentration or sleep, and somatic symptoms.
Impulse control disorders	Repeated failure to resist an impulse to perform some act harmful to oneself or to others.
Learning disorders	Academic functioning that is substantially below the level expected on the basis of the patient's age, intelligence, and education, interfering with academic achievement or other functioning. Included are reading disorder, mathematics disorder, and disorder of written expression.
Mental disorder	Any clinically significant behavioral or psychological syndrome characterized by the presence of distressing symptoms, impairment of functioning, or significantly increased risk of suffering pain, disability, loss of freedom or death. Mental disorders manifest a behavioral, psychological, or biological dysfunction in the individual.
Motor skills disorder	Inadequate development of motor coordination, severe enough to limit locomotion or restrict the ability to perform tasks, schoolwork, or other activities.
Obsessive-compulsive disorder	Anxiety disorder characterized by recurrent obsessions or compulsions, which are severe enough to interfere significantly with personal or social functioning. Performing compulsive rituals may release tension temporarily; resisting them causes increased tension.
Oppositional defiant disorder	Disruptive behavior characterized by a recurrent pattern of defiant, hostile, disobedient, and negativistic behavior directed toward those in authority, including such actions as defying the requests or rules of adults, deliberately annoying others, arguing, spitefulness, and vindictiveness that occur much more frequently than would be expected on the basis of age and developmental stage.
Pain disorder	A somatoform disorder characterized by a chief complaint of severe chronic pain that causes substantial distress or impairment in functioning; the pain is neither feigned nor intentionally produced, and psychological factors appear to play a major role in its onset, severity, exacerbation, and maintenance.
Panic disorder and agoraphobia	Recurrent panic attacks, episodes of intense apprehension, fear, or terror associated with somatic symptoms such as dyspnea, palpitations, dizziness, vertigo, faintness, shakiness; and psychological symptoms such as feelings of unreality, depersonalization, fears of dying, going crazy, or losing control. There is usually chronic nervousness and tension between attacks.

(continued)

**TABLE 4-3 Disorders of Mental Health (DSM-IV) (continued)**

Mental Health Disorders	Explanation or Relevance to Nutrition
Personality disorders	Enduring, inflexible, and maladaptive personality traits that deviate markedly from cultural expectations, are self-perpetuating, pervade a broad range of situations, and either generate subjective distress or result in significant impairments in social, occupational, or other functioning. Onset is by adolescence or early adulthood.
Pervasive developmental disorders	Impaired development in multiple areas, including the acquisition of reciprocal social interaction, verbal and nonverbal communication skills, and imaginative activity and by stereotyped interests and behaviors; included are autism, Rett's syndrome, childhood disintegrative disorder, and Asperger's syndrome.
Premenstrual dysphoric disorder	Premenstrual syndrome with signs of depression, lethargy.
Reading disorder	Learning disorder in which the skill affected is reading ability, including accuracy, speed, and comprehension.
Rumination disorder	Eating disorder seen in infants under 1 year of age. After a period of normal eating habits, the child begins excessive regurgitation and rechewing of food, which is then ejected from the mouth or reswallowed. If untreated, death from malnutrition may occur.
Schizoaffective disorder	A major depressive episode, manic episode, or mixed episode occurs along with prominent psychotic symptoms characteristic of schizophrenia, the symptoms of the mood disorder being present for a substantial portion of the illness, but not for its entirety, and not being due to the effects of a psychoactive substance.
Seasonal affective disorder	A cyclically recurring mood disorder characterized by depression, extreme lethargy, increased need for sleep, hyperphagia, and carbohydrate craving; it intensifies in specific seasons, most commonly winter. It is hypothesized to be related to melatonin levels. "Mood disorder with seasonal pattern."
Separation anxiety disorder	Excessive, prolonged, developmentally inappropriate anxiety and apprehension in a child concerning removal from parents, home, or familiar surroundings.
Shared psychotic disorder	A delusional system that develops in one or more persons as a result of a close relationship with someone who already has a psychotic disorder with prominent delusions.
Sleep disorders	Chronic disorders involving sleep. Primary sleep disorders comprise dyssomnias and parasomnias; causes of secondary sleep disorders may include a general medical condition, mental disorder, or psychoactive substance.
Speech disorder	Defective ability to speak, either psychogenic or neurogenic.
Substance-related disorders	A variety of behavioral or psychological anomalies resulting from ingestion of or exposure to a drug of abuse, medication, or toxin.

**TABLE 4-4 Neurotransmitters and Nutritional Relevance**

Type	Neurotransmitter	Postsynaptic Effect	Functions and Nutritional Relevance
Amino acids	Gamma aminobutyric acid (GABA)	Inhibitory	Glutamate is a precursor. Pyridoxal phosphate is a cofactor for both synthesis and break-down.
	Glycine	Inhibitory	Glycine inhibits neurotransmitter signals in the CNS. Available from dietary proteins, but most contain only small amounts (exception is collagen). Unique role as a type of antioxidant.
	Glutamate	Excitatory	The most important neurotransmitter for normal brain function; >50% of the neurons in the brain release glutamate. Glutamate can be used to synthesize glutamine by taking up ammonia; this reduces excessive ammonia levels in the brain and is important in diseases such as hepatic encephalopathy. The "sodium salt" of glutamic acid, monosodium glutamate (MSG), is responsible for one of the five basic tastes of the human sense of taste, umami; MSG is extensively used as a food additive. No specific dietary precursors. Primarily synthesized in the brain from alpha-keto glutarate and glucose. Glutamate is a precursor of GABA.
	Aspartate	Excitatory	Acidic analog of asparagine. No specific dietary precursors. Synthesized primarily from glutamate.
Biogenic monoamines	Dopamine	Excitatory	A monoamine neurotransmitter, concentrated in the basal ganglia. It is widely distributed throughout the brain in the nigrostriatal, the mesocorticolimbic, and the tuberohypophyseal pathways. Decreased brain dopamine levels contribute to Parkinson's disease, while an increase in dopamine concentration has a role in psychosis. Synthesized from phenylalanine and tyrosine.
Biogenic amine	Acetylcholine	Excitatory	Main neurotransmitter in the parasympathetic nervous system that controls heart rate, digestion, secretion of saliva, and bladder function. Drugs that affect cholinergic activity produce changes in these body functions. Affected by choline from the diet (eggs, soybeans). Some antidepressants act by blocking cholinergic receptors; this anticholinergic activity is an important cause of dry mouth. Botulism suppresses release of acetylcholine, and nicotine increases receptors for acetylcholine. Alzheimer's disease seems to be related to a malfunction in this neurotransmitter.

(continued)

**TABLE 4-4 Neurotransmitters and Nutritional Relevance (continued)**

Type	Neurotransmitter	Postsynaptic Effect	Functions and Nutritional Relevance
	Epinephrine	Excitatory	Affects fight or flight reactions; secreted in greater quantity during anger and fear, with resulting increase in heart rate and hydrolysis of glycogen to glucose. Used as a stimulant in cardiac arrest, as a vasoconstrictor in shock, as a bronchodilator in asthma, and to lower intraocular pressure in glaucoma. Secreted by the adrenal medulla.
	Noradrenaline	Excitatory	Synthesized from phenylalanine and tyrosine. A monoamine neurotransmitter that affects “fight or flight,” attention and arousal, and blood pressure.
	Serotonin	Excitatory	Synthesized from tryptophan in the diet. Affects mood control, regulation of sleep, pain perception, body temperature, blood pressure, and hormonal activity. Also affects gastrointestinal and cardiovascular systems.
	Histamine	Excitatory	A potent agent believed to be involved in sleep–wake cycles and allergy.

**TABLE 4-5 Nutrients for Brain Health**

**Diets that provide adequate amounts of complex carbohydrates, essential fats, amino acids, vitamins and minerals, and water support a balanced mood. Diet is one part of the jigsaw in the promotion of good mental health (Mental Health Foundation, 2009).**

Nutrient or Factor	Role in the Brain	Comments
<b>PROTEINS</b>		
Aromatic amino acids (tryptophan, tyrosine, and phenylalanine)	Precursors of serotonin, dopamine, and norepinephrine	Increase in brain tryptophan from eating a carbohydrate-rich/protein-poor meal causes parallel increases in the amounts of serotonin released into synapses. Tryptophan can induce sleep from high-carbohydrate meals; high-protein meals tend to increase alertness.
Corticotropin-releasing hormone	Disturbances occur in periods of stress in the hypothalamic–pituitary–adrenal axis	Eating is often suppressed during stress due to anorectic effects of corticotropin-releasing hormone and increased during recovery from stress due to appetite-stimulating cortisol. Night eating syndrome is related to cortisol levels.
Cytokines	Influence sleep and eating behaviors; involved in many infectious, inflammatory, neoplastic, metabolic, and degenerative illnesses	Implicated in depressive and anxiety disorders; schizophrenic disorders (chronic and acute); autistic disorder; eating disorders; and obsessive-compulsive disorder.
Dietary antioxidants	Improve cognitive functioning	Fruits, vegetables, coffee, and tea. Strong inverse relationship between coffee intake and risk of suicide (Takeda, 2004). Quercetin (in red apples with skins, onions, blueberries, cranberries, strawberries) seems to protect against brain-cell damage (Silva et al, 2004).
<b>LIPIDS</b>		
Endocannabinoids	A class of lipids including amides, esters, and ethers of long-chain polyunsaturated fatty acids (Battista et al, 2004). They are activated by a CB2 receptor agonist, arachidonoylglycerol, and by elevated endogenous levels of endocannabinoids (Van Sickle et al, 2005)	Anandamide (N-arachidonylethanolamine; AEA) and 2-arachidonoylglycerol are the main endogenous agonists of cannabinoid receptors, able to mimic several pharmacological effects of delta(9)-tetrahydrocannabinol, the active principal component of <i>Cannabis sativa</i> preparations such as hashish and marijuana (Battista et al, 2004). Nonpsychotropic therapeutic interventions using enhanced endocannabinoid levels may be used in localized brain areas (Van Sickle et al, 2005).
Essential fatty acids (EFA)	Fluidity of neuronal membrane, synthesis and functions of brain neurotransmitters, immune system integrity (Yehuda et al, 2005)	The blood–brain barrier determines the bioavailability. The myelination process determines the efficiency of brain and retinal functions of EFA. Since they must be supplied from the diet, a decreased bioavailability induces major disturbances (Yehuda et al, 2005).
Omega-3 fatty acids *DHA, EPA	Control inflammatory and autoimmune processes; part of the brain lipid membranes. DHA depletion leads to losses in neuronal function (Lim et al, 2005)	Helpful in depression, bipolar disorder, multiple sclerosis, and other neurological conditions. DHA and arachidonic acid (AA) may not distribute evenly in the brain. There are age-induced regional changes in fatty acid composition of brain phospholipids. DHA, uridine (as uridine monophosphate), and choline are all found in mother’s milk, and included in most infant formulas; these substances are part of a regulatory mechanism through which plasma composition influences brain development (Wurtman, 2008).
Omega-6 polyunsaturated fatty acids ALA, GLA	Part of the brain lipid membranes	Useful in anorexia nervosa and several neurological conditions. May reduce risk for Parkinson’s disease (de Lau et al, 2005).

(continued)

**TABLE 4-5 Nutrients for Brain Health (continued)**

Nutrient or Factor	Role in the Brain	Comments
<b>MINERALS</b>		
Iron	Normal amounts are required for normal functioning. 7% of the general population, and 19% of women between ages of 12–50 may be deficient (UC Davis, 2009)	Iron sufficiency prevents anemia. Deficiency causes DNA breaks (UC Davis, 2009).
Selenium	Parts of the United States and China have areas where soil is deficient in selenium	Antioxidant properties protect the brain and nerves from damage. Brazil nuts are a rich source.
Zinc	18% of the US population is deficient (UC Davis, 2009)	Zinc functions as part of the insulin molecule and hundreds of enzymes. Deficiency causes DNA damage with chromosome breaks; this leads to brain and immune dysfunction (UC Davis, 2009).
<b>VITAMINS</b>		
Niacin	2% of the general population may be deficient (UC Davis, 2009)	Deficiency disables DNA repair (poly ADP ribose); this leads to neurological damage and memory loss (UC Davis, 2009).
Vitamins B <sub>6</sub> , B <sub>12</sub> , and folic acid	Lower elevated amounts of homocysteine. 10% of the population may be deficient in these B <sub>6</sub> ; 4% may be deficient in B <sub>12</sub> (UC Davis, 2009)	These play a role in many neurological conditions. Methylated forms may be needed in individuals who have the MTHFR genotype. B <sub>12</sub> deficiency leads to neurological damage (UC Davis, 2009).
Vitamins C and E	Vitamins C and E function as antioxidants	Antioxidant properties are protective.
Vitamin D	Vitamin D has been found to delay onset of multiple sclerosis and effects of depression (especially seasonal affective disorder). It is being studied in schizophrenia	Vitamin D has nuclear hormone receptors that regulate gene expression and nervous system development.
<b>OTHER</b>		
<sup>a</sup> Uridine	A pyrimidine nucleoside that is formed when uracil is attached to a ribose ring	Component of RNA. Its nucleotides participate in the biosynthesis of polysaccharide compounds. Foods containing uridine may help to alleviate depression (Carlezon et al, 2005).
<sup>a</sup> Choline	A nutrient that improves the environment of the brain cells (Zeisel, 2004)	Choline is a nutrient found in egg yolks, milk, nuts, fish, liver and other meats, and human breast milk. It is the essential building block acetylcholine, and it plays a vital role in the formation of phospholipids in cell membranes. Pregnant women should include a good source in their daily diets.

<sup>a</sup>NOTE. A preparation containing uridine, docosahexaenoic acid (DHA,) and choline is being tested for improved cognition, and enhanced neurotransmitter release (Wurtman et al, 2009).

## NEUROLOGICAL DISORDERS

## ALZHEIMER'S DISEASE AND DEMENTIAS

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinical-pathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

## DEFINITIONS AND BACKGROUND

**Dementias** include multiple cognitive defects with memory loss; they often involve aphasia, apraxia, agnosia, and disturbed daily functioning. Risk factors include diabetes, cardiovascular disease, stroke, hypertension, head injury, aging, depression, and family history. Of over 50 dementias, **AD** is the most common, with progressive deterioration of intellect, memory, personality, and self-care. Other conditions should be ruled out by medical evaluation. Early stages of AD manifest with short-term memory loss; problems finding the appropriate word; asking the same questions over and over; difficulty making decisions and planning ahead; suspiciousness; changes in senses of smell and taste; denial; depression; loss of initiative; personality changes; and problems with abstract thinking.

AD is characterized by deposition of extracellular neuritic, beta-amyloid peptide-containing plaques in cerebral cortical regions and presence of intracellular neurofibrillary tangles in cerebral pyramidal neurons (Schliebs, 2005). Acetylcholine-containing neurons are especially affected. Acetylcholine normally triggers breakdown of the beta-amyloid precursor protein (APP) in brain cells. Impaired

cerebral energy metabolism and pyruvate dehydrogenase activity are also found (Martin et al, 2005).

Insulin and associated signaling molecules begin to disappear from the brain during early AD, suggesting a form of “type 3 diabetes.” Insulin deficiency and insulin resistance mediate AD-type neurodegeneration; indeed, experimental brain diabetes is treatable with drugs currently used to treat T2DM (de la Monte and Wands, 2008). Altered glycogen synthase kinase-3 (GSK-3) function, decreased serum insulin-like growth factor I (IGF-I) levels, and carotid atherosclerosis are independent risk factors for AD (Lester-Coll et al, 2006; Wantanabe et al, 2005).

Apolipoprotein E (ApoE) is an important determinant of lipoprotein metabolism and risk for oxidative damage (Dietrich et al, 2005). Because ApoE also influence cognitive function and decline, prevention of cardiovascular disease may slow the onset of AD (Kang et al, 2005). Because age-related proinflammatory cytokines are also involved, there is a reduced risk of AD in users of nonsteroidal anti-inflammatory drugs (Staehelin, 2008).

Mood instability and increased distractibility, irritability, agitation, and irregular sleep can be present. Behavioral changes, such as aggressive behavior, psychosis, and overactivity, occur frequently and determine the need for institutionalization or use of mood stabilizers. A lifetime of depression may actually precede AD and should be corrected (Ownby et al, 2006; Rapp et al, 2006).

Declining body mass over time is strongly linked to the risk of developing AD (Buchman et al, 2005). Metabolic acidosis promotes muscle wasting; diets that are rich in net acid-producing protein and cereal grains relative to their content of net alkali-producing fruit and vegetables may therefore contribute to a reduction in lean tissue mass in older adults (Dawson-Hughes et al, 2008).

Circadian patterns of food intake change and disturbed eating patterns occur, with altered macronutrient selection and preference for carbohydrates (Greenwood et al, 2005).

Numerous observational studies demonstrate a positive correlation between a high intake of antioxidants and better cognitive function in the elderly (Staehelin, 2008). Use of nutrients that increase the levels of brain catecholamines and protect against oxidative damage is critical: vitamins C and E, zinc, iron, copper, and selenium should be provided (Squitti et al, 2005). Antioxidants in foods such as blueberries, cranberries, strawberries, kale, and spinach may improve cognitive function; and coffee drinkers tend to have lower levels of AD later in life (Eskelinen et al, 2009). There is substantial epidemiological evidence from a number of recent studies that demonstrate a protective role of omega-3 fatty acids, such as docosahexaenoic acid (DHA), in AD and cognitive decline (Morris, 2009).

Finally, vitamins B<sub>6</sub> and B<sub>12</sub> and folate should be used to lower homocysteine (tHcy) levels. Comprehensive treatment of AD requires thorough caregiver support and thoughtful use of medications for cognition enhancement, neuroprotection, and treatment of agitation. While the prognosis for

AD is improving, death most often occurs from renal, pulmonary, or cardiac complications between 2 and 20 years after onset of symptoms. Pneumonia is a common cause of morbidity and death, related to dysphagia, aspiration, altered mobility, decreased nutritional status, and lowered immune response.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** ApoE epsilon4 allele is a primary gene that has been confirmed in AD. Hypomethylation of the amyloid A4 precursor gene and hyperhomocysteinemia may contribute to the pathophysiology of AD (Abdolmaleky et al, 2004; Aisen et al, 2008). Cerebrospinal fluid biomarkers beta-amyloid 42 (Aβ42), T-tau, and P-tau may identify early-stage AD (Mattsson et al, 2009).

<b>Clinical/History</b>	Mini-Mental State Examination	Glucose (gluc)
Height, weight	Severe	Serum tHcy (elevated?)
Subtle weight loss	Impairment	Serum folate; methyltetrahydrofolate
Current BMI, % change	Battery and Global Deterioration Scale	reductase (MTHFR) levels
Dietary/intake history	Mattis Dementia Rating Scale	Serum vitamin B <sub>12</sub>
Intake and output (I & O)	Behavioral disturbances:	Serum zinc
Anorexia and poor intake	Neuropsychiatric	Serum copper
Nausea, vomiting	Inventory	Alanine aminotransferase (ALT)
Diarrhea	Behavioral function: London Psychogeriatric Rating Scale	Aspartate aminotransferase (AST)
Bowel incontinence		Dopamine (DA)
Electroencephalogram (EEG)	<b>Lab Work</b>	Cerebral spinal fluid (CSF)
Loss of sense of smell	Cerebrospinal fluid biomarkers [Aβ42, T-tau, P-tau]	pyruvate and lactate levels
Hx of Down syndrome or depression?	Choline acetyltransferase activity (ChAT)	Na <sup>+</sup> , K <sup>+</sup>
Computed tomography (CT) scan	C-reactive protein (CRP)	Blood urea nitrogen (BUN)
Brain magnetic resonance imaging (MRI)	Cholesterol (may be thinned)	Creatinine (creat)
Medial temporal lobe thickness (often thinned)		H & H
		Serum Fe
		Albumin or transthyretin

## INTERVENTION

### OBJECTIVES

- To effectively enhance intake, interventions must work with changing needs and intake patterns (Young et al, 2005). Prevent weight loss from altered activity levels, poor eating habits, depression, impaired memory, and self-feeding difficulty.
- Maintain activity to preserve function. Walking 90 minutes per week helps to maintain lean body mass and can possibly help alleviate anorexia.
- Avoid constipation or impaction; support bowel or bladder continence through proper scheduling.
- Encourage self-feeding at mealtimes as long as possible. Begin using finger foods and items easy to consume without utensils.
- Prevent or correct dehydration, pressure ulcers, and other signs of nutritional decline. Preserve muscle mass.
- Monitor dysphagia, pocketing of food, or aspiration. Use gastrostomy feeding, especially in early stages. While the

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Self-Feeding Difficulty

**Assessment Data:** Food records indicating poor intake; weight loss; forgetting how to feed self. Requires total feeding. Anorexia and complaints of taste changes, lost sense of smell. Lab results showing low albumin and transthyretin. Recent dehydration and urinary tract infection (UTI).

**Nutrition Diagnoses (PES):** Self-feeding difficulty related to inability to use utensils (fork, spoon) at advanced stage of Alzheimer's as evidenced by weight loss, I & O with recent dehydration, dietary intake records showing intake of about 25–50% of meals served.

#### Interventions:

Food and Nutrient Delivery:

ND 1.3 Specific foods/beverage—finger foods and nutrient-dense diet.

ND 3.1.1 Commercial beverage supplement 1 can twice daily.

ND 3.2.1 Supplement with multivitamin–mineral once daily.

ND 4.5 Feeding assistance—fed by staff.

**Education:** Educate caregivers about introducing finger foods items, reducing distractions at mealtime, scheduling of meals to give structure, use of frequent and portable snacks throughout the day to improve intake of nutrients and energy. Reinforce safe feeding strategies with caregivers to avoid aspiration.

**Counseling:** C-2.2 Goal setting: improve oral intake, prevent aspiration, regain lost weight. Avoid constipation, dehydration, and impaction.

**Coordination of Nutrition Care:** RC-1.1 Team meeting with nursing, social services, speech therapy, recreation therapy.

**Monitoring and Evaluation:** Improved weight, visceral protein levels; less agitation.

terminal stage of AD is generally indicated by the inability to swallow, the benefit of enteral feeding (EN) is limited at that point.

- Use creative feeding strategies. Offer frequent snacks, day and night if desired.
- Protect patient from injuries and provide emotional support for patient and family.
- To assist with eating-related behavioral problems, there are many tips. For example, for attention deficit, verbally direct the patient through the eating process; make food and fluids visible. Give one food at a time; offer small bites. Serve soft foods to reduce the need for chewing.
- Keep simple routines and a consistent environment. Minimize distractions at mealtime. Provide a quiet environment. If group dining is a concern, provide meals in room or with a single partner.
- Use finger foods and cups with cover/spout if the patient paces.

## FOOD AND NUTRITION

- Ensure a healthy diet, including protein and increased calories for age, sex, and activity, especially for “wanderers” and those who pace. Persons with AD may need 35 kcal/kg of body weight or more.
- Adequate **vitamin E** (such as in nuts, creamy salad dressings). Include nutrient-dense foods that are high in antioxidants. Coffee, cocoa, and red wine contain flavonols that increase blood flow to the brain; one serving of wine daily can be included.
- Provide more oily fish (salmon, halibut, trout, and tuna) for **omega-3 fatty acids**. Fish oil capsules have not been shown to be quite as effective.
- **Omega 6 fatty acids** may also be beneficial, such as from vegetable oils.
- Extra **folic acid** may lessen decline of cognitive function; offer leafy greens, orange juice, broccoli. To lower tHcy levels, folic acid, vitamins B and B<sub>12</sub> are important (Zhou and Practico, 2009). Avoid excesses of vitamin B<sub>12</sub> from red meat and high-fat dairy products.
- Use color-rich fruits and vegetables (blueberries, cranberries, strawberries, spinach, kale, broccoli, oranges, and other citrus fruits). Higher intake of foods rich in potassium, such as fruit and vegetables, favors preservation of muscle mass (Dawson-Hughes et al, 2008).
- Foods high in copper include liver, kidney, oysters, nuts, dried beans and legumes, cocoa, eggs, prunes, and potatoes.
- Offer meals at regular and consistent times each day. Allow sufficient time for eating. Offer one course at a time (first salad, then entree, then fruit dessert) to prevent confusion. Avoid distractions; use calming background music. Cueing to eat is also useful.
- Use dishes without a pattern; white is a good choice.
- Use a simple place setting and a single eating utensil. Use a bowl for easier scooping and special spoons or adaptive equipment as needed. Serve soup in mugs.
- Finger foods, such as sandwiches cut into four, cheese cubes, pancakes or waffles cut in smaller pieces, hard

cooked egg halves, chicken strips, julienne vegetables, and brownies (vs. pie), are easier to eat and help to maintain weight.

- Provide a high-carbohydrate meal for dinner to increase food intake during later stages of the disease; this reflects the preference for high-carbohydrate foods (Young et al, 2005). Plan menus accordingly; offer nutrient-dense desserts, such as fruit tarts, puddings topped with fruit, and custards.
- Tube feed or use texture-altered foods with thickened liquids as needed to compensate for dysphagia.
- Choline may be beneficial; use soybeans or eggs (Michel et al, 2006).
- Adequate fluid intake is essential. Offer regular drinks of water, juice, milk, and other fluids to avoid dehydration.
- Cut back on saturated fats, which increase brain beta-amyloid levels. Omit high-fat dairy products, fast food items, fried foods, and processed foods.

## Common Drugs Used and Potential Side Effects

- See Table 4-6.

## Herbs, Botanicals, and Supplements

- Allopregnanolone (APalpha, a metabolite of progesterone) is reduced in the serum, plasma, and brain of aged individuals and Alzheimer’s patients; researchers are evaluating its possible use (Wang et al, 2008).
- Chinese medicines show promise in combinations; Huperzine A (Chinese club moss,) ginkgo biloba, and ginseng are under study (Fu and Li, 2009).
- Coenzyme Q10 and choline supplements are under study.
- Curry, cumin, and turmeric may block beta-amyloid plaque formation in the brain and can be encouraged as seasonings.
- Folic acid, vitamins B<sub>6</sub>, and B<sub>12</sub> supplements do not slow cognitive decline in dementia but can lower tHcy levels (Aisen et al, 2008; Malouf et al, 2003). Cerefolin<sup>®</sup> contains N-acetylcysteine (NAC) and L-methylfolate. Where there are MTHFR polymorphisms, the active form of folate (methyltetrahydrofolate) may be needed (Mischoulon and Raab, 2007).
- Genetic risk factors for cognitive decline may remain latent pending age-related decline in nutrition, suggesting the importance of early intervention with key dietary supplements (including alpha-lipoic acid [ALA], DHA) to delay the progression of age-related cognitive decline (Suchy et al., 2009).
- Ginkgo biloba interacts with anticoagulants and antiplatelets such as aspirin, warfarin, and dipyridamole. Clinical trials have not shown effectiveness when used alone (Birks et al, 2009).
- Horse balm, rosemary, dandelion, procaine, sage, and lecithin have been suggested but long-term trials have not confirmed their usefulness.

**TABLE 4-6 Medications for Alzheimer's Disease and Possible Side Effects**

Medication	Side Effects
Antidepressants	Minimal improvements have been noted. Mirtazapine may be useful in the treatment of the comorbid symptoms of weight loss, insomnia, and anxiety, a reflection of its enhancement of brain serotonergic and noradrenergic neurotransmission. Large, randomized controlled trials (RCTs) are needed.
Atypical antipsychotics	The efficacy of risperidone and olanzapine for the treatment of psychotic symptoms has been demonstrated by large RCTs in Alzheimer's disease.
Cholinesterase inhibitors donepezil (Aricept®), galantamine (Reminyl® or Razadyne®), rivastigmine (Exelon®)	Can slow agitation and the progression of cognitive and functional deficits in Alzheimer's disease in early stages by blocking acetylcholine breakdown. They improve cognitive function, behavior, and daily functioning. Nausea, diarrhea, insomnia, fatigue and loss of appetite may occur.
Cerefolin®	Contains methylated B <sub>12</sub> and folic acid, as well as N-acetylcysteine.
Coenzyme Q10	Studies are inconclusive at this time. Individuals who take statins may need a supplement to reduce side effects such as rhabdomyolysis.
Hydargine	Relieves symptoms of declining mental capacity. Nausea and gastrointestinal (GI) distress are common.
Ibuprofen and other nonsteroidal, anti-inflammatory drugs	May reduce the risk of development of Alzheimer's disease by reducing inflammatory processes.
Insulin	If Alzheimer's disease is related to diabetes, it may be important to assure that adequate levels of insulin are available to the brain.
Laxatives	To control constipation. Offer high-fiber foods and sufficient fluid.
Mood stabilizers (lithium)	Low doses may be useful when combined with antipsychotics. Lithium regulates amyloid-beta precursor protein processing (Su et al, 2004).
Memantine (Namenda)	This regulates the activity of glutamate, a messenger chemical involved in learning and memory.
Selegiline (Eldepryl)	Selegiline should not be used with ginseng, ma huang (ephedra), yohimbe, or St. John's wort.
Statins	People taking statin drugs may have lower blood cholesterol and less incidence of Alzheimer's disease. They may have the ability to break down plaque-building amyloid protein.
Tacrine (Cognex)	For use in mild-to-moderate AD. May cause nausea, vomiting, or liver damage. Used less often today.
Vitamin E	Use of alpha-tocopherol has had mixed results in the literature (Petersen et al, 2005).

[http://www.alz.org/national/documents/topicsheet\\_treatments.pdf](http://www.alz.org/national/documents/topicsheet_treatments.pdf), accessed September 1, 2009.

- Omega-3 fatty acids are known to reduce cytokines and then lower the AD risk (Fotuhi et al, 2009; Morris, 2009; Staehelin, 2008).
- Panax ginseng has demonstrated efficacy in some studies (Lee et al, 2009).
  - SAM as a supplement can facilitate glutathione and acetylcholine utilization (Chan et al, 2008). Longer trials are needed.
  - Repeat testing of vitamin B<sub>12</sub> every 2 years. Where deficiency occurs, treat and prevent neurological and hematological consequences by providing B<sub>12</sub> (Prodan et al, 2009).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- A nutrition education program intended for caregivers of AD patients can yield positive effects on patient weights and cognitive function.
- There is growing evidence for possible dietary risk factors in the development of AD and cognitive decline with age, such as antioxidant nutrients, fish, dietary fats, and B-vitamins (Morris, 2009). Promote use of the Mediterranean or DASH diets. Encourage use of fruits such as blueberries and other berries. Exercise and an antioxidant-rich diet may be protective against further cognitive decline.
- Encourage routines such as regular mealtimes, and good mouth care. Reduce distractions at mealtime.
- Refer family or caretakers to support groups. Long-term care or home care may be needed at some point in time.
- Special feeding methods may be needed. If the patient must be spoon fed, gently holding his or her nose will force the mouth open.
- Liquid supplements can add extra calories and protein without excessive expense. Baking nutritious cookie bars or snacks enhances calorie intake and addresses the need for sensory stimulation.
- Use unbreakable dishes and utensils to avoid injury. Cutting and preparing foods for the patient are useful.
- Offspring of affected family members should be tested and treated for hypertension; pro-inflammatory cytokines and ApoE genes should also be assessed (van Exel et al, 2009).

### Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for hand washing, especially with incontinence. Use of hand wipes before meals is recommended.

# AMYOTROPHIC LATERAL SCLEROSIS

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Amyotrophic lateral sclerosis (ALS) is a progressive motor neuron disease of adult life that destroys nerve cells from the spinal cord to muscle cells. The name “no muscle nourishment.” Symptoms include muscular wasting and atrophy, drooling, loss of reflexes, respiratory infections or failure, spastic gait, and weakness. Respiratory failure occurs as a result of bulbar, cervical, and thoracic loss of motor neurons; inspiratory muscles are affected.

Men and women are affected equally, in about 20,000 people in the United States. ALS usually occurs after age 40; it is also known as progressive spinal muscular atrophy or Lou Gehrig’s disease. Management of respiratory failure includes the use of strategies that limit aspiration pneumonia, the reduction in secretions, positioning of the patient to a maximal mechanical advantage, and use of noninvasive positive pressure ventilation.

Malnutrition is aggravated by elevated metabolic needs and swallowing dysfunction in the lower set of cranial nerves. The malnutrition produces neuromuscular weakness and adversely affects patients’ quality of life. In later stages of the disease, percutaneous endoscopic gastrostomy (PEG) feeding may be needed. However, consider patient preferences and advance directives; individuals have the right to accept or refuse treatment (American Dietetic Association, 2008).

Quality of life does not necessarily improve (Langmore et al, 2006).

Dietary factors have been suspected of being risk factors for ALS. Lycopene and magnesium are important nutrients (Oyanagi et al, 2006). Environmental exposure to arsenic depletes s-adenosyl-methionine (SAM) especially with folate insufficiency (Dubey and Shea, 2007). Elevated tHcy damages motor neurons and may be linked to faster progression of ALS (Zoccolella et al, 2008). However, there is no known cure at this time and ALS patients usually have respiratory distress, anxiety, pain, choking episodes, or pneumonia at the end of life.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutations in the c-1 (SOD-1) gene result in familial amyotrophic lateral sclerosis (FALS). Over 135 mutations have been identified in the various forms of ALS.

<b>Clinical/History</b>	Electromyogram (EMG)	Ca <sup>++</sup> , Mg <sup>++</sup>
Height	Gag reflex	Albumin (alb), transthyretin
Weight	ALS Functional Rating Scale (ALSFERS-R)	Transferrin
Weight changes	Ventilatory dependency?	BUN, Creat
BMI (<18.5 indicates under-nutrition)		Nitrogen (N) balance
Dietary/intake history	<b>Lab Work</b>	Gluc
Swallowing difficulty	H & H	CRP
Temperature, fever?	Serum Fe	tHcy
I & O	Na <sup>+</sup> , K <sup>+</sup>	Serum folate, B <sub>12</sub> , B <sub>6</sub>
		pCO <sub>2</sub> , pO <sub>2</sub>

## INTERVENTION

### OBJECTIVES

- Maintain good nutrition to prevent further complications. Meet extra energy requirements (Vaisman et al, 2009).
- Reduce difficulties in chewing and swallowing. Monitor gag reflex.
- Reduce the patient's fear of aspiration; test swallowing reflexes with water and feed slowly.
- Minimize the possibility of UTI and constipation.
- Correct negative nitrogen balance and nutritional deficiencies.
- Ease symptoms to maintain independence as long as possible.
- Reduce fatigue from the eating process; provide a slow pace to avoid choking.

### FOOD AND NUTRITION

- In initial stages, use a soft diet. Flaky fish, ground meats, and casseroles may be encouraged, along with foods moistened with gravies and sauces. Provide adequate fiber in

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### Swallowing Difficulty

**Assessment Data:** Food records indicating poor intake; weight loss; paralysis of throat muscles with difficulty swallowing.

**Nutrition Diagnoses (PES):** Difficulty swallowing related to paralysis of throat muscles as evidenced by weight loss and dietary intake records showing 20–25% of meals consumed orally.

**Interventions:** Education of patient and family about structured meals, use of tolerated liquids and pureed foods to improve intake of nutrients and energy, prevent further weight loss.

**Monitoring and Evaluation:** Improved weight; delay of the need for tube feeding, or initiation early in the illness if patient wishes to have it.

the diet, perhaps Benefiber or psyllium when fibrous foods are no longer tolerated.

- The diet should include 2–3 L of water daily. Thicken liquids as needed with commercial thickeners, gelatin powder, or mashed potato flakes. Sips of liquid are best tolerated between bites of food.
- Place food at side of mouth and tilt head forward to facilitate swallowing, when possible.
- Enhance energy intake (Vaisman et al, 2009). Five to six small meals should be scheduled daily.
- Increase protein intake to counteract wasting.
- Diet and feedings should provide antioxidants such as vitamins E and C and selenium; zinc, magnesium, potassium, folate, omega-3 fatty acids, lycopene, and phosphorus.
- Foods should be moistened and not dry or crumbly. Cake and crackers should not be served plain; yogurt, apple-sauce, and pudding generally are acceptable.
- PEG or percutaneous endoscopic jejunostomy (PEJ) tube placement is well tolerated with dysphagia.

### Common Drugs Used and Potential Side Effects

- Ceftriaxone alters glutamate and has been found to prolong survival in animal models of ALS.
- Riluzole (a glutamate release inhibitor and membrane stabilizer) has been used to block nerve cell destruction. It seems to slow the disease but not curb its progress. Adding vitamin E to this therapy does not seem to cause any improvement (Graf et al, 2005).
- Studies suggest that recombinant erythropoietin, magnesium, lithium and valproate, lycopene, or anti-inflammatory drugs may be beneficial; however, more clinical trials are needed.

### Herbs, Botanicals, and Supplements

- While no specific herbs and botanical products have demonstrated efficacy, supplement use is common in this population.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Dietary counseling is important, but oral intake rapidly becomes insufficient and enteral nutritional support may be needed. Discuss care plan in front of patient; include the patient in the decision.
- In early stages, discuss adding fiber to the diet to prevent constipation and explain which foods have fiber.
- Encourage the planning of small, adequately balanced meals.
- Carefully monitor the patient's weight loss; 10% loss is common.
- Lightweight utensils are beneficial. A referral to an occupational therapist is recommended.
- Minimize chewing, but avoid use of baby food. Puree adult foods, especially preferred foods that are seasoned as usual for the individual.

- In later stages, decide if enteral nutrition will be used. If care will be given at home, teach family members what they can do to provide the feedings.

### Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for sanitizing work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of formula in the home and institution.

# BRAIN TRAUMA

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

There are two types of brain injury: nontraumatic or traumatic. Nontraumatic head injury develops slowly, from arthritis, cancer, infections, or degeneration of the vertebrae. Traumatic brain injury (TBI) results from head injury after motor vehicle or industrial accidents, falls, fights, explosions, and gunshot wounds (40% involve alcohol use). The term TBI is not used for persons who are born with a brain injury or for injuries that happen during the birth process.

Any sudden impact or blow to the head (with or without unconsciousness) may cause a TBI, and two thirds of patients with TBI die before reaching a hospital. Low cerebral blood flow and cerebral perfusion pressure (CPP) are associated with poor outcome (White and Venkatesh, 2008).

Immediate signs of concussion (seen within seconds or minutes) include any loss of consciousness, impaired attention, vacant stare, delayed responses, inability to focus, slurred or incoherent speech, lack of coordination, disorientation, unusual emotional reactions, and memory problems. Classification is by location, effect, and severity. **Hypothalamic lesions** can promote hyperphagia. **Lateral lesions** can lead to aphasia and cachexia. **Frontal lobe damage** may result in loss of voluntary motor control and expressive aphasia. **Occipital lobe damage** impairs vision. **Temporal lobe damage** results in receptive aphasia and hearing impairments.

Hours, days, or even weeks after head injury, the patient may have persistent headache, dizziness with vertigo, poor attention or concentration, memory problems, nausea or vomiting, easy fatigue, irritability, intolerance for bright lights or loud noises, anxiety, depression, and disturbed sleep. Long-term TBI patients may exhibit dyspnea, vertigo, altered consciousness, seizures, vomiting, altered blood pressure (BP), weakness or paralysis, aphasia, and problems with physical control of hands, head, or neck with resulting difficulty in self-feeding. A brain injury often causes prob-

lems with understanding words, learning and remembering things, paying attention, solving problems, thinking abstractly, talking, behaving, walking, seeing, and hearing.

Brain trauma is accompanied by regional alterations of brain metabolism, overall reduction in metabolic rates, and persistent metabolic crisis (Vespa et al, 2005). Pyruvate dehydrogenase complex (PDHC) enzyme activity is lost with cerebral ischemia (Martin et al, 2005). Severe head injuries are also associated with negative nitrogen balances. With severe head injuries (Glasgow Coma Scale Score of 8), there is an increased tendency for gastric feeding to regurgitate into the upper airway; keeping the patient upright and checking residuals is important in such patients. Jejunal feedings are less apt to be aspirated. If the gastrointestinal (GI) tract cannot be used to reach nutritional goals within 3 days, total parenteral nutrition (TPN) is begun within 24–48 hours.

New neurons arise from progenitor cells that are maintained throughout adult life; they are enhanced by growth factors, drugs, neurotransmitters, and physical exercise and suppressed by aging, stress, glucocorticoids (Elder et al, 2006). Stem cell therapy has been studied for possible use in brain injuries.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Brain trauma is acquired.

Clinical/History	BMI	BP
Height	Dietary/intake history	Temperature
Weight		

Visual field examination	<b>Lab Work</b>	Total lymphocyte count (TLC)
Glasgow Coma Scale	pCO <sub>2</sub> and pO <sub>2</sub>	Transferrin
Dysphagia?	Alb, transthyretin	H & H
Weight changes	Urinary urea nitrogen (UUN) excretion (24-hour specimens)	Serum Fe
Intracranial pressure	Gluc (increased with brain ischemia)	Na <sup>+</sup> , K <sup>+</sup>
CT scan	CRP	Ca <sup>++</sup> , Mg <sup>++</sup>
Skull x-rays	Folic acid	AST (increased with brain necrosis)
Brain scan	Complete blood count (CBC)	BUN, Creat
Cerebral angiography		Alkaline phosphatase (alk phos)
EEG		Serum ethanol (ETOH)
I & O		

## INTERVENTION

### OBJECTIVES

- Prevent life-threatening complications, such as aspiration pneumonia, meningitis, sepsis, UTIs, syndrome of inappropriate antidiuretic hormone (SIADH), hypertension, pressure ulcers, Curling's ulcer, and GI bleeding.
- Assess regularly the substrate needs to prevent malnutrition, cachexia, or overfeeding. Indirect calorimetry to determine the respiratory quotient and resting energy expenditure should be determined twice weekly.
- Based on the level of nitrogen wasting and the nitrogen-sparing effect of feeding, full nutritional replacement is desirable by day 7.
- Prevent or correct hyperglycemia by carefully regulating glucose and insulin intake.
- Provide adequate protein for improving nitrogen balance (serum albumin tends to be low, especially if comatose, and urinary losses may be twice the normal).
- Monitor hydration; prevent either dehydration or overhydration.
- Correct self-feeding, breathing, and swallowing problems. Promote return to self-care where possible.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Oral Food and Beverage Intake

**Assessment Data:** Food records indicating poor intake; comatose; requiring tube feeding.

**Nutrition Diagnoses (PES):** Inadequate oral food and beverage intake related to coma following TBI as evidenced by requirement for tube feeding to meet elevated energy requirements.

**Interventions:** Provision of enteral nutrition to meet energy, protein, glucose, lipid and micronutrients requirements and prevent weight loss.

**Monitoring and Evaluation:** Tolerance of enteral nutrition; no physical signs of malnutrition; improvement in cognition or resolution of coma through recovery period.

- Prevent or reduce seizure activity, convulsions, intracranial edema, fluid overload (especially with TPN).
- After patient is stabilized, adapt to residual impairments.

## FOOD AND NUTRITION

- EN should begin as soon as the patient is hemodynamically stable, attempting to reach 35–45 kcal/kg and a protein intake of 2.0–2.5 g/kg as soon as possible. Tube feeding is preferable; if malabsorption persists, a short course of supplemental PN may help.
- The need for surgery or ventilation will have an effect on the ability to progress to any oral intake.
- Patients who are immobile for a long period of time may have a 10% decrease in weight from lowered metabolic rate. Energy intake will need to be varied accordingly.
- Increased urinary zinc losses can occur. Monitor potassium, phosphorus, and magnesium requirements as losses are often high. Otherwise, a general multivitamin–mineral supplement should suffice.
- Progress, when possible, to oral intake. A dysphagia may be needed.
- Use of probiotics (such as yogurt or buttermilk) can help to maintain GI integrity and immunity.
- Over time, a patient may gain excessive weight if the brain injury affected the hypothalamus. Some patients forget that they have eaten and state their constant hunger. Monitor energy intake carefully.

### Common Drugs Used and Potential Side Effects

- Analgesics are used for pain. Antacids and Pepcid may then be needed to reduce the onset of stress ulcers.
- Anticonvulsants may be needed to reduce seizure activity; these may deplete folic acid levels and other nutrients. Presence of food reduces effectiveness of the liquid form of phenytoin (Dilantin). Adjust phenytoin dosage rather than holding feedings.
- Insulin is used when hyperglycemia occurs or persists.
- Reglan may be used as a promotility agent in tube-fed patients to assist in transit time and to decrease the risk of aspiration.
- Soluble or mixed fibers (Benefiber or other soluble fiber supplements) or laxatives (Metamucil) are often helpful in alleviating constipation. However, bloating, nausea, diarrhea, or vomiting may result.

### Herbs, Botanicals, and Supplements

- Avoid using phenytoin (Dilantin) with evening primrose oil, ginkgo biloba, and kava.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage the patient to chew and swallow slowly, if and when the patient is able to eat solids.
- Gradually relearn self-feeding techniques.
- Be wary of extreme food temperatures; patients may have become less sensitized to hot and cold.

- Serve colorful and attractive meals for better acceptance.
- The team approach is beneficial, with occupational therapists, speech therapists, psychologists, and physical therapists helping design treatment plans.
- Plate guards, long-handled utensils, and other adaptive feeding devices may be useful. Discuss with the occupational therapist.
- Discuss a healthy eating pattern and use of foods such as yogurt for probiotics.
- Emotional changes are common after a head injury. Family members should be prepared to address changes that relate to mealtimes, eating patterns, weight management, and the need for consistency and structure.
- Many brain injury patients do not receive counseling about the long-term effects of their injury. Provide written instructions for review later.

#### Patient Education—Foodborne Illness

- Careful food handling will be important.
- Sanitize work areas before and after preparing tube feedings to prevent contamination. Formula companies have

good information on safe handling of formula in the home and institution.

## CEREBRAL ANEURYSM

### NUTRITIONAL ACUITY RANKING: LEVEL 2–3

## DEFINITIONS AND BACKGROUND

A cerebral aneurysm may involve the dilation of a cerebral artery resulting from a weakness of the blood vessel wall. Symptoms include altered consciousness, drowsiness, confusion, stupor or coma, headache, facial pain, eye pain, blurred vision, vertigo, tinnitus, hemiparesis, elevated BP, and dilated pupils. Aneurysms may burst and cause hemorrhage. Epidemiological evidence suggests that most intracranial aneurysms do not rupture. It is important to identify which unruptured intracranial aneurysms (UIAs) are at greatest risk of rupture when considering which to repair (Wiebers et al, 2004).

An **intracranial** hemorrhage is bleeding inside the skull, usually from head injury. Bleeding within the brain is **intracerebral**. Hemorrhages between the brain and the subarachnoid space are **subarachnoid hemorrhages**; those between the meninges are **subdural hemorrhages**; and those between the skull and covering of the brain are **epidural hemorrhages**. Hemorrhagic stroke may occur. After an aneurysmal subarachnoid hemorrhage, nearly half of patients die, and the half who survive suffer from irreversible cerebral damage (Chen et al, 2004).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Alagille syndrome (AGS) is a dominantly inherited multisystem disorder involving the liver, heart, eyes, face, and skeleton, caused by mutations in Jagged1; intracranial bleeding is a recognized complication and cause of mortality. Otherwise, most aneurysms are not genetic.

<b>Clinical/History</b>	CT scan results	Triglycerides
Height	Angiography	(trig)
Weight	Cerebrospinal	Alb,
BMI	fluid analysis	transferritin
Weight changes	Pneumonia?	Gluc
Dietary/intake history	Fever?	Na <sup>+</sup> , K <sup>+</sup>
I & O	<b>Lab Work</b>	H & H
BP (increased)	Chol (LDL,	Serum Fe
Brain MRI	HDL)	pO <sub>2</sub> , pCO <sub>2</sub>

## INTERVENTION

### OBJECTIVES

- Limit fluids as necessary to reduce cerebral edema.
- Rest is essential. Avoid constipation and straining at stool.
- Decrease or manage hypertension.
- Prevent further complications and lingering neurological problems.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Oral Food and Beverage Intake

**Assessment Data:** Semi-conscious state, inability to eat orally.

**Nutrition Diagnoses (PES):** Inadequate oral food and beverage intake related to recent TBI after a car accident as evidenced by cognitive deficits and high risk for aspiration and pneumonia.

**Interventions:** EN because oral feeding not safe or feasible. Calculate protein, energy, fluid requirements as well as rate and goal intake.

**Monitoring and Evaluation:** Tolerance of enteral nutrition; labs stable for glucose, prealbumin, electrolytes. Gradual return to oral diet if possible.

- Prepare for surgery if safe and possible. Reduce fever prior to surgery (Todd et al, 2009).
- Gradually encourage self-feeding.

## FOOD AND NUTRITION

- Nothing by mouth unless ordered; appropriate IVs are used. With cognitive progress, a tube feeding or diet will be prescribed.
- Restrict fluid, sodium, saturated fat and cholesterol if deemed necessary. Enhance potassium if necessary.
- Alter dietary fiber intake, as appropriate.
- Offer sufficient antioxidant foods and omega-3 fatty acids where appropriate.

## Common Drugs Used and Potential Side Effects

- In some cases, aspirin may be given at levels of 150–300 mg daily.
- Cardiovascular drugs are usually ordered according to significant parameters. Adjust dietary intake accordingly.
- Diuretics may be used. Monitor potassium replacement if furosemide is prescribed.
- Nimodipine is used to treat symptoms resulting from hemorrhage by increasing blood flow to injured brain tissue.
- Papaverine is used to improve blood flow in patients with circulation problems by relaxing the blood vessels.

## Herbs, Botanicals, and Supplements

- No specific herbs and botanical products have been used for cerebral aneurysm in any clinical trials.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- If enteral nutrition must continue at home, the caregiver should be taught appropriate and safe techniques.
- Discuss fiber sources from the diet. Foods such as prune juice or bran added to cereal can be helpful in alleviating constipation.

- Counsel regarding self-feeding techniques.
- Discuss role of nutrition in preventing further cardiovascular or neurological problems.

### Patient Education—Foodborne Illness

- Careful food handling will be important.
- Sanitize counters or work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of formula in the home and institution.

## COMA OR PERSISTENT VEGETATIVE STATE

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

Coma is the unconscious state in which the patient is unresponsive to verbal or painful stimuli. Impaired consciousness or coma can occur from a stroke, head injury, meningitis, encephalitis, sepsis, lack of oxygen, epileptic seizure, toxic effects of alcohol or drugs, liver or kidney failure, high or low blood glucose levels, or altered body temperature. Coma usually only lasts for a few weeks and most people recover fully. Medical staff use the Glasgow Coma Scale to determine prognosis. Often, the 1-month performance on measures such as Disability Rating Scale (DRS) and Glasgow Outcome Scale (GOS) scores help predict status 6 months post injury (Pastorek et al, 2004). Nutritional support is associated with improved survival in coma patients. Most patients are tube

fed because it is safer and more practical than hand feeding. Clinical care factors such as time delay for orders and enteral access are impediments to EN provision in the first week of neurocritical illness (Zarbock et al, 2008).

A patient in a **permanently vegetative state (PVS)** does not have the ability to request or refuse treatment. The doctor determines the diagnosis of PVS. According to the American Dietetic Association position (2008), the definition of brain death is central to the dilemma of feeding permanently unconscious patients. Dietitians play an integral role with other members of the team in developing and implementing ethical guidelines for feeding patients (American Dietetic Association, 2008). Table 4-7 lists the consequences of withholding food and fluid from patients whose advance directives indicate no “heroic measures.”

**TABLE 4-7** Consequences of Withholding Food and Fluid in Terminally Ill Patients

Neither nutrition nor hydration improves comfort or quality of life in terminally ill patients. Physiological adaptation allows patients not to suffer from the absence of food, as follows:

1. Two thirds of the patients who are not fed or hydrated at the end of life feel no hunger. They usually have loss of appetite and reduced enjoyment of food.
2. Thirst and dry mouth are common initially. Use ice chips, lubricating the lips, and small amounts of food and water to reduce the thirst sensations from dehydration.
3. Dehydration eventually results in hemoconcentration and hyperosmolality with subsequent azotemia, hypernatremia, and hypercalcemia. These changes produce a sedative effect on the brain just before death.
4. Withholding or minimizing hydration can reduce disturbing oral and bronchial secretions, the need for frequent urination, and coughing from diminished pulmonary congestion.

Adapted from: American Dietetic Association. Position of the American Dietetic Association: ethical and legal issues in nutrition, hydration, and feeding. *J Am Diet Assoc*. 108:879, 2008.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Coma is generally a result of an accident or other head injury. Some genetic disorders may lead to coma if undiagnosed and untreated.

Clinical/History	Dietary/intake history	motor, and verbal responses
Height	Unconsciousness	BP
Weight	Glasgow Coma Scale score	I & O
BMI	(>13 mild; <8 severe)	CT scan or MRI
Weight change (using a bed scale)	for eye,	

<b>Lab Work</b>	Trig Alb Gluc BUN, Creat Urine tests for chemicals, glucose	Serum alcohol level tHcy levels Serum folic acid Serum vitamin B <sub>12</sub>
H & H Serum Fe pCO <sub>2</sub> , pO <sub>2</sub> Chol, full lipid profile (HDL, LDL)		

## INTERVENTION

### OBJECTIVES

- Maintain standards related to primary condition.
- When possible, elevate head to prevent aspiration during feeding process.
- Assess daily energy and fluid requirements. Adequate caloric intake is associated with improved outcome (Zarbock et al, 2008).
- Prevent or treat pressure ulcers, constipation, and other complications of immobility.
- For terminally ill patients, follow their wishes as directed by advance directives.

### FOOD AND NUTRITION

- Immediately give intravenous glucose until etiology is clearly identified. Parenteral fluids may also be appropriate at this time.
- Tube feed for increased energy and protein requirements every 2–3 hours, or as ordered by the physician. If tube fed, a formula with fiber can be helpful in preventing or easing constipation; be sure sufficient fluid is included as well.
- TPN may be appropriate for some persons, following evaluation of the original disorder, sepsis, and other complicating factors.
- Progress, when or if possible, to oral feedings.
- For patients who are terminally ill, gradual withdrawal of food and fluid is appropriate if directed by the patient's advance directives.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Energy Intake

**Assessment Data:** Inability to eat orally, leading to poor intake. Weight changes; % usual body weight.

**Nutrition Diagnoses (PES):** Inadequate energy intake related to coma and inability to chew and swallow as evidenced by intake meeting less than 10% of estimated requirements.

**Interventions:** Enteral nutrition to meet estimated needs for energy and nutrients.

**Monitoring and Evaluation:** Weight status, stabilization of labs, and improved energy intake.

## Common Drugs Used and Potential Side Effects

- Anticonvulsants, such as phenytoin (Dilantin), decrease folic acid over time. Avoid use with evening primrose oil, ginkgo biloba, and kava.
- Antacids may be needed to prevent stress ulcers.
- Cathartics are often used. Monitor for electrolyte imbalances.
- Steroids may be used. Side effects include sodium retention, increased losses of potassium and calcium and magnesium, and nitrogen depletion.

## Herbs, Botanicals, and Supplements

- No specific herbs and botanical products have been used in comatose patients in any clinical trials.
- With phenytoin (Dilantin), avoid use with evening primrose oil, ginkgo biloba, and kava.

### INTERVENTION: NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss with caretaker or family any necessary measures that are completed to provide adequate nourishment. Explain importance of prevention of complications such as aspiration.
- Evaluate potential for self-feeding over time.
- A Medic Alert bracelet or other ID is useful for persons with disorders that can lead to unconsciousness.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Caregivers must wash their hands before initiating tube feeding, TPN, or oral feeding process.
- Sanitizing work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of formula in the home and institution.

# EPILEPSY AND SEIZURE DISORDERS

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Epilepsy is a disturbance of the nervous system with recurrent seizures, loss of consciousness, convulsions, motor activity, or behavioral abnormalities. The seizures result from excessive neuronal discharges in the brain. A grand mal seizure involves an aura, a tonic phase, and a clonic phase. A petit mal seizure involves momentary loss of consciousness. A single seizure does not imply epilepsy. There are many forms of epilepsy, each with its own symptoms. In two thirds of cases, no structural abnormality is found. Incidence is two to six in 1000 people. Approximately 45,000 children under the age of 15 develop epilepsy each year, often those with cerebral palsy or spina bifida.

A ketogenic diet should be considered for refractory epilepsy (Papandreou et al, 2006; Vaisleib et al, 2004). Chronic ketosis modifies the tricarboxylic acid cycle, increases GABA synthesis in brain, limits reactive oxygen species generation, and boosts energy production in brain tissue; these changes stabilize synaptic function and increase the resistance to seizures throughout the brain (Bough and Rho, 2007).

A ketogenic diet contains 70–90% fat with the remainder as protein and carbohydrates (CHO). A medium-chain triglyceride (MCT) diet alleviates some of the obstacles of compliance and acceptance. While overall caloric restriction may improve efficacy of the ketogenic diet (Cheng et al, 2004), the diet may slow growth (Peterson et al, 2005). An alternative diet that is not as strict uses a low-glycemic index treatment, with more liberal total carbohydrate intake (Pfeifer and Thiele, 2005).

Bone health, altered hepatic cytochrome P-450 enzymes, decreased metabolism of vitamin D, resistance to parathyroid hormone, inhibition of calcitonin secretion, and impaired calcium absorption are affected by use of antiepileptic drugs (Fitzpatrick, 2004).

EEG	Serum $\text{Ca}^{++}$ ,	Chol, Trig
DEXA scan	$\text{Mg}^{++}$	Serum folate
	$\text{Na}^+$ , $\text{K}^+$	Urinary calcium
<b>Lab Work</b>	Alb, transthyretin	Uric acid
Urinary acetone	H & H	
(AM levels)	Alk phos	

### INTERVENTION

### OBJECTIVES

- Minimize seizures via medications, ketogenic diet, or lesionectomy.
- If drug therapy does not work (as in the case of intractable myoclonic or akinetic seizures of infancy), a ketogenic diet may be used (Neal et al, 2008). Reverse the usual ratio of cholesterol and fat. Provide a diet that avoids excess of CHO. Beware of changing the diet abruptly; a gradual approach is preferred.
- With signs of hyperuricemia or hypercalciuria, increase fluid intake and consider use of diuretics.
- Correct nutritional deficits from long-term anticonvulsant medication use (disorders of vitamin D, calcium, and bone metabolism). Phenytoin therapy (PHT) decreases serum folate by half, thereby increasing risk of deficiency.
- Monitor for possible long-term cardiac problems or a decline in bone health.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** In close relatives (parents, brothers, sisters, and children) of people with generalized epilepsy, the risk of epilepsy is about four times as high as in the general population. In the close relatives of people with partial epilepsy, the risk is twice as high as in the general population.

<b>Clinical/History</b>	BMI	BP
Height	Dietary/intake	I & O
Weight	history of	CT scan
	fatty acids	Skull x-ray

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Intake of Fatty Acids

**Assessment Data:** Frequent, treatment-refractable seizures in child; difficulty with self-feeding.

**Nutrition Diagnoses (PES):** Inadequate intake of fatty acids related to high CHO intake as evidenced by frequent seizures and use of regular diet.

**Interventions:** Food-Nutrient Delivery: Alter diet or tube feeding to increase ratio of lipid to CHO for ketogenic effect. Education of patient/caregiver about the role of lipids in brain health and preparation of the ketogenic diet; consequences of long-term use of anticonvulsants on bone health and folate status.

**Monitoring and Evaluation:** Decreased frequency of seizures, tolerance of ketogenic diet, sufficient growth or weight maintenance, adequate bone density.

## FOOD AND NUTRITION

- Provide a diet reflecting the patient's age and activity. Protein should meet needs; such as 0.8–1 g/kg body weight.
- The high-fat, high-protein, low-carbohydrate Atkins diet is somewhat ketogenic and may be useful in managing medically resistant epilepsy (Kossoff and Rho, 2009).
- The ketogenic diet is a low-carbohydrate, adequate-protein, high-fat diet that biochemically mimics the fasting state and has been used to successfully treat seizures for 85 years (Huffman and Kossoff, 2006). However, the diet may be unpalatable. The diet follows a ratio of 3:1 or 4:1 of fats to carbohydrate and protein.
- MCTs are more ketogenic, having more rapid metabolism and absorption. MCTs provide 60% of kcal (the rest of the diet would consist of 10% other fats, 10% protein, and 20% carbohydrates). Stimulants such as tea, coffee, colas, and alcohol are not usually recommended with the ketogenic diet. If the pure ketogenic diet is not tolerated, modify it with low-glycemic index foods (Pfeifer and Thiele, 2005).
- Supplements may be needed, especially calcium, vitamin D, folic acid, vitamins B<sub>6</sub> and B<sub>12</sub>.
- Add sufficient fiber and fluid for relief of constipation.

## Common Drugs Used and Potential Side Effects

- Cough syrups, laxatives, and other medications may contain a high CHO content; monitor for interactions with the diet.
- Common anticonvulsants and potential side effects are listed in Table 4-8. Anticonvulsant therapy interferes with vitamin D metabolism, leading to a calcium imbalance, rickets or osteomalacia. Therapy with D<sub>3</sub> is recommended.

## Herbs, Botanicals, and Supplements

- Vitamin B<sub>6</sub> is associated with neuronal function. Avoid high doses of pyridoxine with phenobarbital or phenytoin because seizure control might be compromised. If vitamin B<sub>6</sub> is added to either drug regimen, keep it at the lowest effective dose and monitor serum drug levels.
- St. John's wort should not be used with monoamine oxidase inhibitors (MAOI), selective serotonin reuptake inhibitors (SSRIs), cyclosporine, digoxin, oral contraceptives, HIV protease inhibitors, theophylline, warfarin, or calcium channel blockers such as amlodipine, diltiazem,

**TABLE 4-8 Medications Used in Epilepsy**

Generic Name	Trade Name	Possible Side Effects
Carbamazepine	Carbatrol, Tegretol XR, Tegretol	Dry mouth, vomiting, nausea, anorexia, low red blood cell and white blood cell counts.
Clonazepam	Klonopin	Anorexia, weight loss or gain, increased thirst.
Diazepam	Diazepam Intesol, Diastat, Valium	Anorexia, weight loss or gain, increased thirst.
Ethosuximide	Zarontin	Gastrointestinal upset, anemia, and weight loss. Take with food or milk.
Felbamate	Felbatol	Constipation, nausea, vomiting, and anorexia.
Fosphenytoin	Cerebyx	Water-soluble phenytoin. May need vitamin D, calcium, thiamin, magnesium.
Gabapentin	Neurontin	Weight gain and increased appetite occur. Take magnesium supplement separately by 2 hours.
Lamotrigine	Lamictal	Anorexia, weight loss, nausea and vomiting, abdominal pain.
Levetiracetam	Keppra	Anorexia, headache.
Oxcarbazepine	Trileptal	Restrict fluid with hyponatremia.
Phenobarbital	Luminal	Depletes vitamins D, K, B <sub>12</sub> , B <sub>6</sub> , folate, and calcium. Nausea, vomiting, constipation, sedation, and anorexia can occur. Limit caffeine and alcohol. May elevate serum cholesterol levels.
Phenytoin	Dilantin	Gum hyperplasia and carbohydrate intolerance. It binds serum proteins and decreases folate, vitamins B <sub>12</sub> and C, and magnesium absorption. Be careful with vitamin B <sub>6</sub> ; excesses can reduce drug effectiveness. Stop tube feedings 30 minutes before and after administration of the medication; nutritional intake may need to be calculated over 21 versus 24 hours.
Primidone	Mysoline	Gastrointestinal upset, anemia, and weight loss. Take with food or milk. Primidone is similar to a barbiturate; vomiting may occur.
Tiagabine	Gabitril	Mouth ulcers, nausea and vomiting may occur.
Topiramate	Topamax	Weight loss and anorexia are common.
Valproate, valproic acid, divalproex sodium	Depacon, Depakote, Depakene, Depakote ER	Nausea, vomiting, anorexia, weight gain, or hair loss.
Vigabatrin	Sabril	Visual field loss can occur.
Zonisamide	Zonegran	Anorexia and weight loss are common.

or verapamil. Avoid use with benzodiazepines such as alprazolam, clonazepam, diazepam, and midazolam.

- Psyllium and ginseng should not be used with divalproex sodium (Depakote) or lithium.
- With phenytoin (Dilantin), avoid use with evening primrose oil, ginkgo biloba, and kava.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Ketogenic diets cause nausea and vomiting; a small drink of fruit juice can help relieve the symptoms. Regular monitoring of the diet is crucial.
- An ID tag, such as Medic Alert, is recommended.
- To increase long-chain triglycerides (LCTs), add sour cream, whipped cream, butter, margarine, or oils to casseroles, desserts, or other foods. To use MCT, add it to salad dressings, fruit juice, casseroles, and sandwich spreads. Pseudo ice cream may be made with frozen, flavored whipped cream.
- Women who have epilepsy and wish to have children need advice about medications and possible side effects. Pregnancy itself can increase seizure frequency; infants can be born with low birth weight, developmental delay, or epilepsy (Yerby et al, 2004).
- Because of the potential for loss of bone mineral density, discuss use of more calcium and vitamin D-rich foods. A multivitamin–mineral supplement may be recommended.
- Alcohol should be avoided.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## GUILLAIN-BARRÉ SYNDROME

### NUTRITIONAL ACUITY RANKING: LEVEL 3

#### DEFINITIONS AND BACKGROUND

Guillain-Barré syndrome (GBS) is an acute inflammatory demyelinating polyneuropathy with rapidly increasing weakness, numbness, pain, and paralysis of the legs, arms, trunk, face and respiratory muscles. It often occurs after infection with influenza or *Campylobacter jejuni*; bloody diarrhea, fever, cramping, and headache are presenting symptoms. In general, the role of *C. jejuni* has been greatly underestimated (Schmidt-Ott et al, 2006). GBS may progress to respiratory failure; paralysis of lower extremities or quadriplegia; unstable BP; aspiration; dysphagia; difficulty with chewing; impaired speech; muscular pain; low-grade fever; tachycardia; weight loss, anorexia; UTIs. Sometimes ventilatory assistance is needed.

Most people recover fully from GBS, but some may need intensive care support followed by wheelchair assistance. There is no treatment that has been totally effective. Most people recover within a few weeks, but some may still have residual effects for years.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** It is believed that GBS results primarily after infection and not from genetic causes.

Clinical/History	Vomiting Bloody diarrhea? Fatigue and weakness Nerve conduction velocity test Loss of reflexes (knee, etc.)	Lab Work
Height		CBC
Weight		H & H
BMI		Serum Fe
Weight changes		Alb
Dietary/intake history		pO <sub>2</sub> , pCO <sub>2</sub>
BP		Lumbar puncture for CSF protein levels
Temperature		Gluc
Dysphagia		

## SAMPLE NUTRITION CARE PROCESS STEPS

## Intake of Unsafe Food

**Assessment Data:** Diet history revealing intake of undercooked chicken at a sporting event, followed by bloody diarrhea, fever, and vomiting.

**Nutrition Diagnoses (PES):** Intake of unsafe food related to *C. jejuni* and medical diagnosis of Guillain–Barre as evidenced by GI symptoms and bloody diarrhea, weakness, and fatigue.

**Interventions:** Education about proper food handling and consumption of foods properly cooked to desired internal temperature.

**Monitoring and Evaluation:** Improvement in symptoms and gradual improvement in quality of life; better understanding of food handling and issues related to food safety.

## INTERVENTION

## OBJECTIVES

- Meet added energy requirements from fever, weight loss.
- Adjust diet or method of feeding for chewing and swallowing problems.
- Wean, if possible, from ventilator dependency.
- Improve neurological functioning and overall prognosis.

## FOOD AND NUTRITION

- Acute: Intravenous fluids will be required. Tube feeding or TPN may be necessary while patient is acutely ill over a period of time. Increased energy intake and protein may be necessary; increase lipid intake to reduce CO<sub>2</sub> production while on the ventilator.
- Progression: a thick, pureed diet may be beneficial with dysphagia. When safe and tolerated, a soft or general diet may be used.
- Supplement oral intake with frequent snacks, such as shakes or eggnog, if unintentional weight loss has occurred. A vitamin–mineral supplement may be beneficial, especially if intake has been poor.

## Common Drugs Used and Potential Side Effects

- Antibiotics may be needed for UTIs.
- Autoimmune globulin may be given.
- Analgesics are used to reduce pain and inflammation.

- Steroids are seldom used except for chronic relapsing polyneuropathy; their effects can be deleterious over time, especially for bone health.
- Vasopressors may be used.

## Herbs, Botanicals, and Supplements

- High doses of pyridoxine (B<sub>6</sub>) should not be taken with phenobarbital or phenytoin. Keep it at the lowest effective dose and monitor serum drug levels.
- No studies have been conducted for efficacy of herbs or botanical products in GBS.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss adequacy of energy and protein intake to improve weight status and nutritional health.
- Avoid foodborne illnesses, upper respiratory infections, and exposure to other illnesses.
- Avoid constipation by use of fruits, vegetables, crushed bran, prune juice, and adequate fluid intake.
- Encourage self-feeding where possible. Arrange for special feeding utensils if needed.

## Patient Education—Foodborne Illness

- *C. jejuni* is the most frequently diagnosed bacterial cause of human gastroenteritis in the United States. Avoid drinking raw milk; eating raw or undercooked meat, shellfish, and poultry; eating tofu or unwashed raw vegetables.
- Hand washing is important. Wash hands with soap before handling raw foods.
- Prevent cross-contamination in the kitchen. Proper refrigeration and sanitation are also essential.

# HUNTINGTON'S DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

Huntington's disease (HD) is a genetic, autosomal-dominant, neurodegenerative disorder. There is a defective gene that leads to microscopic death of selected neurons (Arrasate et al, 2004; Zhang et al, 2008). Normally, huntingtin's protein is cleared away through the Ubiquitin Proteasome System (UPS) in which proteins that are not needed or that have misfolded are tagged for degradation by ubiquitin (HDSA, 2009). Transglutaminase (TGase) activity is increased in affected regions of the brain.

HD develops in middle to late life, with involuntary, spasmodic, irregular movements (chorea), cerebral degeneration, cognitive decline, and speech difficulties. HD differs from AD in that there is loss of control of voluntary movements. Behavioral changes begin 10 years before the movement disorder, which may begin between age 35 and 40 years.

Nutritional intake plays an important role. Folic acid affects DNA methylation; coenzyme Q10 and unsaturated fatty acids are important for neuroprotection (Bonelli and Wenning, 2006).

Remotivation therapy leads to increased self-awareness, increased self-esteem, and improved quality of life. Duration of HD is generally 13–15 years before death, which often results from pneumonia or a fall. Stem cell transplantation shows promise for treatment; the therapy uses small cell ribonucleic acid (siRNA) to prevent the mutant proteins from being reproduced.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The defective gene on the short arm of chromosome 4 causes abnormal polyglutamine expansion within the protein huntingtin (HTT).

The DNA segment known as a CAG trinucleotide repeats with three DNA building blocks (cytosine, adenine, and guanine) that appear multiple times in a row, usually 10–35 times; the CAG segment is repeated 36–120 times in HD (NIH, 2009).

Clinical/History	Chewing and swallowing difficulties	Dementia
Height	I & O	Grimacing
Weight	Brain CT scan	Involuntary movements
BMI	Depressed mood,	(chorea)
Weight changes	irritability	Unified
Dietary/intake history	Obsessive and compulsive	Huntington's Disease Rating Scale
Ability to self-feed		

### Lab Work

BUN/Creat  
Serum glucose  
H & H  
CRP

Acetylcholine and dopamine levels  
Alb, transthyretin  
tHcy levels

Serum folate  
Vitamin B<sub>12</sub>  
PLP levels or serum  
vitamin B<sub>6</sub>

## INTERVENTION

### OBJECTIVES

- Promote normal nutritional status, despite tissue degeneration. Extra energy intake is important (Trejo et al, 2004).
- Encourage the patient to self-feed until this is no longer possible.
- Swallowing problems are significant (see Dysphagia, Section 7). Avoid aspiration of solids and liquids.
- Manage gluten intolerance if celiac disease is present.

### FOOD AND NUTRITION

- Provide a diet that gives sufficient energy and protein to prevent pressure ulcers and other sequelae. Usually 1–1.5 g/kg protein is needed. A patient with HD may need up to 5000 kcal/d. In later stages, if weight gain is a problem, change diet as needed.
- Use a thick, pureed, or chopped diet as appropriate. Feed slowly to prevent choking. Small, frequent meals are suggested.
- Include adequate liquid as dehydration is common.
- Tube feed when necessary; bolus feedings are usually tolerated.
- Provide adequate fiber (e.g., prune juice or tube feedings that contain fiber) for normal elimination.
- Supplement with a multivitamin–mineral supplement; folic acid and other B-complex vitamins may be especially important.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Swallowing Difficulty

**Assessment Data:** Weight changes and eating difficulty, dysphagia, and lack of muscle coordination.

**Nutrition Diagnoses (PES):** NC 1.1 Swallowing difficulty related to dysphagia and lack of muscle coordination as evidenced by choking at mealtime and with thin liquids and recent loss of 10 lb.

**Interventions:** Education of caregiver about thickening liquids for safer swallowing and the possible use of percutaneous gastrostomy feeding tube as needed.

**Monitoring and Evaluation:** No choking episodes; tolerance of thickened liquids or enteral nutrition. Improved weight status.

- If gluten intolerance occurs, omit gluten from the diet from wheat, barley, rye and oat products, and flours. Label reading is essential.

### Common Drugs Used and Potential Side Effects

- Supplement with vitamin E, antioxidants, and omega-3 fatty acids to reduce inflammation; folic acid, vitamins B<sub>12</sub> and B<sub>6</sub> to lower serum tHcy levels if elevated.
- Minocycline may slow the disease process by blocking caspases from entering the brain.
- Riluzole has been used with some success and few side effects as a membrane stabilizer and glutamate-release inhibitor.
- Tetrabenazine (Xenazine) reduces chorea, and was approved in 2008 in the United States. It can cause insomnia or nausea. Neuroleptics and benzodiazepines may also be used.
- Antiparkinsonian medications such as Sinemet help with hypokinesia and rigidity.
- A new drug is being tested; called ACR16, it stabilizes brain levels of dopamine for motor, cognitive, and psychiatric changes.

### Herbs, Botanicals, and Supplements

- Avoid large doses of vitamin B<sub>6</sub>.
- No clinical trials have proved efficacy for use of herbs and botanicals.

#### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Semisolid foods may be easier to swallow than thin liquids. Teach family or caretakers about the Heimlich maneuver to manage episodes of choking.

- Adding protein and calories through supplements or nutritionally dense foods may be essential.
- If the patient or family wishes to forego tube feeding and hydration, the dietitian should discuss all possible consequences of malnutrition that may occur including dehydration and pressure ulcers.
- Encourage genetic counseling; each child of an affected parent has a 50% chance of inheriting the disease.

### Patient Education—Foodborne Illness

- Careful food handling will be important.
- Sanitize counters or work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of tube feeding formula in the home and institution.

## MIGRAINE HEADACHE

### NUTRITIONAL ACUITY RANKING: LEVEL 1

#### DEFINITIONS AND BACKGROUND

Migraine is a neurological process of the trigeminovascular system. Migraine involves paroxysmal attacks of headache, vasospasm, and increased coagulation, often preceded by visual disturbances. Nausea, vomiting, and acute sensitivity to light or sound may occur. These headaches affect 12% of the adult population (28 million people) in the United States and cause a significant economic loss in productivity. Women may be affected as a result of hormones (Martin et al, 2006). Lack of food or sleep, MT disturbances, exposure to light, anxiety, stress, fatigue, or hormonal irregularities

can set off a migraine attack. In addition, a drop in serotonin or estrogen, or intake of vasodilators in some foods may cause blood vessels to swell and aggravate migraines. Studies have linked migraine with epilepsy, sleep disorders, ear problems, and vertigo (Eggers, 2007). In addition, elevated tHcy levels may contribute. A B-complex vitamin containing riboflavin, folic acid, vitamins B<sub>6</sub> and B<sub>12</sub> is recommended.

Reactions to food are often within 24 hours after consuming the offending food or beverage. Treatment begins with a headache-food diary and the selective avoidance of foods presumed to trigger attacks; omission of all potential

triggers is not recommended. Immunoglobulin E-mediated food allergy is infrequent.

Celiac disease may present with neurological symptoms, including migraines. Migraine may also arise because of disruption in neurovascular endothelia caused by elevated tHcy (Lea et al, 2009). Lowering tHcy through vitamin supplementation reduces migraine disability in some individuals (Lea et al, 2009).

Vascular-amine toxicity causes a rapid increase in BP when high-tyramine foods such as cheese, wine, beer, fava beans, and sauerkraut are eaten in combination with medications such as MAOIs. Limit tyramine to 25 mg/d; provide instructions for patients on MAOIs.

Exercise, relaxation, massage therapy, biofeedback, and other therapies limit discomfort in migraine treatment. Migraines may be reduced with intake of omega-3 fatty acids from fish oil and from intake of olive oil. Long-term prophylactic drug therapy is appropriate after exclusion of headache-precipitating trigger factors, including dietary factors. Improved sleep hygiene, moderation of caffeine intake, regular exercise, and identification of provocative influences such as stress, foods, and social pressures are essential. People who are prone to migraines are at risk for stroke and should be monitored carefully.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Migraine may be caused by inherited abnormalities. Elevated tHcy promotes migraine disability in a subgroup of patients who have the MTH-FRC677 T genotype (Lea et al, 2009).

Clinical/History	Recent illnesses	Prothrombin
Height	Dehydration or edema?	time (PT) or international
Weight	Migraine	normalized
BMI	Disability	ratio (INR)
Dietary/intake history	Assessment Score	Serum Na <sup>+</sup> , K <sup>+</sup> , Ca <sup>++</sup> , Mg <sup>++</sup>
Headache symptoms and duration	Migraine with aura?	Gluc
Foods eaten in past 24 hours; diary	<b>Lab Work</b>	Serum tissue transglutaminase IgA (tTGA) antibodies
History of similar reactions	Serum histamine	

## INTERVENTION

### OBJECTIVES

- Eliminate stressors and triggers (crowds, bright lights, noises). Reduce or eliminate use of foods that cause migraines for the individual.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Poor Food Choices

**Assessment Data:** Food records indicating poor intake of fruits and vegetables, fish, and olive oils while using high amounts of bacon and lard; frequent migraine headaches.

**Nutrition Diagnoses (PES):** Poor food choices related to nutrient density as evidenced by frequent migraine headaches (>2 weekly) and daily intake of bacon and lard while avoiding use of fish, olive oil, fruits, and vegetables.

**Interventions:** Education about nutrient density in foods and encouragement to increase fruits, vegetables, fish, and olive oils and reduce use of other fats.

**Monitoring and Evaluation:** Fewer migraine headaches, better quality of life, reduction in use of migraine medicines.

- Encourage a well-balanced diet, with adequate meal spacing to prevent fasting or skipping of meals.
- Obesity is a factor in some chronic daily headaches; weight loss may be indicated.
- Improve quality of life. Reduce migraine intensity and duration.
- Reduce frequency of migraines and increase responsiveness to therapy.
- Prevent complications, such as ischemic stroke.

## FOOD AND NUTRITION

- Promote regular mealtimes, regular exercise, and adequate relaxation.
- Data surrounding the role of certain foods and substances in triggering headaches are controversial, but certain patients may be sensitive to phenylethylamine, tyramine, aspartame, monosodium glutamate, nitrates, nitrites, alcohol, and caffeine (Sun-Edelstein and Mauskop, 2009). Limit sensitive foods specific to the individual (see Table 4-9).

## Common Drugs Used and Potential Side Effects

- Antiemetics may be prescribed if there is nausea or frequent vomiting.
- Botulinum toxin type A (BoNTA; BOTOX) treatment may be a useful option for headache patients demonstrating poor compliance with oral prophylactic regimens (Cady and Sreiber, 2008).
- Medicines can be used to relieve pain and restore function during attacks. Drugs such as almotriptan, eletriptan, naratriptan, rizatriptan, sumatriptan, and zolmitriptan may be used to enhance the effects of serotonin with few side effects.
- Drugs designed to lower BP also may prevent headaches, such as thiazides, beta-blockers, angiotensin-converting enzyme (ACE) inhibitors, and angiotensin II receptor agonists.
- If effective medicines are not found to treat headache at its onset, daily preventive medicines are sometimes used.

**TABLE 4-9 Foods Implicated in Various Types of Headaches**

Food	Description
Alcohol	Champagne and red wine contain both phenols and tyramine; sulfites may also be involved as a trigger. Beer may be another problem. Alcoholic beverages: limit to two normal size drinks of choices such as Cutty Sark scotch, Seagram's VO whisky, Riesling wine (National Headache Foundation, 2010).
Caffeine-containing products	Coffee, tea, and cola can trigger caffeine-withdrawal headache from methyl xanthines (18 hours after withdrawal); taper withdrawal gradually. Coffee is the major source of caffeine in adults; soft drinks are the major source for children and teens (Frary et al, 2005).
Cheese and tyramine	Aged cheese that contains tyramine has been implicated. Ripened cheeses: cheddar, emmentaler, stilton, brie, and camembert.
Chocolate	Chocolate contains phenylethylamine (no clear relationship to migraine).
Fermented foods	Chicken livers, aged cheese such as cheddar, red wine, pickled herring, chocolate, broad beans, and beer contain tyramine (no clear relationship to migraine).
Fruits	Bananas, figs, raisins; some citrus fruits.
Gluten	Celiac disease has been associated with migraine (Bushara, 2005).
Histamine-containing foods	Scombroid fish (slightly spoiled).
Ice cream	Some individuals are sensitive to the cold.
Nuts, peanuts	Some contain vasodilators. Avoid nuts and peanut butter if necessary.
Processed meats	Hot dogs, bacon, ham, and salami contain nitrites.
Sulfites	Some people respond to the sulfites in shrimp, packaged potato products.
Vegetables	Onions, pea pods, lima beans.

This may include anticonvulsants; nonsteroidal anti-inflammatory drugs (NSAIDs) such as Ibuprofen; tricyclic antidepressants (TCAs), and serotonergic agents.

- MT may be useful in migraine headaches (Masruha et al, 2008; Vogler et al, 2006).
- Avoid using aspirin in children younger than 15 because of the potential for Reye's syndrome.

### Herbs, Botanicals, and Supplements

- While capsaicin from hot chili peppers may be used as a source of relief for cluster headache pain, it does not relieve migraines.
- The following supplements may help in the preventative treatment of migraines, in a decreasing order of preference: magnesium, Petasites hybridus, feverfew, coenzyme Q10, riboflavin, and alpha lipoic acid (Sun-Edelstein and Mauskop, 2009).
- Feverfew and riboflavin have not shown strong efficacy (Tepper, 2008). Side effects of feverfew include decreased platelet aggregation if used with warfarin, aspirin, and ticlopidine. NSAIDs (ibuprofen, indomethacin, advil) decrease the herb's anti-inflammatory action; do not use together.
- Where food-plant sensitivities exist (melon/ragweed, carrot/potato, apple/birch, wheat/grasses, ragweed/dandelion greens) bee pollen and echinacea may cause an allergic reaction.
- Evening primrose, red pepper, willow, and ginger have been recommended; no studies prove efficacy. Counsel about avoiding herbal teas, especially if they contain toxic ingredients.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Fasting can increase likelihood of a headache. Regular mealtimes are important.
- Encourage the patient to identify various, individual triggers. Teach the patient how to keep an accurate food diary for food sensitivities. Read food labels and avoid items containing ingredients that are problematic.
- Monitor drugs taken for underlying conditions such as asthma, reactive airway disease, hypertension, glaucoma, and ear problems. Discuss the possibility of "medication overuse headache" or rebound headaches after caffeine from the diet or medicines.
- Psychotherapy may be useful for mental and emotional stress. Regular sleeping patterns are needed; evaluate for insomnia and sleep apnea.
- Evidence-based behavioral medicine treatments include patient education, cognitive behavioral therapy (CBT), biofeedback, relaxation training, and stress management (Andrasik et al, 2009). Some authorities may also recommend acupuncture.

#### Patient Education—Food Safety

- Food storage is a major issue. Extended holding times, especially in high-protein foods, is a concern.
- Teach safe food handling, handwashing, and other practices.

# MULTIPLE SCLEROSIS

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Asset provided by Anatomical Chart Co.

## DEFINITIONS AND BACKGROUND

Multiple sclerosis (MS) involves scarring and the loss of myelin sheath, the insulating material around nerve fibers. The disease causes progressive or episodic nerve degeneration and disability. Insufficient vitamin D<sub>3</sub> plays a role; persons living in colder climates and those with less sun exposure are more prone (Kantarci and Wingerchuk, 2006). MS has a much higher incidence among Caucasians than in any other race and affects women two to three times as often as men. MS affects over 400,000 people in the United States and 2.5 million people worldwide.

MS is an autoimmune disease. Proinflammatory cytokines such as tumor necrosis factor-alpha (TNF-α) instruct the adaptive immune system (T and B cells and other cells and proteins) to launch an attack to suppress the “invader.” Th17 T-cells are a type of immune cell known to play a role in the onset of MS. Onset is usually between 20 and 40 years of age (average age, 27 years). Symptoms include tingling; numbness in arms, legs, trunk, or face; double vision; fatigue; weakness; clumsiness; tremor; stiffness; sensory impairment; loss of position sense; and respiratory problems. Dysphagia can occur. Spasticity and bladder dysfunction are also common.

After diagnosis, 70% of persons with MS are as active as previously. Relapsing-remitting MS shows clear relapses with some amount of recovery in between; it affects about 80% of all people with MS. Ten percent of individuals with MS have primary progressive MS, without relapses. A description of the types of MS is in Table 4-10.

**TABLE 4-10** Types of Multiple Sclerosis

Name	Characteristics
Relapsing-Remitting Multiple Sclerosis (RRMS)	Symptom flare-ups followed by recovery; stable between attacks
Secondary-Progressive Multiple Sclerosis (SPMS)	Second phase of RRMS; progressive worsening of symptoms with or without superimposed relapses; treatments may delay this phase
Primary-Progressive Multiple Sclerosis (PPMS)	Gradual but steady accumulation of neurological problems from onset
Benign	Few attacks and little or no disability after 20 years
Progressive-Relapsing Multiple Sclerosis (PRMS)	Progressive course from the onset, sometimes combined with occasional acute symptom flare-ups
Malignant or Fulminant Multiple Sclerosis	Rapidly progressive disease course

Multiple Sclerosis Association of America, [http://www.msassociation.org/about\\_multiple\\_sclerosis/commontypes](http://www.msassociation.org/about_multiple_sclerosis/commontypes), accessed May 25, 2009.

During chronic CNS inflammation, nicotinamide adenine dinucleotide (NAD) concentrations are altered by T-helper Th1-derived cytokines; use of pharmacological doses of nontryptophan NAD precursors have been suggested (Penberthy and Tsunoda, 2009).

Magnesium, vitamin B<sub>6</sub>, vitamin B<sub>12</sub>, zinc, vitamin D<sub>3</sub>, vitamin E, selenium, and omega-3 fatty acids have been suggested. Vitamin B<sub>12</sub> is important for proper myelination of the spinal cord (Montanha-Rojas et al, 2005).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** MS tends to run in families. Altered human leukocyte antigen (HLA) genes in chromosome 6; IL2RA and IL7RA as receptors for interleukins; and the gene that encodes kinesin (KIF1B) may enhance the onset of MS.

Clinical/History	Lab Work	H & H
Height	Alb	Serum Fe
Weight	Chol	Gluc
BMI	Trig (may be	MRI scan
Dietary/intake history	low in autoimmune disorders)	Evoked potentials test
BP	Na <sup>+</sup> , K <sup>+</sup>	CSF (WBC, γ-globulin are increased)
I & O	Serum D <sub>3</sub>	EEG
Edema	Alk phos	L:S ratio
Temperature		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Self-Feeding Difficulty

**Assessment Data:** Difficulty with self-feeding, loss of strength in hands, dependent on assistants.

**Nutrition Diagnoses (PES):** Self-feeding difficulty related to poor hand strength and MS as evidenced by inability to use standard meal utensils.

**Interventions:** Alteration of food consistency and use of adaptive feeding utensils to adjust and enhance ability to feed self; finger foods where possible, such as julienne vegetables, sandwiches cut into strips, soup in a mug.

**Monitoring and Evaluation:** Ability to grasp items at mealtime as evidenced by increased ability to do some self-feeding with finger foods and less dependency on staff for assistance.

### INTERVENTION

### OBJECTIVES

- During the chronic phase of the disease, treatment goals are to reduce the incidence of respiratory infections, UTIs, bowel problems, muscle spasms, contractures, pressure ulcers, constipation or fecal impactions.
- Adjust energy intake to avoid excessive weight gain, if this becomes a problem.
- Maintain good nutritional status. Since vitamin D<sub>3</sub> seems to play a role in autoimmunity, supplement with 800 IU daily.
- Reduce fatigue associated with mealtimes. Frequent, small meals may be better tolerated than three large ones.
- During the active phase of the disease, corticosteroids may be used to decrease symptoms. Alter diet accordingly.
- Prevent chronic diseases such as coronary heart disease or osteoporosis, which may occur with immobilization.

### FOOD AND NUTRITION

- Normal protein and adequate carbohydrate intakes are recommended. Use olive oil and fish oil (omega-3 fatty acids) more often.
- Provide adequate intake of multivitamins, especially vitamins D<sub>3</sub> and B<sub>12</sub>.
- Laxative foods and liquids may ease constipation.
- Control sodium intake during steroid therapy. Otherwise, sodium plays an important role in lipid/protein transport in myelin tissues.
- Small, frequent meals may be better tolerated than large meals. If swallowing difficulties increase and coordination decreases, foods may need to be pureed, liquefied or fed by tube.
- To prevent UTIs, cranberry juice is quite effective (Raz et al, 2004).

## Common Drugs Used and Potential Side Effects

- A man-made retinoid (AM80) prevents early symptoms of the autoimmune disease by blocking the function of Th17 T-cells.
- Immune-modifying drugs must have FDA approval. Interferon injections are useful. Interferon- $\beta$ 1a (Avonex or Rebif) may cause nausea, diarrhea, liver damage, flu-like symptoms, headache, infections, or anemia. Interferon- $\beta$ 1b (Betaseron) may cause weight changes, abdominal pain, diarrhea, constipation, fever, headache, hypertension, or tachycardia.
- Corticosteroids are not FDA-approved for use in MS. If used, they require controlled sodium intake. Glucose intolerance, negative nitrogen balance, and decreased serum zinc, calcium, and potassium may occur.
- A combination of CT and a subtherapeutic dose of 1,25(OH)(2)D<sub>3</sub> suppresses autoimmune encephalitis (EAE) without causing hypercalcemia (Becklund et al, 2009). Further studies are needed.
- Antispasticity drugs such as baclofen (Lioresal) may cause nausea, diarrhea, and constipation. If Sinemet (L-dopa) is used, avoid large doses of vitamin B<sub>6</sub>.
- The immunosuppressant azathioprine (Imuran) reduces new brain lesions in relapsing-remitting MS (Massacesi et al, 2005). Its use is still experimental.
- Cannabinoids are potent immunosuppressive and anti-inflammatory agents; cannabinoid receptor 1 (CB1) is expressed on the cells of the CNS and cannabinoid receptor 2 (CB2) is expressed on immune cells; they affect apoptosis, and suppress cytokine and chemokine production (Rieder et al, 2009).
- A complete list of medications is available at: [http://www.msassociation.org/about\\_multiple\\_sclerosis/medications/types/](http://www.msassociation.org/about_multiple_sclerosis/medications/types/)

## Herbs, Botanicals, and Supplements

- Many patients with MS seek alternative therapies for their pain, fatigue, and stress. Diet, essential fatty acid (EFA) supplements, vitamin–mineral supplements, homeopathy, botanicals (Shinto et al, 2004) as well as exercise, herbal therapy, cannabis, massage, and acupuncture (Olsen, 2009).
- Based on available evidence, the prophylactic use of vitamin D is a viable option as an adjunct to conventional medicine (Kimball et al, 2007; Namaka et al, 2008).
- St. John's wort should not be used with MAO inhibitors, SSRI antidepressants, cyclosporine, digoxin, oral contraceptives, HIV protease inhibitors, theophylline, warfarin, or calcium channel blockers such as amlodipine, diltiazem, or verapamil. No studies have been conducted for efficacy in MS patients.
- Stinging nettle, pineapple, black currant, and purslane have been recommended for MS; no clinical trials have proven efficacy.
- Despite beneficial reports regarding nonherbal supplements such as ALA, luteolin, evening primrose oil and

vitamins such as B<sub>12</sub>, the lack of evidence does not support their prophylactic use (Namaka et al, 2008).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach the patient how to control energy intake, especially if inactive.
- Discuss the role of fat and vitamin E in myelin sheath formation and maintenance, and where to find sources of linoleic acid and omega-3 fatty acids from the diet.
- Teach the patient about foods high in fiber.
- Avoid total inactivity. Physical therapy may be beneficial.
- Encourage moderate exposure to sunlight for vitamin D.
- Use tabletop cooking methods and equipment to avoid lifting. Utensils with large handles may be useful in food preparation and self-feeding. Foods may need to be cut before serving.
- Allergen-free, gluten-free, pectin-free, fructose-restricted, raw foods diets, and liquid diets are ineffective.
- Avoid smoking.

## Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for sanitizing work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of formula in the home and institution.

# MYASTHENIA GRAVIS AND NEUROMUSCULAR JUNCTION DISORDERS

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Tasman W, Jaeger E. *The Wills Eye Hospital Atlas of Clinical Ophthalmology*, 2nd ed. Lippincott Williams & Wilkins, 2001.

### DEFINITIONS AND BACKGROUND

Myasthenia gravis (MG) is an autoimmune disorder caused by autoantibodies against the nicotinic acetylcholine receptor on the postsynaptic membrane at the neuromuscular junction (Thanvi and Lo, 2004). The neuromuscular junction lies beyond the protection of the blood–brain barrier and is particularly vulnerable to antibody-mediated attack. Individuals with seronegative MG have autoantibodies to acetylcholine receptors and muscle-specific kinase (MuSK protein) for cell signaling (NINDS, 2009).

Few types are congenital, most are acquired. Acquired neuromuscular junction disorders include botulism, autoimmune MG, and drug-induced MG. General immunosuppression is primary. Treatments that reduce complement-mediated damage or inhibit the binding of pathogenic antibodies are under development (NINDS, 2009). The disease frequently is associated with thymic morphologic abnormalities; removal of the thymus gland works for about 70% of cases (Juel and Massey, 2005).

Symptoms and signs of MG include drooping eyelids (ptosis), double vision (diplopia), fatigue, general weakness, dysphagia, weak voice, inability to walk on heels, pneumonia or respiratory arrest. Diabetes, sleep apnea, and thyroid problems are common in persons who have MG and should be closely monitored.

MG occurs in approximately 18,000 affected people in the United States. Incidence begins with the first peak in the third decade and a second peak in the sixth decade (Thanvi and Lo, 2004). Plasmapheresis can be used during a crisis to remove the abnormal antibodies. A myasthenic crisis is defined as the need for mechanical ventilatory support, usually following progressive weakness and oropharyngeal symptoms (Bershad et al, 2008).

When MG is suspected, a tensilon test involves insertion of a small intravenous catheter through which tensilon is given; this very short-acting drug blocks the degradation of acetylcholine. The short-term availability of acetylcholine results in improved muscle function, often in the eye area.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** In MG, the expression of acetylcholine receptors (AChRs) in the thymus is under the control of the autoimmune regulator protein (AIRE). Polymorphisms in the AChR promote early onset of disease. Congenital myasthenia and congenital myasthenic syndrome are caused by defective genes.

Clinical/History	Tensilon test	Acetylcholine antibodies test
Height	Chest CT scan for thymoma	EMG
Weight	Sleep apnea?	Gluc
BMI		Mg <sup>++</sup> , Ca <sup>++</sup>
Dietary/intake history		Alb
I & O	<b>Lab Work</b>	H & H
Weight changes	Na <sup>+</sup> , K <sup>+</sup>	Serum Fe
Ptosis	BP	T3, T4, TSH
Diplopia	CRP	

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Dysphagia

**Assessment Data:** Swallowing study, weight changes, BMI 17.

**Nutrition Diagnoses (PES):** Difficulty swallowing related to neuromuscular disorder (MG) as evidenced by aspiration of food and liquids into lung on swallowing evaluation and weight loss (BMI now 17).

**Interventions:** Thickened liquids and pureed foods as tolerated; PEG tube placement and enteral nutrition at night to regain lost weight.

**Monitoring and Evaluation:** Weight gain, no further incidents of aspiration, tolerance of thickened liquids and pureed foods and/or enteral nutrition when necessary.

## INTERVENTION

### OBJECTIVES

- Increase the likelihood of obtaining adequate nutrition by altering the consistency of foods. This is necessary when muscles used in chewing and swallowing are weakened. Work with Speech Therapist accordingly.
- Feedings should be small to reduce fatigue. Allow adequate time to complete meals.
- Prevent permanent structural damage to the neuromuscular system during crises.
- Prevent or manage respiratory failure.
  - Encourage participation in rehabilitation programming.

### FOOD AND NUTRITION

- Diet should include frequent, small feedings of easily masticated foods.
- Provide tube feeding when needed.
- If corticosteroids are part of treatment, use a low-sodium diet. Provide adequate potassium supplements.
- Use a high-energy diet if weight loss occurs, which is common.
- Avoid giving medications with thin liquids such as coffee or juice; give with milk and crackers or bread.

### Common Drugs Used and Potential Side Effects

- Prednisone is usually started at a high dose every day, then reduced to every other day. In the event of intolerable side effects or failure of treatment, other immunosuppressants may be used, most commonly azathioprine (Imuran). GI distress, nausea, vomiting, and anorexia may occur.
- Transient symptomatic control can be achieved by the initiation of pyridostigmine (Mestinon) that blocks the degradation of acetylcholine at the neuromuscular junction, increasing the level of acetylcholine with better muscle response to stimulation by the nerve. Mestinon is a temporary symptomatic treatment and does not reverse the course of the illness. Limit sodium intake. Anorexia, abdominal cramps, diarrhea, and weakness may result. Long-acting capsules may be needed if morning weakness persists.
- Long-term use of antacids negatively affects calcium and magnesium metabolism.

## Herbs, Botanicals, and Supplements

- No studies have been conducted for efficacy of herbs or botanicals in MG patients.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Show the patient how to prepare foods and nutrient-dense beverages with the use of a blender, if necessary.
- Indicate how to take medication with food or milk. Discuss potential side effects.
- Avoid alcohol.
- Food and utensils should be arranged within easy reach of the patient; lightweight items are preferable.
- The International Classification of Functioning (ICF), Disability and Health—rehabilitation practitioners is a worldwide accepted model providing a universal language for the description and classification of functioning (Rauch et al, 2008).

### Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for sanitizing work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of formula in the home and institution.

# PARKINSON'S DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Dopamine levels

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Parkinson disease (PD) is an age-related neurodegenerative disorder that affects 1–2% of persons aged 60 years and older (Olanow et al, 2009). There are diminished levels of dopamine at the basal ganglia of the brain, causing tremor of hands, arms, legs, jaw, and face; rigidity of limbs and trunk; slowness of gait; coordination difficulty; chewing problems; dysphagia; problems with speech. A test for PD progression includes a decline in ability to smell and the speed of wrist movements. Depression and dementia-related symptoms may also occur. Levodopa must be provided. Although levodopa continues as the gold standard for efficacy, its chronic use is associated with potentially disabling motor complications (Poewe, 2009).

Approximately 24 conditions are categorized as PDs. Between 1–1.5 million people are affected, men slightly more often than women. Life expectancy is 12.5 years after diagnosis. Yet, causes and pathophysiology are poorly understood. Oxidative stress contributes to apoptotic death of dopamine neurons (Bournival et al, 2009). Long-term exposure to manganese, herbicides, pesticides, or high intake of iron with high manganese may promote PD symptoms (Ascherio et al, 2006; Fitsanakis et al, 2006). Some medications such as major tranquilizers or metoclopramide can also cause PD-like symptoms.

Esophageal motor abnormalities and constipation are common. Constipation appears about 10–20 years prior to motor symptoms (Ueki and Otsuka, 2004). Unintentional weight loss is frequent, resulting in increased morbidity and mortality. Weight loss occurs from increased energy expenditure due to tremor, dyskinesias, and rigidity; reduced energy intake due to olfactory dysfunction, cognitive impairment, depression, dysphagia, and disability; and medication-related side effects, including dry mouth, nausea/vomiting, appetite loss, anorexia, insomnia, fatigue, and anxiety. PD is progressive. Advancing disease is associated with the emergence of freezing, falling, and dementia which are not adequately controlled with dopaminergic therapies (Olanow et al, 2009).

Increased plasma tHcy accelerates the selective dopaminergic cell death underlying PD (De Lau et al, 2005). Adequate

B-complex intake and measurement of serum levels of B<sub>12</sub> may be important. Higher serum vitamin B<sub>12</sub> levels are associated with lower dyskinesia risk (Camicioli et al, 2009), whereas folate therapy does not seem to be singularly protective (Chen et al, 2004).

Overall, neuroprotection is desirable. Oxidative stress initiates or promotes degeneration of neurons; antioxidant therapy may be protective. Resveratrol in grape juice and red wine, and quercetin in green tea are two natural polyphenols that have preventive qualities in PD (Bournival et al, 2009). Drinking 4–5 cups of coffee daily and foods rich in vitamin E and vitamin D<sub>3</sub> may also be protective (Evatt et al, 2008).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** There is significant variation in the prevalence of PD between different populations. Rates are highest in populations of European origin. Melanocortin 1 receptor (MC1R) genes are associated with red hair and fair skin (Han et al, 2006); risk for PD seems to be highest among those with this Cys/Cys genotype (Gao et al, 2009). There are many other candidate genes for PD: alpha-synuclein, DJ-1, PINK-1 (kinase), and UCHL-1. Two mutated copies of the Parkin gene are needed for the rare, autosomal recessive form of PD, with early onset in the fourth decade.

<b>Clinical/History</b>	DEXA for bone mineral density	H & H Serum Fe Alb, transthyretin
Height	Insomnia	Dopamine
Weight	Stooped, shuffling gait	Norepinephrine
BMI	Urinary frequency and urgency	BUN, Creat
Dietary/intake history	Skin evaluation; melanoma?	ALT, AST
BP	Unified Parkinson Disease Rating Scale (UPDRS)	Gluc
I & O		Plasma urate
Dysphagia		Ca <sup>++</sup> , Mg <sup>++</sup>
Tremors		Serum manganese
Bradykinesia		Serum tHcy
Difficulty arising from a chair		Serum folate and B <sub>12</sub>
Slowed activities of daily living		
Depression, anorexia	<b>Lab Work</b>	
Constipation	Plasma 25-hydroxyvitamin D (25[OH]D)	
Micrographia	Na <sup>+</sup> , K <sup>+</sup>	
Reduced arm swing	N balance	
Postural instability		

## SAMPLE NUTRITION CARE PROCESS STEPS

## Dehydration

**Assessment Data:** Weight loss, poor intake of food and fluids, swallowing difficulty, easy fatigue at mealtimes and early satiety, coughing after swallowing, poor skin turgor.

**Nutrition Diagnoses (PES):** Inadequate fluid intake related to swallowing difficulty and poor intake as evidenced by I & O records showing consumption of 25% of estimated needs and decreased intake of thin liquids because of coughing and early satiety.

**Interventions:** Swallowing evaluation (Speech Therapy) with selection of appropriate thickened liquids or pureed foods and ways in which fluids can be added to foods; use of IV fluids as needed.

**Monitoring and Evaluation:** Improvement in I & O related to fluids from food and beverages; improved skin turgor; return to previous weight.

## INTERVENTION

## OBJECTIVES

- Supply dopamine to the brain; monitor diet therapy accordingly.
- Maintain optimal physical and emotional health. Exercise may be protective, especially for men (Carne et al, 2005).
- Improve the ability to eat. Use semisolid foods rather than fluids when sucking/swallowing reflexes are reduced. Drooling may be a problem. Request a swallow evaluation from a speech therapist to determine proper consistency of foods, and (See Dysphagia entry in Section 7).
- Provide adequate energy to prevent weight loss, and avoid gaining excessive weight as well.
- Provide adequate hydration, especially when thickened liquids are needed. Coffee is a good choice.
- Correct alterations in GI function (i.e., increased transit time, heartburn, and constipation).
- Preserve functioning; delay disability as long as possible.
- When used MAOIs, use a tyramine-restricted diet to prevent severe headaches, blurred vision, difficulty thinking, seizures, chest pain or symptoms of a stroke.
- Lower elevated tHcy levels where needed (Caccamo et al, 2007).

## FOOD AND NUTRITION

- A high intake of protein diminishes the effectiveness of levodopa; use 0.5 g/kg of body weight. If unplanned weight loss occurs, up to 1–1.5 g/kg plus extra energy may be needed. For some, a protein redistribution diet is used (i.e., low-protein breakfast and lunch with high-protein dinner and snack). This diet is not always effective, and often provides insufficient protein. Timing of levodopa should be monitored to avoid conflicting responses to protein at mealtimes.
- Plan diet according to results of swallowing evaluation. Cut, mince, or soften foods as required. Use small, frequent meals if needed.

- To increase fiber, add crushed bran to hot cereal or try prune juice.
- A multivitamin–mineral supplement may be beneficial, especially for vitamins C, E, and the B-complex vitamins. Folate, vitamins B<sub>6</sub> and B<sub>12</sub> will be important to lower elevated tHcy levels (Biselli et al, 2007; Grimble, 2006).
- Highlight foods such as vegetable oils, salad dressings, nuts, green tea, coffee, turmeric, and antioxidant-rich fruits and vegetables.
- If needed, follow the Tyramine-restricted diet: avoid aged and fermented meats, sausages, and salamis; pickled herring; spoiled or improperly stored meat, poultry and fish with changes in coloration, odor, or mold; spoiled or improperly stored animal livers; broad bean pods; sauerkraut; aged cheeses; red wines and all varieties of tap beer and beers that have not been pasteurized; over-the-counter supplements containing tyramine; concentrated yeast extract; soybean products such as soy sauce and tofu.

## Common Drugs Used and Potential Side Effects

- Elevated plasma tHcy levels have been observed in PD patients treated with levodopa. New approaches may be needed for management of PD in persons who have MTHFR alleles (Caccamo et al, 2007; Camicioli et al, 2009; Todorovic et al, 2006).
- See Table 4-11 for specific medications used in PD.

## Herbs, Botanicals, and Supplements

- Because creatine kinase/phosphocreatine system plays a significant role in the CNS with the high and fluctuating energy demand, exogenous creatine supplementation tends to reduce neuronal cell loss (Andres et al, 2008).
- Coenzyme Q10 may be beneficial, but more research is needed.
- Other forms of CAM therapy are common, but patients do not always tell their health providers. Because of potential interactions with medications and excess costs, patients should be encouraged to discuss their use with their doctor before taking any forms of alternative medicine. Use of evening primrose, St. John's wort, passionflower, velvet bean, or ginkgo have not been proven effective.
- Kava should not be taken by patients with PD; it decreases effectiveness of medications.
- Ginseng, ma huang (ephedra), yohimbe, and St. John's wort should not be used with MAOIs, including selegiline (Eldepryl).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Education for the patient and family, access to support groups, regular exercise, and good nutrition are essential. Provide tips on antioxidant foods such as blueberries, green tea, coffee.
- Explain how to blenderize food or how to make food and beverages more nutrient dense, as needed.

**TABLE 4-11 Medications for Parkinson's Disease and Possible Side Effects**

Medication	Side Effects
<b>Antidepressants</b>	Weight gain, dry mouth, or nausea can result.
<b>Anticholinergics</b> Cogentin (benztropine), Artane (trihexyphenidyl), Ethopropazine	Confusion, agitation, dizziness, sedation, euphoria, tachycardia, hypotension, dry mouth, constipation, nausea, urinary retention and blurred vision.
<b>Antiviral agent</b> Symmetrel (amantadine)	Possible adverse effects include anorexia, dry mouth, nausea, constipation, dizziness, insomnia, blurred vision, depression, ataxia, confusion, fatigue, leg/ankle edema, hallucinations, anxiety, and livedo reticularis (skin discoloration).
<b>Catechol-O-methyltransferase (COMT) inhibitors</b> Tasmar (tolcapone), Comtan (entacapone)	These drugs slow the breakdown of dopamine. Diarrhea, orthostatic hypotension, hallucinations, sleep disturbances, dyskinesias, muscle cramping, and vivid dreams may occur with use. Liver function testing should be scheduled regularly while on these medications.
<b>Dopamine agonists</b> Parlodel (bromocriptine), Mirapex (pramipexole), Requip (ropinirole)	These stimulate dopamine receptors. Edema, psychosis, nausea, headache, fatigue, confusion, somnolence and "sleep attacks." With ropinirole, fewer side effects, such as dyskinesia, have been identified. Some studies suggest that dopamine agonists, rather than levodopa, should be the initial symptomatic therapy in Parkinson's disease.
Apokyn (apomorphine hydrochloride)	Approved for the treatment of acute, intermittent hypomobility episodes associated with advanced Parkinson's disease.
<b>Ibuprofen</b>	Users of ibuprofen are less likely to develop Parkinson's disease than nonusers.
<b>Levodopa/carbidopa</b> Sinemet, Sinemet CR, Atamet, Madopar	Nausea, vomiting, weakness, hallucinations, mental confusion, orthostatic hypotension, fatigue, sudden daytime sleep onset, insomnia, elevated serum glucose and homocysteine, and anemia. Large neutral amino acids block levodopa absorption, both from the gut and at the blood-brain barrier. Levodopa preparations should be taken 30–60 minutes prior to meals; intake of vitamin B <sub>6</sub> should be limited to DRI levels. Up to 15 mg of vitamin B <sub>6</sub> can be taken daily in either food or supplement form. Today's preparations combine levodopa with carbidopa. Increase intake of foods rich in vitamin B <sub>12</sub> , folate, and vitamin C.
<b>MAO type B inhibitors</b> Eldepryl (selegiline), Azilect (rasagiline)	Insomnia, dry mouth, confusion, hypertension, abdominal pain, and weight loss. Selegiline should not be used with ginseng, ma huang (ephedra), yohimbe, or St. John's wort. A low tyramine diet should be used with rasagiline.

- Help patient to control weight, which may fluctuate from either reduced mobility or the inability to ingest sufficient quantities.
- Place all foods within easy reach of the patient. Braces may help the patient control severe tremors at mealtime.
- Music therapy, Tai Chi, and yoga help to relieve depression and improve balance.
- Discuss how to resolve issues such as weight loss, constipation, osteopenia, gastroesophageal reflux disease (GERD), side effects of medications, xerostomia, and dehydration.
- Deep brain stimulation of the subthalamic nucleus shows promise. Medtronic has two new devices that can be used with PD patients to help control tremors: Activa RC and Activa PC.
- Maintain bone mineral density, as hip fractures are common. BMD is related to leg muscle strength (Pang and Mak, 2009).

#### Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for sanitizing work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of formula in the home and institution.

## SPINAL CORD INJURY

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Spinal cord injury (SCI) is often caused by traffic accidents, falls, diving accidents, sports injury, or gunshot wounds. Partial versus total self-care deficits depend on resulting paralysis or loss of sensation below the site of the injury. Classification usually includes the cause, direction of injury, level of injury, stability of vertebral column, and degree of cord involvement. See Table 4-12.

Most injury causes permanent disability or loss of movement (paralysis) and sensation below the site of the injury. Paralysis that involves the majority of the body, including the arms and legs, is called quadriplegia or tetraplegia because of injuries to one of the eight cervical segments of the spinal

cord. Those with paraplegia have lesions in the thoracic, lumbar, or sacral regions of the spinal cord.

The nervous system of a patient with neurological trauma is vulnerable to variations in oxygen, glucose, and other nutrients. Indirect calorimetry is the best method for identifying energy requirements (Shepherd, 2009). Pressure ulcers are very common in this population; see Section 2.

SCI patients with a BMI of  $>22$  should be considered at risk for obesity (Laughton et al, 2009). After long-term immobility, SCI patients may require weight loss, using varied psychosocial, behavioral, and dietary interventions (Chen et al, 2006).

Treatment using fetal stem cells has profound implications for recovery in the SCI population. More research is forthcoming.

**TABLE 4-12 Expected Functional Level of Spinal Cord Disruption**

Quadriplegia	Paraplegia
<b>C1-C3</b> Vagus domination of heart, respiration, blood vessels, all organs below injury. Movement in neck and above, loss of innervation to diaphragm, absence of independent respiratory function. Ability to drive power wheelchair equipped with portable respirator by using chin control or sip and puff, lack of bowel and bladder control.	<b>T1-T6</b> Sympathetic innervation to heart, vagus domination of the rest. Full innervation of upper extremities, back, essential intrinsic muscles of hands; full strength and dexterity of grasp; decreased trunk stability; decreased respiratory reserve. Full independence in self-care and in a wheelchair, ability to drive a car with hand controls (in most clients), ability to use full body brace for exercise but not for functional ambulation, lack of bowel and bladder control.
<b>C4</b> Vagus domination of heart, respiration, and all vessels and organs below injury. Sensation and movement above neck. Ability to drive power chair using chin control or sip and puff, lack of bowel and bladder control.	<b>T6-T12</b> Vagus domination only of leg vessels, gastrointestinal, and genitourinary organs. Full, stable thoracic muscles and upper back; functional intercostals, resulting in increased respiratory reserve. Full independent use of wheelchair; ability to stand erect with full body brace, ambulate on crutches with swing (though gait is difficult); inability to climb stairs; lack of bowel and bladder control.
<b>C5</b> Vagus domination of heart, respiration, and all vessels and organs below injury. Full neck, partial shoulder, back, biceps; gross elbow, inability to roll over or use hands; decreased respiratory reserve. Ability to drive power chair with mobile hand supports, ability to use hand splints (in some clients), lack of bowel and bladder control.	<b>L1-L2</b> Vagus domination of leg muscles. Varying control of legs and pelvis, instability of lower back. Good sitting balance, full use of wheelchair.
<b>C6</b> Vagus domination of heart, respiration, and all vessels and organs below injury. Shoulder and upper back abduction and rotation at shoulder, full biceps to elbow flexion, wrist extension, weak grasp of thumb, decreased respiratory reserve. Ability to assist with transfer and perform some self-care, feed self with hand devices, push a wheelchair on smooth, flat surface; lack of bowel and bladder control.	<b>L3-L4</b> Partial domination of leg vessels, gastrointestinal, and genitourinary organs. Quadriceps and hip flexors, absence of hamstring function, flail ankles. Completely independent ambulation with short leg braces and canes, inability to stand for long periods, bladder and bowel continence.
<b>C7</b> Vagus domination of heart, respiration, and all vessels and organs below injury. All triceps to elbow extension, finger extensors and flexors, good grasp with some decreased strength, decreased respiratory reserve. Ability to transfer self to a wheelchair, roll over and sit up in bed, push self on most surfaces, perform most self-care; independent use of wheelchair; ability to drive a car with hand controls (in some clients); lack of bowel and bladder control.	

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** A SCI is not usually genetic.

Clinical/History	Indirect	BP (tends to be elevated)
Height	calorimetry	Cervical x-rays
Weight	(rest 30 minutes prior)	Somatosensory-evoked potentials
BMI	Dietary/intake history	Myelogram
	I & O	

MRI or CT scan	Alb	Ca <sup>++</sup> , Mg <sup>++</sup>
DEXA	Serial transthyretin levels	Hypercalciuria
Triceps skinfold	Na <sup>+</sup> , K <sup>+</sup>	Parathormone (may be low)
Mid-arm circumference	Creat	25-hydroxyvitamin D <sub>3</sub>
Pulmonary edema	(eventually decreased)	N balance
Pneumonia	BUN	Erythrocyte sedimentation rate (ESR)
	Gluc	CRP (elevated)
<b>Lab Work</b>	pCO <sub>2</sub> , pO <sub>2</sub>	Serum B <sub>12</sub>
H & H (decreased)	RQ (if over 1.0, evaluate for overfeeding)	
Serum Fe	PT or INR	

## SAMPLE NUTRITION CARE PROCESS STEPS

**Inadequate Protein Intake**

**Assessment Data:** SCI 6 months ago; poor intake of protein foods.

**Nutrition Diagnoses (PES):** Inadequate protein related to poor intake of protein-rich foods as evidenced by dietary recall and early skin breakdown.

**Interventions:** Change diet order to provide protein-enhanced foods that are nutrient dense. Educate patient about rationale for the protein to protect the skin integrity.

**Monitoring and Evaluation:** Improved protein intake; better quality of life by increased ability to participate in physical and occupational therapies.

## INTERVENTION

## OBJECTIVES

*Immediate*

- Monitor for acid–base and electrolyte imbalances. Assess needs on admission and then daily thereafter.
- Maintain blood glucose at or below 140 mg/dL in critical phase (ADA, 2009). If on a ventilator, keep blood glucose levels between 80 and 110 mg/dL.
- Reduce the danger of aspiration by avoiding oral feedings in supine patients. Initiate tube feeding within 24–48 hours after admission to intensive care (Shepherd, 2009). Early EN is desirable because of the demands of the brain and nerves.
- If needed, use parenteral nutrition if there is intolerance of EN, such as high gastric residuals or aspiration.
- Ensure adequate fluid and calcium intake to prevent renal stones.
- Slow down weight loss and any progressive muscle wasting by maintaining protein and energy sufficiency.
- Increase opportunities for rehabilitation by monitoring weight changes; loss of 10–30% in the first month is common.
- Prevent UTIs, paralytic ileus, pneumonia, malnutrition, pressure ulcer, constipation, stress ulcer, and fecal impaction. Note that elevated CRP is associated with UTIs or pressure ulcers within a year (Gibson et al, 2008; Morse et al, 2008).

*Long Term*

- Mobilize, prevent complications, and regain as much independence as possible. Participate in muscle vibration stimulation and other therapies whenever possible.
- Monitor weight gain since excessive weight gain can lead to pressure ulcers and make patient transfers more difficult. Maintain an ideal body weight with a BMI of 18–22 (Laughton et al, 2009).
- Promote neuronal growth and survival, encourage the formation of synapses, enhance the production of myelin, and restore conduction capabilities and thus restore the compromised circuitry in the injured spinal cord.
- Prevent osteoporosis and risk of fractures.
- Manage long-term problems with bowel motility with fiber, fluid and laxatives (Shepherd, 2009).

- Prevent heart disease. While women with paraplegia tend to maintain healthier diets (i.e., lower calorie and fat intakes, more nutrient density, less overweight,) individuals with tetraplegia tend to be overweight or obese (Groah et al, 2009).

## FOOD AND NUTRITION

- Provide patient with intravenous solutions as soon as possible after injury. Check blood gas measurements and chemistries. Once peristalsis returns, patient may be tube fed. Elevate head of bed 45°, if possible, to prevent aspiration (ADA, 2009).
- Determine energy needs by indirect calorimetry. Patients with paraplegia need 28 kcal/kg/d and those with quadriplegia need 23 kcal/kg/d (Shepherd, 2009).
- Paraplegics initially need 1.5–1.7 g protein/kg. Progress to more normal intake, such as 0.8 g/kg, when nitrogen balance returns after several weeks. Patients with large pressure ulcers will need an increase in protein back to 1.5 g/kg.
- Ensure adequate CHO and fat intake, including at least 1–2% EFAs.
- Encourage adequate fluid (1 mL/kcal/d); use more with fever or pressure ulcers.
- Include adequate fiber (15 g/d). Be careful with gas-forming foods; monitor tolerance.
- Ensure adequate intake of thiamin, niacin, vitamins B<sub>6</sub>, B<sub>12</sub>, and C, and amino acids. Monitor iron stores and adjust diet as needed.
- Provide adequate vitamin D<sub>3</sub> and calcium intake.
- With hypertension, the DASH diet may be useful (increases in calcium, potassium, and magnesium are beneficial).
- Increase intake of antioxidant-rich foods and omega-3 fatty acids (DHA) for neuroprotection (King et al, 2006).
- Tube feeding should be used over parenteral nutrition where possible (ADA, 2009). An immune-enhancing formula may be recommended but is not always essential. Do not recommend use of blue dye to detect aspiration (ADA, 2009).

## Common Drugs Used and Potential Side Effects

- Corticosteroids such as prednisone are used to prevent swelling. Long-term use can cause hyperglycemia and nitrogen, calcium, and potassium losses. Sodium retention occurs.
- Analgesics for pain relief (e.g., aspirin/salicylates) can prolong bleeding time. GI bleeding may eventually result.
- Laxatives may be used; encourage fiber and fluid instead.
- For a bowel regimen, use of erythromycin, metoclopramide, a stool softener and a stimulant laxative may be prescribed (Shepherd, 2009). There are no contraindications to the use of promotility agents (ADA, 2009).
- Anabolic steroids (oxandrolone) help alleviate anorexia and may be helpful in managing pressure ulcers.
- To protect against fractures, bisphosphonates may help prevent acute bone loss; use IV rather than oral route to reduce reflux.

## Herbs, Botanicals, and Supplements

- Studies have found usefulness in pretreatment of patients with creatine for neuroprotection before spinal surgery.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help promote a structured feeding routine. Feed slowly (over 30–45 minutes) using small bites of food.
- The majority of people with SCI would benefit from nutritional counseling to prevent emerging secondary conditions (Groah et al, 2009; Tomey et al, 2005).
- Provide weight control measures for successful rehabilitation (Chen et al, 2006).
- Teach patient about good sources of iron and other minerals, vitamins, and protein.
- Discuss long-term risks of heart disease.
- Encourage participation in weight-bearing exercise to reduce calcium loss and risk of fracture or osteoporosis.

### Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for sanitizing work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of formula in the home and institution.

# STROKE (CEREBROVASCULAR ACCIDENT)

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

A cerebrovascular accident (CVA) (stroke) is caused by damage to a portion of the brain resulting from loss of blood supply due to a blood vessel spasm, clot, or rupture. Sporadic strokes can occur, but most have a genetic, polygenic component. Eighty percent of strokes are ischemic. Transient ischemic attacks (TIAs) are brief episodes of blood loss to the brain from a clot or an embolism; 10% of victims will have a major CVA within a year. Stroke patients need to be seen medically within 60 minutes to begin appropriate treatment. Some

people recover completely; others may be seriously disabled or die. The urgent presenting symptoms are listed in Table 4-13.

Hypertension, smoking, diabetes mellitus, atrial fibrillation, and oral contraceptive use are key risk factors for strokes. Unconsciousness, paralysis, and other problems may occur depending on the site and extent of the brain damage. Left CVA affects sight and hearing most commonly, including the ability to see where foods are placed on a plate or tray. Patients with a right-hemisphere, bilateral, or brain-stem CVA have significant problems with feeding and swallowing of food; speech problems also occur.

**TABLE 4-13 Most Common Stroke Symptoms**

- Sudden numbness or weakness of face, arm, or leg, especially on one side of the body
- Sudden confusion, trouble speaking or understanding
- Sudden trouble seeing in one or both eyes
- Sudden trouble walking, dizziness, loss of balance or coordination
- Sudden severe headache with no known cause

Neurogenic deficits may include motor deficits with muscle weakness of the tongue and lips; nerve damage with resulting lack of coordination; apraxia; sensory deficits with an inability to feel food in the mouth. Cognitive deficits include difficulty sustaining attention, poor short-term memory, visual field problems, impulsiveness, aphasia, and judgment problems such as not knowing how much food to take or what to do with the food once it reaches the mouth. Strokes cause 10% of all fatalities in the United States.

A dietary pattern with high intakes of red and processed meats, refined grains, sweets and desserts may increase stroke risk, whereas a diet higher in fruits and vegetables, fish, and whole grains may protect against stroke. Intake of cruciferous and green leafy vegetables, citrus fruits, and carotenoids seem to be protective. Among elderly individuals, consumption of tuna or other broiled or baked fish is associated with lower risk of ischemic stroke, while intake of fried fish is associated with higher risk (Mozaffarian et al, 2005). Both fish and omega-3 fatty acids seem to prevent thrombotic strokes.

Individualized dietary advice to those with coronary heart disease can reduce stroke mortality and morbidity, yet this is often overlooked by physicians (Spence, 2006). Risk reduction from controlled trials with supplemental vitamins C or E has not been consistent. Vitamin E influences the activity of enzymes PKC, PP2 A, COX-2, 5-lipoxygenase, nitric oxide synthase, NADPH-oxidase, superoxide dismutase, and phospholipase A2 and modulates gene expression. Vitamin C levels tend to be lower among stroke patients, probably due to the relationship to inflammation and oxidative stress.

Lowering elevated serum tHcy is also important. For example, homocystinuria is a metabolic disorder that is a known life-threatening risk factor for ischemic stroke. Folate deficiency and hyperhomocysteinemia increase oxidative DNA damage and ischemic lesion size in stroke patients (Endres et al, 2005). Intake of folate, vitamins B<sub>6</sub> and B<sub>12</sub> should be maintained in high-risk groups.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Pro-inflammatory gene polymorphisms are related to both coronary heart disease and stroke. Alterations in the 9p21 chromosome relate to atherosclerotic stroke (Gschwendtner et al, 2009),

whereas MTHFR C677 T, beta-Fg—455 A/G, beta-Fg—48 T/C, PAI-1 4G/5G, and ApoE epsilon2–4 are associated with ischemic stroke (Xu et al, 2008).

<b>Clinical/History</b>	Gag reflex absent?	Ca <sup>++</sup> , Mg <sup>++</sup>
Height	BP	Chol (total, HDL, LDL)
Weight	Temperature	Trig
BMI	Visual field scan	tHcy
Waist to hip ratio	EEG	Serum folate
Dietary/intake history	Carotid ultrasound	Ferritin
Positron emission tomography (PET) scan	CT scan or MRI I & O	H & H
Sleep apnea	<b>Lab Work</b>	Gluc (often increased)
Chewing ability	CRP	Creatine phosphokinase (CPK)
Hand to mouth coordination	PT	Serum uric acid
	INR: 2.0–4.0	
	desirable	
	Na <sup>+</sup> , K <sup>+</sup>	

## SAMPLE NUTRITION CARE PROCESS STEPS

### Imbalance of Nutrients

**Assessment Data:** Food records indicating high sodium intake and limited use of fruits and vegetables for calcium, magnesium, and potassium.

**Nutrition Diagnoses (PES):** Imbalance of nutrients related to dietary intake of mostly processed, high sodium foods and few fruits, vegetables, or dairy as evidenced by diet history.

**Interventions:** Education about use of the DASH diet (enhanced fruits, vegetables, low fat dairy) and whole grains.

**Monitoring and Evaluation:** Improved BP; no more TIAs or strokes; improved balance between sodium and other minerals (calcium, potassium, magnesium).

### Difficulty Swallowing

**Assessment Data:** Results of swallow study and x-rays, food diary, and problems noted with specific types of liquids/foods; swallow studies and conferences with speech therapist; patient is also aphasic.

**Nutrition Diagnoses (PES):** Swallowing difficulty related to consumption of general diet after CVA as evidenced by coughing after intake of thin liquids.

**Intervention:** Alter diet to thicken liquids with all meals, snacks, medication passes, special events, dining out. Provide recipes for use of thickened liquids in daily meals.

**Monitoring and Evaluation:** Reduced incidence of coughing after drinking beverages; no hospital admissions for pneumonia. Able to communicate in spite of aphasia using head nod and eyes to communicate preferences and choices.

## INTERVENTION

## OBJECTIVES

- **Immediate treatment:** Maintain fluid-electrolyte balance for lifesaving measures.
- **Ongoing treatment:** Improve residual effects such as dysphagia, hemiplegia, and aphasia. Correct side effects such as, constipation, UTIs, pneumonia, renal calculi, and pressure ulcers.
- If the patient is excessively overweight, weight reduction is necessary to lower elevated BP or lipids and to lessen the workload of the cardiovascular system.
- Chewing should be minimized with dysphagia; prevent choking. Avoid use of straws if there is dysphagia.
- Lower elevated serum lipids; try to improve HDL cholesterol levels.
- Promote self-help, self-esteem, and independence.
- Prevent additional strokes, which are common. See Table 4-14. Since inflammation may be caused by a response to oxidized low-density lipoproteins, chronic infection, or other factors, monitor CRP.

TABLE 4-14 Strategies Used to Prevent Strokes

GOAL: Lower or Less	<p>Blood pressure at 120/80 or below. Smoking; quitting is best. Limit sodium from salt shaker, processed meats, pickles, and olives. Maintain serum cholesterol levels of 200 or lower; LDL of 100 or lower; triglycerides of 150 or less Energy intake: avoid obesity.</p>
GOAL: Higher or More	<p>Exercise moderately each day for at least 30–60 minutes. Brisk walking (about 3 mph) is most protective; but any walking is good. High-dose statin, low to standard doses of antihypertensive therapy, aspirin, cardiac rehabilitation (Robinson and Maheshwari, 2005). Eat a balanced diet including fruits, vegetables, whole grains, low fat dairy products for more potassium, vitamin C, calcium, magnesium. Include omega-3 fatty acids in foods regularly (fatty fish, flaxseed, and walnuts). May use omega-3 fish oil. Include natural sources of fatty acids and vitamin E, such as mayonnaise, creamy salad dressings, margarine, and nuts. Vitamin K may curtail vascular calcification; 500 µg may be needed. Take a multivitamin–mineral supplement daily, especially for folic acid, vitamins B<sub>6</sub>, and B<sub>12</sub>, to reduce homocysteine levels and to help lower blood pressure. Achieve and maintain body weight within BMI range for height. Maintain or elevate HDL to &gt;60. Drink alcoholic beverages in moderation only (one drink for women, two for men per day). Alcohol boosts HDL and may reduce clot formation.</p>

## FOOD AND NUTRITION

- **Initial treatment:** Nothing by mouth (NPO) with intravenous fluids for 24–48 hours. Avoid overhydration. Tube feeding may be needed, especially gastrostomy or jejunostomy. If the patient is comatose, tube feeding definitely is required, and the head of the bed should be elevated at least 30°–45° during feeding to prevent aspiration.
- **Recovery:** Treatment should progress from NPO to liquids. Sip feeding may improve nutrient intake and nutritional status of stroke patients who do not have swallowing difficulties with liquids.
- Provide adequate energy intake (patient's weight should be checked frequently). Monitor the patient's activity levels. From 25–45 kcal/kg and 1.2–1.5 g protein/kg may be needed, depending on weight status and loss of lean body mass.
- Texture modification to compensate for dysphagia should be made to reduce risk of choking and/or aspiration. Thick pureed liquids or a mechanical soft diet may be needed. Liquids can be thickened with gels.
- Always start with small amounts of food. Use easy-to-chew foods and spoon rather than fork foods. Progress slowly.
- With dysphagia, avoid foods that cause choking or that are hard to manage (e.g., tart juices and foods, dry or crisp foods, fibrous meats, unboned fish, chewy or stringy meats, sticky peanut butter or bananas, thinly pureed foods that are easily aspirated, mixed foods with varying consistency, excessively sweet drinks or tart fruits that aggravate drooling, raw vegetables). Mashed potatoes or soft breads for some patients may be hard to swallow.
- With decreased salivation, moisten foods with small amounts of liquid. Use thickener products to make semi-solids out of soup, beverages, juices, and shakes. Test swallowing periodically. When ready, use of a syringe or training cup is beneficial.
- The amount of saturated and trans fatty acids in the planned diet should be <10% of total calories, and the dietary cholesterol intake should be <300 mg/d. A useful recommendation is to reduce the quantity of fat by 20–25%, reduce animal fats, and decrease the amount of salt added to foods in cooking and at the table.
- Replace saturated fat with monounsaturated sources; use more olive, soybean or canola oils and nuts such as walnuts, almonds, macadamias, pecans, and pistachios. Walnuts contain alpha linolenic acid; almonds are a good source of vitamin E. Nuts also contain flavonoids, phenols, sterols, saponins, elegendic acid, folic acid, magnesium, copper, potassium, and fiber. The Mediterranean diet is a useful diet to follow; in this diet, unsaturated fats replace most of the saturated fat, and fruits and vegetables are highlighted (Spence, 2006).
- Use plant sterols and stanols, as from margarines and related products.
- Increase omega-3 fatty acids from fish.
- Use skim milk products whenever possible. Milk fat is negatively correlated with certain cardiovascular disease risk factors.
- Increase potassium to reduce risk of additional strokes. Avoid use of potassium-sparing diuretics or with end-stage

renal disease. Fruits and vegetables are the best sources (oranges, bananas, prunes, baked potatoes); milk is another good source. Magnesium, vitamin E, folic acid, and vitamins B<sub>12</sub> and B<sub>6</sub> should be included in sufficient quantities to meet at least minimum daily requirements. Use the DASH diet plan (see Section 6).

- Fluid should be given in sufficient quantity if tolerated; estimate needs at 30 mL/kg and increase to 35 mL/kg if dehydration occurs. Give oral beverages at the end of the meal to increase solid food intake in patients who have early satiety or fatigue with meals.
- The diet should provide adequate fiber from prune juice, bran, whole grain breads and cereals, oatmeal, bran, wheat germ, popcorn, brown rice.
- Use caution with supplemental vitamin C; excesses may act as a pro-oxidant.
- Flavonoids such as grape juice, green tea, and red wine are useful if the patient can tolerate thin liquids.

### Common Drugs Used and Potential Side Effects

- Angiotensin-converting enzyme inhibitors/angiotensin receptor blockers may cause diarrhea or GI distress. Atacand, Teveten, Avapro, Cozaar, Benicar, Micardis, or Diovan should be used with a low sodium, low calorie diet. They may cause anemia or hyperkalemia. Be careful with salt substitutes; read contents carefully.
- Anticoagulants used to prevent thromboembolism, such as warfarin (Coumadin), require a controlled amount of vitamin K. Monitor tube feeding products and supplements. Many patients who are taking warfarin can safely monitor their INR levels at home and adjust their medications accordingly. Monitor supplements containing vitamins A, C, and E with these drugs because of potential side effects. Avoid taking with dong quai, fenugreek, feverfew, excessive garlic, ginger, ginkgo, and ginseng.
- Aspirin is often used to prevent future strokes as a blood thinner (generally 1 tablet per day). Monitor for GI bleeding or occult blood loss. Aspirin is safer than warfarin and just as effective for treating blocked arteries in the brain (Koroshetz, 2005).
- Grapefruit juice decreases drug metabolism in the gut (via P450-CYP3A4 inhibition) and can affect medications up to 24 hours later. Avoid taking with alprazolam, buspirone, cisapride, cyclosporine, statins, tacrolimus, and many others.
- Products containing phenylpropanolamine (PPA) are a risk for stroke. PPA has been pulled from the shelves but may still be in some cough medicines in the home.
- Statins (Lipitor, Lescol, Mevacor, Pravachol, Crestor, and Zocor) are commonly prescribed. Nausea, abdominal pain, and other GI effects are common. Do not take with grapefruit juice or St. John's wort. Monitor liver enzymes.
- Stool softeners may be used. Tube feeding containing a mix of soluble and insoluble fiber can be used. If a low-residue formula is used, a fiber supplement such as Bene-fiber can be mixed with water and administered via Y-port.
- Thiazide diuretics, such as Lasix, may be used and can deplete potassium.

### Herbs, Botanicals, and Supplements

- The patient should not take herbals and botanicals without discussing with the physician.
- Coenzyme Q10 should not be used with gemfibrozil, TCAs, or warfarin. Coenzyme Q10 may act similarly to vitamin K.
- Niacin (nicotinic acid) should not be taken with statins, antidiabetic medications, and carbamazepine because of potentially serious risks of myopathy and altered glucose control.
- Large doses of vitamin E should not be taken with warfarin because of possible increased bleeding. Avoid doses greater than 400 IU/d.
- Garlic, willow, pigweed, ginkgo, or evening primrose have been recommended; no clinical trials have proven efficacy.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help the patient simplify meal preparation. Arrange food and utensils within reach. Discuss the use of appropriate assistive devices.
- Explain which sources of adequate nutrition do not aggravate the patient's condition. Discuss fat, cholesterol; sodium, potassium, calcium, magnesium, specific vitamins, and other nutrients in the DASH diet. Correlate with drug therapy.
- Help the patient make mealtime safe and pleasant. Encourage small bites of food and slow, adequate chewing.
- Discuss ways to prevent future strokes; linolenic acid from walnut, canola, and soybean oils may be protective. Increased fruit and vegetable intake is also protective.
- Physical therapy is very important in early stages after a stroke, especially to regain use of limbs such as hands and arms.
- Manage depression, which is common after a stroke. Treatments may include patient and family counseling and education, reestablishment of sleep pattern, improving diet, regular physical activity, or medication.
- Future prevention strategies should be taught to stroke patients and their families. Modifiable risk factors include hypertension, exposure to cigarette smoke, diabetes, atrial fibrillation and certain other cardiac conditions, dyslipidemia, carotid artery stenosis, sickle cell disease, postmenopausal hormone therapy, poor diet, physical inactivity, and obesity and body fat distribution (Goldstein et al, 2006). Potentially modifiable risk factors include the metabolic syndrome, alcohol use, oral contraceptive use, migraine headache, hyperhomocysteinemia, inflammation (Goldstein et al, 2006).
- The American Heart Association, American Cancer Society, and American Diabetes Association agree that lifestyle changes are essential for prevention of stroke and associated disability.

### Patient Education—Foodborne Illness

- Careful food handling will be important. If tube feeding is needed, discuss proper sanitation of work counters during preparation.

- Hand washing is important, especially for caregivers if the patient is unable to feed himself or herself.

## TARDIVE DYSKINESIA

### NUTRITIONAL ACUITY RANKING: LEVEL 2

#### DEFINITIONS AND BACKGROUND

Tardive dyskinesia (TD) is a movement disorder characterized by involuntary oro-facial, limb, and truncal movements (Tsai et al, 2009). It is usually caused by the use of drugs that block dopamine receptors (dopamine receptor antagonists [DRAs]). When used in the classic sense, TD is produced by the long-term use of drugs to treat SCZ that act by blocking dopamine receptors. TD occurs in 20–40% of all patients receiving long-term antipsychotic drugs. Patients are often elderly and chronically institutionalized.

Phenylalanine sensitivity has been speculated as the cause of TD. Amine-depleting agents such as reserpine (Serpasil, Serpasil) and tetrabenazine (Nitoman) deplete dopamine, norepinephrine, and serotonin. Tarvil, a medical food with high branched-chain amino acids, targets excess phenylalanine and has few side effects.

serotonin, glutamate, and GABA pathways) and composite genotypes for 10 drug-metabolizing enzymes. No single marker or haplotype association reached statistical significance after adjustment for multiple comparisons (Tsai et al, 2009).

Clinical/History	Abnormal Involuntary Movement Scale	Serum prolactin (often increased)
Height	Tremors	Acetylcholine levels
Weight		Gluc
BMI		Alb,
Dietary/intake history	<b>Lab Work</b>	transferrin
BP	CRP	Ceruloplasmin
Chorea, athetosis, dystonia	BUN, Creat	Serum Cu
Tics or facial grimacing	H & H	Serum
	Serum Fe	phenylalanine
	Serum tHcy	
	Serum folate	

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** There have been a sizeable number of candidate gene studies. A total of 128 candidate genes were studied in 710 subjects—2580 SNPs in 118 candidate genes selected from the literature (e.g., dopamine,

### INTERVENTION

#### OBJECTIVES

- Prevent or correct malnutrition, weight loss, and other problems.
- Identify and assist with problems, such as puckering of the lips, difficulty sucking and eating.
- Restore capacity for eating orally as far as possible.
- Alter textures as necessary (eating problems are rare or occur late in the condition).

## SAMPLE NUTRITION CARE PROCESS STEPS

## Self-Feeding Difficulty

**Assessment Data:** Food intake sporadic because of difficulty feeding self; weight loss.

**Nutrition Diagnoses (PES):** Self-feeding difficulty related to dyskinesia as evidenced by food intake <75% desirable amount and weight loss of 10 lb in past 3 months and BMI 18.

**Interventions:** Enhance nutrient intake and offer easy to handle finger foods at frequent intervals. Educate about nutrient density. Counsel about ways to increase energy intake to improve weight.

**Monitoring and Evaluation:** Improved weight status. Increased ability to eat sufficient amounts of kilocal and nutrient-dense choices using finger foods and frequent meals or snacks.

## FOOD AND NUTRITION

- Offer the usual diet with soft textures to reduce chewing as needed.
- Decrease energy intake if obese; increase intake if underweight.
- Carbohydrate craving is common. Watch overall intake of sweets or offer nutrient-dense varieties to reduce hyperglycemia.
- Increase dietary choline from foods such as eggs, soybeans, peanuts, and liver.
- Moisten foods with gravy, sauces, and liquids if dry mouth is a problem.
- Alter fiber intake if needed to prevent or correct constipation.
- Ensure adequate intake of antioxidants and omega-3 fatty acids (colorful fruits and vegetables, nuts, fish and seafood).

## Common Drugs Used and Potential Side Effects

- Psychiatric conditions are often treated with phenothiazines, butyrophenones, dibenzodiazepines, indolones, diphenylbutylpiperidines, and thioxanthenes. These are more likely to cause TD than the newer antipsychotic agents.
  - Incidence of TD with the use of newer atypical antipsychotic agents such as clozapine (Clozaril), olanzapine (Zyprexa), risperidone (Risperdal), and quetiapine (Seroquel) is minimal (Casey, 2006). Risperidone (Risperdal) appears to bring out the symptoms of TD more frequently, as compared to the other newer atypical antipsychotic agents.
- Drugs other than those used to treat psychiatric illnesses can also block the dopamine receptors. These

include anticholinergics and SSRIs, which are used to treat depression. Whether MAOIs and tricyclics cause TD is not known.

- Reduction in the use of the drugs that caused TD is desirable. Changing to a different medication, such as an atypical antipsychotic, is recommended. Patients on antipsychotics should be checked regularly.
- TD has also been known to develop in patients who have been treated for digestive and GI disorders with medications such as metoclopramide (Reglan).
- Tetrabenazine, a medication that reduces levels of dopamine, has been of some use in treating TD symptoms.
- “Anti-Parkinsonian” drugs such as Aricept and Miraplex appear to offer some benefit.

## Herbs, Botanicals, and Supplements

- No studies have been conducted for efficacy of herbs or botanicals in TD.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Diet instructions should be offered directly to the patient unless this is not possible.
- Discuss major issues related to nutrition, self-feeding practices, moistening of foods, use of adaptive equipment as needed.
- Discuss sources of foods that contain branched-chain amino acids and how to obtain medical foods that may be used.

## Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for hand washing.

# TRIGEMINAL NEURALGIA

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

### DEFINITIONS AND BACKGROUND

Trigeminal neuralgia (TN) or tic douloureux manifests as a disorder of the fifth cranial nerve and is characterized by paroxysms of excruciating pain of a burning nature. The painful periods alternate with pain-free periods. The frequency of the paroxysms ranges from a few to hundreds of attacks a day; remission can last for months to years, but tend to shorten over time (Zakrewska and Linskey, 2009).

The disorder is rare before 40 years of age and is more common in elderly women. The right side of the face is affected more often; the pain can be incapacitating. Dentists often play a role in identifying this condition (Bagheri et al, 2004). Loss of taste after surgery can occur. Recent use of radiosurgery or a gamma knife procedure has shown promise.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Whether TN is related to celiac disease has yet to be determined.

<b>Clinical/History</b>	Temperature	Na <sup>+</sup> , K <sup>+</sup>
Height	EEG	Folate
Weight	Carotid	Ca <sup>++</sup> , Mg <sup>++</sup>
BMI	ultrasound	Chol (total,
Dietary/intake	CT scan or MRI	HDL, LDL)
history	I & O	Trig
PET scan	<b>Lab Work</b>	Ferritin
Chewing ability		H & H
BP	CRP	Gluc

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Difficulty Chewing

**Assessment Data:** Problems with weight loss, pain with eating meals, difficulty chewing solids.

**Nutrition Diagnoses (PES):** Inadequate oral food and beverage intake related to difficulty chewing as evidenced by diagnosis of TN with excruciating pain, especially with solids.

**Interventions:** Education of patient about pureed foods and liquefying meal items to reduce chewing; nutrient-dense food and beverage choices.

**Monitoring and Evaluation:** Regain of lost weight, no further complaints of pain with chewing, improved nutrient intake.

### INTERVENTION

### OBJECTIVES

- Control pain with medications, especially before meals.
- Provide appropriate counseling and assistance with consistency of meals (foods and beverages).
- Individualize for preferences and tolerances.
- Maintain body weight within a desirable range.
- Manage celiac disease if present.

### FOOD AND NUTRITION

- Use a normal diet as tolerated, perhaps altering to soft or pureed foods as needed. Omit gluten if celiac disease is diagnosed.
- Small, frequent feedings may be better tolerated than large meals.
- Liquids may be preferred if given by straw. Individualize.
- Avoid extremes in temperature.
- Use nutrient-dense foods if weight loss occurs.

### Common Drugs Used and Potential Side Effects

- Anticonvulsants such as topiramate, phenytoin (Dilantin) or carbamazepine (Tegretol) are used. Diarrhea, nausea, and vomiting are common (He et al, 2006). Ensure adequate intake of folate.
- Nonsteroidal anti-inflammatory medications or narcotics may be used to reduce pain.
- Opiate-based analgesics offer the best relief. In some cases, Botox has been used.
- Baclofen may help patients eat when jaw movement tends to aggravate the symptoms.

### Herbs, Botanicals, and Supplements

- No studies have been conducted for efficacy of herbs and botanicals in TN.
- With anticonvulsants such as phenytoin (Dilantin), avoid use with evening primrose oil, ginkgo biloba, and kava.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The importance of oral and dental hygiene should be stressed, even with pain. Use pain medications as directed.
- The patient should be encouraged to avoid eating when tense or nervous.
- Relaxation therapy, yoga, tai chi, and biofeedback may be beneficial.

**Patient Education—Foodborne Illness**

- Careful food handling will be important. The same is true for hand washing.

**PSYCHIATRIC DISORDERS—EATING DISORDERS****ANOREXIA NERVOSA****NUTRITIONAL ACUITY RANKING: LEVEL 3****DEFINITIONS AND BACKGROUND**

Anorexia nervosa (AN) is an eating disorder (ED) in which the patient severely rejects food, causing extreme weight loss, low basal metabolic rate, and exhaustion. About 6–15% of the population is affected. AN is more common in girls, especially just after, peaking at 12–13 and 19–20 years of age. But AN can occur at any age.

Signs include relentless pursuit of thinness, misperception of body image, and restrained eating, binge eating, or purging (see Bulimia and Binge Eating Disorder entries). Generally, cases are separated into “restricting” or “binge-purging” types: anorectic restrictor (AN-R) and anorectic bulimics (AN-B). Fear of fatness and a codependent focus outside of one’s self are common in AN. The intense fear of becoming fat (not diminishing as weight loss progresses) has no known physical cause. Patients with EDs may have dermatologic manifestations secondary to starvation; recognition of these signs can lead to early diagnosis and treatment.

Weight is 85% or less of former weight; there is usually amenorrhea. Length of amenorrhea, estrogen exposure (age minus age at menarche minus years of amenorrhea), and body weight have independent effects on bone densities; therefore, osteopenia is common. Long-term sequelae may include Cushing’s disease and osteoporosis. Without treatment, death may occur, usually from cardiac arrhythmias.

Problems include perfectionism, denial, impulse control, manipulative behavior, trust issues, power and misinformation within the family, low tolerance for change and new situations, fear of growing up and assuming adult responsibilities. Individuals with AN are overly dependent on parents or family, obsessive-compulsive, meticulous, introverted, emotionally reserved, socially insecure, overly rigid in thinking, self-denying, and overly compliant. Individuals with AN have high constraint, constriction of affect and emotional expressiveness, abhondia and asceticism; restricting food intake becomes powerfully reinforcing because it provides a temporary respite from dysphoria (Kaye, 2009).

Because patients deny the severity of their illness, they delay seeking psychiatric treatment. Teens with ED often use subterfuge to give the impression that they are cooperating with

treatment plans, when they in fact are not. These behaviors prolong treatment and can lead to malnutrition. Group parenting education may be quite helpful (Zucker et al, 2006).

Some careers promote a thin body for success (e.g., fashion, air travel, entertainment, and athletics). Many female athletes struggle with an ED. The main concern is inadequate energy intake (Gabel, 2006). Studies suggest that individuals with AN have lower than optimal levels of polyunsaturated fatty acids (including ALA and GLA). Two or more consecutive spontaneous menses implies resumption of menses; this depends on body weight but not on body fat. Weight regain in subjects with AN is associated with an increase in serum leptin concentrations (Mauler et al, 2009). Insulin-like growth factor I (IGF-I) is a biochemical marker of malnutrition and a sensitive index of nutritional repletion in patients with EDs. Fortunately, the majority of patients with EDs make a full recovery.

Dietitians must be able to identify and refer patients with EDs. Death by suicide occurs in a disproportionate percentage of individuals with AN (Zucker et al, 2007). Yet, evidence for successful treatment is weak (Bulik et al, 2007). Tube feeding, when accepted, helps to increase weight and improve cognitive and physical functioning. Medical nutrition therapy for EDs is a specialization that requires training beyond entry level. The American Dietetic Association has recommended eight medical nutrition therapy visits by a trained professional for persons who have EDs.

**ASSESSMENT, MONITORING, AND EVALUATION****CLINICAL INDICATORS**

**Genetic Markers:** A genetic component may play a role in determining a person’s susceptibility to anorexia. Researchers are currently attempting to identify the particular gene or genes that might affect a person’s

tendency to develop this disorder. The agouti gene may play a role in AN.

### Clinical/History

Height  
Present weight  
Usual weight  
Recent weight  
Percentage of weight changes  
BMI (often <17.5)  
Weight goal/timing  
Dietary/intake history  
Bulimia or vomiting?  
Tooth erosion or decay  
Laxative or diuretic abuse?  
BP; hypotension?  
Amenorrhea  
Blotchy or yellow skin  
Lanugo hair  
Muscle wasting  
Edema  
Blood in stool?  
MRI or CT scan for ventricular enlargement from malnutrition  
DEXA (after 6 months underweight)

### EKG

Arrhythmias?  
Parental Authority Questionnaire (PAQ)  
Eating Disorders Inventory-2 (EDI-2)  
Eating Attitudes Test (EAT-26)  
Perfectionism, compulsiveness

### Lab Work

Luteinizing hormone (LH) response to gonadotropin-releasing hormone (GnRH)  
Follicle-stimulating hormone (FSH)  
IGF-I  
Serum estradiol (low)  
Serum cortisol (high)  
Urinary cortisol (high)  
Sex hormone-binding globulin (SHBG)

### Alb,

transferrin,  
N balance  
Chol (low?)  
Trig  
Gluc  
BUN (low?)  
H & H  
Serum Fe  
Thyroid-stimulating hormone (TSH)  
TLC; Leukopenia?

K<sup>+</sup> (hypokalemia?)  
Serum amylase (with vomiting)  
Serum Ca<sup>++</sup>, Mg<sup>++</sup>  
Serum phosphorus  
Liver function tests  
Leptin levels  
\*Ghrelin levels  
\* Plasma levels of ghrelin increase before meals and decrease strongly after meals.

## INTERVENTION

### OBJECTIVES

- Restore normal physiological function by correcting starvation and its associated changes, including electrolyte imbalance, bradycardia, and hypotension.
- Check weight or growth charts to determine difference and to set goals. Promote weight gain of 1–3 lb weekly (in-patient) and 0.5–1 lb weekly (outpatient) to reach a weight closer to a healthy BMI.
- Promote adequate psychotherapy and use of medications to protect the heart, fluid, and electrolytes, which are the most important.
- Obtain diet history to assess bulimia, vomiting, and use of diuretics or laxatives.
- Do not force feedings; rejection of food is part of the illness. Promote normal eating behavior instead.
- Gradually increase intake to a normal or high-energy intake to lessen likelihood of edema and other consequences of malnutrition.
- For young women, promote normal menstrual cycles. Estrogen seems to be correlated with cognitive function (Chui et al, 2008).
- Reduce preoccupation with weight and food. Erroneous perceptions of “normal” should be alleviated. Promote adequate self-esteem.
- Refer to appropriate care for psychiatric maladies and comorbid conditions, especially insulin-dependent diabetes mellitus.
- Coordinate nutrition education and counseling with the overall team plan. Table 4-14 shows how average women compare with “fashion women”; counseling will need to be adjusted according to the individual’s self-perception.

### FOOD AND NUTRITION

- Serve attractive, palatable meals in small amounts, observing food preferences. Small, frequent meals are useful. Encourage variety.
- Limit bulky foods during the early stages of treatment; GI intolerance may persist for a long time. Assure the patient that constipation will be alleviated.
- Diet should be called a “low-calorie diet for AN” to convince the patient of the counselors’ good intentions.
- According to the standards set by the APA (2005): start at 30–40 kcal/kg (about 1000–1600 kcals/d) and increase as possible. Promote weekly weight gain by gradually attaining intake of up to 70–100 kcal/kg for some patients. Weight maintenance may need to be 40–60 kcal/kg.
- Protein refeeding takes a long time. Repletion may not be complete until weight has returned to normal. Monitor for improved biochemical results (BUN, albumin).
- Monitor serum cholesterol levels; low levels have been correlated with suicidality (Favaro et al, 2004).
- While not a preferred method, use tube feeding if necessary (i.e., only if the patient weighs 40% of lower end of BMI range for normal). Nocturnal tube feeding may be especially helpful.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Harmful Beliefs About Food And Nutrition

**Assessment Data:** BMI charts and current versus desirable weight for height; body fat measurements.

**Nutrition Diagnosis (PES):** Disordered eating pattern related to complaints of being “too fat” as evidenced by current weight of 82 lb and self-limited dietary intake of 450 kcals daily on nutrient analysis.

**Intervention:** Provide meals appropriate for refeeding protocol; education and counseling about appropriate body size, weight, BMI; goal setting for self-management.

**Monitoring and Evaluation:** Improved weight and height for age; intake records; discussion about perceptions of mealtimes and eating, body image.

- Help the patient resume normal eating habits. Have the patient measure and record food intake at first; then, gradually lessen the emphasis on food.
- A “no added salt” diet may reduce fluid retention.
- It may be useful to avoid caffeine because of stimulant/diuretic effect.
- A vitamin–mineral supplement may be needed for zinc and other nutrients.

### Common Drugs Used and Potential Side Effects

- Pharmacotherapy is not always successful in AN. Olanzapine may have some benefit with reductions in depression and anxiety. Dry mouth and constipation are the most common side effects.
- Antidepressants may be prescribed; nutritional side effects should be monitored carefully. SSRIs are considered to be more effective. However, fluoxetine has failed to demonstrate protection against relapse in AN (Walsh et al, 2006).
- Antiepileptic drugs (AEDs) may be used. Carbamazepine and valproate may be effective in treating patients with AN when used to treat an associated mood or seizure disorder (McElroy et al, 2009).

### Herbs, Botanicals, and Supplements

- No specific herbs and botanical products have been used for AN in clinical trials.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Most treatments are based on consensus rather than evidence (Gowers, 2008). At this time, the evidence base is strongest for family therapy for AN (Keel and Haedt, 2008).
- The RD is uniquely qualified to provide medical nutrition therapy for the normalization of eating patterns

**TABLE 4-15** Average Woman Versus “Fashion Woman”

	Average Woman	Barbie Doll	Store Mannequin
Height	5'4"	6'0"	6'0"
Weight	145 lbs	101 lbs	Not available
Dress size	11–14	4	6
Bust	36–37"	39"	34"
Waist	29–31"	19"	23"
Hips	40–42"	33"	34"

Anorexia Nervosa and Related Eating Disorders. “Statistics: How many people have eating disorders?” <http://www.anred.com/stats.html> ANRED. 2005, accessed July 1, 2008.

and nutritional status (American Dietetic Association, 2006).

- See Table 4-15.

### Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for sanitizing work area before and after preparing tube feedings to prevent contamination. Formula companies have good information on safe handling of formula in the home and institution.

# BINGE EATING DISORDER

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### DEFINITIONS AND BACKGROUND

Food intake and energy balance are regulated by two complementary drives: the homeostatic pathway increases motivation to eat following depletion of energy stores, and the hedonic (reward-based) pathway increases the desire to consume foods that are highly palatable during periods of abundance (Lutter and Nestler, 2009). Binge eating disorder (BED) involves recurrent episodes of eating in a discrete period of time an amount of food larger than most people would eat in the same time, a sense of lack of control over the eating episodes, rapid or secretive eating, guilt, and shame. BED is far more prevalent than AN and BN. The DSM-V will make BED an official diagnosis with frequency and duration at once per week for 3 months (Wilfrey et al, 2007).

Episodes may involve three or more of the following behaviors: eating more rapidly than normal, eating until uncomfortable, eating when not physically hungry, eating these foods alone, and feeling disgusted, guilty, or depressed. Adolescent and young adult vegetarians may be at increased risk for binge eating with loss of control (Robinson-O'Brien, 2009).

Binge eating is a serious problem among a subset of the obese. Weight cycling involves weight loss followed by weight regain along with psychological distress. Chronic dieting may predispose vulnerable individuals to binge eating, alcoholism, or drug abuse.

Many individuals with this problem have a personal or parental history of substance abuse. Persons with BED tend to be depressed and overweight. A single traumatic event, several years of unusual stress or pain, an extended period of emotional pain, or a mood disorder may be involved. Regardless of actual weight, there are high degrees of psychological distress in this group of individuals (Didie and Fitzgibbon, 2005). “Clinical” perfectionism involves both the determined pursuit of self-imposed standards and extremely vulnerable self-evaluation.

Socially Prescribed Perfectionism Scale	Eating Attitudes Test (EAT-26)	Gluc Urinary acetone Chol, Trig
Parental Authority Questionnaire (PAQ)	<b>Lab Work</b>	
Eating Disorders Inventory-2 (EDI-2)	Serum cortisol (high?)	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
	BUN, Creat	

### INTERVENTION

### OBJECTIVES

- Support the individual's counseling and therapy to identify the causes of binges. Help them follow a step-wise plan using self-monitoring records; regular patterns of eating to displace binge eating; alternative behaviors to help resist urges.
- Educate about food, eating, body shape, and weight patterns. Eliminate all aspects of restrained eating.
- Develop skills for dealing with difficulties that triggered past binges. Identify and challenge problematic ways of thinking.
- Consider the origins of the binge eating problem and then evaluate family and social factors that can be changed.
- Plan for the future. Have realistic expectations and strategies ready for when problems occur.
- Encourage a return to eating that is under the control of the individual.
- Correct any imbalances that have occurred as a result of the binges (e.g., weight, electrolyte imbalances).
- Support therapy, especially if there is a dual diagnosis, such as substance abuse.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** People who have this disorder may be genetically predisposed to weigh more than the cultural ideal, so they may eat little, get hungry, and then binge in response to that hunger.

Clinical/History	% Weight changes	Binge pattern and frequency
Height	Dietary/intake history	
Weight		
BMI		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Oral Food and Beverage Intake

**Assessment Data:** Food records indicating periods of binge eating twice a week for the past 8 months.

**Nutrition Diagnoses (PES):** Excessive oral food and beverage intake related to binge episodes as evidenced by food diary and intake records showing emotional binges when under stress.

**Interventions:** Education about the hazards of purging and the benefits of eating healthy portions and nutrient-dense foods. Coordination of care with psychotherapist to manage stress through yoga, CBT, and appropriate levels of physical activity.

**Monitoring and Evaluation:** Reports of fewer episodes of binge-purge cycles; improved quality of life; weight within desirable BMI range.

## FOOD AND NUTRITION

- A balanced diet, using principles of the dietary guidelines and the Food Guide Pyramid, should be planned according to age, sex, and goals for BMI.
- A slightly higher protein intake than usual helps to reduce binge eating, provide more satiety, and lower overall food intake.
- Alter diet according to medications, therapies, medical recommendations, and interdisciplinary care plan. This may include restriction of CHO, protein, fat, sodium, or other nutrients accordingly.

### Common Drugs Used and Potential Side Effects

- Pharmacotherapy is often beneficial in addition to psychotherapy. Antidepressants may be useful; monitor their specific effects.
- Topiramate (Topamax) may be an effective BED treatment; it has mild side effects, such as weight loss, that may be desirable.
- Sibutramine significantly reduces binge eating behavior and body weight in BED.

### Herbs, Botanicals, and Supplements

- No specific herbs and botanical products have been used for binge eating in any clinical trials.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage use of a food diary to record time, place, foods eaten, cues, binge feelings, and other comments.

- Discuss exercise and its effect on sense of well-being; shopping, holidays, and stressors.
- Discuss not skipping breakfast and lunch. This may lead to bingeing late into the evening or night.
- Focus on self-efficacy and proper assertiveness for coping with stressors.

### Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for hand washing.
- Note any unusual behaviors, such as pica, and discuss food safety issues if relevant.

# BULIMIA NERVOSA

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

Adapted from: Langlais RP, Miller CS. *Color Atlas of Common Oral Diseases*. Philadelphia: Lea & Febiger, 1992.

## DEFINITIONS AND BACKGROUND

BN is an ED with food addiction as the primary coping mechanism. Criteria for diagnosis include recurrent episodes of binge eating, sense of lack of control, self-evaluation unduly influenced by weight or body shape, recurrent and inappropriate compensating behavior two times weekly for 3 months or longer (vomiting, use of laxatives or diuretics, fasting, excessive exercise). In BN, repeated binge episodes increase gastric capacity, which delays emptying, blunts cholecystokinin (CCK) release, and impairs satiety response.

Of the 5–30% of the population with bulimia, 85% are college-educated women. Weight may be normal or near-normal. When not bingeing, individuals with BN tend to be dieting; when hungry, they may binge and purge again. Their self-worth tends to be associated with thinness. The

most restrained patients with BN have the greatest desire to lose weight (Lowe et al, 2007).

Pathogenesis of BN suggests functional abnormalities within a neural system for self-regulatory control, which may contribute to binge eating and other impulsive behaviors (Marsh et al, 2009). Individuals with BN may experience loneliness, irritability, passivity, sadness, addictive behavior patterns, or suicidal behavior. Individuals with BN may shoplift, be promiscuous, and abuse alcohol, drugs, or credit cards. Disordered eating may occur for some time before drug or alcohol problems. Because disturbances in neuronal systems modulate feeding, mood, and impulse control, altered serotonin levels contribute to the disordered eating.

Significantly, the drive for thinness and body dissatisfaction relate to the patient's perception of father as "authoritarian" (Enten and Golan, 2009). Bulimics use food as a coping mechanism. Codependency is a dysfunctional pattern of relating to feelings. Individuals with BN focus on others or on things outside of themselves and deny their feelings. Fear, shame, despair, anger, rigidity, denial, and confusion are integral. Because of the low self-esteem, cognitive dysfunction, use of food or substance to relieve anxiety or depression, secretiveness, social isolation, and denial, psychotherapy is of primary importance. The team approach is best coordinated with the physician, a nutritionist, and a mental health professional.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Alterations in the serotonin (5-HT) 2A receptor are associated with behavioral impulsiveness and BN. Disturbances of 5-HT function occur when people are ill, and persist after recovery (Kaye, 2009).

<b>Clinical/History</b>	Knuckles with rough skin	Eating Disorders Inventory-2 (EDI-2)
Height	Broken blood vessels in the eye	Eating Attitudes Test (EAT-26)
Weight, current	Salivary gland swelling	<b>Lab Work</b>
Usual weight	Excessive bathroom use (to vomit)	Serum amylase (high)
BMI	Perfectionism, obsessive-compulsive-ness, dysphoria	Chol, Trig
Percentage of weight changes	Parental Authority Questionnaire (PAQ)	Gastrin
Hx of laxative and diuretic abuse		LH, FSH (may be low)
BP		Gluc
Dietary/intake history		Alb
Oral and dental concerns		Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
Tooth enamel erosion (perimolysis)		Serum cortisol
		Serum folate
		BP
		H & H

## SAMPLE NUTRITION CARE PROCESS STEPS

### Disordered Eating Pattern

**Assessment Data:** Food records; binge-purging behaviors as indicated in food diaries.

**Nutrition Diagnosis (PES):** Disordered eating pattern related to harmful belief about food and nutrition (i.e., that kcals are not available after using vomiting or use of laxatives) as evidenced by purging behaviors after a binge.

**Intervention:** Educate and counsel about food and absorption after meals, dangers of vomiting and laxatives for weight control. Counsel about stress management and coping mechanisms using biofeedback, yoga or other techniques besides use of food.

**Monitoring and Evaluation:** Improved food records; decreased use of vomiting and laxatives as a weight-control measure; improved self-esteem and quality of life.

## INTERVENTION

### OBJECTIVES

- Stabilize fluid and electrolyte imbalances.
- Individualize care plan to address weight history, dieting and binge eating episodes, purging behaviors, meal and exercise patterns.
- Promote effective weight control along with stress management. Establish a target weight in accordance with present weight, desirable BMI, reasonable time frame for recovery, and related factors. Modest energy restriction does not promote disordered eating (Wadden et al, 2004).
- Correct or prevent edema.
- Counteract lowered metabolic rate with balanced diet and exercise.
- Prevent oral health problems from vomiting and poor eating habits. About one third of persons with this condition will have erosion. Table 4-16 elaborates the oral manifestations and issues of concern in BN.

## FOOD AND NUTRITION

- Use controlled portions of a regular diet, usually with three meals and two snacks.
- Provide basal energy needs plus 300–400 calories as a beginning stage.
- Decrease sugar and alcohol intake, stressing the importance of other key nutrients. Highlight nutrient density and impact on health, appearance, and stamina.
- Encourage exercise along with diet and psychotherapy. Exercise decreases negative mood, improves EDs, and leads to more overall weight loss (Fossati et al, 2004).

## Common Drugs Used and Potential Side Effects

- The anticonvulsant Topiramate has shown good results in both binge and purge symptoms; it causes anorexic symptoms and weight loss.

**TABLE 4-16** Tips for Helping Patients with Eating Disorders (EDs)

Goal	Suggested Action
Full participation, especially in-patient	Manage anxiety disorders, which may precede onset of the ED. Patients with the binge eating/purging type of anorexia nervosa are significantly less likely to complete in-patient treatment.
Manage avoidant personality style	Persons with anorexia nervosa and avoidant personality style may discontinue therapy early.
Become an effective, independently functioning person	Convey principles rather than rigid “rules” to avoid reinforcing the patient’s compulsive rituals, preoccupation with food, and perfectionism.
Positive, regular habits	Behavioral contracting is useful.
Balanced diet	Discuss how a balanced diet affects weight goals. Encourage healthy snacks. Medical nutrition therapy and education are cornerstones of therapy.
Identify hunger cues	Discuss signs of hunger and satiety.
Positive family relationships and healthy conflict management	Family dynamics play a role. Include family members in education and counseling sessions. Conflict management, support for individuality and personal opinions, and discussion of emotions will be part of therapy.
Healthy assertiveness and self-efficacy	Codependent behavior generally is a problem. Help the individual develop healthy reconnections and assertiveness. Computer-based psychosocial counseling may be helpful (Low et al, 2006).
Address social pressure for thinness	Preventive actions during middle school years may be helpful. For older individuals, open discussion of these issues may be useful as well.
Prevent relapse, which is common	Starvation and self-imposed dieting may lead to binges once food is available. Preoccupation with food and eating, emotional lability, dysphoria, and distractibility are common.
Monitor patients who have type 1 diabetes	Monitor for poor control, bulimia, skipping meals, hypoglycemia, hyperglycemia, and complications. Eating disorders are common in type 1 DM.
Support healthy pregnancies	Successful treatment includes appropriate pattern of weight gain, decreases in bingeing and purging behaviors, and normal infant birth weight. Special guidance is needed to achieve positive fetal outcomes. Use a team approach.
Promote healthy levels of physical activity	Discuss goals for the individual. Sometimes exercise is a goal in itself; therapy may be needed to address this issue along with eating patterns. Excessive exercise and hyperactivity are common.

- Antidepressants such as sertraline may be used (O’Reardon et al, 2004). Monitor side effects such as glucose changes, dry mouth, constipation, increased BP, abdominal cramps, and weight changes. Avoid use with ma huang (ephedra), St. John’s wort, and ginkgo biloba because they may enhance the effects and cause restlessness.
- Fluoxetine can help reduce binge eating and purging behaviors (Shapiro et al, 2007).
- Laxative and diuretic abuse can cause cardiac arrest and other problems. Discourage this practice.

### Herbs, Botanicals, and Supplements

- Alternative medicines are frequently used in this population; many products are available with potentially significant toxicities, especially diet pills and diuretics.
- Ma huang (ephedra), St. John’s wort, and ginkgo biloba may enhance the effects of antidepressants and cause restlessness.
- With anticonvulsants, avoid use with evening primrose oil, ginkgo biloba, and kava.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The four elements of successful treatment in adolescents are (Kreipe and Yussman, 2003):
  - Recognizing the disorder and restoring physiological stability early in its course.
  - Establishing a trusting, therapeutic partnership with the adolescent.
  - Involving the family in treatment.
  - Using an interdisciplinary team approach.
- The combination of cognitive-behavioral therapy (CBT) with a nutritional education and a physical activity program helps to decrease depression and anxiety (Fossati et al, 2004).
- Help the patient rediscover the ability to be alone without giving in to the urge to binge. Assertiveness training may be of great benefit.
- Information, as from basic nutrition texts, can also encourage improved habits.
- Discuss the outcomes of electrolyte imbalance, such as muscle spasms, kidney problems, or cardiac arrest.
- Assert that there is “no such thing as a forbidden food.” Discuss how to handle the cycle of bulimia: hopelessness or anxiety leading to gorging, leading to fear of fatness, leading to vomiting or drug abuse, leading to release from fear, leading to guilt, etc.
- Stringent oral hygiene after vomiting may reduce dental erosion.
- Self-help groups are often beneficial.
- Table 4-17 describes other disordered eating patterns and some tips.
- Use of a biopsychosocial approach offers a means of working toward healing the whole person (Kreipe, 2006).

**TABLE 4-17 Assessment of Oral Manifestations in Bulimia Nervosa**

Condition	Issues of Concern
Enamel erosion (perimolysis)	Thermal sensitivity and pain
Salivary gland swelling (sialadenosis)	Hypertrophy from regurgitation of acidic contents; malnutrition
Dry mouth (xerostomia)	From vomiting, laxative, or diuretic abuse
Increased serum amylase	Two to four times increased levels occur after bingeing and vomiting; a marker for bulimia
Mucosal trauma	Abrasions and bleeding from rapid, forceful regurgitation
Gingival recession	From frequent and rigorous tooth brushing
Dental caries	From increased intake of junk foods, candy, sweets

**Patient Education—Foodborne Illness**

- Careful food handling and hand washing are important. If constant hand washing is a concern, referral to a mental health provider may be useful.

**MENTAL DISORDERS—OTHER****BIPOLAR DISORDER****NUTRITIONAL ACUITY RANKING: LEVEL 1–2****DEFINITIONS AND BACKGROUND**

Abnormalities in brain biochemistry and circuits are responsible for the extreme shifts in mood, energy, and functioning that characterize BD. Bipolar affective disorders are characterized by mood swings from mania (exaggerated feeling of well-being, stimulation, and grandiosity in which a person can lose touch with reality) to depression (overwhelming feelings of sadness, anxiety, and low self-worth, which can include suicidal thoughts and suicide attempts). The disorders affect men and women equally. Children are rarely diagnosed. See Table 4-18.

The old name for BD is manic-depressive illness. The spectrum involves depression with varying degrees of excitatory signs and symptoms. Genetics seem to be involved. Relatives of people with bipolar affective disorder and depression are more likely to be affected. In general, the less severe the case, the later the onset of clinically observable mood disorder.

According to the DSM-IV, BD is a severe, recurrent, life-long illness that affects up to about 7% of Americans. Lifetime prevalence rates for bipolar I and II disorder range up to 2%; for cyclothymia, a milder form of BD, prevalence

ranges from 3% to 5%. More recent prevalence estimates are even higher. The World Health Organization reports that BD is the sixth leading cause of years lived with disability, worldwide.

For doctors working in a primary care setting, it is important to recognize the signs and symptoms of BD; it is commonly misdiagnosed as unipolar depression. Patients with bipolar depression are significantly more likely to report hallucinations, current suicidal ideation, and low self-esteem than patients with unipolar depression but less likely to report disturbed appetite (Das et al, 2005; Olfson et al, 2005).

The cyclical nature of the disorder poses challenges and barriers. Mood swings significantly impair the ability to function in social situations and to hold down a job. Patients often need to take days off from work either due to worsening clinical symptoms or hospitalization. When at work, problems may result from mood episodes such as poor concentration or low motivation during depression and inappropriate behavior during mania.

In mania, a person's behavior is often reckless and self-damaging. During mania, patients may spend excessive amounts of money or may have excessive urges to drive fast.

**TABLE 4-18 Other Disordered Eating Patterns**

Disorder	Description
Anorexia athletica (compulsive exercising)	The person repeatedly exercises beyond the requirements for good health and is a fanatic about weight and diet. Not a formal diagnosis; behaviors are usually a part of anorexia nervosa, bulimia, or obsessive-compulsive disorder. Focuses on challenge and does not savor victory; proud of being an "elite athlete." Rarely satisfied with athletic achievements or performance. Needs a team approach for therapeutic intervention.
Body dysmorphic disorder (BDD)	BDD is thought to be a subtype of obsessive-compulsive disorder. It is not a variant of anorexia nervosa or bulimia nervosa. The person feels "ugly" and suffers from shyness and acts withdrawn in new situations or with unfamiliar people. Often strikes before age 18; affecting 2% of people in the United States. Sufferers are excessively concerned about appearance, in particular perceived flaws of face, hair, and skin. They are convinced these flaws exist despite reassurances from friends and family members who usually can see nothing to justify such intense worry and anxiety. High risk for despair and suicide; may undergo unnecessary expensive plastic surgery. BDD is treatable and begins with an evaluation by a physician and mental health care provider. Treatments include medication that adjusts serotonin levels in the brain and cognitive-behavioral therapy. A clinician makes the diagnosis and recommends treatment based on the needs and circumstances of each person.
Cyclic vomiting syndrome	Cycles of frequent vomiting, usually (but not always) found in children, often related to migraine headaches. Careful medical assessment is needed. Not a true eating disorder.
Eating disorders not otherwise specified (ED-NOS)	Official diagnosis describing atypical eating disorders where a person meets some but not all criteria for one specific eating disorder. Food behaviors are not normal and healthy; for example, behavior that resembles bulimia nervosa because of purging but without binge eating.
Gourmand syndrome	Person is preoccupied with fine food, including its purchase, preparation, presentation, and consumption. Exceedingly rare; thought to be caused by injury to the right side of the brain (as from tumor, concussion, or stroke). Relationship to addictions or obsessive-compulsive disorder possible. Had normal relationship with food prior to injury. Start with a neurologist evaluation.
Muscle dysmorphic disorder (bigorexia)	Sometimes called bigorexia, muscle dysmorphia is the opposite of anorexia nervosa. People with this disorder obsess about being small and undeveloped. They worry that they are too little and too frail. Even if they have good muscle mass, they believe their muscles are not big enough or are inadequate. Depression is the underlying concern. May understand the risks of steroid use but continue anyway. This condition results in disordered eating with very high protein and very low fat and often very low carbohydrate, often combined with excessive supplements.
Night eating syndrome	Affects 1–2% of general population. Likely that over one quarter of all morbidly obese persons may have this condition. This disorder is being considered for next psychiatric diagnostic classification manual. The person has little or no appetite for breakfast, delays first meal for several hours after waking up, and is often upset about how much was eaten the night before. Most calories are eaten late in the day or during the night. Sertraline, a selective serotonin reuptake inhibitor, may be beneficial in the treatment of night eating syndrome (O'Reardon et al, 2004). Psychotherapy is recommended. Self-help groups such as Overeaters Anonymous or group therapy can help.
Nocturnal sleep-related eating disorder	More of a sleep disorder than a true eating disorder. Individual eats while asleep and may sleep walk. No conscious memory of eating when they awaken again. Much guilt and confusion ensues.
Orthorexia nervosa	Eating the "right" food becomes an important, or even the primary, focus of life. One's worth or goodness is seen in terms of what one does or does not eat. Personal values, relationships, career goals, and friendships become less important than the quality and timing of what is consumed. May be a type of obsessive-compulsive disorder.
Pica	A craving for nonfood items such as dirt, clay, plaster, chalk, or paint chips. Pica may occur in pregnancy, in people whose diets are deficient in minerals found in the substances, in people with psychiatric conditions or developmental disabilities, or in people with family history of similar customs. Sometimes people who diet become hungry and ease their hunger with nonfood substances. May cause a medical emergency if obstruction or severe constipation occurs or if electrolyte imbalances occur.
Rumination syndrome	Person eats, swallows, and then regurgitates food back into the mouth where it is chewed and swallowed again. Process may be repeated several times or for several hours per episode. Process may be voluntary or involuntary. Ruminators report that regurgitated material does not taste bitter and that it is returned to the mouth with a gentle burp, not violent gagging or retching, not even nausea. Consequences range from minor inconveniences to life-threatening crises and include bad breath, indigestion, chapped lips and chin, damage to dental enamel and tissues in the mouth, aspiration pneumonia, failure to grow (children), weight loss, electrolyte imbalance, and dehydration.

From: O'Reardon RP, Stunkard AJ, 2004. Anorexia Nervosa and Related Eating Disorders, Inc., <http://www.anred.com/defslessor.html>, accessed January 18, 2005.

During the depressive phase of the illness, patients may try to self-medicate themselves with alcohol or other substances, leading to problems with abuse or dependence. A series of four or more manic or depressive episodes in 12 months is known as "rapid cycling," a condition that can be more difficult to treat. Patients with bipolar I disorder are

ill nearly half the time and have a high probability of relapse; bipolar II is more chronic, more depressive, and associated with more neuroticism and emotional instability between episodes than bipolar I (Keller, 2004).

Magnetic resonance spectroscopy imaging (MRSI) of the brains of patients (before starting medication) shows

different patterns in the chemical fingerprint in more severe cases than patients with mild-to-moderate disease. Severe BD requires more aggressive treatment. Cholesterol levels are lower during manic and depressive phases. Individuals treated with omega-3 fatty acids (in combination with their usual mood stabilizing medications) for 4 months experience fewer mood swings (Keck et al, 2006).

For treatment of resistant BD, high-dose thyroid hormones, calcium channel blockers, electroconvulsant therapy, omega-3 fatty acids, vitamin D<sub>3</sub>, and psychosocial strategies have been investigated. Comorbid conditions are almost always involved. Anxiety, substance use, and conduct disorders are the most common; overeating, hypersexuality, attention-deficit hyperactivity, impulse control, autism spectrum disorders, and Tourette's syndrome are less common (McElroy, 2004). For these "dual diagnoses," both psychotherapy and appropriate medications are important (Levin and Hennessey, 2004).

The most common medical comorbidities include migraine, thyroid illness, obesity, type 2 diabetes, cardiovascular disease, chronic fatigue syndrome, asthma, chronic bronchitis, multiple chemical sensitivities, hypertension, and gastric ulcer tend to be significantly higher in bipolar patients (McElroy, 2004; McIntyre et al, 2006). Painful physical symptoms are common. Treatment of both physical and emotional symptoms associated with mood disorders may increase a patient's chance of achieving remission; abnormalities of serotonin and noradrenaline are strongly associated (Wise et al, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** BD and severe major depression are highly heritable, but differ from single-gene (Mendelian) diseases in that they are the end products of multiple causes (Cannon and Keller, 2006).

Clinical/History	Sheehan	Alb
Height	Disability	Chol with full
Weight	Scale	profile
BMI	Clinical Global	Trig
Dietary/intake	Impression	Serum tHcy
history	Severity and	CRP
BP	Improvement	Serum Ca <sup>++</sup> ,
I & O	Scores for	Mg <sup>++</sup>
Constipation	Bipolar	Gluc
Food pica?	Disorder	Serotonin
Disordered	(CGI-BP)	Thyroid tests
eating?	DEXA scan	(T3, T4,
Bipolar		TSH)
symptoms	<b>Lab Work</b>	Na <sup>+</sup> , K <sup>+</sup>
Mood Disorder	H & H	
Questionnaire	Serum Fe	

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Intake of Certain Types of Fats

**Assessment Data:** Low serum cholesterol (LDL and HDL); cycling BD with little or no intake during manic and depressive phases; low weight for height.

**Nutrition Diagnoses (PES):** Inadequate intake of omega-3 fatty acids related to cycling BD with poor appetite and low fat intake as evidenced by total cholesterol <140 (low LDL and HDL) and BMI of 17.5.

**Interventions:** Food and nutrient delivery related to change in diet to include more omega 3 fatty acids and total kilocal. Education about the role of lipid in proper brain functioning. Counseling about healthy "brain foods" such as salmon, tuna, antioxidant foods.

**Monitoring and Evaluation:** Dietary intake records showing improved intake of omega-3 fatty acids, energy, and regular meals; BMI improving and closer to low normal (18.5).

## INTERVENTION

## OBJECTIVES

- Support efforts at maintaining a balance between nutritional intake, physical activity, medications, and well-being.
- Monitor energy intake; counsel appropriately and offer tips for reducing kilocal from meals, snacks, and beverages. Metabolic syndrome can result.
- Monitor for medical problems related to weight gain, such as low HDL and high LDL cholesterol levels, elevated triglyceride levels, hyperglycemia or diabetes, and cardiovascular problems.
- Seek stable periods that are relatively normal ("euthymia"). Reduce stress, which elevates protein kinase C levels in the brain.
- Manage comorbid conditions that occur, such as diabetes, obesity, cardiovascular disease, and thyroid disorders.
- Maintain bone density since losses are common with use of various medications.

## FOOD AND NUTRITION

- Persons with BD may need an energy-controlled diet if their medications cause weight gain or obesity. Those who eat poorly will need a change in habits to gain weight.
- Snacks that are low in energy or fat may be useful between meals. Offer suggestions on what to keep on hand.
- During episodes of depression, keep prepared meals such as frozen dinners or packaged meals on hand.
- Discuss fluid and fiber if constipation is a problem.
- Include sufficient to higher levels of calcium and vitamin D intake from diet; a multivitamin-mineral supplement may be beneficial.
- Include omega-3 fatty acids. Fish oil-enriched diets increase omega-3 fatty acids in tissue phospholipids; flax oil increases circulating 18:3ω-3, thereby presenting tissue with this EFA for further elongation and desaturation (Barcelo-Coblijn et al, 2005).

## Common Drugs Used and Potential Side Effects

- Because of the risks of treating BD with antidepressant monotherapy, physicians should assess their depressed patients for mania before prescribing antidepressants (Olfson et al, 2005).
- The APA guideline for the treatment of BD recommends optimizing individual medications before switching to combination therapy, especially preventing discontinuation of therapy because of side effects (Bowden, 2004). Depressive symptoms of BD have a more negative impact on a patient's life than manic symptoms (Gao and Calabrese, 2005).
- **New antipsychotics** are effective for acute mania, and some may ultimately prove effective in acute depression (e.g., olanzapine combined with fluoxetine, quetiapine) and maintenance (Gao and Calabrese, 2005). Some antipsychotics, particularly olanzapine, clozapine, chlorpromazine, and thioridazine, result in serious weight gain. Energy expenditure is lower in people taking atypical antipsychotics; weight management programs may need to offer 280 kcals less per day (Sharpe et al, 2005). Aripiprazole (Abilify) is effective and has fewer side effects than some of the other atypical antipsychotics (Perlis et al, 2006).
- **Mood stabilizers**, such as lithium carbonate (Lithane, Lithobid, Lithotabs) and valproate, stabilize mood by significantly decreasing the manic, hypomanic, and depressive symptoms. Lithium causes weight gain; up to 25% of lithium users become clinically obese. Lithium requires constancy in sodium intake and limits on caffeine. Metallic taste, nausea, vomiting, and diarrhea may also occur. Valproate increases testosterone levels in teenage girls and may lead to polycystic ovary syndrome; careful monitoring is needed. These medications are contraindicated in pregnancy and lactation; lithium is associated with cardiac malformations, and valproate has been associated with neural tube defects.
- **New anticonvulsants** may be useful for aspects of BDs. Lamotrigine is used for maintenance or for acute bipolar depression. Compared with lithium and divalproex, lamotrigine is more effective in preventing bipolar depression (Gao and Calabrese, 2005). Topiramate may be used for problems related to obesity, bulimia, alcohol dependence, and migraine.
- **Multinutrient combinations** of vitamins, minerals, herbals, and the omega-3 fatty acids eicosapentaenoic acid (EPA) and DHA have been found to be somewhat effective (Kidd, 2004). Pramipexole, a dopamine D2/D3 receptor agonist, and omega-3 fatty acids are used to augment mood stabilizers and are excellent in reducing depressive symptoms (Gao and Calabrese, 2005).
- Treatment of comorbid conditions may include use of gabapentin for anxiety or pain and zonisamide for obesity.
- **Medicines that can cause mania** include: amphetamines, Antabuse, anticholinergics, baclofen, benzotropine, bromocriptine, bupropion, captopril, cimetidine, corticosteroids, cyclosporine, hydralazine, isoniazid, levodopa, MAOIs such as Nardil or Parnate, Ritalin, Synthroid, opioids, procarbazine, and yohimbe.
- **Medicines that can cause depression** include: acyclovir, alcohol, anticonvulsants, asparaginase, baclofen, barbiturates, benzodiazepines, beta-blockers, bromocriptine,

calcium channel blockers, corticosteroids, cycloserine, dapsone, estrogens, fluoroquinolone, histamine H<sub>2</sub>-receptor antagonists, interferon, isotretinoin, mefloquine, methyl-dopa, metoclopramide, narcotics, progestins, statins, sulfonamides.

## Herbs, Botanicals, and Supplements

- Ginger, licorice, purslane, rosemary, and ginseng have been suggested; no clinical trials have proven efficacy in BDs.
- Ginseng and yohimbe should not be used with MAO inhibitors.
- Ginkgo biloba interacts with anticoagulants and antiplatelets such as aspirin, warfarin, and dipyridamole.
- L-tryptophan may be tried for insomnia or depression. Do not use with MAO inhibitors, SSRI antidepressants, or serotonin receptor antagonists.
- Ma huang (ephedra) and kava should not be taken by patients with depression.
- Omega-3 fatty acids have a benefit in managing depression. Supplementation may improve symptoms of depression in children and BD in adults; 360 mg/d EPA and 1560 mg/d DHA for 6 weeks show good results (Clayton et al, 2009).
- Psyllium and ginseng should not be used with divalproex or lithium.
- St. John's wort is used as a natural antidepressant. Do not use with MAO inhibitors, SSRI antidepressants, cyclosporine, digoxin, oral contraceptives, HIV protease inhibitors, theophylline, warfarin, or calcium channel blockers such as amlodipine, diltiazem, or verapamil.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach creative menu planning and food preparation methods that address the side effects and symptoms the patient is experiencing.
- Teach the patient how to moisten foods for dry mouth syndrome resulting from certain medications. Sugar-free candy may help.
- Limit caffeine-containing foods and beverages in the late evening to improve sleep.
- Individuals who are prone to bouts of depression or mania may find it difficult to eat properly. Simple meals and snacks should be readily available.
- Since there is a higher risk for suicide, individuals with BD should be carefully monitored for signs of severe depression and should seek help from a mental health professional immediately.
- Functional outcomes are reliable measure of response to treatment. Changes in circadian rhythm and sleep patterns may predict onset of relapse. Patients and families may benefit from education and therapy.

## Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for hand washing.

## DEPRESSION

### NUTRITIONAL ACUITY RANKING: LEVEL 1 (MILD); LEVEL 2 (NUMEROUS MEDICATIONS)

#### DEFINITIONS AND BACKGROUND

Depression involves changes in body chemistry (neurotransmitters) because of genetics or after a traumatic event, hormonal changes, altered health habits, the presence of another illness, or substance abuse. Persons with major depressive disorder (MDD) have had at least one major depressive episode over a 14-day period or longer. It may be recurrent throughout their lives. MDD is debilitating and has a high morbidity rate (Farah, 2009).

The lifetime risk for depression is 10–25% in women, 5–12% in men (Fava, 2007). Depression frequently develops between the ages of 25 and 44. Approximately 20 million adult Americans experience depression every day. Diagnosis of depression is indicated by four of eight of the following symptoms: SIGECAPS—Sleep changes, loss of Interest, inappropriate Guilt (hopelessness), Energy decline, Concentration changes, Appetite changes, Psychomotor changes, and Suicidal tendencies. In addition, prolonged sadness and unexplained crying spells, chronic irritability and agitation or anxiety, chronic pessimism or indifference, indecisiveness, social withdrawal, and unexplained aches and pains may also be present.

Folate seems to have a causal relationship in depression (Lewis et al, 2006). When there are lower red blood cell folate levels, episodes of depression are longer and more severe (Fava, 2007). Deplin® contains 7.5 mg L-methylfolate and may help in managing depressive episodes. It unmasks

vitamin B<sub>12</sub> anemia whereas folic acid masks vitamin B<sub>12</sub> anemia. After 4-week trials of Deplin®, if patients are not feeling better, psychiatrists often recommend doubling the dose to 15 mg/d (Zajacka, 2007).

Depression is a leading cause of disability in the United States. Careful assessment is needed to determine the specific type of depression and its most effective treatments. **Dysthymia** is a chronic, moderate type of depression expressed as poor appetite or overeating, insomnia or oversleeping, low energy, fatigue, irritability, and high stress. Children and teens who experience depression may experience frequent headaches and absences from school. Men often mask signs of depression by working long hours or drinking too much. Women may have depression during times of hormonal change (menstruation, pregnancy, miscarriage, the postpartum period, and menopause). **Postpartum depression** negatively affects both mother and child; early detection and treatment are needed.

Older individuals may experience depression along with a chronic disease such as heart disease, diabetes, or hypertension. CRP tends to be elevated in depression and may contribute to heart disease (Ford and Erlinger, 2004). Elevated tHcy levels should be treated. In nursing homes, it is expected that about 50% of individuals will have some form of depression for which medication should be prescribed.

Many persons with depression have a deficiency of brain serotonin. A mixed diet of protein/CHO should provide tryptophan, a precursor of serotonin. Intake of dietary protein

high in tryptophan increases the ratio of tryptophan to large neutral amino acids (LNAA). Antidepressants that are serotonin reuptake modulators actually promote growth of serotonin innervation in the forebrain (Zhou et al, 2006). Painful physical symptoms commonly exist comorbid with depressive disorders; abnormalities of serotonin and norepinephrine are strongly associated and play a role in pain perception (Wise et al, 2005).

Psychotherapy can change brain chemistry after cognitive restructuring. For some persons for whom medications and therapy are not effective, electroconvulsive therapy (ECT) may also be helpful. A pacemaker-like device that sends electrical stimulations into the vagus nerve of the neck may help to alleviate depressive symptoms. And, recent studies show that vitamin D is an important component for alleviating depression. SAD increases with latitude, so vitamin D and sunlight or light therapy may be beneficial.

Monitoring physical health, including nutrition, is an important adjunct to medication or psychotherapy. Adequate intake of the omega-3 fatty acids may reduce depression (Casper, 2004). The omega-3 fatty acids are important components of nerve cell membranes and help nerve cells communicate with each other. In medicated patients, added treatment with omega-3 fatty acids, particularly EPA, may ameliorate symptoms of MDD (Casper, 2004). Finally, use of fresh versus highly processed foods should be considered. A highly processed food dietary pattern is a risk factor for depression years later, whereas a whole food pattern is protective (Akbaraly et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** About 40% of risk for major depression is inherited; 60% is from environmental factors such as substance abuse. Multiple genes play a role in depression (Psychiatric GWAS Consortium, 2009). Individuals with the C>T type of MTHFR allele are at high risk for depression (Almeida et al, 2008). Testing for MTHFR levels and augmenting therapy with methylfolate and omega-3 fatty acids is suggested (Fava, 2007; Shelton, 2007). Research has identified some genetic mutations found only in women, related to female hormone regulation; these biological differences are being clarified.

<b>Clinical/History</b>	Constipation	Thyroid tests
Height	DEXA scan	(T3, T4, TSH)

BP	Alb	Serum folate
Food pica	Ca <sup>++</sup> , Mg <sup>++</sup>	and B <sub>12</sub>
I & O	Gluc	CRP
	Serotonin	

## SAMPLE NUTRITION CARE PROCESS STEPS

### Altered Nutrient Utilization

**Assessment Data:** Altered methyltetrahydrofolate reductase (MTHFR) with C>T allele; signs of severe depression with insomnia and poor dietary intake; elevated tHcy levels.

**Nutrition Diagnoses (PES):** Altered nutrient utilization of folate related to MTHFR allele as evidenced by lab test, diagnosis of MDD, and poor intake from oral diet.

**Interventions:** Education about the role of folate in depression; discussion about genetics and how the C>T allele can aggravate depression. Counseling about use of L-methylfolate and dietary sources of folate, vitamins B<sub>6</sub> and B<sub>12</sub>.

**Monitoring and Evaluation:** Improved lab results for tHcy; fewer episodes of prolonged depression; improved quality of life.

## INTERVENTION

### OBJECTIVES

- Provide adequate nutritional intake (e.g., excessive weight loss or shock therapy requires increased energy intake). Monitor weight at least twice monthly to evaluate status and changes.
- Assess usual eating habits and related problems, which may include loneliness, difficulty in activities of daily living, boredom, lack of hobbies and interests, and poor sleep habits. Adequate drug therapy usually helps appetite improve.
- Monitor for consequences from certain antidepressants, such as weight gain.
- Assure adequate intake of amino acids, omega-3 fatty acids, folic acid, vitamins D<sub>3</sub> and B<sub>12</sub>.
- Reduce stress, which elevates protein kinase C levels in the brain.

## FOOD AND NUTRITION

- Use a diet providing high-quality protein. Inadequate protein intake may reflect decreased intake of iron, thiamine, riboflavin, niacin, and vitamins B<sub>6</sub> and B<sub>12</sub> as well.
- Increase intake of omega-3 fatty acids and uridine from foods such as fish, walnuts, molasses, and sugar beets (Carlezon et al, 2005). Supplements may also be used, but dietary change is beneficial.
- Low serum folate is common in many depressed adults, especially women (Ramos et al, 2004; Tolmunen et al, 2004). Intake of 400 µg is needed daily. Use L-methylfolate where MTHFR alleles have been identified.
- Vitamin D<sub>3</sub> and calcium should be supplemented (Mussolino et al, 2004; Payne et al, 2008).
- If serum tHcy levels are high, include vitamins B<sub>6</sub> and B<sub>12</sub> in addition to folate.
- Use a tyramine-restricted diet for patients given MAOI drugs. Such a diet excludes aged cheese, beer, red wine, ale, chicken livers, broad bean pods, sausage, salami,

pepperoni, commercial gravies, ripe avocado, fermented soy sauce, and pickled or smoked herring.

- If overeating, limit access to food and provide low-calorie diet information.
- Encourage increased physical activity, which often helps to lift depressed moods.
- Sometimes a craving for carbohydrates occurs; monitor if weight gain is a problem or if overall nutrient density decreases.
- Liquid supplements may be useful when preparing meals seems overwhelming.
- TPN is not advised for patients who are suicidal.

### Common Drugs Used and Potential Side Effects

- SSRIs and TCAs do not always provide symptom relief. Yet, the SSRIs increase the density of nerve-impulse carrying axons in the brain, thus rewiring the neocortex and limbic system (Zhou et al, 2006). Their use may be more beneficial than previously anticipated.
- Some serotonergic antidepressants (e.g., fluoxetine, Prozac) can reduce hyperglycemia, normalize glucose homeostasis, and increase insulin sensitivity, whereas some noradrenergic antidepressants (e.g., desipramine) exert opposite effects (McIntyre et al, 2006).
- L-methylfolate may be needed to help alleviate depression (Mischoulon and Raab, 2007; Stahl, 2007).
- See Table 4-19 for more details.

### Herbs, Botanicals, and Supplements

- Ginseng and yohimbe should not be used with MAO inhibitors.
- Licorice, ginger, purslane, rosemary, and ginseng have been suggested for depression; no clinical trials prove efficacy.
- L-tryptophan may be tried for insomnia or depression. Do not use with MAO inhibitors, SSRI antidepressants, or serotonin receptor antagonists.
- Ma huang (ephedra) and kava should not be used with antidepressants.
- Omega-3 fatty acids (EPA and DHA) may be taken in capsule form; usually 1000 mg several times a day will be needed.
- St. John's wort is used as a natural antidepressant. Do not use with MAO inhibitors, SSRI antidepressants, cyclosporine, digoxin, oral contraceptives, HIV protease inhibitors, theophylline, warfarin, or calcium channel blockers such as amlodipine, diltiazem, or verapamil.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage full involvement with psychotherapy, CBT, or interpersonal therapy (IPT). These are helpful adjuncts for medication. Hopefulness and resilience are also important.

**TABLE 4-19 The Bipolar Spectrum and Symptoms**

Bipolar type I	Depression and varying degrees of excitatory signs and symptoms up to full mania	Onset during teens and early adulthood; 60% will have problems with substance abuse
Bipolar type II	Discrete hypomanic episodes; may appear to have just depression, but mood stabilizers seem to help more than antidepressants	50% will have problems with substance abuse
Bipolar type III	Hypomania associated with antidepressants and/or psychostimulants	
Bipolar type IV	Hyperthymic temperament	Onset during 4th or 5th decade of life
Bipolar type V	Recurrent depressions without discrete irritability, hypomania, but mixed hypomanic episodes with agitation, and racing thoughts during depression	
Bipolar type VI	Alzheimer's type	Onset in the 6th or 7th decade
Manic symptoms	Severe changes in mood, either extremely irritable or overly silly and elated Overly inflated self-esteem, grandiosity Increased energy Decreased need for sleep, ability to go with very little or no sleep for days without tiring Increased talking, talks too much, too fast; changes topics too quickly; cannot be interrupted Distractibility, attention moves constantly from one thing to the next Hypersexuality, increased sexual thoughts, feelings, or behaviors; use of explicit sexual language Increased goal-directed activity or physical agitation Disregard of risk, excessive involvement in risky behaviors or activities	
Depressive symptoms	Persistent sad or irritable mood Loss of interest in activities once enjoyed Significant change in appetite or body weight Difficulty sleeping or oversleeping Physical agitation or slowing Loss of energy Feelings of worthlessness or inappropriate guilt Difficulty concentrating Recurrent thoughts of death or suicide	

- Teach creative menu planning and food preparation methods that address the side effects and symptoms the patient is experiencing.
- Promote the use of whole foods (fruits, vegetables, fish) and discourage processed foods (fried foods, sweetened desserts, processed meats; Akbarahly et al, 2009).
- Teach the patient how to moisten foods for dry mouth syndrome resulting from certain medications. Sugar-free candy may help.
- Promote exercise, which seems to help reduce symptoms of depression. Teens may be especially vulnerable to depression, and exercise may help improve other health-related behaviors, including eating better (Fulkerson et al, 2004).
- Limit caffeine-containing foods and beverages in the late evening to promote better sleep.
- Nicotine dependence and major depression are often related; treat mutually (Manley et al, 2009).
- After giving birth, postpartum “blues,” postpartum depression, or postpartum psychosis may occur. Maternal depression in the perinatal period may lead to poor growth for infants (Rahman et al, 2004). Education is needed for new mothers.
- In the elderly, “failure to thrive” usually includes impaired physical function, malnutrition, depression, and cognitive impairment (Robertson and Montagnini, 2004). Treatment of depression may help to improve appetite. Adding breakfast to homebound meals is a good start (Gollub and Weddle, 2004).

### Patient Education—Foodborne Illness

- Careful food handling will be important. The same is true for hand washing.

# SCHIZOPHRENIA

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

Adapted from: Gottesman, 1991, p. 96.

### DEFINITIONS AND BACKGROUND

**SCZ** is a group of disorders manifested by disordered thinking, hallucinations, delusions, apathy, social withdrawal, and mood or behavioral disturbances (delusional, catatonic, or paranoid). In the resulting psychosis, the individual loses contact with reality. SCZ has a heritability estimated at 73–90% (International Schizophrenia Consortium, 2008).

SCZ can be either episodic or chronic. When patients are at risk of self-harm or harm to others, hospital treatment is appropriate. Delusions may involve control, persecution, grandiosity, or abnormal fears. Hallucinations are perceptions of an external stimulus without a source in the external world.

Nearly 1% of the population develops SCZ, with onset generally between ages 15 and 25 years (earlier in males). SCZ has been thought to have a genetic component and is associated with reduced dopamine signaling and executive function impairment (Roffman et al, 2007). However, there are many structural DNA copy number variants (CNVs) in the brains of individuals with SCZ; these rare deleterious variants may be more important in SCZ predisposition than common polymorphisms (Need et al, 2009).

Molecular mechanisms critical for adolescent brain development are disturbed in SCZ patients from genes associated with energy metabolism and protein and lipid synthesis (Harris et al, 2009). Oxidative stress, oxidative injury, and abnormal membrane phospholipid metabolism suggest that PUFA fatty acid depletion occurs (duBois et al, 2005). Similar to diabetes, conversion of ALA to EPA or DHA is inefficient in SCZ. Supplementation with antioxidants and omega-3 fatty acids is

recommended. Otherwise, effective serum lipid control is difficult to attain (Weiss et al, 2006).

Low vitamin D availability during brain development interacts with susceptibility genes to alter brain development. Vitamin D supplementation during the first year of life is important, especially in families with a history of SCZ.

Folate, cobalamin (B<sub>12</sub>), tHcy, and MTHFR polymorphisms are also found in SCZ. Patients with SCZ who have the MTHFR A>C genotype have a slight correlation with positive symptoms such as hallucinations and hearing voices, whereas the C>T allele promotes negative symptoms (depression, dysthymia) but actually protects against positive symptoms (Roffman et al, 2007; Zintzaras, 2006). Both folate and cobalamin deficiencies should be identified (Miller, 2008). Supplementation with S-adenosylmethionine (SAM) may be useful (Frankenburg, 2007; Gilbody et al, 2007).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** No single gene has been identified. Reelin (a secretory protease that manages neuronal migration, dopamine signaling, and synaptogenesis) is heavily methylated in SCZ (Guidotti et al, 2009; Roffman et al, 2007; Suzuki et al, 2008). Viral infections

reduce reelin levels and may trigger SCZ. If the reelin-VLDLR/ApoER2 signaling pathway is significant, peripheral VLDLR mRNA levels may be biological markers of SCZ (Suzuki et al, 2008). Other susceptibility genes are neuregulin 1 (NRG1); DISC-1 genes (Lipska et al, 2006); catechol-O-methyltransferase (COMT) for dopamine transmission (Roffman et al, 2008; Woodward et al, 2007); and the potassium channel KCNH2 gene, for neuronal firing and higher mental functions (Huffaker et al, 2009).

MTHFR alleles promote some symptoms seen in SCZ (Roffman et al, 2007) and the tryptophan-serotonin pathway has been implicated from 5-HTT gene polymorphic variants. SCZ patients may have large deletions on chromosome 15q13.3 and 1q21.1 (International Schizophrenia Consortium, 2008). However, very few SCZ patients share identical genetic alterations; this complicates efforts to personalize treatment regimens (International Schizophrenia Consortium, 2008; Need et al, 2009).

<b>Clinical/History</b>	Asociality	Creatine phosphokinase (CPK)
Height	Anhedonia	(elevated in acute episodes)
Weight	Heightened emotionality to stress	Chol (total profile)
Weight changes	Disorganized speech and thought disorder	Trig
BMI	EEG and brainwave patterns	Alb,
Dietary/intake history	MRI with hippocampus reduction (Velakoulis et al, 2006)	transferritin
I & O	PET scans	Na <sup>+</sup> , K <sup>+</sup>
BP		H & H
Global Assessment of Functioning Scale (GAF)		Serum Fe
Positive and Negative Syndrome Scale (PANSS)		tHcy
Delusions, auditory hallucinations		Methylmalonic acid
Blunted speech		MTHFR polymorphisms
Flat affect		Serum folate and B <sub>12</sub>
Lack of motivation		CRP
		Serum insulin
		Serum D <sub>3</sub>
		Ca <sup>++</sup> , Mg <sup>++</sup>

#### Lab Work

## INTERVENTION

### OBJECTIVES

- Develop a trusting relationship; make expectations clear to the patient.
- Provide adequate nourishment to prevent significant weight changes; gain is common with many antipsychotic medications.
- Correct any nutritional deficits in folate, vitamins B<sub>6</sub> and B<sub>12</sub>, and vitamin D. Use L-methylfolate with MTHFR alleles.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Poor Food Choices

**Assessment Data:** Food records indicating poor intake; weight gain; elevated serum LDL and triglycerides; hypertension; high waist circumference.

**Nutrition Diagnoses (PES):** Poor food choices related to regular intake of high fat, fast foods and few fruits and vegetables as evidenced by weight gain while on antipsychotics, BP of 170/95, LDL 190, triglycerides 300, waist circumference 42 and BMI 32.

**Interventions:** Education about better food choices to lower serum lipids and BP; importance of managing weight and health status to prevent cardiovascular disease. Counseling about regular mealtimes, ways to increase fiber, antioxidant-rich fruit and vegetable intake. Use motivational interviewing.

**Monitoring and Evaluation:** Improved weight status (lower BMI, waist circumference); lipids closer to normal for age and sex; no further weight gain with medicines; better food choices as indicated on food records.

- Promote a normal pattern of dietary intake and exercise routines.
- Prevent or correct constipation or impaction.
- Manage diabetes and coronary heart disease, which tend to be common and often under-diagnosed (Henderson, 2005). Metabolic syndrome is—two to four times higher in SCZ than in the general population (Ellingrod et al, 2008; McEvoy et al, 2005). Both decreased MTHFR activity (in C>T allele carriers) and elevated tHcy can increase risk of cardiovascular disease (Ellingrod et al, 2008).
- Reduce stress, which increases protein kinase C in the brain, increases forgetfulness, and speeds up the aging process.

## FOOD AND NUTRITION

- A balanced diet for age and sex should be used. Reduce sugars and saturated fats if diabetes or metabolic syndrome are present.
- Adjust calories according to goal weight for patient and medications.
- Reduce potential accidents by avoiding glass containers and serving dishes.
- Vitamins C, D, B<sub>6</sub>, and B<sub>12</sub>, folate, and selenium levels may be low in persons with SCZ; encourage improved intake accordingly.
- Highlight the use of antioxidant-rich foods (berries, nuts, green tea) and omega-3 fatty acids (salmon, tuna, sardines).
- Suggest use of the DASH diet if BP is high.

## Common Drugs Used and Potential Side Effects

- Some drugs can cause psychiatric symptoms. Anxiety, mania, hallucinations, suicidal thoughts, and bizarre

behavior may result from various medications, and a doctor should be contacted if these occur:

Confusion: acyclovir, propoxyphene (Darvon), and cimetidine (Tagamet)

Depression: oral contraceptives, ibuprofen, metronidazole (Flagyl), barbiturates, cimetidine, and diazepam (Valium)

Excitement or agitation: alprazolam, amphetamines, barbiturates, metronidazole, and diazepam  
Insomnia: acyclovir and alprazolam

Paranoia: amphetamines, cannabis, ibuprofen, cimetidine, and TCAs

- Try offering a beverage or snack to reduce anxiety before adding new medications (Ativan, Xanax, Klonopin, Paxil).
- To reduce hypermethylation of GABAergic promoters, COX-2 inhibitors or valproate may be used along with atypical antipsychotics (Table 4-20).
- What works for one person may not work for another. See Table 4-21 for more guidance on medications.

### Herbs, Botanicals, and Supplements

- Ginseng should not be used with CNS stimulants, caffeine, hormones, steroids, antipsychotics, MAO inhibitors, lithium.
- Ginkgo biloba interacts with anticoagulants and antiplatelets such as aspirin, warfarin, and dipyridamole.
- Indian snakeroot is used for mental illness in some cultures. Do not use with digoxin, phenobarbital, levodopa, albuterol, furosemide, thiazide diuretics, MAO inhibitors, beta-blockers such as atenolol or propranolol, or tranquilizers. Problems include potential sedation, increased BP, arrhythmias, and CNS excitation.

- Kava and valerian should not be taken with anxiety-reducing drugs (e.g., alprazolam, diazepam, lorazepam).
- Tryptophan metabolism may be altered by proinflammatory cytokines; this affects serotonin production and functioning. If L-tryptophan is taken, avoid use with MAO inhibitors, SSRI antidepressants, or serotonin receptor antagonists. Deaths have been related to the use of L-tryptophan in the past.
- Ma huang (ephedra) and kava should not be taken in patients with depression.
- Psyllium should not be used with divalproex or lithium.
- St. John's wort should not be used with MAO inhibitors, SSRI antidepressants, cyclosporine, digoxin, oral contraceptives, HIV protease inhibitors, theophylline, warfarin, or calcium channel blockers such as amlodipine, diltiazem, or verapamil.
- Yohimbe should not be used with MAO inhibitors.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach nutrition principles to the patient or the caregiver.
- Encourage self-care. Successfully terminate client relationship when independence is possible.
- Provide follow-up, especially with regression. If daily medications are a problem, monthly injectable medications may be useful.
- Trauma, pain, endocrine disorders, infection, and metabolic disorders may cause agitation (Marco and Vaughan, 2005). A quiet environment is needed, especially for meals.
- Weight gain is common (Patel et al, 2009). Weight loss programs, cholesterol-lowering (TLC) plans, or the DASH diet may be needed.

**TABLE 4-20 Antipsychotic Medications and Possible Side Effects**

Medication	Side Effects
Tranquilizers	Triavil combines an antidepressant with a tranquilizer. Nausea, diarrhea, and vomiting may result.
Typical antipsychotics: clozapine (Clozaril), butyrophenone (Haldol), thiothixene (Navane)	May cause dizziness, drowsiness, dry mouth, weight gain, edema, nausea, constipation, or vomiting. They help to quiet symptoms and help when the patient is resistant to other drugs and alternatives.
Phenothiazines: perphenazine (Trilafon), fluphenazine (Prolixin), prochlorperazine (Compazine), chlorpromazine (Thorazine)	Chlorpromazine (Thorazine) contains sulfites. It may cause dry mouth, constipation, and weight gain.
Atypical antipsychotics (aAPs): aripiprazole (Abilify), quetiapine (Seroquel), risperidone (Risperdal), olanzapine (Zyprexa), ziprasidone (Geodon)	<p>The phospholipids in the neuronal membranes of the brain are rich in highly unsaturated essential fatty acids (EFAs). With a beneficial effect on dyskinesia as well, EPA is an effective adjunct to antipsychotics.</p> <p>Aripiprazole exhibits high affinity for dopamine, serotonin, and histamine receptors. Ziprasidone is not as likely to cause weight gain as some other antipsychotics. Olanzapine performs modestly better than most other medications, but weight gain can be significant. Long-acting risperidone injection may increase adherence and lead to improved clinical and economic outcomes for individuals with schizophrenia (Edwards et al, 2005).</p> <p>Typical doses may be: olanzapine (schizophrenia: 15 mg; mania: 20 mg); quetiapine (schizophrenia: 750 mg; mania: 800 mg); ziprasidone (schizophrenia and mania: 160 mg); aripiprazole (schizophrenia and mania: 30 mg).</p>
SSRIs and obsessive-compulsive disorder medications	Prozac, Anafranil, Luvox, and Zoloft have been used with some success. Avoid use with ma huang (ephedra) and St. John's wort. Fluvoxamine (Luvox) is an SSRI that may cause anorexia, dry mouth, nausea, diarrhea, and constipation.

**TABLE 4-21 Medications for Depression and Mood Disorders and Possible Side Effects**

Medication	Side Effects
Dual-mechanism antidepressants: Cymbalta (duloxetine), Effexor (venlafaxine)	Approved for the treatment of major depressive disorder in 2004, these are serotonin and norepinephrine reuptake inhibitors. Dual-mechanism antidepressants do not appear to disrupt glucose homeostatic dynamics. Brain-derived neurotrophic factor, which is increased with antidepressant treatment, appears to influence regulation of mood and perception of pain; evidence indicates that dual-acting agents may have an advantage in modulating pain over those agents that increase either serotonin or noradrenaline alone (Wise et al, 2005).
Other antidepressants	Clomipramine (Anafranil) is used in obsessive-compulsive disorders. Dry mouth is common; hard sugarless candy or chewing gum may be useful. Anorexia and abdominal pain are also common. Norpramin (desipramine) may cause abdominal cramps, altered blood glucose levels, and vomiting. Avoid use with ma huang (ephedra), St. John's wort, and ginkgo biloba. Nortriptyline (Aventyl, Pamelor) may cause increased appetite for sweets, GI distress, vomiting, and diarrhea. Wellbutrin (bupropion) tends to have a stimulating effect but may also cause weight loss, dry mouth, nausea, and vomiting. It may be used to help with smoking cessation.
Monoamine oxidase inhibitors: Parnate (tranylcypromine), Nardil (phenelzine), Marplan (isocarboxazid)	Nonselective hydrazine monoamine oxidase inhibitors (e.g., phenelzine) are associated with hypoglycemia and an increased glucose disposal rate (McIntyre et al, 2006). Tyramine is a pressor amine. Tyramine-restricted diet to prevent hypertensive crisis: spoiled, overripe, and aged products are the most problematic. Beware of Chianti wines, beer, fava beans, and sauerkraut. Constipation, weight gain, and GI distress are common side effects. Avoid ginseng, L-tryptophan, yohimbe, St. John's wort, kava, and ma huang (ephedra).
SAME (S-5-adenosyl-methionine)	Useful for mild depression but may trigger coronary problems. A positive side effect is that it may actually help with degenerative joint disease symptoms.
Selective serotonin reuptake inhibitors (SSRIs): Paxil (paroxetine), Prozac (fluoxetine), Zoloft (sertraline)	May cause abdominal pain, anorexia, diarrhea, and weight changes; SSRIs are used to treat despair and helplessness. Prozac may also cause nausea, vomiting, glucose changes, and decreased sodium. Do not use in pregnancy; neurobehavioral effects have been noted in otherwise healthy infants. Fetal exposure to a mother's antidepressants during pregnancy may leave her newborn in withdrawal, known as neonatal abstinence syndrome (Levinson-Castiel et al, 2006). Zoloft can cause dry mouth and diarrhea; avoid use with St. John's wort and ma huang (ephedra).
Tranquilizers, benzodiazepines: Halcion (triazolam), Versed (midazolam), Serax (oxazepam), Librium (chlordiazepoxide), Xanax (alprazolam), Restoril (temazepam), Ativan (lorazepam), Klonopin (clonazepam), Tranxene (clorazepate) Valium (diazepam), Dalmane (flurazepam)	The main use of the short-acting benzodiazepines is in insomnia, while anxiety responds better to medium- to long-acting substances that will be required all day. Benzodiazepines may cause either weight loss or gain and GI distress. Avoid use with sedatives or chamomile. Increased thirst is common.
Tricyclic antidepressants: Tofranil (imipramine), Elavil (amitriptyline), Asendin (amoxapine), Doxepin (sinequan)	May cause dry mouth, increase in appetite, weight gain, nausea, vomiting, syndrome of inappropriate antidiuretic hormone (SIADH), constipation, anorexia, or stomatitis.

- Osteoporosis may be a problem with long-term medication use; monitor carefully (Hummer et al, 2005).
- Breastfeeding mothers should avoid use of medications as much as possible. Should psychiatric medication be necessary, available information regarding the effects of these medications on the infant should be provided.
- Nicotine addiction is much higher in the SCZ population. Cigarette smoke contains many pro-oxidants that contribute directly to oxidative stress. Support efforts to quit, but make sure the patient is aware that psychotic symptoms may be heightened during that time.
- Substance abuse reduces the effectiveness of treatment; amphetamines, cocaine, PCP, and marijuana may make the symptoms of SCZ worse.

### **Patient Education—Foodborne Illness**

- Careful food handling will be important. The same is true for hand washing.

## SLEEP AND CIRCADIAN RHYTHM DISORDERS

## NUTRITIONAL ACUITY RANKING: LEVEL 1

## DEFINITIONS AND BACKGROUND

Primary insomnia is described as difficulty getting to sleep or staying asleep over a time period of at least one month; it occurs in 10% of the population. This equals about 70 million people. The prevalence of insomnia is high among older adults; 44% of older persons experience nighttime symptoms of insomnia at least a few nights per week (National Sleep Foundation, 2009).

Circadian rhythm sleep disorders have wake-sleep cycles differ from the typical pattern. Delayed sleep phase syndrome involves a longer time to get to sleep with periods of alertness during the night. The irregular sleep-wake pattern causes the individual to sleep at irregular times, with wakefulness at night and naps during the day. Other sleep disorders include sleep apnea, where breathing is interrupted during sleep, daytime sleepiness (narcolepsy), and restless legs syndrome.

Sleep affects energy balance. Short sleep duration may be related to high BP, depression and obesity in children and teens (Javaheri et al, 2008; Landhuis et al, 2008; Liem et al, 2008; Shaikh et al, 2008).

MT is an indole formed from L-tryptophan that plays a major role in sleep and circadian rhythm (Konturek et al, 2007).

MT is produced primarily in the GI tract, but it is also found in the pineal gland, retina, lens, bone marrow, and

skin (Pandi-Perumal et al, 2008). Its production increases with darkness and drops again with light, including artificial lighting. Production also decreases with age.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Sleep disorders with an established genetic basis include fatal familial insomnia, familial advanced sleep-phase syndrome, chronic primary insomnia, and narcolepsy with cataplexy. Recent gene association studies have identified multiple gene mutations in several other sleep disorders.

Clinical/History	EEG	(NREM)
Height	EMG	sleep
Weight	Wake (W),	Rapid eye movement (REM)
BMI	nonrapid eye	sleep
Obesity?	movement	

BP	<b>Lab Work</b>	Gluc
Loud snoring?	Ca <sup>++</sup> , Mg <sup>++</sup>	Chol (total
Restless leg syndrome	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>	profile)
Depression or anxiety	H & H	
	Serum Fe	

## INTERVENTION

### OBJECTIVES

- Improve nutritional status and outcome.
- Calculate energy requirements and promote a weight loss program if obesity is a problem.
- Manage intake of bioactive substances that affect sleep (i.e., caffeine, alcohol).
- Teach principles related to good health: balanced diet without excessive energy intake, adequate physical activity, routine sleeping habits.

### FOOD AND NUTRITION

- Adequate intake of thiamin and other B-complex vitamins, zinc, protein, vitamin A, and any other depleted nutrients will be important.
- An energy controlled plan may be needed. The DASH diet may also be beneficial with hypertension.
- Limit caffeine and alcohol, especially later in the evening.

## Common Drugs Used and Potential Side Effects

- Benzodiazepines are commonly used. They may cause dry mouth or dehydration.
- MT analogues have a rapid onset of action, improve sleep quality, and enhance mood. Agomelatine has 5-HT<sub>2c</sub> antagonist properties that may be used in treating patients with major depression, insomnia, and some other sleep disorders (Pandi-Perumal et al, 2008). Ramelteon is another MT agonist recently approved for long-term treatment of insomnia.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Bioactive Substance Intake

**Assessment Data:** Sleep problems; no hx of medical conditions that cause insomnia; diet hx with high caffeine intake.

**Nutrition Diagnoses (PES):** Excessive bioactive substance intake (caffeine) related to consumption of 10–12 cups of coffee throughout the day as evidenced by insomnia, chronic fatigue, and heartburn.

**Interventions:** Education about the need to reduce caffeine intake to promote healthier sleep.

**Monitoring and Evaluation:** Fewer complaints about heartburn; better sleeping habits and less chronic fatigue; intake of two to three cups of coffee per day and increased intake of other beverages.

- MT, when taken with calcium, acts as an immunostimulator. Because this could aggravate conditions such as rheumatoid arthritis, use these supplements with caution.
- As appropriate, antidepressants or anti-anxiety medications may be prescribed. Side effects vary.
- Pain may cause insomnia. Cancer, arthritis, and other conditions may be present. Adequate pain medication will be needed.

## Herbs, Botanicals, and Supplements

- Valerian is a popular botanical used for insomnia. Side effects may include pruritis, headache, or GI distress.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- CBT and family, group, and self-help therapies are all recommended.
- Many people benefit from relaxation training.
- If the individual is obese, a weight management program, sleep enhancement, and exercise plan will be needed.
- Avoid alcohol, nicotine, and caffeine for 3–4 hours before bedtime.
- Exercise in the afternoon rather than too close to bedtime.

### Patient Education—Foodborne Illness

- Basic food handling and handwashing techniques are important.

# SUBSTANCE USE DISORDERS AND ADDICTION

## NUTRITIONAL ACUITY RANKING: LEVEL 1 (WITHDRAWAL/REHABILITATION)

### DEFINITIONS AND BACKGROUND

Substance use often leads to addiction. Addiction is a brain disorder, a chronic disorder with compulsive and relapsing behavior. Three predisposing factors exist: constitutional liability (biochemical), personality factor (psychological vulnerability), and social factors (environmental conditioning). Sensitivity to reward (STR) seems to play a role (Davis et al, 2004). The master “pleasure” molecule of addiction is dopamine (D2 receptor gene). Heroin, amphetamines, marijuana, alcohol, nicotine, and caffeine all trigger the release of dopamine. Abnormalities in the metabolism of dopamine, serotonin, and norepinephrine contribute to substance dependency. In some cases, use of antidepressant medications alleviate the dependency.

Abuse of chemical substances may be chronic or acute and may involve abuse of alcohol, prescription or over-the-counter drugs, or illicit drugs. Initial use of drugs of abuse converge on the mesolimbic dopamine pathway from the ventral tegmental area (VTA); these drugs modulate glutamatergic transmission activating the dopamine neurons, a critical early stage in the development of addiction (Heikkinen et al, 2009; Xiao et al, 2009). Physiological problems that result are definite, specific to the abused substance. Social, emotional, vocational, and legal problems may arise.

Persons with substance dependency tend to have type A personalities and are prone to perfectionism and depression. Substance abusers are codependent, neglecting their own feelings and emotions. EDs and substance disorders may represent different expressions of the same underlying problem, with cognitive dysfunction, use of food or substance to relieve negative affect (anxiety or depression), secretiveness about the problem, and social isolation. Addiction to food may also be a reality; brain circuits can also be deranged with natural rewards such as food (Davis et al, 2004). Overweight individuals may use food as a reward, just as substance abusers use pharmacological substances for a reward for the dopamine-specific part of the brain.

Alcoholism is a chronic relapsing disease that is frequently unrecognized and untreated; approximately one third of patients remain abstinent, and one third are fully relapsed 1 year after withdrawal from alcohol (Oroszi and Goldman, 2004). Many alcoholics are malnourished; nutritional interventions are needed to prevent liver disease. Antioxidants as precursors of endogenous glutathione show promise (Lieber, 2003). Protein calorie malnutrition (PCM) is predictive of mortality in alcoholic liver disease; deficiencies of folate, thiamine, pyridoxine, and vitamin A promote anemia, altered cognitive states, and night blindness (Halsted, 2004).

Addictions share some of the same biological pathways. Because polydrug use may alter food intake, taste preferences, and nutrient metabolism and because denial is common, psychotherapy along with substance withdrawal is recommended. Dysfunctional eating patterns and excessive weight gains have been observed during recovery from drug and alcohol addictions; food deprivation during

active addiction may contribute (Cowan and Devine, 2008). Assertive outreach is effective in engaging and linking persons to substance abuse treatment services, even if they are homeless (Fisk et al, 2006). Giving up should not be an option (Table 4-22).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The collaborative study on genetics of alcoholism (COGA) supports the premise that alcohol dependence is inherited in 50–60% of cases (Dick et al, 2008). Alcohol dehydrogenases, catechol-O-methyltransferase (COMT), opioid receptors, and HTTLPR (which alters serotonin transport) all affect the process of addiction and relapse (Oroszi and Goldman, 2004). In addition, the gamma-amino-butyric acid (GABA) neurotransmitter mediates actions of alcohol.

Clinical/History	Lab Work	Serum folate Serum B <sub>12</sub> Serum tHcy CRP Liver function tests
Height	Prolactin levels	
Weight	Serotonin levels	
BMI	Ca <sup>++</sup> , Mg <sup>++</sup>	
Weight changes	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>	
Dietary/intake history	H & H	
I & O	Serum Fe	
BP	Alb or transthyretin	
Tremors, delirium?	Gluc	
Multidimensional Addictions and Personality Profile (MAPP)	Chol (total profile)	
	Trig (often very high in alcoholics)	
	Serum thiamin	

### INTERVENTION

### OBJECTIVES

- Normalize brain levels of neurotransmitters.
- Correct fluid and electrolyte imbalances or dehydration.
- Protect during withdrawal (e.g., alcohol detoxification may cause tremors, hallucinations, seizures, and delirium tremens). Of persons with delirium tremens, 20% may die, even with therapy; monitor closely.
- Modify diet for medical conditions. Alcoholics experience problems such as liver failure, cirrhosis, pancreatitis, GI

**TABLE 4-22 Common Addictions and Issues**

Substance	Issues
Alcohol	The most consistent predictor of alcohol dependency is alcoholism in a biological parent. Alcoholics are more likely to die from stroke or cirrhosis. An estimated 3 million children between 14 years and 17 years of age are problem drinkers; the earlier the exposure, the more likely dependency will occur. To assess for problems, C-A-G-E questions include: Have you tried to cut back? Has anybody ever annoyed you regarding this behavior? Have you ever felt guilty about it? Have you ever needed an early morning eye opener? With two or more yes answers, a problem should be addressed.
Caffeine	Caffeine and nicotine are the most common psychostimulant drugs used worldwide. Caffeine affects the brain in ways that are similar to cocaine and other stimulants, but it is not as addictive overall.
Chocolate	Chocolate may be used as self-medication for low magnesium levels and to balance low neurotransmitters for mood (serotonin and dopamine). Chocolate contains methylxanthines, biogenic amines, and cannabinoid-like fatty acids. Chocolate cravings may occur (Smit et al, 2004), especially related to menses in women.
Club drugs: LSD (acid), MDMA (Ecstasy), GHB, GBL, ketamine (special K), Fentanyl, Rohypnol, amphetamines, methamphetamine	"Club drug" is a vague term that refers to a wide variety of drugs including MDMA (ecstasy), GHB, Rohypnol, ketamine, methamphetamine, and LSD. Uncertainties about the drug sources, pharmacological agents, chemicals used to manufacture them, and possible contaminants make it difficult to determine toxicity, consequences, and symptoms. Serious health problems may result from their use.
Cocaine	The pure chemical, cocaine hydrochloride, has been an abused substance for more than 100 years, and coca leaves, the source of cocaine, have been ingested for thousands of years. Use has increased, and now over 1.5 million Americans are users. Young adults aged 18–25 are most likely to initiate use. Years later, cocaine use may be linked to Parkinson's disease. A herbal supplement can reduce the cravings associated with chronic cocaine use. N-acetylcysteine (NAC) is a potential agent to modulate the effects of cocaine addiction, heroin addiction, and possibly alcoholism.
Heroin	Heroin is processed from morphine, a naturally occurring substance extracted from the seedpod of the Asian poppy plant. Heroin usually appears as a white or brown powder. Street names for heroin include smack, H, skag, and junk. Other names may refer to types of heroin produced in a specific geographical area, such as Mexican black tar. Use of heroin may be fatal. Use during pregnancy may cause spontaneous abortion.
Marijuana	Marijuana is the most commonly used illicit drug in the United States. The main active chemical in marijuana is THC (delta-9-tetrahydrocannabinol). The membranes of certain nerve cells in the brain contain protein receptors that bind to THC. Once in place, THC kicks off a series of cellular reactions that ultimately lead to the high that users experience.
Nicotine	Along with directly stimulating the brain's reward system, nicotine stimulates it indirectly by altering the balance of inputs from two types of neurons that help regulate its activity level.
Prescription medications	Pain relievers, tranquilizers, stimulants, and sedatives are very useful treatment tools. When people do not take them as directed, they may become addicted. Inappropriate or nonmedical use of prescription medications is a serious public health concern. Nonmedical use of prescription medications like opioids, central nervous system (CNS) depressants, and stimulants can lead to abuse and addiction, which are characterized by compulsive drug seeking and use.
Steroids, anabolic	Anabolic-androgenic steroids are man-made substances related to male sex hormones. They are available legally only by prescription to treat conditions that occur when the body produces abnormally low amounts of testosterone, such as in delayed puberty and impotence. They are also prescribed to treat body wasting in patients with AIDS and other diseases that result in loss of lean muscle mass. Athletes may abuse anabolic steroids to enhance performance and also to improve physical appearance. Anabolic steroids are taken orally or injected, typically in cycles of weeks or months (referred to as "cycling"), rather than continuously.

Sources: <http://www.nida.nih.gov/Drugpages/>, accessed June 15, 2009; Smit HJ, et al. Methylxanthines are the psycho-pharmacologically active constituents of chocolate. *Psychopharmacology*. 176:412, 2004.

- bleeding, esophageal varices, renal impairment, ascites, and edema. Intravenous drug users are at risk for contracting hepatitis C or HIV infection. See appropriate entries.
- Reorient to reality; develop trusting relationships between patient and care providers. Promote abstinence and long-term treatment.
- Improve nutritional status and outcome. Dietitians can provide nutrition education and can help in drug treatment and rehabilitation programs (Grant et al, 2004).
- Prevent or correct EDs, present in approximately 50% of this population. Avoid major changes in food choices and intake during recovery to prevent drastic weight fluctuations.

- Use motivational interviewing to work through problems, such as resistance and ambivalence for making life changes (Westra, 2004).

## FOOD AND NUTRITION

- According to I & O values, adjust fluid intake. Offer beverages that are nonalcoholic favorites. Reductions in the use of caffeine are often suggested.
- Encourage nutrient-dense foods. Fruits, vegetables, whole grains, and fish are important inclusions.
- Adequate intake of protein will be essential.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Excessive Alcohol Intake**

**Assessment Data:** Food recall/diet history; alcohol intake; assessment of access to food and resources (money, family support, social service agencies, alcohol counseling or therapy).

**PES:** Excessive alcohol intake related to social anxiety as evidenced by patient report, admission with alcohol intoxication, and history of rehabilitation for alcohol dependence.

**Intervention:** Provide nourishing foods and beverages. Counsel about the role of nutrient-dense foods and how alcohol provides only heat and kilocalories. Coordinate with social services for additional rehab if appropriate.

**Monitoring and Evaluation:** Report of improved food and beverage intake; alcohol-free lifestyle changes; improved self-esteem and quality of life; reduced social anxiety after rehab program.

- Include adequate calories, especially because patients often become hypoglycemic. Feed several times daily to help regulate blood glucose.
- Adequate intake of thiamin, other B-complex vitamins, zinc, protein, vitamin A, or other depleted nutrients is important during recovery.
- Adjust diet, as appropriate, to reduce excess sweets; many chemical abusers tend to substitute CHO for their dependency drug.
- Adequate fiber intake may be useful to correct or prevent constipation.

**Common Drugs Used and Potential Side Effects**

- Antabuse, when mixed with alcohol, can cause severe nausea, vomiting, low BP, and flushing.
- Bromocriptine (Parlodel) may also be used for some drug-recovery patients. Nausea, vomiting, or constipation may occur.
- Methadone maintenance therapy continues to be one of the major effective forms of addiction pharmacotherapy and underscores the importance of biological factors in the physiology and treatment of the addictive diseases (Kreek et al, 2004).
- Naltrexone decreases the pleasurable sensation of alcohol; it is used for narcotic dependency after detoxification. Anorexia, weight loss, nausea, vomiting, and abdominal cramping or pain may occur.
- Subutex/Suboxone (buprenorphine/naloxone) are oral tablets used for the treatment of opiate dependence.
- Stool softeners may be beneficial if constipation results after withdrawal, as with cocaine abuse.
- TCAs (imipramine, desipramine) are often beneficial with some side effects such as dry mouth.

**Herbs, Botanicals, and Supplements**

- No studies have been conducted for efficacy of herbs or botanicals in substance abuse patients.
- St John's wort should not be taken with antidepressants.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Help the patient accept responsibility for his or her own actions. CBT and family, group, and self-help therapies are all recommended.
- Treatment should focus on sufficient duration and intensity, family support, after-care and follow-up, self-help groups, collaboration with social services, and a drug-free lifestyle. One of five individuals will be drug free or sober after 5 years. New studies will include new, effective medications and evaluations of the changes that occur in the brain.
- Help to maintain abstinence. Avoid discussion of unanswerable questions such as “why” substances have been abused.
- In recovery, simple guidelines are useful: eat breakfast and regular meals daily; eat a variety of foods; make meal-times pleasant and unhurried; choose healthy snacks; drink decaffeinated coffee.
- Discuss issues regarding personal “control.” Coping skills will be needed to reduce helplessness. Include patient in decision making to increase self-esteem and confidence.
- Discuss the dangers of diet pills and starvation to control appetite and weight.
- Long-term alcohol abuse can specifically target beta cells of the pancreas, increasing risk of diabetes. Heroin use can cause glucose intolerance, but unlike in alcohol abuse, this usually resolves with abstinence.
- Heavy drinkers tend to have higher total and HDL cholesterol levels than controls. Moderate alcohol intake does not seem to be protective against coronary heart disease through lipid reduction alone; resveratrol may be one protective factor.
- Sports teams can provide peer-led education about healthy lifestyles and reduction in disordered eating patterns or substance abuse (Elliott et al, 2004).
- If a person smokes cigarettes, having smoking cessation interventions seems to help long-term sobriety for other addictions (Prochaska et al, 2004).
- Help plan adequate discharge planning, follow-up, and family therapy or other support group interactions.

**Patient Education—Foodborne Illness**

- Careful food handling will be important. The same is true for hand washing.

# Pulmonary Disorders

## CHIEF ASSESSMENT FACTORS

- Altered Respirations
- Anorexia
- Blood Gases: Partial Pressure of Oxygen ( $pO_2$ ); Partial Pressure of Carbon Dioxide ( $pCO_2$ )
- Clubbing of Nail Beds
- Confusion, Somnolence
- Cough, Especially with Chest Pain
- Cyanosis of Lips, Nail Beds
- Dizziness
- Elevated Blood Pressure (BP)
- Engorged Eye Veins
- Fever or Chills
- Flaring Nostrils; Red, Swollen Nose
- Hemoptysis (Coughing Up Blood)
- Hoarseness
- Orthopnea, Tachypnea
- Pain (Chest, Abdominal)
- Pallor; Ashen or Gray Coloring
- Poor Exercise or Activity Tolerance
- Rapid Breathing, Excessive Perspiration
- Restlessness, Irritability
- Shortness of Breath (Dyspnea)
- Stridor (Crowing Sound on Inhalation)
- Wheezing (Whistling, Musical Sound from Obstructed Airways)

## PULMONARY NUTRITION NOTES

Asset provided by Anatomical Chart Co.

Pulmonary surfactant is a complex and highly active material composed of lipids and proteins that is found in the fluid lining the alveolar surface of the lungs. It protects the lungs from injuries and infections caused by inhaled particles and micro-organisms (Wright, 2005a). The role for surfactant was first studied in premature infants with respiratory distress syndrome (RDS), which is now routinely treated with an exogenous replacement (Stevens et al, 2004). Biochemical surfactant abnormalities have been described in asthma, bronchiolitis, chronic obstructive pulmonary disease, lung transplantation; infectious and suppurative lung diseases (cystic fibrosis [CF], pneumonia;) adult RDS, pulmonary edema, chronic lung disease of prematurity, interstitial lung diseases. Surfactant replacement therapy has been tested with positive outcomes. In acute respiratory syndrome, exogenous surfactant does not improve survival, but patients who received surfactant had a greater improvement in gas exchange during 24-hour treatment (Spragg et al, 2004).

The evidence for the role of diet in pulmonary disease is clear. Intake of fruit, fish, antioxidant vitamins, fatty acids, sodium or magnesium, helps to alleviate symptoms of asthma and Chronic obstructive pulmonary disease. Because antioxidant nutrients are positively corrected with lung function, vitamin C, vitamin E, beta-carotene, and selenium are important. Flavonoids, such as quercetin and

**TABLE 5-1 Causes of Malnutrition in Patients with Pulmonary Disease**

Aerophagia and rapid breathing
Anemia (low oxygen-carrying capacity)
Anorexia of chronic illness
Cellular hypoxia
Chronic debility
Decreased lung immunity
Decreased lung surfactant and elasticity
Depression, anxiety with anorexia
Difficulty in eating with continuous dyspnea
Fever
Gastric hypomotility
Hypermetabolism, as in chronic obstructive pulmonary disease (COPD)
Increased mechanical work of breathing
Increased workload of the heart
Inflammation
Lung cancer
Malabsorption, as in cystic fibrosis
Medications causing nausea and anorexia
Pneumonia
Polypharmacy
Poor respiratory muscle strength and endurance
Restricted diet
Right-sided heart failure
Vitamin deficiency, leading to poor epithelial integrity and weak lung muscles

NOTE. Death in patients with COPD is typically due to acute respiratory failure, pneumonia, lung cancer, cardiac disease, or pulmonary embolism.

Adapted from: Merck Manual: Chronic obstructive pulmonary disease; Accessed January 28, 2006, at <http://www.merck.com/mrkshared/mmg/sec10/ch78/ch78a.jsp>.

resveratrol, in apples, onions, oranges, berries, and red wine support lung health (Arts and Hollman, 2005; Donnelly et al, 2004; Neuhouwer, 2004). Vitamin D helps to maintain healthy lung function (Wright, 2005b). Vitamin E helps to stave off upper respiratory infections; 200 IU daily gives better response to vaccines for diseases such as flu, ear infections, pneumonia, bronchitis, sinusitis, and other pathological conditions (Meydani et al, 2004). Almonds, mango, sunflower seeds, vegetable oils, and whole grains are good sources. Table 5-1 lists factors that contribute to malnutrition with pulmonary disease.

Omega-3 fatty acids can calm inflamed airways; include salmon, respiratory quotients (RQs) tuna, mackerel, walnuts, and flaxseed oil more often. Table 5-2 lists the RQs for fats, protein, and carbohydrates (CHO). In general, it is assumed that fats decrease CO<sub>2</sub> output more than CHO.

**TABLE 5-2 Respiratory Quotient (RQ) and Nutrients**

RQ = $V_{O_2}/V_{CO_2}$
RQ from fat = 0.7
RQ from protein = 0.8
RQ from carbohydrates (CHO) = 1.0

## ASTHMA

### NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: Neil O. Hardy. Westport, CT. *Stedman's Medical Dictionary*, 27th ed. Baltimore: Lippincott Williams & Wilkins, 2000, p. 158.

### DEFINITIONS AND BACKGROUND

Bronchial asthma involves paroxysmal dyspnea accompanied by wheezing and is caused by spasm of the bronchial tubes or swelling of their mucous membranes. Bronchial asthma differs from wheezing caused by cardiac failure (cardiac asthma), in which an x-ray shows fluid in the lung. Asthma involves inflammation of the lining of the airways, obstruction, and increased sensitivity of the airways. Table 5-3 provides a checklist for signs and symptoms of asthma.

Between 10 and 15 million Americans are affected by asthma, including about 5% of children. Asthma seems to be inherited in two thirds of cases. Two main types of bronchial asthma are recognized: allergic (extrinsic) and nonallergic (intrinsic or infectious). Exercise-induced bronchospasm is much less common.

Children who are exposed to second-hand smoke may have chronic cough or symptoms of asthma. Chronic poor control can lead to a serious condition, status asthmaticus, which generally requires hospitalization and can be life threatening. Brittle asthma is a rare form of asthma with repeated attacks; food intolerance is common. Many infants with wheezing have transient conditions that resolve. The common cold virus and rhinovirus (RV) are major triggers; this pattern continues for adults with allergic asthma (Tan, 2005).

Breastfeeding provides immunological protection when the infant's immune system is immature and a modest protective effect against wheeze in early childhood (Kim et al, 2009; Oddy et al, 2004). Longer duration of breastfeeding seems to be more protective. Supplementation of maternal diet with fish oil is associated with altered neonatal immune responses to allergens (Devereux, 2009). Reduced maternal

**TABLE 5-3 Early Warning Signs of Asthma**

Head/eyes	Glassy eyes; dark circles; watery eyes; headache; feverish; pale
Nose	Stuffy nose; runny nose; sneezing
Mouth/throat	Chin or throat itches; change in sputum; dry mouth; funny feeling in chest
Chest/lungs	Fast heartbeat; coughing; changes in breathing; downward trend in peak flow numbers
Behavior/mood	Easily upset or irritable; weak; slowing down; feeling sad; more quiet, excited or restless than usual; desire to be alone; insomnia
Exercise tolerance	Poor tolerance for exercise; sweaty; easy fatigue

intake of vitamins D and E, zinc during pregnancy seems to be associated with increased asthma and wheezing outcomes in children up to the age of 5 years (Devereux, 2009).

Nutritional status is important for healthy lungs. Intravenous treatment with multiple nutrients may be of considerable benefit; pulmonary function improves progressively with longer treatment (Schrader, 2004). Diet affects the pathophysiology of asthma by altered immune or antioxidant activity with consequent effects on airway inflammation. Maternal intake of vitamins D and E and zinc can modify fetal lung development (Devereux, 2009). Low serum vitamin D has been shown to be a marker for severity of childhood asthma (Brehm et al, 2009).

Overall, dietary modification may help patients manage their asthma and their overall health. A multidisciplinary approach is required to move forward and understand the complexity of the interaction of dietary factors and asthma (Kim et al, 2009). Obesity and overweight may lead to less-effective therapy from inhaled corticosteroid treatments (Sutherland et al, 2009). While there is currently no conclusive evidence about the role of specific nutrients, food types, or dietary patterns past early childhood on asthma prevalence (Kim et al, 2009); Table 5-4 lists various nutrients and their potential effects on asthma.

**TABLE 5-4 Nutrients and Their Potential Mechanisms in Asthma**

Nutrient(s)	Activity and Potential Mechanisms of Effect
Vitamins A (carotenoids), C, and E	Antioxidants for protection against endogenous and exogenous oxidant inflammation
Vitamin C	Prostaglandin inhibition (Harik-Kahn et al, 2004)
Vitamin D	Vitamin D modulates T-cell responses (Devereux, 2009)
Vitamin E	Membrane stabilization, inhibition of immunoglobulin E (IgE) production. Modulation of T-cell responses (Devereux, 2009)
Flavones and flavonoids	Antioxidants; mast cell stabilization
Magnesium	Smooth muscle relaxation, mast cell stabilization (Schrader, 2004)
Selenium	Antioxidant cofactor in glutathione peroxidase
Copper, zinc	Antioxidant cofactors in superoxide dismutase. Zinc modulates T-cell responses (Devereux, 2009)
Omega-3 fatty acids	Leukotriene substitution, stabilization of inflammatory cell membranes (Wong, 2005). PUFA modulate T-cell responses (Devereux, 2009)
Omega-6 polyunsaturated/trans fatty acids	Increased eicosanoid production (Nagel and Linseisen, 2005)
Sodium	Increased smooth muscle contraction; reductions can increase airway responsiveness (Mickleborough and Gotshall, 2004)

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Tobacco smoke and genetic susceptibility are risk factors for wheezing and asthma (Sadeghnejad et al, 2008). Interleukin 6 (IL6) IL6 receptor (IL6R), and IL13 are candidate genes. Maternal diet plays an epigenetic role by sensitizing fetal airways to respond abnormally to environmental insults (Devereux, 2009; Kim et al, 2009). In addition, beta2-adrenergic receptor (beta2AR) gene polymorphisms are associated with asthma in different racial or ethnic populations.

Clinical/History		
Height	Tachycardia	Hemoglobin and hematocrit (H & H)
Weight	Cyanosis	
Body mass index (BMI)	Anxiety	
BP	Pulmonary edema	Serum Fe, ferritin
Hypotension?	Dehydration	Transferrin
Temperature	Hard and dry cough	Serum vitamin D <sub>3</sub>
Intake and output (I & O)	Distended neck veins	Serum lipids
Spirometry test	Food or sulfite allergies?	Uric acid
GERD?	Skin testing	Bilirubin
Respiratory distress		Ca <sup>++</sup> , Mg <sup>++</sup>
Audible wheezing	<b>Lab Work</b>	Cholesterol (Chol)
Decreased breath sounds	pCO <sub>2</sub> , pO <sub>2</sub>	Triglycerides (Trig)
	Glucose (Gluc)	C-reactive protein (CRP)
	Albumin (Alb)	

## INTERVENTION

### OBJECTIVES

- Prevent distention of stomach from large meals, resulting in distress, GERD, or aggravation of asthma.
- Prevent lung infection and inflammation. Promote improved resistance against infections.
- For allergic asthma, identify and control allergens in the environment.
- Promote adequate hydration to liquefy secretions.
- Optimize nutritional status. Sufficient vitamins C, B<sub>6</sub>, D, and E, selenium and magnesium are important. Reduce intake of oleic acid, but increase omega-3 fatty acids if tolerated.
- Encourage a health maintenance program, including physical activity where possible.
- Caffeine relaxes muscles and opens the airways; 2–3 cups of coffee daily may be useful in adults.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Overweight**

**Assessment Data:** BMI >90%tile for age; complaints of heartburn and GERD after meals; asthma triggered by allergies; diet hx showing frequent intake of high sugary snacks between meals.

**Nutrition Diagnoses (PES):** Overweight related to excessive intake of energy as CHO with asthma as evidenced by BMI >90%tile for age, GERD, and diet hx revealing intake of high CHO snacks throughout the day.

**Interventions:** Education about the role of weight management and asthma; review of any known food allergies; discussion about appropriate energy intake for age and activity. Counseling about alternative snacks with a mix of protein-CHO-fats.

**Monitoring and Evaluation:** BMI closer to desirable range; fewer complaints of GERD; better tolerance of drug therapy for asthmatic episodes; improved quality of intake for meals and snacks.

## FOOD AND NUTRITION

- Infants should be exclusively breastfed to reduce the risk of asthma in susceptible families.
- Provide balanced, small meals that are nutrient dense (high-quality protein, vitamins, and minerals), to reduce risk of infections.
- Lose weight by following a lower energy intake if needed (Oddy et al, 2004; Sutherland et al, 2009).
- Encourage extra fluids unless contraindicated. Theobromine in cocoa tends to increase blood flow to the brain and to reduce coughing; use often.
- Use less sodium (Mickleborough and Gotshall, 2004).
- Highlight foods rich in vitamins A and C, magnesium, and zinc. Use more broccoli, grapefruit, oranges, sweet peppers, kiwi, tomato juice, and cauliflower for vitamin C.
- Quercetin in apples, pears, onions, oranges, and berries should be encouraged (5 or more servings per week). Other nutrients that support immunocompetence should be included.
- Omit specific food allergens for children if identified: as milk, eggs, seafood, tree nuts, peanuts, fish, wheat or soy. For adults, tree nuts, peanuts, fish and shellfish allergies tend to persist.
- Sulfites/salicylates may aggravate asthma in 5% of this population, especially adults with severe disease. Sulfite-containing foods or beverages should be avoided.
- Salicylate sensitivity is common in 5–20% of asthmatics who are hypersensitive to aspirin. Many fruits and some vegetables contain salicylates.
- If fish is tolerated, consumption of fish two to three times weekly may help reduce leukotriene synthesis (Wong, 2005). If nuts are tolerated, include selenium from Brazil nuts and vitamin E from most nuts.
- Omega-3 fatty acids from fish oils, walnuts, and flaxseed have been suggested. Some studies suggest that EPA is more useful than DHA (Mickleborough et al, 2009) whereas others suggest the opposite (Weldon et al, 2007). The evidence is not yet clear.
- Saturated fatty acids (SFAs) and oleic acid (from margarine) may contribute to clinical onset of asthma; limit their use (Nagel and Linseisen, 2005).

## Common Drugs Used and Potential Side Effects

- An airway renin–angiotensin system is triggered by release of mast-cell renin; ANG II is a critical factor for new therapeutic targets in the management of airway disease (Kano et al, 2008; Reid et al, 2007).
- See Table 5-5.

## Herbs, Botanicals, and Supplements

- Many patients with asthma use alternative therapies. Antioxidant and natural anti-inflammatory and immunomodulatory remedies may prove beneficial.
- In China, a combination of three herbal extracts (ASHMI) may be used in anti-asthma intervention (Wen et al, 2005). Seaweed may be used to treat asthma in Vietnamese and oriental cultures (Dang and Hoang, 2004).
- Dietary fatty acids such as gamma linolenic acid (GLA; borage oil) modulate endogenous inflammatory mediators without side effects (Ziboh et al, 2004).
- Ephedra (ma huang) is an effective bronchodilator, but it increases BP significantly. Problems with blood glucose, arrhythmias, increased heart rate, and central nervous system (CNS) stimulation can also occur. The Food and Drug Administration (FDA) has removed it from the market, but some forms are still available.
- Stinging nettle, licorice, ginkgo, and anise have not shown efficacy; side effects must be evaluated.
- St. John's wort can inhibit theophylline's effectiveness.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Mild, chronic asthma can be a warning; if untreated, it can lead to an acute exacerbation.
- Waiting to introduce solids to an infant does not necessarily protect against onset of asthma and allergy (Zutavern et al, 2004).
- Early multivitamin–mineral supplementation may trigger asthma in susceptible children; the exact reasons are not clear (Milner et al, 2004). A healthy, nutrient-dense diet should be consumed instead.
- All medications should be taken as directed by the physician. An emergency pack should be carried at all times containing a rescue inhaler and, if needed, epinephrine injection device and a chewable antihistamine tablet.
- Work with the patient/family to avoid precipitating triggers. Reduce exposure to triggers such as pet dander, food allergens, second-hand smoke. Discuss exercise, rest, and nutrition.
- Massage therapy enhances relaxation, decreases anxiety, and promotes better lung function.

**TABLE 5-5 Medications Used in Asthma**

Medication	Description
Antibiotics	Long-term use can cause diarrhea and other problems. Penicillin should not be taken with fruit juices.
Anticholinergics (Atrovent, Combivent)	Quick-relief asthma medications. Dry mouth is common side effect.
Beta-agonists (metaproterenol albuterol; levalbuterol; salbutamol)	Relaxes smooth muscle around airways. Side effects include shakiness, rapid heart rate, nervousness and elevated blood glucose. Metaproterenol (Metaprel, Alupent) may alter taste and cause nausea or vomiting. Albuterol (Ventolin, Proventil) may have cardiac side effects or may cause nausea or diarrhea.
Bronchodilators: theophylline (Theo-Dur, Slo-BID, Slo-Phyllin, Theolair, Uniphyll)	No longer first choice of asthma medication. Nausea, vomiting, and sleeplessness can be a problem. Theophylline metabolism is affected by protein and CHO availability; avoid extreme changes in protein and CHO intake. Because it is a methylxanthine, avoid extreme changes in usual intakes of caffeine-containing foods. Theophylline depresses levels of vitamin B <sub>6</sub> . In addition, lipid levels (cholesterol, HDL, and LDL) are higher in children who take theophylline.
Corticosteroids (methylprednisolone [Medrol], Deltasone, Orapred, Prelone)	Many side effects such as fluid retention, low serum potassium, GI distress, retaining excess sodium, causing hyperglycemia, and other problems. Monitor carefully, especially if needed over a long period of time. AeroBid contains an anti-inflammatory steroid and is inhaled; it may cause nausea, vomiting, or diarrhea. Bone mineral density is often decreased after long-term use of inhaled corticosteroids.
Epinephrine	May be required for emergencies. Intravenous (IV) administration of epinephrine results in a prolonged increase in resting energy expenditure (REE) as measured by respiratory quotient (RQ); fuel for this is increased CHO oxidation.
Expectorants	Potassium iodide may affect existing thyroid problems.
Long-term control medications	Anti-immunoglobulin E: Reduces histamine release; may be useful with allergic form of asthma. Combination therapy (Advair): Combining an inhaled corticosteroid and a long-lasting beta <sub>2</sub> -agonist seems to provide consistent relief for people with asthma. Intal (cromolyn) and Tilade (nedocromil) are inhaled medications useful for asthma triggered by cold weather, exercise, and allergies. Inhaled nasal steroids: AeroBid (flunisolide), Azmacort (triamcinolone), Flovent (fluticasone), Pulmicort (budesonide), and Qvar (beclomethasone HFA). These prevent inflammation and reduce swelling inside airways; they also reduce mucus production. Leukotriene modifiers: Accolate, Singulair, Zflo. These relax the smooth muscle around the airways and reduce inflammation. Serevent (salmeterol xinafoate), Advair (fluticasone propionate and salmeterol inhalation powder), and Foradil or Tubuhaler Aerolizer (formoterol fumarate); these medications can worsen asthma or cause death. Formoterol may deplete potassium levels and cause heart palpitations.
Omega-3 fatty acid supplements	Omega-3 fatty acid supplements may decrease inflammation and improve lung function in adults with asthma, but there is no conclusive evidence. Omega-6 fatty acids tend to increase inflammation and worsen respiratory function.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## BRONCHIECTASIS

### NUTRITIONAL ACUITY RANKING: LEVEL 1

#### DEFINITIONS AND BACKGROUND

Bronchiectasis (BX) is an irreversible widening of portions of the bronchi resulting from damage to the bronchial wall with chronic dilation. It may be present with recurrent bronchitis or pneumonia. The most common acquired cause is acute respiratory illness in patients with COPD. Other causes include measles, whooping cough, tuberculosis (TB), fungal infection, inhaled object, lung tumor, CF, ciliary dyskinesia, immunoglobulin deficiency syndromes, rheumatoid arthritis, ulcerative colitis, human immunodeficiency virus (HIV) infection, and heroin abuse.

BX secondary to primary immunodeficiency in childhood is not always progressive; it is possible to slow or prevent disease progression with appropriate treatment (Haidopoulou et al, 2009). In non-CF BX, airway obstruction deteriorates over time; precaution must be taken to prevent significant morbidity and mortality (Twiss et al, 2006).

Relapse can be controlled with antibiotics, chest physiotherapy, inhaled bronchodilators, proper hydration, and good nutrition. Surgical resection or bilateral lung transplantation may be an option for improving quality of life that has few complications.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Congenital BX usually affects infants and children related to problems with lung development in a fetus but is not genetic in origin.

Clinical/History	Chest high-resolution computed tomography (HRCT)	Early morning paroxysmal cough
Height		Decreased breath sounds
Weight		Weight loss, anorexia
BMI		
Weight loss?	Altered respiratory rate	
Diet history	Chronic cough	
BP		
I & O		

Pneumonia?	Sputum culture:	Ca <sup>++</sup> , Mg <sup>++</sup>
Fever?	profuse, foul, or purulent	Chol
Shortness of breath (SOB)		Trig
Fatigue	<b>Lab Work</b>	H & H
Bluish skin or paleness	Transferrin	Serum Fe
Coughing up blood	Retinol-binding protein (RBP)	Transferrin
Chest x-ray	Gluc Na <sup>+</sup> , K <sup>+</sup>	Blood urea nitrogen (BUN)
		pO <sub>2</sub> , pCO <sub>2</sub>

#### INTERVENTION

#### OBJECTIVES

- Promote recovery and prevent relapse of symptoms. Prevent lung collapse or atelectasis.
- Avoid fatigue associated with mealtimes.
- Prevent or correct dehydration.
- Improve weight status, when necessary.
- Reduce fever and inflammation.
- Support lung function with higher antioxidant intake.
- Prepare patient for surgery if needed.

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### Unintentional Weight Loss

**Assessment Data:** Fever, anorexia, fatigue, chronic cough with purulent sputum, weight loss of 15 lb in past 2 months.

**Nutrition Diagnoses (PES):** Unintentional weight loss related to fever, fatigue and poor appetite as evidenced by loss of 15 lb in 2 months.

**Interventions:** Food and nutrient enhancement through nutrient-dense, energy-rich foods and beverages. Education about recipes and beverages to replace weight that are easy to prepare and consume.

**Monitoring and Evaluation:** Regain of lost weight; improved appetite; more destable BMI.

## FOOD AND NUTRITION

- Use a diet with 1.0–1.25 g protein/kg and sufficient calories to meet elevated metabolic requirements appropriate for age and sex.
- Small, frequent feedings may be better tolerated.
- Fluid intake of 2–3 L daily may be offered, unless contraindicated.
- Intravenous fat emulsions may be indicated (eicosanoids are inflammatory modulators, and thromboxanes and leukotrienes tend to be potent mediators of inflammation). Omega-3 fatty acids should be enhanced in the oral diet by including salmon, tuna, sardines, walnuts, and flaxseed. Supplements may also be useful.
- Adequate antioxidant use with vitamins C and E and selenium may be beneficial. Ensure adequate potassium intake, depending on medications used.

### Common Drugs Used and Potential Side Effects

- Antibiotics are used if the condition is bacterial. Aerosol administration of high-dose tobramycin in non-CF bronchiectatic patients is safe (Drobnic et al, 2005).
- Expectorants help bring up the mucus. Mucus thinners help make it easier to cough.
- Bronchodilators help open up the airways and corticosteroids help reduce airway swelling and inflammation. Monitor side effects according to the specific drugs used.

### Herbs, Botanicals, and Supplements

No clinical trials have proven efficacy for use of herbs or botanicals in BX.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of nutrition in health and recovery; emphasize quality proteins and nutrient-dense foods, especially if the patient is anorexic.
- A flu shot or pneumonia shot may be needed annually.
- Emphasize fluid intake, perhaps juices or calorie-containing beverages instead of water.
- Discuss desirable sources of fatty acids, such as omega-3 foods.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# BRONCHITIS (ACUTE)

## NUTRITIONAL ACUITY RANKING: LEVEL 1

### DEFINITIONS AND BACKGROUND

Bronchitis is caused by inflammation of the air passages. Acute bronchitis is an acute respiratory infection that is manifested by cough and sputum production that lasts for no more than 3 weeks (Braman, 2006). The acute form may follow a cold or other upper respiratory infection, producing hemoptysis, sore throat, nasal discharge, slight fever, cough, and back and muscle pain.

Causes include *Mycoplasma pneumoniae*, *Chlamydia*, or exposure to strong acids, ammonia, or chlorine fumes, air pollution ozone, or nitrogen dioxide. The chronic

form from cigarette smoking and air pollution can produce breathing difficulty, wheezing, blueness, fits of coughing, and sputum production. (See Chronic Obstructive Pulmonary Disease entry.)

Risks for acute bronchitis are much higher in smokers. Mental patients and homeless persons tend to smoke more than other individuals and are at higher risk for acute bronchitis (Himelhoch et al, 2004; Snyder and Eisner, 2004). In addition, smoking has negative consequences for maternal health as well as fetal health during pregnancy; the risk of bronchitis is 15 times higher for smokers than for nonsmokers (Roelands et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Tachykinins NK receptors, substance P, T lymphocytes, and neurokinin A appear to influence human airway health and susceptibility to bronchitis.

<b>Clinical/History</b>	Green or yellow sputum	Serum lipids (decreased?)
Height	Breathing difficulty	H & H, serum Fe
Weight	Chest x-ray	Alb,
BMI		transferrin
I & O		Oxygen saturation
Hydration status	<b>Lab Work</b>	CRP
Edema	Gluc	
Productive cough longer than 3 weeks	Na <sup>+</sup> , K <sup>+</sup>	
	Ca <sup>++</sup> , Mg <sup>++</sup>	

## INTERVENTION

### OBJECTIVES

- Normalize body temperature when there is fever.
- Replenish nutrients used in respiratory distress.
- Prevent complications such as dehydration and otitis media; avoid further infections.
- Allow ample rest before and after feedings.
- Prevent dehydration. Extra fluids are needed.
- Relieve discomfort.
- Support lung function through high antioxidant foods.

### FOOD AND NUTRITION

- Provide a regular or high-calorie diet, specific to the patient's needs.
- If milk gives a sensation of thickening mucus secretions, skim milk may be better tolerated and is important for adequate calcium consumption.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Fluid Intake

**Assessment Data:** Poor skin turgor, low I & O, frequent cough making drinking difficult, weight loss.

**Nutrition Diagnoses (PES):** Inadequate fluid intake related to frequent coughing spells and difficulty drinking beverages as evidenced by poor skin turgor, loss of 2 kg fluid, and low I & O.

**Interventions:** Food and nutrient delivery enhancement with nutrient and calorie-dense beverages such as shakes or nutritional supplements. Education about recipes for calorie-rich beverages.

**Monitoring and Evaluation:** Improved I & O and skin turgor; improved fluid intake, and recovery of lost weight.

- Provide adequate amounts of vitamins C and E, selenium, and potassium.
- Increase the intake of fluids (2–3 L), unless contraindicated.
- Appropriate fatty acid intake may be beneficial to reduce inflammation.
- A low energy intake may be needed after the acute phase to promote weight loss, improve BMI, and promote a healthier level of respiratory functioning (Canoy et al, 2004).

### Common Drugs Used and Potential Side Effects

- Bronchodilators can cause gastric irritation. They should be taken with milk, food, or an antacid.
- Theophylline can be toxic if a diet high in CHO and low in protein is used. Avoid large amounts of stimulant beverages, namely, coffee, tea, cocoa, and cola, unless the physician permits.
- Use of antibiotics for the treatment of acute bronchitis is not justified (Braman, 2006).

### Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for eucalyptus, mullein, horehound, stinging nettle, or marshmallow.
- Belladonna leaf and root are respiratory antispasmodic agents. They should not be used with tricyclic antidepressants, some antihistamines, phenothiazines, or quinidine. Sedation, dry mouth, and difficult urination may occur.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain to patient that adequate hydration is one of the best ways to liquefy secretions.
- Maintain body weight within a healthy range.
- Promote healthy diet that includes a balance of nutrients, with anti-oxidant-rich foods.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# CHRONIC OBSTRUCTIVE PULMONARY DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Nettina, Sandra M., MSN, RN, CS, ANP, *The Lippincott Manual of Nursing Practice*, 7th ed. Lippincott, Williams & Wilkins, 2001.

### DEFINITIONS AND BACKGROUND

Chronic obstructive pulmonary disease (COPD) may result from a history of emphysema, asthma, or chronic bronchitis with persistent lower airway obstruction. COPD is the fourth leading cause of death in the United States. Smoking is the most common cause. According to the Centers for Disease Control and Prevention (CDC), approximately 440,000 persons die each year of a cigarette smoking-attributable illness in the United States. Nonsmoking causes of COPD include alpha-1 antitrypsin deficiency, connective tissue diseases, HIV infection, and some metabolic disorders.

COPD is associated with muscular impairment, nutritional depletion, and systemic inflammation. Symptoms and signs of COPD include dyspnea on exertion, frequent hypoxemia, decreased forced expiratory volume in 1 second (FEV<sub>1</sub>), and destruction of the alveolar capillary bed. In COPD, total air quantity is blown out much sooner. COPD is a leading cause of death in the United States.

Chronic bronchitis (“blue bloater”) patients have inflamed bronchial tubes, excess mucus production, chronic cough (for 3 months each year), SOB, and no weight loss. Cardiac enlargement with failure is common.

Emphysema (“pink puffer”) patients have weight loss and thinness without heart failure. It is characterized by tissue destruction, distention, and destruction of pulmonary air spaces by smoking and air pollution. Wheezing, SOB, and chronic mild cough result. Nutritional depletion is significantly greater in patients who have emphysema than in those who have chronic bronchitis. Serious weight loss occurs from anorexia, secondary to significant SOB and gastrointestinal (GI) distress. Malnutrition, tissue wasting, and oxidative stress play a role.

Approximately 75% of patients with COPD suffer from weight loss, where chronic mouth breathing, dyspnea, aerophagia, certain medications, and depression often act in concert. Low body weight or recent weight loss and, in particular, depleted lean body mass (LBM) in patients with COPD are predictors of mortality, outcomes after acute exacerbations, hospital admission rates, and need for mechanical ventilation (Mallampalli, 2004). Risk of respiratory mortality is high.

Elevated resting and activity-related energy expenditure, reduced dietary intake relative to resting energy expenditure, accelerated negative nitrogen balance, medication effects, and an elevated systemic inflammatory response contribute to weight loss (Mallampalli, 2004).

Nutritional supplementation may have a role in the management of COPD when provided as part of an integrated rehabilitation program incorporating a structured exercise component.

The pathological mechanisms of COPD involve neutrophil granulocytes, cytotoxic T cells, macrophages, and mast cells (Ekberg-Jansson et al, 2005). Interventions aimed at controlling cytokine production may be required to reverse cachexia. Starvation, as in anorexia nervosa, can cause emphysema, even without smoking (Coxson et al, 2004).

Recommendations for fats, CHO, proteins, and water must be individualized. For patients with acute exacerbations of COPD in the intensive care unit (ICU), serum total protein is associated with hospital mortality; therefore, protein intake must be carefully monitored (Yang et al, 2004).

Nutritional support is a mainstay of the comprehensive therapeutic approach to patients with COPD because of progressive malnutrition, due to reduced energy intake, increased energy expenditure, and impaired anabolism (Anker et al, 2009).

Fruit and vegetable intake is important and protective. Foods such as meats, vegetables, and coffee may be more bland to the patient than he or she remembers; recognition of this may be important in planning meals.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Copeptin is a prognostic marker for short-term and long-term prognoses in patients with COPD requiring hospitalization (Stolz et al, 2007). In addition, glutathione-S transferase omega (GSTO) is a candidate gene for COPD (Wilk et al, 2007) and the vitamin D endocrine system is being studied (Janssen et al, 2009).

<b>Clinical/History</b>	Morning headache	Hct >48% may reflect chronic hypoxemia
Height	Anorexia, depression	Serum vitamin D <sub>3</sub>
Weight	BP	TLC
BMI	Chest x-ray	pH
Diet history	Electrocardiogram (ECG)	pO <sub>2</sub> <50 mm Hg
Temperature	Respirations	PaCO <sub>2</sub> >50 mm Hg
I & O	Ascites	Hg
Pulmonary function tests	Edema	Alb, transthyretin
Spirometry	<b>Lab Work</b>	BUN
Expiratory airflow limitation	Gluc	CRP
Excessive mucus production	Na <sup>+</sup> , K <sup>+</sup>	Chol
Wheezing	Ca <sup>++</sup> , Mg <sup>++</sup>	Trig
SOB	Serum Fe	
	Hemoglobin	

## SAMPLE NUTRITION CARE PROCESS STEPS

### Early Satiety and COPD

**Assessment:** Food intake records, weight, preferred foods. Early satiety and problems with coordination of breathing and swallowing.

**Nutrition Diagnosis (PES):** Involuntary weight loss related to early satiety, problems with breathing and swallowing, and inadequate intake of calorie-dense foods as evidenced by 20-lb weight loss and fatigue at mealtimes.

**Intervention:** Frequent small meals of easily digested foods with added fats and calorie-dense oral supplements.

**Monitoring and Evaluation:** Weight changes, improvement in calorie intake, less fatigue while eating.

## INTERVENTION

## OBJECTIVES

- Screen early and correct any malnutrition. Because there is less oxygen available for energy production, the patient is less active, and there is less blood flow to the GI tract and muscles. Malnutrition increases likelihood of infections. Provide medical nutrition therapy (MNT) focusing on prevention and treatment of weight loss and related conditions, especially in underweight patients (ADA, 2009).
- Promote intake of a nutrient-dense diet rich in antioxidant foods.
- Overcome anorexia resulting from slowed peristalsis and digestion. Patient lethargy, poor appetite, and gastric ulceration resulting from inadequate oxygen to the gut.
- Improve ventilation before meals with intermittent positive-pressure breathing and overall physical conditioning to strengthen respiratory muscles. Lessen work efforts by losing excess weight, if needed.
- Prevent respiratory infections or respiratory acidosis from decreased elimination of CO<sub>2</sub>.
- Alleviate difficulty in chewing or swallowing related to SOB. Patients with COPD have disrupted coordination of breathing and swallowing and may be at risk for aspiration (Gross et al, 2009). Breathe carefully, eat slowly, and rest when the meal is finished.
- Prevent or correct dehydration, which thickens mucus.
- Avoid constipation and prevent straining with defecation at stool.
- Avoid distention from large meals or gaseous foods. Eat while sitting up to lessen discomfort.
- Ensure adequate flavor of foods because taste is often minimized (Wardwell et al, 2009).
- Consider nutritional support to prevent progressive weight loss, since restoration of lean and fat body mass may not be achievable (Anker et al, 2009). Medical food supplements should be influenced more by the patient's preference than nutritional factors such as percentage of fat or CHO, as there is limited evidence to support consumption of a particular macronutrient composition (ADA, 2009).
- Assess and help improve quality of life of people with COPD, especially as it relates to their ability to obtain,

prepare, and consume food to meet nutritional needs; impairment with activities of daily living is common (ADA, 2009).

## FOOD AND NUTRITION

- A high-protein/high-calorie diet is necessary to correct malnutrition. Use 1.2–1.7 g protein/kg and sufficient kilocalors for anabolism (start with 30–35 kcal/kg, depending on current weight). Use BMI and weight change to assess weight status, body composition, and calorie needs (ADA, 2009).
- A diet without tough or stringy foods and an antireflux regimen are useful. Gas-forming vegetables may cause discomfort for some patients.
- Increased use of omega-3 fatty acids in foods such as salmon, haddock, mackerel, tuna, and other fish sources may be beneficial (ADA, 2009; Romieu et al, 2005).
- Encourage a diet that meets Recommended Dietary Allowances for antioxidant vitamins A, C, and E (ADA, 2009). To enrich the diet with antioxidants, use more citrus fruits, whole grains, and nuts. There is a protective effect of fruit and possibly vitamin E.
- Fluid intake should be high, especially if the patient is febrile. Use 1 mL/kcal as a general rule. This may translate to eight or more cups of fluid daily. For discomfort, consume liquids between meals to increase ability to consume nutrient-dense foods at mealtimes.
- Limit salt intake. Too much sodium can cause fluid retention or peripheral edema, which may interfere with breathing.
- Fiber should be increased gradually, perhaps through use of psyllium, crushed bran, prune juice, or extra fruits and vegetables.
- Use small, concentrated feedings at frequent intervals to lessen fatigue. For example, egg-nogs and shakes may be helpful between meals.
- Morning may be the best meal of the day for many patients with COPD. See Tables 5-6 and 5-7 for ways to add extra protein or calories to the diet.
- Parenteral nutrition (PN) is reserved for patients in whom malabsorption has been documented where enteral nutrition has failed (Anker et al, 2009).

## Common Drugs Used and Potential Side Effects

- Bronchodilators (Atrovent, Theo-Dur, etc). are used to liquefy secretions, treat infections, and dilate the bronchi. They can cause gastric irritation and ulceration.
- Antibiotics, steroids, expectorants, antihistamines, diuretics, anticholinergics, and other drugs may be used. Monitor side effects accordingly.
- Oral or parenteral corticosteroids significantly reduce treatment failure and the need for additional medical treatment; adverse drug reactions may occur (Wood-Baker et al, 2005).

## Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of mullein, camu-camu, licorice, red pepper, peppermint, or eucalyptus.
- Ephedra (ma huang) is an effective bronchodilator, but it increases BP significantly. Avoid taking with digoxin, hypoglycemic agents for diabetes, monoamine oxidase inhibitor (MAOI) antidepressants, antihypertensive medications, oxytocin, theophylline, caffeine, and dexamethasone steroids. Problems with BP, blood glucose, arrhythmias, increased heart rate, and CNS stimulation can occur.
- Vitamin D supplementation may be beneficial to prevent upper respiratory infections (Ginde et al, 2009).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Early detection, prevention, and early treatment of involuntary weight loss means putting more emphasis on dietary change (Brug et al, 2004; Weekes et al, 2009). Explain how to concentrate protein and calories in five to six small meals a day rather than three large ones.
- To conserve energy while preparing meals at home, choose foods that are easy to prepare. Try having the main meal early in the day to have more energy later.

**TABLE 5-6 Tips for Adding Calories to a Diet**

Food	Tip
Fats	Butter or margarine, cream, sour cream, gravies, salad dressings, and shortening. Mix butter into hot foods such as soups and vegetables, mashed potatoes, cooked cereals, and rice. Serve hot bread with lots of melted butter. Mayonnaise can be added to salads or sandwiches. Sour cream or yogurt can be used on vegetables such as potatoes, beans, carrots, and squash. Try sour cream or yogurt in gravy or salad dressings for fruit. Whipping cream has 60 kcal per tablespoon; add it to pies, fruits, pudding, hot chocolate, gelatin, egg-nog, and other desserts. Fry the entree (e.g., chicken, meat, fish) and sauté vegetables in butter or oil.
Sweets	Spread jelly or honey on toast or cereal; mix honey in tea. Add marshmallows to hot chocolate.
Snacks	Have snacks ready to eat, such as nuts, dried fruits, candy, buttered popcorn, crackers and cheese, granola, ice cream, and popsicles.
Beverages	Drink milk shakes with lots of ice cream added; these will be high in calories and protein. Use sugar-sweetened beverages such as carbonated beverages, coffees with whipped cream and sugar, and sugar-sweetened ades.

**TABLE 5-7 Tips for Adding Protein to a Diet<sup>a</sup>**

Food	Tip
Meats and meat substitutes	Add diced or ground meat to soups and casseroles. Serve a chef salad with cheese, ham, turkey, and sliced egg. Peanut butter can be spread on crackers, apples, celery, pears, and bananas. Nuts are a good snack with both fat and protein.
Dairy products	Add milk powder to hot or cold cereals, scrambled eggs, mashed potatoes, soups, gravies, ground meats (e.g., meat patties, meatballs, meatloaf), casserole dishes, and baked goods. Use milk or half and half instead of water when making soups, cereals, instant puddings, cocoa, and canned soups. Add grated cheese or cheese chunks to sauces, vegetables, soups, casseroles, hot crab dip, and mashed potatoes. Add extra cheese to pizza. Use yogurt as a fruit dip, or add yogurt to sauces and gravies.
Milk powder	Add skim milk powder to the regular amount of milk used in recipes or for a beverage. For double-strength milk, add 1 cup of dry powder to 1 quart of fluid milk, let it sit overnight for 286 kcals and 15 g of protein.
Beverages	Add protein powder to casseroles, soups, sauces, gravies, milkshakes, and eggnogs. One scoop may have 4 or 5 g of protein, depending on the brand. Some do not stir in as well as others; some dissolve better in hot foods. Buy instant breakfast mixes and use them instead of milk with meals or as snacks; one 8-oz glass provides 280 kcal. Formula products that are high in protein may be useful as supplements with or between meals or with medication pass in an institution.
Desserts	Choose dessert recipes that contain egg such as sponge or angel food cake, egg custard, bread pudding, and rice pudding.

<sup>a</sup>Protein can be added to many foods without having to increase the number of foods eaten.

Encourage slow eating and rest periods before and after meals.

- Encourage the patient to make small, attractive meals.
- Explain that excessively hot or cold foods may cause coughing spells for some individuals.
- Limit fluid intake with meals to decrease early satiety and subsequent decreased food intake.
- Schedule treatments to mobilize mucus (postural drainage, aerosol treatment) 1 hour before and after meals to prevent nausea.
- Improve physical conditioning with planned exercises, especially strengthening exercises and dancing. Consumption of an oral supplement may be beneficial to support exercise.
- If using oxygen, be sure the cannula is worn during and after meals. Eating and digestion require energy and oxygen.
- Maintain a relaxed atmosphere to make meals enjoyable.
- Promote good oral hygiene; periodontal disease is common.
- MNT should be coordinated with the team of clinical professionals to integrate rehabilitative elements into a system of patient self-management and regular exercise (ADA, 2009).

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# CHYLOTHORAX

## NUTRITIONAL ACUITY RANKING: LEVEL 2–4

### DEFINITIONS AND BACKGROUND

Chylothorax involves accumulation of clear lymph (chyle) in the pleural or thoracic space. It may be spontaneous or caused by amyloidosis, congenital chylothorax, coronary artery bypass grafting (CABG), violent vomiting, lymphoma, thoracic cage compression after cardiopulmonary resuscitation (CPR), thoracic duct trauma or surgery, sarcoidosis, or TB. Chylothorax is caused by surgical procedures in about half of all cases (Maldonado et al, 2009).

Chylous effusions look like milk. Since chyle represents direct absorption of fat from the small intestine lacteals, it is rich in triglycerides. Management of chylothorax may include use of total parenteral nutrition (TPN), low-fat enteral nutrition, thoracentesis to remove the chylous fluid, or surgical ligation of the thoracic duct (Suddaby and Schiller, 2004).

In the congenital form, breast milk and/or regular infant feeding formula should be used before proceeding to medium-chain triglyceride (MCT)-rich formula. Surgery may be considered if conservative management fails. Surgery is needed in the care of small babies with massive chylothorax, such as daily output exceeding 50 mL/kg per day (Cleveland et al, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Congenital chylothorax is the leading cause of pleural effusion in newborns but is not genetic in origin.

<b>Clinical/History</b>	Dyspnea	TLC
Height	Tachypnea	(decreased)
Weight	Decreased	Gluc
BMI	breath	Ca <sup>++</sup> , Mg <sup>++</sup>
Weight changes	sounds	Na <sup>+</sup> , K <sup>+</sup>
Temperature		CRP
I & O	<b>Lab Work</b>	BUN, creatinine
Lung x-ray	Alb, transthyretin	(Creat)
Pleural fluid	Chol	pCO <sub>2</sub> , pO <sub>2</sub>
analysis for	Trig	
triglyceride		
>110 mg/dL		

### INTERVENTION

### OBJECTIVES

- Offer continuous chest-tube drainage to decrease pleural chyle.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inappropriate Intake of Types of Fats

**Assessment Data:** Chylothorax with high pleural triglyceride levels in infant.

**Nutrition Diagnoses (PES):** Inappropriate intake of types of fatty acids related to chylothorax as evidenced by pleural triglyceride levels of 120 mg/dL.

**Interventions:** Use of breast milk or MCT oil formula in the infant.

**Monitoring and Evaluation:** Reduced pleural triglycerides and signs of chylothorax.

- Drainage of chyle from the chest or abdomen results in rapid weight loss and profound cachexia. Lessen consequences of a nutritional or immunological nature from drainage (e.g., sepsis, protein-calorie malnutrition, decreased lymphocytes).
- Replace fat, protein, and micronutrient losses from exudates.
- Achieve a positive nitrogen balance.
- Support involvement of a surgical nutrition support team, which is associated with better patient management and a reduction in inappropriate TPN orders (Saalwachter et al, 2004).

### FOOD AND NUTRITION

- Decrease enteral fat intake for patients who are tube fed. For patients who are fed orally, reduce total fat intake until condition is resolved; also for these patients, a low-fat diet may be used alone or with an elemental product.
- Some patients may be able to tolerate a low long-chain fatty acid formula given as a tube feeding (TF) (Cormack et al, 2004).
- For patients without sepsis, TPN may be indicated; care is needed to avoid aggravating the condition.
- Replace exudate losses of nutrients such as vitamin A and zinc. Check serum levels and replace with higher levels of the recommended intakes if necessary.

### Common Drugs Used and Potential Side Effects

- Octreotide (Sandostatin) may be given as conservative medical management (Paget-Brown et al, 2006; Suver et al, 2004). Nausea, vomiting, abdominal pain, diarrhea, and flatulence can occur. Use with the low-fat diet to decrease GI side effects.

- Medications are given, as appropriate, for the etiology. Monitor side effects accordingly, especially in conditions such as TB or cancer in which numerous side effects are created from drug therapies.
- Bronchodilators may be used. Some nausea and vomiting may occur.

### Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of herbs or botanicals in chylothorax.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the importance of adequate nutrition in recovery.
- Discuss interventions that are appropriate for the conditions and diagnoses involved.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## COR PULMONALE

### NUTRITIONAL ACUITY RANKING: LEVEL 2–4

### DEFINITIONS AND BACKGROUND

Acute cor pulmonale (right ventricular failure) occurs when relevant increases in pulmonary vascular resistance overwhelm compensatory mechanisms. Cor pulmonale may be acute, subacute, or chronic. The acute form is generally caused by acute respiratory failure (RF) or pulmonary embolism. A heart disease that follows disease of the lung (such as end-stage emphysema, silicosis), chronic cor pulmonale creates hypertrophy and eventual failure.

The body secretes B-type natriuretic peptide (BNP) from the cardiac ventricles in response to ventricular stretch and pressure overload; this counteracts vasoconstriction that occurs as a compensatory mechanism (Prahash and Lynch, 2004).

Long-term exposure to combustion-related fine particulate air pollution is a risk factor. Pulmonary hypertension (PH) and cor pulmonale may affect patients with COPD or CF. Children who have Prader-Willi syndrome may also experience obesity-related cor pulmonale (Stevenson et al, 2004).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Genes important in early lung development are also important in determining adult risk for COPD and its consequences (Bush, 2008). Glucocorticoid resistance may be related to cytokines, excessive activation of the transcription factor activator protein 1, reduced histone deacetylase-2 (HDAC2) expression, and increased P-glycoprotein-mediated drug efflux (Barnes and Adcock, 2009).

#### Clinical/History

Height  
Weight  
BMI  
Obesity?

Diet history  
I & O  
Edema of feet,  
ankles  
Chest x-ray

Echocardiography  
BP (hypertension?)

Right upper quadrant (RUQ) pain	Clubbing of fingers and toes	Na <sup>+</sup>
SOB	Sleep apnea?	K <sup>+</sup>
Distended neck veins	Cyanosis	Ca <sup>++</sup> , Mg <sup>++</sup>
Hypoxia	Hepatomegaly	H & H
Wheezing, cough	<b>Lab Work</b>	Serum Fe
Fatigue, weakness	BNP	BUN, Creat
	Alb	pCO <sub>2</sub> (increased)
		pO <sub>2</sub> (decreased)
		CRP

## INTERVENTION

### OBJECTIVES

- Improve the patient's capacity to eat meals without straining the diaphragm.
- Correct malnourished status but avoid weight gain that stresses the heart.
- Reduce or prevent fluid retention and edema to lessen cardiac workload.
- Prevent additional damage to cardiac and respiratory tissues.
- Improve energy levels and stamina. Oxygen may be needed, even at mealtimes.
- Support adequate lung function with higher antioxidant intake.

### FOOD AND NUTRITION

- Recommend small, frequent meals or oral supplements rather than three large meals (Anker et al, 2006).
- Use a nutrient-dense diet with concentrated protein sources. Double-strength milk, foods with milk powder added to them, high-calorie supplements, and addition

## SAMPLE NUTRITION CARE PROCESS STEPS

### Excessive Sodium Intake

**Assessment Data:** Diet history revealing intake of 8–10 g sodium daily, low intake of potassium, calcium and magnesium; ankle and foot edema; SOB.

**Nutrition Diagnoses (PES):** Excessive sodium intake related to dietary habits and long-term hypertension as evidenced by BP 212/100, elevated BNP, and dietary intake low in potassium, calcium and magnesium.

**Interventions:** Offer DASH diet education and alter diet to enhance fruits and vegetables and low-fat dairy products. Monitor sodium intake and offer alternatives for recipes and menu planning. Counsel about dining out and traveling. Evaluate medications for nutritional side effects.

**Monitoring and Evaluation:** Improved BP and fewer incidents of SOB; alleviation of edema. Improved BNP levels and fewer signs of heart failure.

of extra gravies or sauces to meals are useful when quantity of food must be kept minimal because of dyspnea.

- Restrict sodium or adjust fluid restriction as needed.
- Use foods that reduce likelihood of gastric irritation and reflux. For example, use low-acidic fruits, vegetables, and juices.
- Provide adequate potassium and magnesium intake with the Dietary Approaches to Stop Hypertension (DASH) diet.
- Include adequate levels of vitamins C, D, and E and selenium for antioxidant properties (Barnes and Adcock, 2009).
- Control CHO if needed. Insulin resistance is also common (Zamanian et al, 2009).
- Oral nutritional supplements or TF enables nutritional intake to be maintained or increased when usual intake is inadequate (Anker et al, 2006).

## Common Drugs Used and Potential Side Effects

- Bosentan or sildenafil may be given by mouth
- Calcium channel blockers and anticoagulants may be used. Monitor specific medicines for side effects.
- Thiazide diuretics can cause potassium depletion.
- Anabolic pharmacotherapy has the potential to improve nutritional status and function (Anker et al, 2006).
- To reverse glucocorticoid resistance, vitamin D may restore interleukin-10 response and use of antioxidants may be recommended (Barnes and Adcock, 2009).

## Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of herbs or botanicals in cor pulmonale.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Plan small, attractive meals that are nutrient dense. If fluid and sodium must be limited, provide tips.
- Recommend snacks that are nutrient dense and protein-rich but do not provide excessive sodium.
- Emphasize the importance of eating slowly to reduce SOB.
- Weight loss may be needed (Olson and Zwillich, 2005).
- Monitor heart murmurs in children to identify potential risks or need for surgery. If untreated, cor pulmonale can lead to right-sided heart failure and death.

## Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# CYSTIC FIBROSIS

## NUTRITIONAL ACUITY RANKING: LEVEL 3

## DEFINITIONS AND BACKGROUND

CF is a life-limiting, autosomal recessive inherited disease characterized by thick mucus and frequent pulmonary infections. There is general dysfunction of mucus-producing exocrine glands; high levels of sodium and chloride in the saliva, tears, and sweat; and highly viscous secretions in the pancreas, bronchi, bile ducts, and small intestine. Meconium ileus is a classic sign in newborn infants with CF; it is thicker than usual and passes more slowly.

CF affects approximately 30,000 children and adults in the United States. About one in 3200 Caucasians is affected; 2–5% of Caucasians carry the CF gene. The majority of CF patients have been diagnosed by age 3, but about 10% are not diagnosed until age 18 or older. The median life expectancy for CF patients is 33 years.

The CFTR system controls the efflux of physiologically important anions, such as glutathione (GSH) and bicarbonate, as well as chloride (Hudson, 2004). Interleukin-8 and cytokines also play a role in CF (Augarten et al, 2004). Anti-inflammatory and antioxidant treatments are recommended, including use of omega-3 fatty acids and selenium (Innes et al, 2007). Foods rich in lecithin, choline, betaine, and DHA can safely be recommended to reduce the effects of oxidative stress in CF.

The percentage of CF children who are malnourished varies; weight-based indicators greatly underestimate the extent. A link has been established between the degree of malnutrition and the severity of the disease. Inadequate intake, malabsorption, and increased energy requirements are common. Careful follow-up, better knowledge of energy requirements, dietary counseling, and nutritional intervention help optimize the growth of these patients.

A major goal is to maintain a good nutritional status because it improves long-term survival. Early diagnosis of CF and aggressive nutritional therapy are important to prevent growth failure and malnutrition (Farrell et al, 2005). When appropriate, lung transplantation may be considered.

Pancreatic insufficiency occurs in 80–90% of CF patients; 85% show growth retardation. Intestinal malabsorption is severe in virtually all people who have CF. Deficiency of pancreatic enzymes, bicarbonate deficiency, abnormalities of bile salts and mucosal transport, and anatomical structural changes are relevant. Appropriate pancreatic replacement therapy, combined with pharmacotherapy to address increased acidity of the intestines, achieves near-normal absorption in many patients.

Decreased bone density and increased risk of fractures are seen in patients with CF. Nutrition problems, hypogonadism, inactivity, corticosteroid use, and cytokines may contribute to the low bone mass. Treatment may include calcium, vitamin D<sub>3</sub>, vitamin K, bisphosphonates, and exercise.

Diabetes may also occur in persons with CF (more commonly in older individuals), reflecting impairment of beta-cell function, which is probably genetically determined. Onset of CF-related diabetes (CFRD) is often associated with a decline in health and nutritional status. Energy requirements may be higher than usual for patients with CF. Microvascular complications are common in CFRD; microalbuminuria is a sensitive indicator of progression to diabetic nephropathy in non-CF diabetes, but it is less sensitive for CF patients (Dobson et al, 2005).

Some patients are diagnosed in adulthood; patients diagnosed as adults differ distinctly from long-term CF survivors diagnosed as children (Nick and Rodman, 2005). While respiratory symptoms are not as severe and prognosis is more favorable, pancreatitis is more common (Nick and Rodman, 2005).

Progressive pulmonary disease associated with chronic bacterial infection and inflammation is the major cause of morbidity and mortality; CRP and IgG levels are indicators of severity (Levy et al, 2007). With anemia from chronic inflammation, treat the underlying inflammation rather than using supplemental iron (Fischer et al, 2007).

Overall, patients with CF who receive optimal nutrition have better growth, maintain better nutritional reserves, and have better pulmonary function than patients with CF who have poor nutrition (Hart et al, 2004). Metabolic and immunological response to infection and the increased work of breathing escalate calorie requirements.

Research supports the potential benefits of gene therapy; compacted DNA is used to get healthy genes into CF cells. Lung transplantation may be needed. Other treatments include use of antibiotics for infections and inhaled medicines to open the airways. Because no single strategy works for every patient, close monitoring of growth, symptoms, and changes in respiratory status must occur. The American Dietetic Association recommends a minimum of 4 MNT visits for patients who have CF.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** CF is genetic, inherited when both parents are carriers of the CF gene. There are hundreds of gene mutations, so each person's symptoms will be unique. The CF transmembrane conductance regulator (CFTR) is an important molecule for chloride that affects sodium transport, fluid, and ion management. CFTR is also expressed in the neurons of the human spinal cord.

Clinical/History	Upper GI or small bowel series	H & H
Height, weight		Serum Fe, ferritin
Growth chart for height and weight		Pancreatic enzymes (amylase, lipase)
BMI	<b>Lab Work</b>	White blood cell count (WBC)
Diet history	Pilocarpine iontophoresis sweat test (>60 mEq/L)	Prothrombin time (PT)
Foul smelling stools	pCO <sub>2</sub> , pO <sub>2</sub>	International normalized ratio (INR)
pH	Chol, Trig (elevated?)	Serum vitamin K
Chest x-ray or CT scan	Na <sup>+</sup> , K <sup>+</sup> , CL <sup>-</sup>	
Pulmonary function test	Alb	
DEXA scan		

Gluc CRP	Secretin stimula- tion test	Fecal elastase-1 in stool
Serum carotene levels	Trypsin or chy- motrypsin in stool	Serum copper (Cu)
Ca <sup>++</sup> , Mg <sup>++</sup>		

## INTERVENTION

### OBJECTIVES

- Determine current level of care needed (Table 5-8). Effective treatment should allow a normal diet, symptom control, malabsorption correction, and attainment of a normal nutritional state and growth.
- Achieve or maintain desirable BMI. BMI percentile is a better evaluation than % ideal body weight (IBW) in CF patients; %IBW underestimates the severity of malnutrition in children with short stature and overestimates the severity of malnutrition in children with tall stature (Zhang and Lai, 2004).
- Correct anorexia from respiratory distress.
- Provide optimal amounts of protein for growth, development, and resistance to infection. Increase LBM if depleted. Spare protein by providing up to twice the normal amount of calories from CHO and fat as in usual diet plans. Stunting may require extra protein, as from TF (Geukers et al, 2005).
- Decrease electrolyte losses in vomiting and steatorrhea. Replace lost electrolytes.
- Achieve adequate enzyme replacement to bring about near-normal digestion. Reduce excessive nutrient losses from maldigestion and malabsorption.
- Provide essential fatty acids in a tolerated form. Reduce arachidonic acid use to lessen inflammatory cascade. Include omega-3 fatty acids and antioxidants such as selenium and vitamins C and E. Vitamin E may be especially important for improving cognitive function (Koscik et al, 2004).
- Promote adequate bone mass, as serum levels of vitamins D and K may be low (Grey et al, 2008).
- Correct edema, diarrhea, anemia, azotorrhea, and steatorrhea.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Poor Nutritional Quality of Life

**Assessment Data:** Low BMI, anorexia, polypharmacy, depression.

**Nutrition Diagnoses (PES):** Poor nutritional quality of life related to GI distress with meals and polypharmacy as evidenced by depression, low BMI and anorexia.

**Interventions:** Offer nutrient dense foods. Collaborate with medical team to address depression and polypharmacy. Assure intake of pancreatic enzymes with meals to reduce GI distress.

**Monitoring and Evaluation:** Improved appetite and intake; BMI closer to normal range; improved nutritional quality of life.

**TABLE 5-8 Nutritional Management for Cystic Fibrosis (CF)**

Routine care	Within desired BMI
Anticipatory guidance	At 90–95% desired BMI
Supportive intervention	At 85–90% desired BMI
Rehabilitative care	At 75–85% desired BMI
Resuscitative or palliative care	Below 75% desired BMI

- Prevent progressive pulmonary disease or complications such as glucose intolerance, intestinal obstruction, cirrhosis, and pancreatic or cardiac diseases.
- Improve lung function outcomes from better nutrition and fewer chronic infections (McPhail et al, 2008).

## FOOD AND NUTRITION

- Energy expenditure may be as high as 199% of predicted in CF patients. CF patients may need to be given 120–150% more calories than for age-matched and gender-matched controls; this may mean 3000–4000 kcal for teens.
- Design the plan for 45–65% CHO and 20–30% fat. For persons with acute disease, starch and fat will not be well tolerated unless adequate levels of pancreatic enzymes are provided. Calorie intake should be about 150 kcal/kg for children and 200 kcal/kg for infants. Specific interventions for increasing total energy intake in CF patients are the role of the dietitian (Powers et al, 2004). Many supplements are available at little or no cost to the patient.
- Manage glucose levels if CF diabetes mellitus (CFDM) develops. Intensive insulin therapy and CHO counting will be important.
- Protein should be 10–35% of total calories. This may translate into 4 g/kg for infants, 3 g/kg for children, 2 g/kg for teens, and 1.5 g/kg for adults.
- Increase fat:CHO ratio with respiratory distress. Special respiratory formulas may be useful during those times, or use of MCTs and safflower oil may be beneficial. Be sure to time intake according to the use and type of pancreatic enzymes.
- Encourage intake of omega-3 fatty acids (DHA and EPA), selenium, betaine, and choline to reduce inflammation and enhance immunity.
- Supplement the diet with two times the normal RDAs for fat-soluble vitamins A, D, and E (use water-miscible sources such as “ADEKS” brand).
- Replace vitamin K as needed; check levels regularly. Either 1 mg or 5 mg doses of vitamin K will help replenish low levels (Drury et al, 2008).
- Use extra riboflavin if there is cheilosis; include the other B-complex vitamins and vitamin C at recommended levels.
- Be sure that iron, zinc, copper, selenium intakes meet recommended levels.
- Use liberal amounts of salt to replace perspiration losses.
- Lactose intolerance is common. Omit milk during periods of diarrhea if lactose intolerance persists.
- Intolerance for gas-forming foods and concentrated sweets may occur; alter dietary plans accordingly.

- Soft foods may be useful if chewing causes fatigue.
- Fluid intake should be liberal unless contraindicated.
- Use of turmeric and cumin in foods may be beneficial for CF patients (Berger et al, 2005). Research is ongoing to determine overall practicality of uses.
- Infants can tolerate most formulas (may need 24 kcal/oz) and commercial products that include some MCT oil. Do not add pancreatic enzymes to formula because desired amounts may not be totally consumed or enzymes may block the opening of the nipple.
- Nocturnal TF may be appropriate with growth failure. With reflux, a gastrostomy feeding tube may be well tolerated (Oliver et al, 2004). PN is not recommended due to high risk of infection.

### Common Drugs Used and Potential Side Effects

- Growth hormone may be used to bring onset of puberty in prepubescent children who have CF (Vanderwel and Hardin, 2006).
- New aerosol treatments show promise. See Table 5-9 for alternative therapies.

### Herbs, Botanicals, and Supplements

- Interesting studies suggest that curcumin may directly stimulate CFTR  $\text{Cl}^-$  channels (Berger et al, 2005). Use of turmeric and cumin in foods served to this population may have therapeutic benefits.
- Dietary supplement use is prevalent among CF children. Identify use of nonprescribed supplements because of unknown effects on growth and development and the potential for adverse drug interactions (Ball et al, 2005).

- The individual with CF should work with the CF nutritionist to maintain a healthy diet before considering adding herbal therapies. Each label on any supplement should be read carefully; some ingredients that can be toxic to people with CF.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Diet must be periodically reevaluated to reflect growth and disease process.
- New foods may be introduced gradually.
- A behavioral and nutrition intervention can be used with children to enhance weight and height velocities (Powers et al, 2005).
- To liquefy secretions, adequate fluid intake should be ensured. Discuss signs of dehydration and how to prevent or correct.
- Bronchopulmonary drainage, three times daily, may be required. Plan meals to be 1 hour before or after therapy.
- Ensure that all foods and beverages are nutrient dense.
- As needed, discuss issues related to fertility (most males with CF are infertile, but females are not).
- In adults with CF, 40% have glucose intolerance. Discuss how to manage diabetes in those cases.
- Discuss reimbursement issues for TFs and pumps.
- Depression is common and should be adequately managed (Quittner et al, 2008). Hypnosis may be useful in reducing pain from frequent intravenous injections or other treatments.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

**TABLE 5-9 Medications Used in Cystic Fibrosis (CF) and Potential Side Effects**

Medication	Description and Side Effects
Aerosolized antibiotics	TOBI (tobramycin solution for inhalation) can be delivered in a more concentrated dose directly to the site of CF lung infections and is preservative free.
Antibiotics	Antibiotics are needed during infections. Monitor for magnesium depletion.
Azithromycin	Azithromycin is an antibiotic that is effective in people with CF whose lungs are chronically infected with the common <i>Pseudomonas aeruginosa</i> bacteria.
Bisphosphonates	Bisphosphonates may be used to increase bone density.
Bronchodilators	Bronchodilators are used to open breathing passages. Monitor for side effects.
Glutathione (GSH)	Buffered GSH has been tested in some CF patients. Nebulized buffered GSH may ameliorate CF disease; longer and larger studies of inhaled GSH are warranted (Bishop et al, 2005).
L-arginine	Oral L-arginine (200 mg) may reduce nitric oxide levels, which can be detrimental (Grasemann et al, 2005). More studies are needed.
Mucolytics	Mucolytics, such as potassium iodide, liquefy secretions.
Pancreatic enzymes (pancrelipase)	Pancreatic granules (Viokase or Cotazym) are used to help improve digestion/absorption. Enteric preparations (Pancreas) act in the duodenum, so give before meals; for nocturnal feedings, give before, during, and after feedings. Avoid mixing with milk or ice cream. If too much is given, anorexia and constipation may result. Return of a voracious appetite and increase in stool bulk suggest an inadequate dosage. Dosing should be based on stool tests for malabsorption.
Pulmozyme	A mucus-thinning drug shown to reduce the number of lung infections and improve lung function.
Ursodeoxycholic acid	Used for meconium ileus and liver disease associated with CF (Lamireau et al, 2004).

NOTE. The need to take up to 40–60 pills daily is common in CF.

## INTERSTITIAL LUNG DISEASE

### NUTRITIONAL ACUITY RANKING: LEVEL 1–2

Adapted from: Cagle PT, MD. *Color Atlas and Text of Pulmonary Pathology*. Philadelphia: Lippincott Williams & Wilkins, 2005.

### DEFINITIONS AND BACKGROUND

Interstitial lung disease (ILD) is a general term that includes a variety of chronic lung disorders, sometimes also known as “interstitial pulmonary fibrosis.” In ILD, the lung tissue is damaged; the walls of the air sacs in the lung become inflamed; and, finally, scarring (fibrosis) occurs in the interstitium (tissue between the air sacs). The lung becomes stiff.

Although the histologic patterns of ILD in children and adults share similar features, important differences exist in etiology, clinical manifestations, and outcome (Young et al, 2008). Causes of adult ILD include environmental exposure to inorganic dust (such as silica) or organic dust (such as animal or bacterial proteins); exposure to gases, fumes, or poisons; or medical conditions such as sarcoidosis, scleroderma, rheumatic arthritis, and lupus. Agricultural workers also can be affected, with moldy hay causing allergic reactions in a disorder known as Farmer’s Lung.

Breathlessness during exercise and dry cough can be the first symptoms. Other symptoms vary in severity. Further testing is usually recommended to identify the specific type

of ILD a person has; some have known causes and some have unknown causes (idiopathic). The course of these diseases is unpredictable.

Some ILDs improve with medication if treated when inflammation occurs. Inflammation of these parts of the lung may heal or may lead to permanent scarring of the lung tissue. Fibrosis results in scarring and permanent loss of that tissue's ability to transport oxygen. The level of disability that a person experiences depends on the amount of scarring of the tissue. Oxygen may be needed; some patients need it all of the time, and others need it only during sleep and exercise.

A pulmonary rehabilitation program is often recommended for education, exercise conditioning, breathing retraining, energy-saving techniques, respiratory therapy, nutritional counseling, and psychosocial support. Lung transplantation has become an option for some patients.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Prevalence of ILDs is low in children. A total of 10–16% may be familial, with mutations in surfactant proteins or the SFTPC and ABCA3 gene (Nogee, 2006).

Clinical/History		Lab Work
Height, weight	Chest x-ray or CT scan	pCO <sub>2</sub> , pO <sub>2</sub>
Growth chart for height and weight	Pulmonary function test	Chol, Trig
BMI	Exercise function test	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
Diet history	Clubbing of fingers	Alb
Fecal fat study	Dry cough	H & H
pH	Cyanosis	Serum Fe
Bronchoalveolar lavage (BAL)		WBC count
Lung biopsy		PT or INR
		Gluc
		Ca <sup>++</sup> , Mg <sup>++</sup>

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Underweight

**Assessment Data:** Poor dietary intake, underweight for height.

**Nutrition Diagnoses (PES):** Underweight (NC 3.1) related to inadequate energy intake as evidenced by low percentile height, weight 30%tile on growth chart and estimated intake approximately 500 calories below estimated needs.

**Interventions:** Enhance intake through adding protein and calories to casseroles and foods served. Educate about nutrient density and increasing calories. Counsel with tips about eating slowly and frequently.

**Monitoring and Evaluation:** Weight gain closer to desired BMI; improved intake of energy and nutrients.

## INTERVENTION

### OBJECTIVES

- Early identification and aggressive treatment are needed to lessen inflammation and prevent further lung damage.
- Remove the source of the problem, if known.
- Lessen the effect of complications.
- Maintain nutritional immunity as far as possible. Improve poor status.
- Provide nutritional repletion before surgery, if surgery is scheduled.

### FOOD AND NUTRITION

- If not contraindicated, offer 3–3.5 L fluid daily to liquefy secretions and to help lower temperature.
- A high-calorie, soft diet is recommended, especially if oxygen is used. Frequent, small meals may be beneficial.
- Discuss how to make mealtimes relaxed, especially if oxygen is required at the same time. Plan for longer mealtimes accordingly.
- A multivitamin–mineral supplement may be beneficial, especially for vitamins A, C, and E. Vitamin E reduces the extent of pulmonary damage in some types of ILD (Card et al, 2003).
- Ensure adequate potassium intake, as from fruits and juices.
- When possible, add more fiber to prevent constipation.
- TF at night may be beneficial if intake is poor during the day. A gastrostomy or transpyloric feeding tube may be desirable.

### Common Drugs Used and Potential Side Effects

- Oral prednisone or methylprednisone is frequently the first medication used to help decrease inflammation.
- Cyclophosphamide (Cytoxan) may be used if steroid therapy fails or if it is not possible. It reduces inflammation by killing some inflammatory cells and suppressing their function. Response to therapy may require up to 6 months or longer. In some cases, a combination of prednisone and cyclophosphamide is used with good results. Side effects include GI irritation, bladder inflammation, bone marrow suppression, infection, and blood disorders.
- Azathioprine (Imuran) is used if there are problems tolerating the side effects of the above medications. It is not as effective as cyclophosphamide, but side effects are more tolerable. Side effects include fever, skin rash, GI irritation, and blood disorders.
- Interferon has been tested in clinical trials with some promising results.

### Herbs, Botanicals, and Supplements

- Herbs and botanicals should not be used for ILD because there are no controlled trials to prove efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss how a balanced diet supports overall immunity and health status. Teach principles of the Food Guide Pyramid and the Dietary Guidelines.
- Teach how to incorporate antioxidants and related nutrients in the diet, especially if energy intake is low because of poor appetite.
- Influenza vaccine and pneumococcal pneumonia vaccine are both recommended for people with ILD.
- Rehabilitation and education programs may help some people. Local support groups have benefited people with ILD and their family members and friends.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# PNEUMONIA

## NUTRITIONAL ACUITY RANKING: LEVEL 1-2

### DEFINITIONS AND BACKGROUND

Pneumonia involves acute inflammation of the alveolar spaces of the lung. Lung tissue is consolidated as alveoli fill with exudate, usually after a cold or the flu. To protect against pneumonia, dental and oral health care are important. Dental plaque germs may be inhaled and may lead to onset of pneumonia; regular tooth brushing, flossing, and dental check-ups are recommended (El-Solh et al, 2004).

A productive cough that is painful and incessant (generally with green/yellow sputum that progresses to pink, brown, or rust color) may be indicative. Pneumonia may be classified as community acquired, hospital acquired, or atypical. Table 5-10 describes the common types of pneumonia. The most common form is community-acquired pneumococcal pneumonia. With treatment, most types of bacterial pneumonia can be cured within 1-2 weeks; viral pneumonia may last longer. Mycoplasmal pneumonia resolves in 4-6 weeks. Before antibiotics, pneumonia caused many deaths in elderly individuals; it now ranks sixth among causes of death in the United States.

People at high risk for pneumonia include the elderly; the very young; those with COPD, diabetes mellitus, congestive heart failure, sickle cell anemia, AIDS, or asthma; and people undergoing cancer therapy or organ transplantation. Nursing home residents have chronic medical conditions that gradually lead to "decompensation" in functional status, nutritional status, and pulmonary clearance. Elderly patients with low body weight and hypoalbuminemia are more likely to die from pneumonia than healthy patients.

Inflammation may cause low serum albumin levels in many pneumonia patients. GSH is the primary antioxidant that lines alveolar space; selenium, vitamins E and C may be

beneficial. However, supplementation alone will not prevent pneumonia in well-nourished older individuals (Merchant et al, 2004).

Enteral feeding provides nutrients for patients who require endotracheal tubes and mechanical ventilation. There is a presumed increase in the risk of ventilator-associated pneumonia (VAP) with TF, but this is not always true.

Pneumonia due to immune system suppression and membrane damage induced by oxidative stress suggest that sufficient fatty acid intake may be useful in the nutritional repletion of such patients with pneumonia. The American Dietetic Association previously recommended 3 MNT visits for persons who have pneumonia.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Genes that have inflammatory molecules such as tumor necrosis factor, interleukin-10, and angiotensin-converting enzyme may play a role in susceptibility to pneumonia. Population studies are needed.

<b>Clinical/History</b>	BMI	Chills, fever
Height	I & O	(102–106°F),
Weight	Diet history	delirium
	BP	Pleuritic pain

TABLE 5-10 Types of Pneumonia

Type	Description
Allergic	From sensitivity to dust or pollen.
Aspiration	From swallowing a foreign substance. The gastric volume predisposing to aspiration is larger than 30 mL (Kalinowski and Kirsch, 2004). Just a few hours with “nothing by mouth” helps prepare for surgery because risk of aspiration is lower than previously believed. Ventilator-associated pneumonia, a common and serious complication in critically ill patients who require a ventilator, results from pneumonia occurring >48 hours after endotracheal intubation (Parker and Heyland, 2004). It is caused by microaspiration of contaminated oropharyngeal or gastrointestinal secretions into the airways (Parker and Heyland, 2004).
Bacterial	From bacteria normally present in mouth/throat. Quick onset with high fever and rapid breathing. Several bacteria may be relevant. <i>Streptococcus pneumoniae</i> causes about 25% of bacterial types. <i>Mycoplasma</i> causes walking pneumonia, notorious for sore throat and headache in addition to the usual symptoms; causes about 20% of all kinds of pneumonia. When pneumonia is due to pertussis (whooping cough), long coughing spells, turning blue from lack of air, and making a classic “whoop” sound when trying to take a breath will occur. <i>Haemophilus influenzae</i> type b (Hib) is America’s most common cause of bacterial meningitis; it is also an agent of pneumonia.
Chemical	From accidental inhalation of toxic fumes and chemicals, often in the workplace or when using cleaning agents such as bleach in a closed space.
Healthcare-associated pneumonia	Pneumonia in any patient who has been hospitalized in an acute care hospital for 2 or more days within the past 90 days; residents of a nursing home or long-term care facility; recipients of recent intravenous antibiotic therapy, chemotherapy, or wound care within the past 30 days; or patients who have attended a dialysis clinic.
Hypostatic	In bedridden persons, usually elderly individuals.
<i>Pneumocystis carinii</i> pneumonia	Caused by a fungus, primarily in AIDS patients.
Viral	More common; leads to about 50% of pneumonia cases. Symptoms appear more gradually; less severe than bacterial form. Wheezing is common in this type. Adenoviral infections often affect infants and young children. Other viruses that can cause pneumonia include rhinovirus, influenza, respiratory syncytial virus, and parainfluenza virus (croup).

Difficult, painful respirations	Tachypnea, tachycardia	pCO <sub>2</sub> , pO <sub>2</sub>
SOB, rales, rhonchi	Anorexia, malaise	Na <sup>+</sup> , K <sup>+</sup>
Bronchoscopy	Abdominal distention	Ca <sup>++</sup> , Mg <sup>++</sup>
Productive cough (purulent, green, or rust)	Anxiety, restlessness	Alb, transthyretin
Respiratory rate (increase)	Cyanosis of nail beds	CRP
Fatigue, weakness	<b>Lab Work</b>	H & H
	WBCs (increased)	Serum Fe, ferritin
		Transferrin
		Gluc
		BUN, Creat

## INTERVENTION

## OBJECTIVES

- Prevent or correct dehydration.
- Relieve breathing difficulty and discomfort. Oxygenate all tissues.
- Prevent weight loss from a hypermetabolic state.
- Support diet with adequate antioxidants and nutrient-dense foods.
- Avoid additional infections; prevent sepsis and multiple organ dysfunction syndrome.
- In convalescent stage, avoid constipation.

## FOOD AND NUTRITION

- If not contraindicated, offer 3 L or more of fluid daily to liquefy secretions and to help lower elevated temperature.
- Progress, as tolerated, to a high-calorie diet. If overweight, allow normal calorie intake for age and sex.
- Early enteral nutrition, properly administered, can decrease upper GI intolerance and nosocomial pneumonia (Kompan et al, 2004).
- Frequent, small meals and a soft diet may be tolerated better.
- A multivitamin–mineral supplement may be beneficial, especially including selenium and vitamins E and C. Vitamin A is needed to keep mucous membranes healthy.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Inadequate Fluid Intake

**Assessment Data:** Dehydration, rapid breathing, poor skin turgor, I & O records.

**Nutrition Diagnoses (PES):** Inadequate fluid intake related to fever of 103°F, and pneumonia as evidenced by signs of dehydration and low I & O.

**Interventions:** Encourage intake of fluids at all meals and between meals as well. Keep water or a beverage on hand within easy reach.

**Monitoring and Evaluation:** Improved I & O records; reduction of fever; normal skin turgor.

- When possible, add more fiber to prevent constipation.
- Ensure adequate potassium intake, as from fruits and juices.

### Common Drugs Used and Potential Side Effects

- A 7-day course of low-dose hydrocortisone infusion speeds recovery from community-acquired pneumonia (CAP) and prevents complications due to sepsis (Confalonieri et al, 2005).
- Antibiotics, such as clarithromycin (Biaxin), are used in bacterial pneumonia. Nausea, diarrhea, and abdominal pain can occur.
- Telithromycin (Ketek) is used for the treatment of infections caused by bronchitis, bacterial sinusitis, and CAP.
- Analgesics are used to reduce pain and antipyretics are used to lessen fever.
- Cephalosporins are often useful for nursing home-acquired pneumonia (Muder et al, 2004). Ceftriaxone may be used against MRSA, *Enterococcus faecalis*, *Enterobacteriaceae*, and *Pseudomonas aeruginosa*.

### Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of herbs or botanicals, such as echinacea, honeysuckle, garlic, dandelion, astragalus, and baikal skullcap in pneumonia patients.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of diet and fluid intake in recovery.
- Loss of swallowing function can lead to dehydration, malnutrition, pneumonia, and reduced quality of life for senior citizens; increasing strength of head and neck musculature can be recommended (Ney et al, 2009). In hypostatic pneumonia, occupational or physical therapy may be beneficial.
- Fruit and vegetable juices add calories, fluid, and sometimes fiber to the diet and can be available at bedside.
- Routine immunizations are available against *Haemophilus influenzae* and pertussis beginning at 2 months of age; pertussis immunization is the “P” part of the routine DtaP or DTP.

- Vaccines are now also given against the pneumococcus organism (PCV), a common cause of bacterial pneumonia. Although the polysaccharide pneumococcal vaccine (PPV) does not prevent CAP, it might still improve outcomes in those who develop pneumonia (Johnstone et al, 2007).
- Flu vaccines are recommended for individuals with chronic illnesses such as heart and lung disorders, including asthma. Premature infants may need protection against respiratory syncytial virus (RSV). Individuals who have HIV infection may need protection against *Pneumocystis carinii*.
- Protect people who have pneumonia from others who have respiratory tract infections, such as the common cold.

### Patient Education—Foodborne Illness

- Careful food handling will be important.
- Hand washing is key as well, especially after sneezing and coughing and before eating.

## PULMONARY EMBOLISM

### NUTRITIONAL ACUITY RANKING: LEVEL 1–2

### DEFINITIONS AND BACKGROUND

A pulmonary embolism is caused by a partial or complete occlusion of a pulmonary artery from a blood clot from another part of the body that has found its way to the lung. The condition can be life-threatening. Sudden, sharp substernal pain, SOB, cyanosis, pallor, faintness, fever, hypoten-

sion, and wheezing can occur, sometimes followed by right heart failure. Approximately 10% of patients suffer some form of tissue death or pulmonary infarction.

Venous thrombosis most often starts in the calf veins and moves on to the lung. Thrombosis in the veins is triggered by venostasis, hypercoagulability, and vessel wall inflammation (the Virchow triad).

Common causes include recent surgery, fractures, immobility, burns, obesity, chemotherapy, old age, heart failure, polycythemia, ulcerative colitis, homocystinemia, and even pregnancy. It is actually one of the primary concerns during pregnancy (Stone and Morris, 2005). Hormone replacement therapy (HRT) is no longer recommended for women after menopause because of the increased risk for pulmonary embolism (Hillman et al, 2004).

Massive pulmonary embolism causes hypotension, with a systolic arterial pressure less than 90 mm Hg; mortality ranges from 30% to 60%. Nonmassive pulmonary embolism presents with systolic arterial pressure greater than or equal to 90 mm Hg and is much more common. Oxygen therapy is always initiated, and fibrinolytic therapy is the primary mode of treatment.

Interesting studies have been conducted to evaluate the role of diet on embolism. In the Iowa cohort study of older women, greater intake of alcohol was associated with a lower risk of incident thromboembolism; no associations were seen with “Western” or “Prudent” dietary patterns, fruit, vegetables, dairy, meat, refined grains, whole grains, regular soda, vitamins E, vitamin B<sub>6</sub>, vitamin B<sub>12</sub>, folate, omega-3 fatty acids, or saturated fat (Lutsey et al, 2009). In the Longitudinal Investigation of Thromboembolism Etiology study, greater intake of fish, fruit, and vegetables were noted as beneficial (Steffen et al, 2007). Clearly, more research is needed.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Hereditary factors that may produce a hypercoagulable state include Antithrombin III deficiency, Protein C or Protein S deficiency, Factor V Leiden, plasminogen or fibrinogen abnormalities.

Homocysteine, factor VIII and von Willebrand factor levels are risks for embolism and they are influenced by dietary intake (Steffen et al, 2007).

Clinical/History	Arterial blood gases	Low oxygen saturation (hypoxia)
Height	Diaphoresis	Perfusion scans
Weight	Temperature (fever)	CT pulmonary angiography
BMI	I & O	Cyanosis
Sudden SOB	Sharp chest pain	
Hemoptysis with pink, foamy mucus	ECG	<b>Lab Work</b>
Tachypnea (respiratory rate >16/min)	Echocardiography	Alb,
Tachycardia (heart rate >100/min)	Doppler ultrasound	transferrin
	Cardiac murmur	Na <sup>+</sup> , K <sup>+</sup>
	Palpitations	Ca <sup>++</sup> , Mg <sup>++</sup>
		PT or INR

WBCs  
(increased)  
Troponin  
(high?)

H & H, Serum Fe  
Elevated BNP?  
Liver function tests

Homocysteine  
Folic acid and B<sub>12</sub> levels

## INTERVENTION

### OBJECTIVES

- Prevent right-sided heart failure, atelectasis, and bleeding.
- Stabilize PT and INR if warfarin (Coumadin) is used.
- Maintain lung function through higher antioxidant intake.
- Normalize body temperature where there is fever.
- Replenish nutrients depleted by respiratory distress.
- Oxygenate tissues.
- Eliminate edema when present.

## FOOD AND NUTRITION

- Use a regular or high-calorie diet; use a low-sodium diet for patients with edema.
- Increase fluid intake as tolerated.
- Control vitamin K in diet when PT cannot be stabilized.
- Small meals may be needed.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Involuntary Weight Loss

**Assessment Data:** Poor oral intake and weight loss of 15 lb in 6 months; swallowing difficulty; decreased appetite and frequent coughing during meals.

**Nutrition Diagnoses (PES):** Involuntary weight loss related to poor oral intake, coughing at meals and swallowing difficulty as evidenced by 15 lb weight loss in 6 months.

### Interventions:

ND 4.5 Patient to use oxygen via nasal cannula during meals to assist with breathing and swallowing and to improve energy levels.

E2.2 Basic education tips on managing discomfort related to SOB by using—five to six small meals throughout the day that are easily prepared; consume main meal early in the day; drink fluids between meals; add protein and calories into meal items.

RC2.2 Refer to local meals on wheels program for home-delivered meals 5 days per week.

**Monitoring and Evaluation:** Improvement in oral intake and weight status; fewer complaints of fatigue at mealtime; better appetite.

- Provide sufficient antioxidants such as vitamins C and E and selenium. A diet including more plant foods, alcohol, and fish and less red and processed meat may be suggested (Lutsey et al, 2009; Steffen et al, 2007).

### Common Drugs Used and Potential Side Effects

- Rivaroxaban is a novel oral direct factor Xa inhibitor for prophylaxis in total knee and hip replacements, with few side effects and low potential for drug–food interactions (Chen and Lam, 2009). Liver enzymes should be checked during use.
- Heparin slows down clot progression and reduces risk of further clots. Warfarin (Coumadin) increases clotting times by thinning the blood. If problems in stabilizing the PT exist, controlled vitamin K may be needed. Use stable amounts of green leafy vegetables and fish.
- Fibrinolytic therapy is a primary treatment. Alteplase is generally infused over several hours. Tissue plasminogen activator (tPA) is also available for thrombolysis.
- Estrogen-containing contraceptives and hormone replacements may promote an embolism in susceptible women. Close medical monitoring is advised.

### Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of herbs or botanicals in pulmonary embolism.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain sources of vitamin K in the diet. Therapy often continues for 3–6 months.
- Individuals on long airline flights should try to obtain some physical activity to prevent embolism.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## RESPIRATORY DISTRESS SYNDROME

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

Phase 1. Injury reduces normal blood flow to the lungs. Platelets aggregate and release histamine (H), serotonin (S), and bradykinin (B).

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

RDS may occur as part of systematic inflammatory response syndrome (SIRS), affecting approximately 70% of patients in the ICU. Acute respiratory distress syndrome (ARDS) develops within 24–48 hours in patients who have sepsis or who are critically ill, in shock, or severely injured. Other causes include infectious pneumonia, aspiration of food into the lung, several blood transfusions, pulmonary embolism, chest injury, burns, near drowning, cardiopulmonary bypass surgery, pancreatitis, overdose of drugs such as heroin, methadone, or aspirin.

ARDS has three pathologic stages: exudative, proliferative, and fibrotic. Patients often have pulmonary edema but have normal left atrial and pulmonary venous pressures.

In infants, RDS occurs in premature or low birth weight babies as hyaline membrane disease. Such babies are often born to mothers who have diabetes. Surfactant treatment may be of significant benefit in newborn infants with respiratory compromise (Finer, 2004).

One of the most common causes of ARDS in adults is sepsis. Here, a high-fat diet or formula with EPA may be beneficial. In ARDS, an overwhelming inflammatory response damages the endothelial-alveolar units, reducing oxygen diffusion and increasing pulmonary workload (Singer and Shapiro, 2009). Specialized enteral formulas may be beneficial adjunctive therapy by reducing lung inflammation and improving oxygenation (Malik and Zaloga, 2010; Priestley and Helfaer, 2004).

Indirect calorimetry (IC) accurately estimates a patient's energy expenditure; this helps the health care team when there is weaning failure.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** ARDS may have a relationship with tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin- $\beta$  (IL- $\beta$ ), interleukin 10 (IL-10), and soluble intercellular adhesion molecule 1 (sICAM-1).

Clinical/History	Lab Work	
Height	Complete	Transferrin
Weight	blood count	pCO <sub>2</sub> , pO <sub>2</sub>
BMI	(CBC)	Transthyretin
Growth profile	Low blood	Na <sup>+</sup> , K <sup>+</sup>
Diet history	pH (acidic)	Ca <sup>++</sup> , Mg <sup>++</sup>
IC	H & H	Serum
I & O	Serum Fe,	phosphorus
BP	ferritin	BUN, Creat
Temperature		
RQ		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Enteral Nutrition

**Assessment Data:** Ventilator dependency for acute respiratory distress, ICU admission, inability to consume oral food and beverages, IC indicates energy needs as 1400 kcal/d; current TF order for 2000 kcal

**Nutrition Diagnoses (PES):** Excessive enteral nutrition related to overfeeding with order for 2000 kcal as evidenced by IC results suggesting 1400 kcal as sufficient.

**Interventions:** Nutrition prescription should change to match energy needs. Educate nutrition support team about results of IC (1400 kcal vs. current order for 2000 kcal). Suggest immunomodulating diet (IMD) formula supplemented with fructooligosaccharides (FO).

**Monitoring and Evaluation:** Improved arterial blood gases; enteral nutrition formula tolerated; able to gradually wean from ventilator.

## INTERVENTION

### OBJECTIVES

- Identify the cause and remove the ongoing insult. Promote rapid recovery and oxygenation of tissues; support ventilator management.
- Prevent relapse. Avoid secondary insults through aggressive immune surveillance, complete nutrition, and adequate oxygen delivery.
- Counteract side effects of medications as ordered.
- Replace essential fatty acids, carnitine, and other nutrients.
- Prevent malnutrition, which depresses CNS output for ventilatory drive. Starvation decreases the desire to breathe, causing an abnormal breathing pattern, pneumonia, and atelectasis. Muscle mass (including diaphragm) varies with body weight, and refeeding may take 2–3 weeks.
- Prevent overfeeding (hepatic dysfunction, fatty liver, and CO<sub>2</sub> overproduction) and underfeeding (morbidity, mortality, and decreased response to therapy). Avoid refeeding syndrome.
- Prevent fluid overload.
- Support lung function, which is found to be better with higher antioxidant intake levels (Singer et al, 2006).
- An IMD that is supplemented with FO improves the outcome of medical ICU patients with SIRS/sepsis and ARDS (Marik and Zaloga, 2010).

### FOOD AND NUTRITION

- Provide parenteral fluids and oxygen as needed.
- Progress, when possible, to oral feedings. Use TPN only if GI tract is nonfunctional. TPN-induced changes in CO<sub>2</sub> production occur if overfed (Plurad et al, 2009).
- For calories, use 30–35 kcal/kg. Nonprotein calories should come from 50% glucose and 50% lipid.
- Increased fat may be required to normalize the RQ. Fat also adds extra energy intake and palatability to the diet.
- Ensure adequate provision of EFA. Low linoleic acid status in critically ill RDS infants may require IVs with a fat emulsion added.
- Increase intake of omega-3 fatty acids, especially EPA and GLA (Singer et al, 2006). Enteral administration of fish oil, antioxidants and arginine improves oxygenation and clinical outcomes (Singer and Shapiro, 2009). Provide vitamins C and E and selenium at slightly higher than RDA levels, and fat-soluble vitamins in water-miscible form if necessary.
- Inositol supplementation promotes survival of premature infants with RDS (Howlett and Ohlsson, 2003).

### Common Drugs Used and Potential Side Effects

- Heparin or warfarin (Coumadin) may be used as a blood thinner.

- Ventilator-dependent surgical patients receiving oxandrolone have prolonged courses of mechanical ventilation; oxandrolone may enhance collagen deposition and fibrosis in the later stages of ARDS and thus delay recovery (Bulger et al, 2004).

## Herbs, Botanicals, and Supplements

- Use of n-3 PUFA targets the inflammatory response in ARDS (Singer and Shapiro, 2009).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of fat intake on respiratory requirements. Fat decreases CO<sub>2</sub> production.
- Small, frequent feedings may be beneficial.
- Tight glucose control is needed.
- Prone positioning, especially for meals, is recommended.

## Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# RESPIRATORY FAILURE AND VENTILATOR DEPENDENCY

## NUTRITIONAL ACUITY RANKING: LEVEL 4

Adapted from: Springhouse. *Lippincott's Visual Encyclopedia of Clinical Skills*. Philadelphia: Wolters Kluwer Health, 2009.

## DEFINITIONS AND BACKGROUND

RF involves ineffective gas exchange across the lungs by the respiratory system. Arterial blood gases should be used to determine the presence of RF and Table 5-11 lists common causes. Acute respiratory failure (ARF) involves sudden

absence of respirations, with confusion or unresponsiveness and failure of pulmonary gas exchange mechanism. Chronic pulmonary disease or an acute injury can cause ARF, which requires mechanical ventilation.

**TABLE 5-11 Causes of Respiratory Failure**

Symptom	Cause
Airway obstruction	Chronic bronchitis, emphysema, bronchiectasis, cystic fibrosis, asthma, bronchiolitis, inhaled particles, subglottic stenosis, tumor, laryngeal edema
Poor breathing	Obesity, sleep apnea, drug intoxication, trauma, hypothyroidism
Neuromuscular disease	Myasthenia gravis, muscular dystrophy, polio, Guillain-Barré syndrome, botulism, polymyositis, stroke, amyotrophic lateral sclerosis, spinal cord injury
Abnormality of lung tissue	Acute respiratory distress, drug reaction, pulmonary fibrosis, fibrosing alveolitis, widespread tumors, radiation therapy, sarcoidosis, burns
Abnormality of chest wall	Kyphoscoliosis, chest wound

Mechanical ventilation can be delivered with a plastic tube inserted through the nose or mouth into the trachea. A tracheostomy is safer and more comfortable for long-term ventilation for either pure oxygen or a mixture of oxygen and air.

Anabolic and catabolic hormones, muscle work, and nutritional status affect skeletal muscle mass and muscle strength. Substrate plus muscle work help to stimulate protein synthesis. Randomized controlled trials comparing early aggressive use of enteral nutrition with delayed, less-aggressive use of enteral nutrition suggest that providing early, aggressive enteral nutrition promotes improved clinical outcomes (Stapleton et al, 2007). In starvation, respiratory muscles are catabolized to meet energy needs; refeeding helps ventilatory response. Enteral feedings started within 24–48 hours may reduce length of time on a ventilator.

Daily screening of ventilator patients is recommended, followed by trials of spontaneous breathing. The process of weaning takes a few days and requires proper refeeding. Table 5-12 identifies ventilator-dependency feeding stages. The length of ventilator dependency time relates to energy and CHO intake. Aggressive immune surveillance, nutritional support, and fluid management are critical (Michaels, 2004).

Older patients are more at risk for RF and may be harder to wean (Sevransky and Haponik, 2003). Attention must be paid to factors such as electrolytes, infections, anemia, heart failure, medications, or hypothyroidism (Datta and Scalise, 2004). Use of an evidence-based nutrition support protocol improves the likelihood of meeting nutritional requirements (Mackenzie et al, 2005). Patients with RF often have 30% or higher increase in oxygen requirements. Too much oxygen can be damaging, though, so careful monitoring is needed. Lung function is found to be better with higher antioxidant levels.

**TABLE 5-12 Ventilatory-Dependency Feeding Stages**

Stage	Objectives and Actions
Intubation/ Acute Phase	Replenish muscle glycogen stores and reverse catabolism. Enteral nutrition by day 3; parenteral by day 7 if GI tract not functioning.
Prewaning	Maintain positive nitrogen balance, improve visceral protein stores, improve lean body mass, and promote weight gain. Evaluate albumin or prealbumin levels.
Weaning 1–4 weeks	Provide energy substrates to cover needs of respiratory muscles that are working harder; minimize CO <sub>2</sub> production. Be careful not to overfeed. Check prealbumin levels and monitor fatigue. Get a Speech evaluation for swallowing. Assess for gastrostomy if needed.
Rehabilitation	Maintain nutrient needs despite anorexia or dysphagia; support anabolism. Maintain enteral nutrition at night until oral intake meets needs. If aspiration risk remains, continue gastrostomy.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutations in the ABCA3 transporter have been associated with childhood respiratory disease; there is a role for surfactant, a mixture of phospholipids, cholesterol, and hydrophobic proteins (Fitzgerald et al, 2007; Shulenin et al, 2004).

Clinical/History	Temperature (fever?)	H & H Serum Fe, ferritin
Height	Forced vital capacity (FVC)	Na <sup>+</sup> , K <sup>+</sup>
Weight	Skinfold thickness	Ca <sup>++</sup> , Mg <sup>++</sup>
BMI		WBC (elevated)
Resting energy expenditure (REE) from IC	<b>Lab Work</b>	Chol, Trig
Diet history	Hypophos- phatemia (can cause ARF)	Transferrin
I & O	Gluc	Thyroid tests
PaO <sub>2</sub> < 60 mm Hg	Urinary Gluc	CRP
PaCO <sub>2</sub> > 50 mm Hg	Transthyretin (decreased)	pH (acidemia below 7.4, alkalemia above 7.4)
Respiratory rate	TLC (decreased)	
RQ		
BP		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive CHO Intake

**Assessment Data:** IC indicates need for 1675 kcals daily. TF provides 65% CHO, 20% lipid, 15% protein; 2300 kcals total. ARF with ventilator dependency post motor vehicle accident. BMI 24. Serum glucose levels 350, 250, 301 on 3 days.

**Nutrition Diagnoses (PES):** Excessive CHO intake related to high CHO and energy content of TF formula as evidenced by ventilator dependency, elevated CO<sub>2</sub> levels, and inability to wean.

**Interventions:** Evaluate enteral needs and select TF product that has less CHO. Calculate energy, protein, and fluid needs with a new product and provide rate and amount using continuous drip equal to 1675 kcals daily. Monitor use of insulin and adjust according to serum glucose levels.

**Monitoring and Evaluation:** Gradual weaning from ventilator dependency. Improved blood gases and lower CO<sub>2</sub> production. Weight maintenance; BMI remaining at 24. Serum glucose within acceptable range.

**INTERVENTION****OBJECTIVES**

- Promote normalized nutritional intake despite hypermetabolic status of the patient and the prohibition of oral intake due to endotracheal tubes.
- Oxygenate tissues and relieve breathlessness; decrease CO<sub>2</sub> production.
- Monitor sensations of hunger when patients are unable to communicate their hunger and thirst.
- Prevent respiratory muscle dysfunction by ensuring that the patient is properly nourished.
- Provide intensive metabolic support with insulin therapy, an appropriate blood glucose target, nutrition risk assessment, early or combined enteral nutrition and PN, and close nutritional monitoring (Mechanick and Chiolerio, 2008).
- Counteract hypotension caused by positive-pressure ventilation, acidosis, or both.
- Provide nutritional substrates that will maintain surfactant production and LBM. Achieve or maintain weight; note that not all patients are malnourished.
- Prevent atelectasis, pulmonary infection, sepsis, glucose or lipid intolerance, multiple organ dysfunction syndrome, and aspiration.
- Alleviate GI complications, which are a concern with mechanical ventilation. Hypomotility and diarrhea are common.
- Protocol-driven weaning reduces use of mechanical ventilation (Dries et al, 2004; Graham and Kirbey, 2006). Adjust goals as appropriate.
- Maintain flexible approaches to patient requirements. Nutritional supplements containing selenium, vitamins, and antioxidants may provide needed support to shift from catabolic to anabolic, reduce free radicals, and quiet inflammation (Meltzer and Moitra, 2008).

**FOOD AND NUTRITION**

- Begin nourishing the patient as soon as possible to wean the patient from the ventilator. Start a TF of low osmolality slowly to avoid gastric retention or diarrhea. Advance gradually and use continuous administrations unless contraindicated. Do not add blue food coloring to feedings to detect aspirate in tracheal secretions (Kattelman et al, 2006).
- Ambulatory adults need about 30 kcal/kg daily. In ICU, the goal of 20–25 kcal/kg is sought; if it cannot be met, then combined enteral and PN should be considered to reduce the risk of complications and longer length of stay (Scurlock and Mechanick, 2008).
- Increased needs occur from labored breathing; monitor using IC. Use of specialty products such as Pulmocare or Respalor may be recommended, but they are not always necessary. Include 2% of total fat as essential fatty acids with some omega-3 fatty acids.
- Provide 1.2–1.5 g protein/kg/d (Mechanick and Chiolerio, 2008).
- While hypermetabolism and malnutrition are common, there is no need for supplemental PN to increase

caloric delivery in the early phase of critical illness (Stapleton et al, 2007). Monitor TPN carefully for complications such as pneumonia, refeeding syndrome from high-calorie loading, and increased CO<sub>2</sub> production.

- Patients with pulmonary edema should have their sodium intake reduced if needed. Include adequate protein in the diet to prevent additional fluid retention from lowered colloidal osmotic pressure.
- Supplement diet with a multivitamin supplement. Include antioxidant-rich foods for vitamins E, selenium, carotenoids, and vitamin C. Phosphorus and magnesium may be needed if stores are depleted.

**Common Drugs Used and Potential Side Effects**

- Bronchodilators, antibiotics, diuretics, or corticosteroids may be needed. Monitor side effects.
- For diarrhea, treatment depends on the cause. For *Clostridium difficile* infection, antibacterial therapy should be discontinued, if possible, and treatment with oral metronidazole should be initiated (Mutlu et al, 2003).

**Herbs, Botanicals, and Supplements**

- No clinical trials have proven efficacy for use of herbs or botanicals in RF.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- A daily calorie count may be needed to assess the patient's nutritional status.
- The greatest danger in using enteral nutrition is aspiration. Low-osmolality products are essential, as well as elevation of the head of the bed.
- Discuss early satiety, bloating, fatigue, dyspnea as related to food or TF intake.
- Delivery of enteral nutrition in patients receiving mechanical ventilation is interrupted by practices required for the care of these patients (O'Meara et al, 2008). Discharge planning for the ventilator patient to return home is ideal.

**Patient Education—Foodborne Illness**

- Careful food handling will be important. Hand washing is key as well.

## SARCOIDOSIS

### NUTRITIONAL ACUITY RANKING: LEVEL 1–2

#### Granulomatous tissue formation

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Sarcoidosis is a disease of undetermined origin with tiny patches of inflammation (granulomas) occurring in almost any organ. Pulmonary effects are most common. It develops most often between ages 20 years and 40 years, more often among women than men, and more commonly among Swedes, Danes, and African Americans. Sarcoidosis is more common among nonsmokers than among smokers.

In children, renal impairment of sarcoidosis usually is caused by either hypercalcemia leading to nephrocalcinosis or interstitial nephritis with or without granulomata (Thumfart et al, 2005). Lofgren's syndrome is a classic set of signs and symptoms involving fever, enlarged lymph nodes, arthritis in the ankles, or erythema nodosum. Overall, prognosis is good for most cases, and most sarcoidosis subsides on its own within 3 years. In 10% of cases, the condition becomes chronic. Sarcoidosis leads to organ damage in about one third of the people diagnosed; the lungs, heart, or brain may be affected.

Hypercalcemia can occur in patients with granulomatous disorders such as sarcoidosis, often related to high serum 1,25-dihydroxyvitamin D (OHD) concentrations (Falk et al, 2007). Endogenous antioxidant defense is significantly reduced, and oxidative stress underlies the pathology of this disease (Boots et al, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Sarcoidosis CD4+ T cells are primarily responsible for the systemic responses. The 1-alpha-hydroxylase gene affects alveolar macrophages and disturbances in calcium metabolism.

<b>Clinical/History</b>	BMI	BP
Height	Weight loss?	Fever
Weight	Diet history	

Tender red lumps on shins or ankles	PH cor pulmonale	Alkaline phosphatase (Alk phos)
Lupus pernio (painful sores on face)	Clubbing of fingers, hypoxemia	Nitrogen (N) balance
Granulomas	Iritis, glaucoma, blindness	Transferrin
Enlarged liver or spleen	Chest pain, even heart failure	Globulin (increase common)
Uveitis	Chest x-ray	Serum Ca <sup>++</sup> (increased)
SOB, cough	Biopsy	Ca <sup>++</sup> in urine (increased?)
Night sweats	Gallium scan	Serum vitamin D <sub>3</sub>
Bone or joint pain	TB test (rule out tuberculosis)	Na <sup>+</sup> , K <sup>+</sup> , Mg <sup>++</sup>
Anorexia, weakness, aching joints	Pulmonary function tests	Uric acid (increased)
Abdominal pain, lymphadenopathy	<b>Lab Work</b>	PO <sub>4</sub>
Bone cysts in hands and feet	H & H (anemia common)	Kveim test
	Serum Fe, ferritin	Erythrocyte sedimentation rate (ESR)
	Alb (decreased)	
	CRP (elevated)	

## INTERVENTION

### OBJECTIVES

- Reduce heart failure, BX, and related problems.
- Correct weight loss, anorexia, fever, and abdominal pain.
- Improve ability to breathe and eat normally.
- Prevent further deterioration of organ functions with any and all affected organ systems.
- Prevent or correct fluid retention.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Imbalance of Nutrients

**Assessment Data:** Altered lab values, elevated uric acid, and ESR; uveitis, wheezing, coughing, Dx of sarcoidosis; diet hx showing minimal intake of vitamins and minerals.

**Nutrition Diagnoses (PES):** Imbalance of nutrients related to minimal intake of omega-3 fatty acids, vitamins, and minerals as evidenced by chronic inflammation and altered labs (uric acid, ESR, CRP).

**Interventions:** Modify dietary intake to increase antioxidants from fruits, vegetables, whole grains, and nuts as well as omega-3 fatty acids from salmon/tuna/sardines. Provide multivitamin—mineral supplement. Educate about the natural role of diet in reducing inflammation.

**Monitoring and Evaluation:** Improved balance of nutrients from diet and supplementation; normalized labs including CRP, ESR, uric acid.

- High levels of calcium may accumulate in the blood and urine. Monitor for related nausea, anorexia, vomiting, thirst, excessive urination, or renal failure.

## FOOD AND NUTRITION

- Restrict salt if necessary for heart failure or for use of corticosteroids. A 2- to 3-g sodium diet may be beneficial.
- Use a diet containing adequate to high potassium (unless medications are used).
- Patients might benefit from antioxidants such as quercetin (Boots et al, 2009). More fruits and vegetables should be consumed.

## Common Drugs Used and Potential Side Effects

- Prednisone is used to suppress severe symptoms such as SOB. Watch electrolytes, nitrogen balance, and other changes. Treatment may require several years.
- Methotrexate works best for treating sarcoidosis that affects lungs, eyes, skin, or joints. Folic acid depletion can occur (Low et al, 2008).
- Calcium-chelating agents may be used if hypercalcemia persists.
- Sarcoid granulomatous interstitial nephritis may respond to infliximab therapy (Thumfart et al, 2005). The drug seems to work against elevated TNF.
- For pain or fever, nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen may help.

## Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of herbs or botanicals in sarcoidosis.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- If the patient is using steroids, antacids could also be taken to reduce GI side effects. Check with the doctor.
- Discuss the role of diet in maintaining immunocompetence and in improving tolerance for other therapies.
- Follow regarding calcium and vitamin D supplements to avoid prolonged hypercalcemia and hypercalciuria. If needed, avoid intake of fish oils and excessive sun exposure.

## Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# SLEEP APNEA

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

Obstructive sleep apnea (OSA) can lead to chronic disease, such as cardiopulmonary disease.

## DEFINITIONS AND BACKGROUND

Approximately 4% of middle-aged men and 2% of middle-aged women suffer from obstructive sleep apnea (OSA). OSA affects 12–18 million Americans and is associated with irritability, excessive daytime sleepiness, an inability to concentrate, depression, morning headaches, and decreased job performance in adults. Untreated sleep apnea also can increase an individual's risk of heart attack, high BP, diabetes, stroke, and automobile accidents. OSA is often undiagnosed and is a major contributing factor in the development of essential hypertension.

Sleep apnea occurs in both genders and in all ages, weights, and ethnicities. Certain risk factors are associated with a higher incidence, such as excess weight or obesity (BMI >25); family history of sleep apnea; male sex; large neck (greater than 17 inches in men, greater than 16 inches in women); recessed chin; physical abnormality in the nose, throat, or upper airway structure; older age; smoking; use of alcohol or sleeping pills; ethnicity (African Americans, Pacific Islanders, and Hispanics seem to be at an increased risk); and snoring.

Sleep apnea may develop in any patient who has an endocrine disorder or is receiving certain hormonal therapies. Increases in habitual sleep duration is associated with elevations in CRP and IL-6 while reduced sleep duration is associated with elevated TNF $\alpha$  levels; activation of pro-inflammatory pathways may represent a mechanism by which extreme sleep habits affect health (Patel et al, 2009). IL-6, TNF $\alpha$ , and insulin levels are elevated in sleep apnea independently of obesity; visceral fat is the primary parameter linked with sleep apnea (Vgontzas, 2008).

Effective assessment and management of OSA may lead to a reduction in insulin resistance and hypertension as well as other markers of vascular risk in patients with metabolic syndrome (Yee et al, 2004). Untreated severe OSA results in elevated CRP levels and cardiovascular risks. Clinicians should be aware. Both atherosclerosis and OSA are associated with endothelial dysfunction; increased CRP, interleukin-6, fibrinogen, and plasminogen activator inhibitor; and reduced fibrinolytic activity. OSA has also been associated with enhanced platelet activity and aggregation and leukocyte adhesion on endothelial cells (Parish and Somers, 2004).

Obstructive sleep-disordered (OSD) breathing is common in children (3–12% of children snore); mild sleep apnea affects 1–10% of children (Chan et al, 2004). Risk factors of children who are more at risk for OSA are physical abnormalities of the face or skull, cerebral palsy, muscular dystrophy, Down syndrome, sickle cell disease, obesity, and mouth breathing. Consequences of untreated OSA include failure to thrive, enuresis, attention-deficit disorder, behavior problems, poor academic performance, and cardiopulmonary disease (Chan et al, 2004). Sleep deprivation and sleep apnea may even be related to some sudden infant death syndrome (SIDS) cases; upper airway obstruction and depressed arousability from sleep may contribute (Franco et al, 2004).

Treatment includes the use of continuous positive airway pressure (CPAP), weight loss in obese children, or adenotonsillectomy. Use of a CPAP device can be worn while sleeping. This device works to keep the airway open by continuously blowing air through the nasal passages at a high pressure. CPAP may help medically treated patients with heart failure and other cardiovascular conditions. In addition, some dental appliances may reposition the tongue or lower jaw so that the airway remains open while the patient sleeps, thus preventing the apnea. Surgical treatments may

also be done, such as septoplasty, tonsillectomy, uvulopalatopharyngoplasty (UPPP, also known as UP3), and laser-assisted uvulopalatopharyngoplasty (LAUP).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** IL-6, TNF $\alpha$ , and insulin levels are elevated in sleep apnea.

Clinical/History	Apnea–hypopnea index (AHI)	H & H (anemia common)
Height	Respiratory disturbance index (RDI)	Serum Fe, ferritin
Weight	Epworth Sleepiness Scale (ESS)	CRP
BMI		Homocysteine
Abdominal adiposity?		Alb, transthyretin
PCOS?		Ca <sup>++</sup> , Mg <sup>++</sup>
Diet history		Na <sup>+</sup> , K <sup>+</sup>
BP		pCO <sub>2</sub> , pO <sub>2</sub>
Chest x-ray	<b>Lab Work</b>	
Polysomnography (sleep study)	Gluc	
Hypopnea (less than normal breath)	Serum insulin	
	CBC	

## INTERVENTION

### OBJECTIVES

- If obese, weight loss will be beneficial. Obesity is associated with comorbidities such as PH, hypoventilation, and sleep apnea that may lead to disability or death (Poirier et al, 2009).
- In children with sleep apnea and failure to thrive, medical or surgical treatments may help to alleviate the problem so catch-up growth can occur. These children may have reduced upper airway muscle tone, evident mostly during REM sleep stages (Eckert et al, 2009).
- Lessen insulin resistance, where possible.
- Manage other medical and health complications that are present in the individual; cardiovascular disease, hypertension, or metabolic syndrome may coexist with OSA.

### FOOD AND NUTRITION

- Lower energy intake to promote weight loss of 1–1.5 lb weekly if possible.
- Alter diet plan if needed to manage diabetes, sickle cell anemia, or other underlying conditions.
- The DASH diet or a calorie-controlled diet may be useful.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Obesity and Metabolic Syndrome

**Assessment Data:** Divorced male, age 45, BMI 31, chronic hypertension, central adiposity, hx of sleep apnea with snoring, HDL 40, LDL 210, diet hx shows eating away from home six to eight times weekly, no cooking skills or interest, drinks two to three alcoholic beverages daily.

**Nutrition Diagnoses (PES):** Obesity related to excessive intake of energy-dense foods as evidenced by BMI 31, hypertension, sleep apnea, and central adiposity (waist 46”).

**Interventions:** Educate about simpler meals that are nutrient-dense and less energy-dense, lower in fat and alcohol; good choices from grocery store or dining at restaurants. Materials from Cooperative Extension or Health Department on “eating for one.” Referral go to Sleep Disorder Clinic if interested.

**Monitoring and Evaluation:** Meal and food choices; improvement in BMI, BP, lipids; less problem with snoring and sleep apnea. Participation in Sleep Disorder Clinic evaluation.

## Common Drugs Used and Potential Side Effects

- OSA can be induced, unmasked, or exacerbated by the effects of sedative, analgesic, and anesthetic agents (Jain and Dhand, 2004). Sleeping agents are not generally recommended.
- Treatment of depression or mood disorders may be needed. In patients who are on chronic neuroleptic drugs for schizophrenia, weight management will be very important.

## Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of herbs or botanicals in sleep apnea.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Typically, patients diagnosed with sleep apnea are advised to avoid tobacco, alcohol, sedatives, and medications that relax the airway and/or reduce respiratory function.
- Regular exercise and weight reduction can help some patients with mild or moderate sleep apnea minimize their symptoms.
- Sleep apnea sufferers are advised to avoid sleeping on their back, if possible. Using pillows and other devices that help the patient sleep in a side position may help.
- The relationship of OSA with hypertension, stroke, and cardiovascular disease should be discussed.
- Help with obesity if needed, especially central adiposity (Schwartz et al, 2008).
- Patients who have a cough, OSA, rhinosinusitis, and esophageal reflux clustered together can be categorized as having CORE syndrome (Arter et al, 2004).

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## THORACIC EMPYEMA

### NUTRITIONAL ACUITY RANKING: LEVEL 2

#### DEFINITIONS AND BACKGROUND

Thoracic empyema involves accumulation of pus in the pleural cavity, sometimes as a complication of pneumonia. Complications may include septic shock, multiple organ failure, cardiac insufficiency, and end-stage renal failure. A chest tube may be placed (thoracentesis) to drain the infection.

In diaphragmatic injury, empyema is a rare but serious complication that can lead to prolonged hospital or ICU lengths of stay; gastric trauma is often associated (Bramparas et al, 2009). Use of prophylactic antibiotics may be prescribed.

An increase in the incidence of thoracic empyema in children has been noted, and the causative pathogen is often unknown (Sagiani et al, 2005). *Staphylococcus aureus* is a common micro-organism isolated from the bacterial cultures, as is *Mycobacterium tuberculosis* (Ozel et al, 2004). With an increasing incidence of *S. aureus*, particularly MRSA, the use of video-assisted thoracoscopy (VATS) results in a decreased duration of fever and length of hospitalization (Schultz et al, 2004).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Most empyema is from pneumonia or trauma. The noted virulence of invasive pneumococcal disease (IPD) after the initiation of vaccine has led to speculation about antibiotic resistance in some individuals.

Clinical/History	Productive cough I & O Dyspnea, orthopnea Constant localized chest pain Tachycardia, tachypnea CT scan Ultrasound Tachycardia? #### SAMPLE NUTRITION CARE PROCESS STEPS

##### Inadequate Oral Food and Beverage Intake

**Assessment Data:** Chronic cough and chest pain, fatigue and anorexia with weight loss of 12 lb in past month. Fever 102°F for past 3 days.

**Nutrition Diagnoses (PES):** Inadequate oral food and beverage intake related to anorexia, fever, tachycardia, chronic cough and chest pain from thoracic empyema as evidenced by weight loss of 12 lb in past month.

**Interventions:** Educate about simple, nutrient and energy-dense meals and snacks. Counsel about ways to lessen fatigue with meal-time preparation. Coordinate care with home-delivered meals or shopping assistance when discharged.

**Monitoring and Evaluation:** Improved oral food and beverage intake as per patient food diary and weight gain of 5 lb in 3 weeks after returning home. Fewer complaints of anorexia or poor nutrition quality of life.

**INTERVENTION****OBJECTIVES**

- Lessen fatigue; promote improved well-being.
- Reduce fever. Prevent sepsis, organ failure, and other complications.
- Correct weight loss.
- Control and reduce anorexia.
- Support the capacity for wound healing if surgery is needed.

**FOOD AND NUTRITION**

- Provide diet as ordered. Patient may need high-calorie/high-protein foods served at frequent intervals.
- Two or more liters of fluid may be needed daily, unless contraindicated.
- Meals should be served in an attractive manner to stimulate appetite.
- A multivitamin–mineral supplement may be useful.

**Common Drugs Used and Potential Side Effects**

- Antibiotics such as streptokinase are common (Cameron and Davies, 2004). Monitor side effects accordingly.
- Monitor effects of other medications as prescribed.

**Herbs, Botanicals, and Supplements**

- No clinical trials have proven efficacy for use of herbs or botanicals in thoracic empyema.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Discuss the role of nutrition in illness and recovery, especially as it relates to immunocompetence.
- With family, discuss signs to observe for future problems or relapses.

**Patient Education—Foodborne Illness**

- Careful food handling will be important. Hand washing is key as well.

# TRANSPLANTATION, LUNG

**NUTRITIONAL ACUITY RANKING: LEVEL 3–4****DEFINITIONS AND BACKGROUND**

Lung transplantation (LTX) is an accepted treatment for end-stage pulmonary parenchymal and vascular diseases. LTX is a well-tolerated, effective therapy for RF with interstitial lung disease, CF or COPD. The International Society for Heart and Lung Transplantation and the Cystic Fibrosis Foundation have uniform guidelines for transplantation candidate selection. Over 13,000 LTXs have occurred worldwide (Tynan and Hasse, 2004).

Proper nutrition plays a key role in preparing for LTX. Therefore, the LTX dietitian plays an important role and meets with the patient for an initial interview. Weight and weight history, foods typically eaten, and appetite are reviewed. Being at ideal body weight range for height helps assure good physical condition for pretransplantation pulmonary rehabilitation and for the transplantation itself. Certain patients with advanced pulmonary disease are unable to eat enough to maintain ideal body weight because of

increased metabolic demands and breathlessness with eating. In such situations, it may be recommended that a percutaneous endoscopic gastrostomy (PEG) feeding tube be placed.

Proper nutrition is critical to maximize the chances of a successful transplantation. Occasionally, listing for transplantation will be delayed until the patient's nutritional status improves. LBM depletion may be associated with more severe hypoxemia, reduced walking distance, and a higher mortality. Both undernutrition and obesity should be carefully managed before surgery. Diabetes is a common problem after LTX in CF patients even though quality of life is dramatically improved (Hadjiliadis, 2007).

As with other types of transplantations, graft–host resistance and sepsis are the major concerns after LTX. Infections are the most common cause of morbidity and mortality in LTX recipients. Immunosuppressive therapy with glucocorticoids contributes to protein degradation.

Nitrogen balance after LTX is negative because of high glucocorticoid requirements; aggressive nutritional intervention and increased nitrogen intake are needed to reduce protein losses in these patients. Chronic infection (bronchiolitis obliterans syndrome) is the most common cause of death after transplantation (Quattrucci et al, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Organ transplant researchers are increasingly using microarrays to identify specific patterns of gene expression that predict and characterize acute and chronic rejection. Increased expression of genes involved in inflammation, apoptosis, and T-cell activation and proliferation may play a role in organ rejection (Lande et al, 2007).

Clinical/History	Lab Work	
Height	Alb,	BUN, Creat
Weight	transferrin	Na <sup>+</sup> , K <sup>+</sup>
BMI	CRP	Ca <sup>++</sup> , Mg <sup>++</sup>
Weight changes	Transferrin	PO <sub>4</sub>
Diet history	Chol, Trig	AST, ALT
RQ	H & H	Lactate
Ventilator	Serum Fe,	TLC
support	ferritin	CRP
I & O	Gluc	pCO <sub>2</sub> , pO <sub>2</sub>

## INTERVENTION

### OBJECTIVES

#### Preoperative

- Because nutritional depletion in LTX candidates is highly prevalent, it should be precisely assessed both before and after LTX. Attempts should be made to increase LBM and reverse cachexia and vitamin and mineral deficiencies before LTX.
- Prepare for a surgical procedure. Most patients will require sodium or fluid restrictions; monitor serum potassium as well.
- Allow for mild weight loss with a planned diet if the patient is obese and has time to do this.

#### Postoperative

- Prevent infection, surgical complications, organ rejection, and organ failure.
- Promote wound healing.
- Support ideal body weight and LBM maintenance.
- Reduce protein losses, support nitrogen balance, and correct hypoalbuminemia.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Protein Intake

**Assessment Data:** BMI 18, recent weight loss of 20 lb, lung failure with planned Tx surgery, low serum albumin.

**Nutrition Diagnoses (PES):** Inadequate protein intake related to loss of LBM and insufficient oral intake as evidenced by albumin 2.1 and diet history showing low meat and milk consumption.

**Interventions:** Enhance meals by adding dry milk powder to recipes such as mashed potatoes and casseroles; offer puddings, eggnog and oral supplements between meals; add protein powder scoops to milkshakes or soups. Educate patient and family about the importance of protein for maintaining LBM and wound healing.

**Monitoring and Evaluation:** Improved intake of protein-rich foods. Successful wound healing after surgery. Improvement in weight and BMI over several months.

- Prevent aspiration.
- Wean from ventilator or oxygen when possible.
- Treat comorbid conditions such as cardiovascular disease (CVD), osteoporosis, dyslipidemia, diabetes, hyperglycemia, metabolic syndrome, and hyperkalemia (Tynan and Hasse, 2004).

## FOOD AND NUTRITION

#### Preoperative

- Prepare patient nutritionally to alleviate malnutrition in advance (Inouye et al, 2004). Home enteral or PN may be useful.
- Promote adequate intake of kcal (25–30 kcal/kg) and protein (1 g/kg body weight).
- Manage coexisting problems such as diabetes, heart disease, and hypertension with an appropriate diet such as the DASH diet.

#### Postoperative

- Return to oral intake by 48–72 hours postoperatively, when possible. Limit simple CHO when there are signs of hyperglycemia (Tynan and Hasse, 2004).
- Promote adequate intake of kcal (30–35 kcal/kg) and protein of 1.3–1.5 g/kg body weight (Tynan and Hasse, 2004). Use high nitrogen TF when needed, but do not overfeed, and monitor for needed changes in electrolytes according to lab values. Discontinue TF when intake meets >60% of estimated needs (Tynan and Hasse, 2004).
- Parenteral solutions may be used if the gut is nonfunctioning (Tynan and Hasse, 2004).
- Calorie-dense options should be considered if fluid restriction is required. Use caution with high-caloric loads because of RQ; maintain sufficient fat intake to prevent excess CO<sub>2</sub> production from a high-CHO intake.
- Restrict sodium and potassium if needed to improve cardiac or renal status.

**TABLE 5-13 Medications Used for Lung Transplant Patients**

Medication	Description
Azathioprine (Imuran)	May cause leukopenia, thrombocytopenia, oral and esophageal sores, macrocytic anemia, pancreatitis, vomiting, diarrhea, and other side effects that are complex. Folate supplementation and other dietary modifications (liquid or soft diet, use of oral supplements) may be needed. The drug works by lowering the number of T cells; it is often prescribed along with prednisone for conventional immunosuppression.
Corticosteroids (such as prednisone, hydrocortisone)	Used for immunosuppression. Side effects include increased catabolism of proteins, negative nitrogen balance, hyperphagia, ulcers, decreased glucose tolerance, sodium retention, fluid retention, and impaired calcium absorption and osteoporosis. Cushing's syndrome, obesity, muscle wasting, and increased gastric secretion may result. A higher protein intake and lower intake of simple CHOs may be needed.
Cyclosporine	Does not retain sodium as much as corticosteroids do. Intravenous doses are more effective than oral doses. Nausea, vomiting, and diarrhea are common side effects. Hyperlipidemia, hypertension, and hyperkalemia also may occur; decrease sodium and potassium as necessary. Elevated glucose and lipids may occur. The drug is also nephrotoxic; a controlled renal diet may be beneficial.
Immunosuppressants	Less nephrotoxic than cyclosporine but can cause nausea, anorexia, diarrhea, and vomiting. Monitor carefully. Fever (muromonab [Orthoclone OKT3] and stomatitis also may occur; alter diet as needed and antithymocyte globulin).
Diuretics	Diuretics such as furosemide may cause hypokalemia. Low-sodium/low-calorie diets may be indicated. If spironolactone is used, it spares potassium.
Tacrolimus (Prograf, FK506)	Suppresses T-cell immunity; it is 100 times more potent than cyclosporine, thus requiring smaller doses. Side effects include GI distress, nausea, vomiting, hyperkalemia, and hyperglycemia. Tacrolimus therapy has aided in success of lung transplantation and has become the primary immunosuppressant agent used (Fan et al, 2009; Garrity and Mehra, 2004). A low-potassium diet may be needed to prevent cardiac arrhythmia (Tynan and Hasse, 2004).

- Reduce energy intake and increase activity if weight gain or diabetes occurs after long-term corticosteroid use (Tynan and Hasse, 2004).
- Prevent osteoporosis by using adequate calcium and vitamin D. Provide sufficient magnesium and vitamins to heal and promote adequate nutritional status.

### Common Drugs Used and Potential Side Effects

- Using tacrolimus as primary immunosuppressant for lung transplant recipient results in comparable survival and reduction in acute rejection episodes when compared with cyclosporine (Fan et al, 2009). See Table 5-13 for more information.

### Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of herbs or botanicals after LTX.

#### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss appropriate calorie and protein levels. Protein helps to heal after surgery.
- Drink plenty of water until restriction is prescribed.
- Decreased saturated fat and cholesterol intakes may be useful to decrease cardiac risks and to prevent unwanted weight gain, which is common. Read food labels and monitor portions carefully. Choose condiments such as mustard rather than mayonnaise or salad dressing. Choose

healthy cooking methods. Instead of frying, try baking, grilling, broiling, or steaming foods; instead of oil, use nonstick, fat-free spray or sauces.

- Adequate fiber (from fresh fruits, vegetables, and whole grains) is important.
- A gradual return to activity will be important.
- Eat a minimum amount of salt, processed foods, and snacks. Use herbs and spices to add flavor instead of salt.
- Add calcium by eating calcium-rich foods, such as low-fat dairy products and green, leafy vegetables, or by using calcium supplements.
- Avoid alcohol and do not use drugs that are not prescribed.

### Patient Education—Foodborne Illness

- Preventing infection is very important after transplantation surgery. Hand washing is critically important.
- Careful food handling will be important.

# TUBERCULOSIS

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

**A** is an X-ray of tubercular lungs. **B** shows the presence of TB by circled areas.

Adapted from: Engleberg NC, Dermody T, DiRita V. *Schaecter's Mechanisms of Microbial Disease*, 4th ed. Baltimore: Lippincott Williams & Wilkins, 2007.

## DEFINITIONS AND BACKGROUND

TB is caused by a tubercle bacillus (*Mycobacterium tuberculosis*) invading the lungs and setting up an inflammatory process. Healing occurs with a calcification of the tubercular cavity. TB causes loss of appetite, constant fatigue, tissue wasting, exhaustion, hemoptysis, cough lasting 3 weeks or longer with occasional blood-tinged sputum, fever or chills, profuse night sweats, and weight loss. The acute form resembles pneumonia; the chronic form causes low-grade fever.

Nearly one third of the world's population is infected with *M. tuberculosis* (Pai et al, 2006). More than 9 million new cases were reported in 2007, many of them in Africa. An increase in TB in the United States may be related to inadequate compliance with prescribed drug therapy or to recently acquired or reactivated latent infections. Among U.S. born citizens, non-Hispanic African American, Mexican Americans, and individuals living in poverty have the highest risk for TB (Bennett et al, 2008). Immunocompromised persons are more vulnerable to the effects of TB, especially those persons who have HIV infection. Hypermetabolism appears to play a role in the wasting process in

patients infected with both HIV and TB. HIV infection is associated with a significant downregulation of whole-body protein flux, adding to the nutritional decline if TB is also present (Paton et al, 2003).

Vitamin D signaling within macrophages enables them to respond to and kill *Mycobacterium tuberculosis* organisms (Bikle, 2008; Shapira et al, 2009). This is an intracrine–autocrine–paracrine system for vitamin D that is just being recognized (Adams et al, 2007).

Active TB begins in the lungs but often spreads through the bloodstream as extrapulmonary TB. Fatigue, abdominal tenderness, painful urination, headache, SOB, arthritis-like symptoms, kidney damage, and pain in the spine and bones can occur. TB meningitis is a very dangerous complication, especially for the elderly.

Many TB patients have early, unplanned readmission and often need assistance with activities of daily living. They may have drug complications, the need to use a nonstandard drug regimen, and other illnesses. With a high prevalence of malnutrition, a relatively low utilization rate of nutritional services, and the potential effect of adverse reactions to therapeutic drugs, careful attention is needed for this patient population.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** It is suspected that TB has connections with allergy. There are higher levels of specific IgE, interleukin (IL)-6, and interferon (IFN) gamma to different inhalant allergens in TB patients; successful treatment lowers these levels (Ellertsen, 2009). In addition, polymorphisms in the gene that encodes the vitamin D receptor (VDR) influence host response to *Mycobacterium tuberculosis* (Roth et al, 2004).

Bioconversion of 25-hydroxyvitamin D<sub>3</sub> (25D<sub>3</sub>) into bioactive 1,25D<sub>3</sub>, leading to VDR activation and antimicrobial activity against intracellular TB (Krutzik et al, 2008).

<b>Clinical/History</b>	Biopsy or sputum test for <i>M. tuberculosis</i>	Lymphopenia? H & H
Height		Serum Fe, ferritin
Weight	Temperature, fever or chills	Normocytic anemia?
BMI	Night sweats	Serum pyridoxine
Diet history	Anorexia	N balance
BP	Spinal tap for polymerase chain reaction (PCR)	Chol (decreased)
Mantoux skin test	I & O	Na <sup>+</sup> , K <sup>+</sup>
QuantiFERON®-TB Gold test (QFT-G)		Ca <sup>++</sup> , Mg <sup>++</sup>
T-SPOT® TB test		Serum folate
Chest x-rays (irregular white areas on dark background)	<b>Lab Work</b>	Transferrin
Bronchoscopy	Alb, transthyretin	BUN, Creat
Blood-tinged sputum	CRP	Liver function tests (from medication use)
	RBP	
	TLC	

## INTERVENTION

### OBJECTIVES

- Maintain or prevent losses in weight. Reduce fever. The basal metabolic rate is 20–30% above normal to counteract fever of 102°F or higher.
- Normalize serum calcium and vitamin D<sub>3</sub> levels; either hypocalcemia or hypercalcemia may occur.
- TB often coincides with nutritional deficiencies; micronutrient supplementation may improve the outcome in patients undergoing TB treatment (Villamor et al, 2008).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Involuntary Weight Loss

**Assessment Data:** Analysis of estimated oral intake below estimated needs.

**Nutrition Diagnosis (PES):** Involuntary weight loss related to insufficient intake and frequent coughing spells, medication-related GI symptoms as evidenced by 15-lb weight loss since TB diagnosis months ago.

**Intervention:** Food and nutrient delivery with careful timing of meals and snacks in relation to medication administration and coughing episodes. Small, frequent meals and oral supplements.

**Monitoring and Evaluation:** Monitor and evaluate changes in intake and weight; tolerance for medications; and nutritional quality of life.

- Replace nutrient losses from lung hemorrhage, if present.
- Promote healing of the cavity.
- Counteract neuritis from isoniazid (INH) therapy, when used.
- Stimulate appetite, which is generally poor.
- Prevent dehydration.
- Prevent lung inflammation, infections, and complications.

### FOOD AND NUTRITION

- Use a well-balanced diet containing liberal amounts of protein and adequate calories. It may be useful to calculate needs as 35–45 kcal/kg if weight loss has been significant.
- Use adequate fluids (35 cc/kg) unless otherwise contraindicated.
- Add more omega-3 fatty acids; they may improve food intake, restore normal eating patterns, and prevent body weight loss (Ramos et al, 2004).
- Ensure that the diet provides sufficient levels of calcium and vitamin D.
- Iron and vitamin C are needed for proper hemoglobin formation and wound healing.
- B-complex vitamins, especially vitamin B<sub>6</sub>, are needed to counteract INH therapy.
- Use supplemental vitamin A as carotene as it is poorly converted.
- Alcohol should not be used as a calorie replacement or appetite enhancer.

### Common Drugs Used and Potential Side Effects

- Current anti-TB chemotherapies, although effective, are associated with side effects and are limited in treating drug-resistant strands (Shapira et al, 2009).
- See Table 5-14 for more drug therapies.

**TABLE 5-14 Medications Used for Tuberculosis (TB)**

Medication	Description
Aminosalicylic acid	Interferes with vitamin B <sub>12</sub> and folate absorption. Nausea and vomiting are common.
Chemotherapy	Chemotherapy can increase serum calcium levels.
Ethionamide (Trecator-SC)	Requires a vitamin B <sub>6</sub> supplement. It may cause anorexia, metallic taste, nausea, vomiting, diarrhea, weight loss, and hypoglycemia.
Ethambutol (Myambutol)	May cause GI distress, nausea, or anorexia. It should not be used longer than 2 months because it can harm the eyes.
Immunotherapy	According to the Centers for Disease Control and Prevention (2004): TB disease is a potential adverse reaction from treatment with tumor necrosis factor-alpha (TNF- $\alpha$ ) antagonists infliximab (Remicade), etanercept (Enbrel), and adalimumab (Humira). These products block TNF- $\alpha$ , an inflammatory cytokine, and are approved for treating rheumatoid arthritis and other selected autoimmune diseases. Blocking TNF- $\alpha$ can allow TB disease to emerge from latent <i>Mycobacterium tuberculosis</i> infection. Health care providers should take steps to prevent TB in immunocompromised patients and remain vigilant for TB as a cause of unexplained fever.
Isoniazid (INH)	May cause neuritis by depleting vitamin B <sub>6</sub> ; usual dose is 300 mg INH with 50 mg pyridoxine. Bad taste can be disguised in pureed fruit or jam to make it palatable, especially for pediatric patients. Niacin, calcium, and vitamin B <sub>12</sub> are also depleted. Nausea, jaundice, vomiting, stomach cramping, and dry mouth are common. INH must be taken for 9 months to eradicate the condition completely.
Pyrazinamide (PZA)	May cause anorexia, nausea, and vomiting. It can be hepatotoxic.
Rifampin (Rifadin, Rimactane)	Has side effects such as anorexia and GI distress.
Streptomycin	One of the first drugs used to treat TB. It is given by injection. Use of longer than 3 months can affect balance and hearing.

NOTE. Therapy always involves two or more drugs because of the long-term treatment period required.

## Herbs, Botanicals, and Supplements

- No clinical trials have proven efficacy for use of eucalyptus, echinacea, garlic, licorice, honeysuckle, or forsythia in TB management.
- Deficiencies of multiple micronutrients (MMN) are common in developing countries or where TB is common; outcomes are better using MMN than when providing just one to two micronutrients (Allen et al, 2009). Vitamins D, E, and selenium are supplements that should be highlighted.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Add protein powders or nonfat dry milk to beverages, casseroles, soups, and desserts to increase protein and calcium intake, unless contraindicated for other medical reasons.
- Encourage preparation of small, appetizing meals. Plan rest periods before and after meals.
- Discuss tips for managing anxiety related to weight loss, night sweats, loss of strength, high fever, and abnormal chest x-rays.
- Discuss communicability of TB. Family members and those living in proximity should have x-rays and other tests. About 5% of exposures result in TB within 1 year; others may be dormant until another condition sets in such as HIV infection, diabetes, or leukemia.
- Promote adequate rehabilitation if the patient is an alcoholic.
- Promote as much quality of life as possible; this is often overlooked (Marra et al, 2004).

- A TB vaccine is available. The BCG (bacille Calmette-Guérin) vaccine for TB disease is not widely used in the United States, but it is often used in other countries where TB is common.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Foodservice employees who are exposed to those at risk for active TB should be tested regularly. People are at risk and may need to be tested if they:
  - Have symptoms of active TB disease
  - Have been exposed to someone (family member, friend, or coworker) who has active TB
  - Have HIV infection, diabetes, or chronic kidney failure
  - Take steroids or other immune-suppressing drugs for chronic medical conditions
  - Live or work in a homeless shelter, prison, hospital, nursing home, or other group setting
  - Have recently moved from a region with active TB (Africa, Asia, the Caribbean, Eastern Europe, and Latin America).
- When preparing food:
  - Separate raw meat from cooked or ready-to-eat foods. Do not use the same chopping board or the same knife for preparing raw meat and cooked or ready-to-eat foods.
  - Do not handle either raw or cooked foods without washing hands in between.
  - Do not place cooked meat back on the same plate or surface it was on before it was cooked.
  - All foods from poultry should be cooked thoroughly, including eggs. Egg yolks should not be runny or liquid. Because influenza viruses are destroyed by heat,

the cooking temperature for poultry meat should reach 70°C (158°F).

- Wash egg shells in soapy water before handling and cooking, and wash hands afterwards.
- Do not use raw or soft-boiled eggs in foods that will not be cooked.
- After handling raw poultry or eggs, wash hands and all surfaces and utensils thoroughly with soap and water.
- Do not eat uncooked or undercooked poultry or poultry products, including food with uncooked poultry blood.

# Cardiovascular Disorders

## CHIEF ASSESSMENT FACTORS

- Age: Males  $\geq 45$  Years of Age and Females  $\geq 55$  Years of Age
- Alcohol Use (none, moderate, excessive)
- Angiograms, ECG, Echocardiograms
- Ascites, Edema
- Blood Pressure
- Cardiogenic Shock: Low Systolic Blood Pressure (BP), Cool and Moist Skin, Decreased Urinary Output, Pulmonary Edema, Tachycardia, Weak Pulse
- Chest Pain
- Cholesterol and Lipid Profiles (higher HDL is protective, small dense LDL is atherogenic)
- Contraceptive Use or Menopause
- C-Reactive Protein (CRP) and CoQ10 serum levels
- Decreased Cardiac Output: Arrhythmias, Fatigue, Labored Respirations, Pallor, Rales, Vertigo
- Diabetes
- Dietary Pattern with High Saturated Fat Intake
- Electrolyte Balance
- Exercise Patterns
- Family Hx (Use ATP III Guidelines) or Sibling Cardiovascular Disease
- Herbs or Botanical Product Use
- Homocysteinemia and Genetic Alleles Predisposing to Heart Diseases
- International Normalized Ratio (INR) Coagulation Index
- Lactic Acid Dehydrogenase (LDH), Creatine Phosphokinase (CPK) Levels
- Medications
- Obesity
- Smoking and Tobacco Use
- Type A Personality, Stressful Lifestyle
- Serum Vitamin D<sub>3</sub> levels
- Xanthomas

## OVERVIEW: DIET IN HEART DISEASE

Adapted from: Michael W. Mulholland, Ronald V. Maier et al. *Greenfield's Surgery Scientific Principles And Practice*, 4th ed. Philadelphia: Lippincott Williams & Wilkins, 2006.

## LIPIDS

Cardiovascular disease (CVD) includes hypertension, coronary heart disease (CHD), heart failure (HF), congenital heart defects, and stroke; CHD accounts for thousands of deaths annually. CVD accounts for almost 50% of all deaths in industrialized nations. Estimates for the year 2006 are that 80,000,000 people in the United States have one or more forms of CVD (American Heart Association, 2009). Despite a dramatic decline in mortality over the past three decades, CHD remains a leading cause of death and disability. Death rates for women have not declined as much as those for men.

Classic cardiovascular risk factors are common but largely undertreated and undercontrolled in many regions of the world (Bhatt et al, 2006). Seventy percent of CVD can be prevented or delayed with dietary choices and lifestyle modifications (Forman and Bulwer, 2006). There are 12 modifiable dietary, lifestyle, and metabolic risk factors: high blood glucose, low-density lipoprotein (LDL) cholesterol (Chol), and blood pressure (BP); overweight-obesity; high dietary trans fatty acids and salt; low dietary polyunsaturated fatty acids, omega-3 fatty acids (seafood), and fruits and vegetables; physical inactivity; alcohol use; and tobacco smoking (Danaei et al, 2009). Of these factors, tobacco smoking and high BP are responsible for the most causes of death in the United States.

Many patients with classic CVD risk factors can achieve risk-reduction goals without medications within 3 months after initiating therapeutic lifestyle changes (TLCs). TLC includes exercise training, nutrition counseling, and other appropriate lifestyle interventions based on several well-established behavior change models. The benefits of primary prevention of CVD are greatest for people who have multiple risk factors. Secondary prevention is beneficial for high-risk and low-risk patients. The Adult Treatment Panel (ATP III) report provides scientific evidence for dyslipidemia management. While dyslipidemia with small dense LDL molecules is atherogenic, dietary Chol is only one of

many factors to play a role in the etiology of heart disease. Chol is readily made from acetate in all animal tissues and has many roles in the body. In children and teens, widespread Chol screening is not warranted, except where there is early cardiovascular morbidity and mortality in immediate family members. There is a strong, independent relationship of vitamin D<sub>3</sub> [25(OH)D] deficiency (levels <20 ng/mL) with prevalent CVD in a large sample of the U.S. adult population; this has implications for both angina and myocardial infarction (MI, Kendrick et al, 2009). Other nutrients also play a role. Studies show a link between intake of fruit, vegetables, and whole grains and protection against CHD due to fiber, vitamin, mineral, and phytochemical content. Folate, vitamins B<sub>6</sub>, B<sub>12</sub>, E, and C, flavonoids, phytoestrogens, and a wholesome total dietary pattern may be protective.

In a specific analysis of "low-fat" diets, there were no significant effects on the incidence of stroke and CHD, but there were small reductions in LDL and total Chol (TC) levels, diastolic BP, and factor VIIc levels (Howard et al, 2006). There are indirect benefits of a diet with a lower intake of saturated and trans fats, higher intake of vegetable and fruits, use of specific types of fats including fish oils, as well as fish, and perhaps energy restriction (Anderson, 2006). Epidemiologic data suggest that omega-3 fatty acids derived from fish oil reduce CVD (Marik and Valon, 2009).

An Elderly Dietary Index (EDI) is useful for assessing risk factors for CVD in older adults (Kourlaba et al, 2009). Because kidney disease is a risk factor for mortality and CVD in older adults, elevated cystatin C and albuminuria are independent, graded risk factors for CVD and mortality (Rifkin et al, 2009).

Nutrition counseling should receive high priority, both in medical training and in patient care for both men and women (Krummel, 2008). The American Dietetic Association estimates cost savings per cardiovascular case to be nearly \$2500 annually with nutrition counseling, thereby reducing the need for many medications. Key components of counseling include: (1) reduced caloric intake; (2) reduced total fat, saturated fat, trans fat, and Chol with proportional increases in monounsaturated, omega-3, and omega-6 fatty acids; (3) increased dietary fiber, fruit, and vegetables; (4) increased micronutrients (e.g., folate and vitamins B<sub>6</sub> and B<sub>12</sub>); (5) increased plant protein in lieu of animal protein; (6) reduced portions of highly processed foods; (7) adopting a Mediterranean dietary pattern; (8) adding physical activity; and smoking cessation (Forman and Bulwer, 2006). See Table 6-1 regarding evidence for dietary recommendations in heart disease.

The Women's Nutrition Intervention Study used a low-fat eating plan that serves as a model for implementing a long-term dietary intervention in clinical practice (Hoy et al, 2009). Table 6-2 lists other influential factors on diet and its relationship to heart disease. In the future, the development of functional foods that contain ingredients that have preventive benefits will be important. Products that contain green tea with Epigallocatechin-3-gallate (EGCG), omega-3 fatty acids, folate, vitamins C and E, flavonoids such as quercetin, eritadenine in mushrooms will be popular (Ferguson, 2009). Table 6-3 provides a list of commonly used herbs and botanical products in heart disease.

**TABLE 6-1 Levels of Best Evidence in Dietary Recommendations for Heart Disease<sup>a</sup>**

Dietary Recommendation	Evidence Level	Dietary Recommendation	Evidence Level
<i>Antioxidants</i>		<i>Omega-3 Fatty Acids</i>	
Supplemental beta-carotene (60–200 mg/d) does not decrease the risk for cardiovascular death or nonfatal myocardial infarction (MI) in primary and secondary prevention patients.	I	Approximately 1 g/d of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) from a supplement or fish decreases the risk of death from cardiac events in patients with heart disease.	II
Supplemental vitamin E, given in both natural and synthetic forms, in doses of 30–600 mg/d or 400–800 IU/d, alone or in combination with other antioxidants, is not harmful but has not been shown to decrease the risk for cardiovascular death or MI.	II	Regular consumption of an average of two servings of fatty fish per week (about 3.5 oz per serving; high in EPA and DHA) is associated with a 30–40% reduced risk of death from cardiac events.	II
Supplemental vitamin E (100–1200 IU/d) alone or in combination with other antioxidants has not been shown to have a favorable or unfavorable effect on serum lipids.	II	Increased plasma levels and adipose tissue and cholesterol ester concentrations of alpha linolenic acid, EPA, and DHA have been associated with reduced risk of mortality.	II
Supplemental vitamin C (50–1000 mg/d) in combination with other antioxidants (vitamin E, beta-carotene, selenium) has not been shown to have any effect on cardiovascular death or MI.	II	<i>Nuts</i>	
Supplemental beta-carotene (60–120 mg/d) is associated with an increase in all-cause mortality and cardiovascular death in patients at increased risk for lung cancer.	II	Consumption of 50–113 g (1/2 to 1 cup) of nuts daily with a diet low in saturated fat may decrease total cholesterol by 4–21% and LDL cholesterol by 6–29% when weight is not gained.	II
Supplemental vitamins C and E, beta-carotene, and selenium should not be taken with simvastatin–niacin drug combinations because this may lower HDL2 cholesterol, a beneficial subfraction of HDL cholesterol.	II	Consumption of 5 oz of nuts per week is associated with reduced risk of CVD.	II
<i>Hypertension</i>		<i>Soy Protein</i>	
Consuming a diet rich in fruits and vegetables and low-fat dairy products and low in sodium and saturated fat will decrease blood pressure. Reductions have been 4–12 mm Hg in systolic and 1–3 mm Hg in diastolic blood pressure. This dietary pattern is enhanced by weight loss and increased physical activity.	I	Studies varied greatly in their estimation of the effect of diets low in saturated fat and cholesterol containing ~26–50 g of soyprotein either as food or as a soy supplement, with 0–165 mg of isoflavones. Studies of individuals with normal or elevated total cholesterol >200 mg/dL and individuals with diabetes varied, showing either 0–20% lower serum total cholesterol; 0–22% lower triglycerides; 4–24% lower LDL cholesterol.	II
<i>Fiber</i>		Diets containing up to 30 g of soy protein (as supplements) per day are well tolerated.	II
Consuming diets high in total fiber (17–30 g/d) and soluble fiber (7–13 g/d) as part of a diet low in saturated fat and cholesterol can further reduced total cholesterol by 2–3% and LDL by up to 7%.	I	<i>Statins, Stanols, and Sterols</i>	
Diets high in total dietary fiber (>25 g/d) are associated with decreased risk for coronary heart disease (CHD) and Cardiovascular disease (CVD).	II	Plant sterols and stanols are potent hypocholesterolemic agents. Daily consumption of 2–3 g (through margarine, low-fat yogurt, orange juice, breads, and cereals) lowers total cholesterol concentrations in a dose-dependent manner without changing HDL cholesterol or triacylglycerol concentrations.	I
<i>LDL Cholesterol Reduction</i>		For patients receiving statin therapy, plant stanols further reduce LDL and total cholesterol.	I
A diet consisting of 25–35% total fat, <7% saturated and trans fat, and <200 mg dietary cholesterol lowers serum total and LDL cholesterol 9–16% and decreases the risk of CHD.	I	The total and LDL cholesterol-lowering effects of stanols and sterols are evident even when sterols and stanols are consumed as part of a cholesterol-lowering diet.	I
Iso calorically replacing saturated fatty acids with MUFA and PUFA is associated with reductions in LDL cholesterol.	I	Sterols lower total cholesterol by 6–11% and LDL cholesterol by 7–15%. Stanols lower total cholesterol by 4–10% and LDL cholesterol by 7–14%.	II
		An intake of 2–3 g of plant sterols and stanols per day generally appears to be safe.	II

Adapted from: American Dietetic Association, Evidence analysis library. Web site accessed July 1, 2009, at <http://www.adaevidencelibrary.org/>. Key: Level I evidence = strong evidence from randomized controlled trials; level II evidence = moderate evidence.

**TABLE 6-2 Key Influences and Factors Related to Heart Disease**

Influence	Description
Alcohol	Moderate red wine consumption may be associated with desirable changes in HDL cholesterol. The “French paradox” suggests that wine intake and type of fat consumed are protective.
Alpha linolenic acid (ALA)	ALA in flaxseed, walnuts, and canola oil may protect against sudden cardiac death and cardiac arrhythmias.
Aspirin and salicylates	Aspirin (usually 80 mg/d) and other salicylates inhibit production of enzymes that influence platelet release and aggregation, vasoconstriction, and vasodilation. Salicylates have analgesic, antipyretic, and anti-inflammatory properties. They occur naturally in many foods, including herbs, spices, fruits, and tomatoes.
Apolipoprotein (Apo) E phenotype	ApoE genotype modifies the serum lipid response to changes in dietary fat and cholesterol intake. Inherited hypercholesterolemias are common disorders characterized by elevated LDL cholesterol levels and premature coronary heart disease.
Carbohydrate	High glycemic index foods should be studied further for their effects on heart disease.
C-reactive protein (CRP)	Inflammation is important in atherosclerosis. CRP is one of the acute phase proteins that increase during systemic inflammation. Dietary/lifestyle factors that decrease CRP levels are: weight loss, alpha linolenic acid, vegetarian diet, and moderate alcohol intake.
Cholesterol, total serum	The NHLBI promotes <200 mg/dL as desirable; 200–239 mg/dL is borderline high; >240 mg/dL is high. Age, lifestyle habits (smoking high BMI), and high serum cholesterol levels are consistently associated with CHD mortality. The ATP III report found that even older persons with established CHD can show benefit from LDL-lowering therapy.
Cholesterol, HDL	Low levels of HDL cholesterol are an independent risk factor for cardiovascular death; HDL <40 mg/dL is low and not desirable; >60 mg/dL is high and better. In women, changes in HDL cholesterol and triglyceride levels are good predictors of coronary risk.
Cholesterol, LDL (see Table 6-1)	Initiate therapeutic lifestyle changes (TLC) if LDL is above goal; this is a primary target of therapy. LDL <100 mg/dL is optimal; 100–129 mg/dL is near-optimal; 130–159 mg/dL is borderline high; 160–189 mg/dL is high; and >190 mg/dL is very high. Statins can help lower LDL levels.
Copper	Elevated serum copper levels are strong pro-oxidants. Supplementation is not recommended; the relationship of copper and zinc is complex and excesses are not desirable.
Dairy products	Low fat dairy products provide a major source of vitamins and minerals.
Diabetes	Elevated systolic and diastolic blood pressure, high serum cholesterol level, high body mass index, presence of diabetes, and smoking status are key risks for CHD. Replace saturated fat with monounsaturated fat.
Eggs	Limit intake to no more than 1 whole egg daily, especially with diabetes.
Erythrocyte sedimentation rate (ESR)	ESR is a marker of inflammation but whether this signifies an independent marker for heart disease remains to be seen.
Estrogen	High plasma triglycerides are an independent risk factor for CHD. Hormone replacement therapy may protect younger more than older women.
Exercise	Low fitness in adolescents and adults is common in the U.S. population and is associated with an increased prevalence of CVD. Increased exercise is associated with a lower waist circumference and higher HDL cholesterol levels. Inactive individuals benefit by even slightly increasing activity, such as walking.
Fats, monounsaturated (MUFA) (see Table 6-1)	Nuts are a good source of MUFA. Substitution of extra virgin olive oil for saturated fats will not only decrease SFA but provide phytochemicals.
Fats, saturated (SFA)	SFA is more important than total cholesterol intake in affecting total and LDL cholesterol levels, and risk of CHD, in women especially.
Fiber and whole grains (see Table 6-1)	Whole grains and high fiber from cereals, vegetables, and fruits are protective against CHD. Fiber may protect against CHD by lowering blood cholesterol (soluble fibers), attenuating blood triglyceride levels (mostly soluble fibers), decreasing hypertension (all fibers), and normalizing postprandial blood glucose levels (all fibers). Total fiber is important.
Flavonoids	There are over 6000 so far. Chocolate decreases blood pressure and enhances blood flow. Dark chocolate also improves insulin sensitivity. Soy isolate protein and green tea tend to be helpful in lowering CVD risks. Flavonoids in red wine, grape juice, grapefruit, tea, onions, apples, cloves, licorice, and sage are beneficial.
Folic acid	Diets that are low in folate and carotenoids (beta-carotene, lutein, zeaxanthin) contribute to increased coronary risk mortality.
Glycemic load, high	High glycemic load due to high intake of refined carbohydrates is positively related to CAD risk, independent of other known risk factors.
Homocysteine (tHcy)	Elevated tHcy levels are associated with increased risk of cardiac disease, stroke, and peripheral artery disease. Therapy with folic acid and vitamins B <sub>6</sub> and B <sub>12</sub> can reduce plasma tHcy levels. Fortified breakfast cereals that contain 200 µg folic acid are useful. The Dietary Approaches to Stop Hypertension (DASH) diet also reduces tHcy; the diet includes high quantities of fruits, vegetables, low-fat dairy products, whole grains, poultry, fish, and nuts.

(continued)

**TABLE 6-2 Key Influences and Factors Related to Heart Disease (continued)**

Influence	Description
Iron	High heme iron intake may increase risks of coronary heart disease (CHD) while anemia is damaging to the heart. A carefully balanced iron intake is a safe recommendation.
Mediterranean diet	A Mediterranean diet is protective. Mediterranean diets have a healthier balance between omega-3 and omega-6 fatty acids. The Mediterranean diet does not include much meat (high omega-6 fatty acids;) it emphasizes whole grains, fresh fruits and vegetables, fish, olive oil, garlic, and wine.
Metabolic syndrome	Atherogenic dyslipidemia is characterized by three lipid abnormalities: elevated triglycerides, small LDL particles, and reduced HDL cholesterol. Dyslipidemia, elevated blood pressure, impaired glucose tolerance, and central obesity comprise the metabolic syndrome. Prevention includes (1) correcting overweight by reducing energy density of the diet and (2) improving insulin sensitivity and associated metabolic abnormalities through a reduction of dietary saturated fat, partially replaced with MUFA and PUFA. Mild-to-moderate alcohol intake is protective while excessive intake is detrimental.
Methionine	Found in red meats, methionine may contribute to fatty plaque buildup by its relationship to elevated homocysteine.
Nicotinic acid	Niacin has a potent effect on high-density lipoprotein (HDL) cholesterol levels. Data on cardiovascular event rate reductions are limited.
Nuts and seeds (see Table 6-1)	Nuts and seeds provide monounsaturated fat, natural vitamin E, magnesium, and other heart-healthy nutrients. Walnuts and almonds are especially effective for reducing lipids.
Obesity	Individuals who are obese in middle age have a higher risk of hospitalization and mortality from CHD. A major goal of dietary prevention and treatment is to attain and maintain weight within a healthy body weight range. Decreasing excess calories, reducing total fat intake, adding fiber, reducing excess intake of refined carbohydrates, and increasing exercise can help achieve this goal.
Omega-3 fatty acids (see Table 6-1)	Both eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) in foods and supplements decrease production of inflammatory mediators. Omega-3 s may reduce CHD events. Japan has the lowest heart disease rate in the world; fish is a common part of that diet. RBC <sup>15</sup> N is a biomarker of EPA and DHA intake; it is rapid and inexpensive (O'Brien et al, 2009).
Oral health	Poor oral health may be a risk factor for CHD; improvement of periodontal status may influence the related systemic inflammation.
Phytosterols and stanols (see Table 6-1)	Plant stanol or sterol esters are phytosterols found in plant foods such as corn, soy, and other vegetable oils. Plant stanol esters block intestinal absorption of dietary and biliary cholesterol. Fat-soluble vitamins are not significantly affected. Sunflower kernels, pistachio nuts, sesame seeds and wheat germ are good sources.
Plasma lipoprotein (a) [Lp(a)]	Elevated plasma Lp(a) is an independent risk factor of heart disease. Ethnicity-related differences in Lp(a) levels exist.
Quercetin and antioxidants from fruits and vegetables	Vegetables, citrus fruits, seeds, olive oil, tea, and spices are antioxidant foods to include in the diet. Fruits are more protective than vegetables. Quercetin (in apples, onions) protects against CHD and hypertension. Pomegranate can lower cholesterol synthesis and spices and herbs can suppress inflammatory pathways.
Smoking	Both active smoking and secondary exposure are associated with the progression of atherosclerotic heart disease. Smoking is of greater concern among persons who also have diabetes mellitus and hypertension, or who drink a lot of alcohol (Cullen et al, 2009).
Soy protein (see Table 6-1)	The FDA permits labeling of products high in soy protein as helpful in lowering heart disease risk; products must contain at least 6.25 g per serving. Tofu contains 13 g of soy protein in one 4-oz serving; one soy burger contains 10–12 g of protein; 1/4 cup of soy nuts and 1/2 cup of tempeh contain 19 g of protein each.
Trans fatty acids (TFAs)	TFAs are strongly associated with systemic inflammation in patients with heart disease. Food labels must list the amount of TFAs.
Triglycerides	High levels of triglycerides are an independent risk factor of cardiovascular death. A low-fat diet can help.
Vitamin C (see Table 6-1)	Vitamin C has a role in cholesterol metabolism and affects levels of LDL cholesterol. Men, smokers, elderly individuals, and persons with diabetes or hypertension tend to have lower levels of serum ascorbic acid and higher risks for heart disease.
Vitamin E (see Table 6-1)	Alpha-tocopherol decreases lipid peroxidation and platelet aggregation and functions as a potent anti-inflammatory agent. Prospective human clinical trials with alpha-tocopherol have not shown effectiveness in lowering CHD risk.
Vitamin K	Vitamin K influences vascular health. Use darker greens or red leaf lettuce to increase vitamins A and K.

Cullen MW, et al. No interaction of body mass index and smoking on diabetes mellitus risk in elderly women. *Prev Med.* 48:74, 2009.

**TABLE 6-3 Commonly Used Herbs and Botanical Products in Heart Disease**

Chromium	Chromium is sometimes used for dyslipidemia. Do not use excesses of chromium with insulin or hypoglycemic agents because chromium may lower glucose levels excessively.
Coenzyme Q10 (CoQ10; ubiquinone)	Statins block production of farnesyl pyrophosphate, an intermediate in the synthesis of ubiquinone. Because CoQ10 and statins share a similar pathway, they can be taken simultaneously (Mabuchi et al, 2005; Strey et al, 2005). While there is insufficient evidence to prove the role of CoQ10 deficiency in statin-associated myopathy, there are no specific risks for this supplement. Do not take with gemfibrozil, tricyclic antidepressants, or warfarin.
L-arginine	Arginine appears to reduce endothelin, a protein that causes blood vessel constriction and is found in high amounts in HF patients; avoid use after an MI (Schulman et al, 2006).
Danshen	Used for ischemic heart disease. Avoid large amounts with warfarin, aspirin, and other antiplatelet drugs as it can increase risk of bleeding or bruising.
Fenugreek	This product may improve serum lipid levels slightly. Do not take with diuretics.
Garlic	Garlic may have short-term effects on blood lipids. Avoid use in large amounts with warfarin, aspirin, and other antiplatelet drugs because of increased risks of bleeding or bruising. It may also increase insulin levels with hypoglycemic results; monitor carefully in patients with diabetes.
Grapefruit	Grapefruit juice decreases drug metabolism in the gut (via P-450-CYP3A4 inhibition) and can affect medications up to 24 hours later. Consistency of use is more important than total quantity. Avoid taking with alprazolam, buspirone, cisapride, cyclosporine, statins, tacrolimus, and other cardiac drugs.
Guggul; Gugulipid	This yellowish resin from mukul myrrh tree is used in Indian Ayurveda medicine. It lowers low-density lipoprotein (LDL) and increases high-density lipoprotein (HDL) because of its plant sterols; it also stimulates the thyroid, is an anti-inflammatory, and works like an antioxidant. Gugulipid is the safest form, but a high dose is needed. Gastrointestinal discomfort may occur. Do not take with Inderal or Cardizem, and do not use during pregnancy or lactation.
Hawthorn	This is used for heart failure in Germany. Hawthorn should not be taken with digoxin, angiotensin-converting enzyme (ACE) inhibitors, and other cardiovascular drugs.
Niacin (nicotinic acid)	Do not take with statins, antidiabetic medications, or carbamazepine because of potentially serious risks of myopathy and altered glucose control.
Omega-3 fatty acids	Some studies support the role of DHA and EPA in preventing heart failure, but not with a high-fat diet (Shah et al, 2009). Fish oil capsules can cause hypervitaminosis A and D if taken in large doses. Avoid use in pregnant or lactating women. Avoid taking with warfarin, aspirin, and other antiplatelet medications because of the risk of increased bruising or bleeding.
Psyllium (metamucil)	Used to lower total and LDL cholesterol levels; evidence is slim.
Vitamin C and E, beta-carotene, and selenium	Do not take with simvastatin–niacin drug combinations because the combination of these antioxidants may lower HDL2 cholesterol, a beneficial subfraction of HDL cholesterol.
Vitamin E	Do not take with warfarin because of the possibility of increased bleeding. Avoid doses greater than 400 IU/d.

**SODIUM AND OTHER MINERALS**

A majority of Americans over age 60 have high BP with a shortened life expectancy. High BP affects over 73,600,000 in the United States (American Heart Association, 2009). Hypertension increases the risk for coronary artery disease (CAD), MI, stroke, renal failure, and HF. Careful attention to hypertension is essential in all ages and both sexes. African Americans and Hispanics of Caribbean descent tend to have a high prevalence of hypertension. Vitamin D plays a role in heart health (Martins et al, 2007). Increasing sun exposure or using a supplement may be indicated (Scragg et al, 2007). There are also many benefits in reducing sodium intake while increasing intakes of potassium, calcium, magnesium, and whole grains. Table 6-4 highlights key nutrients (folic acid, potassium, magnesium, and calcium) and provides heart healthy food choices based on the Dietary Approaches to Stop Hypertension (DASH) diet principles.

Excessive alcohol intake is one of the major causes of magnesium loss from various tissues, including the heart; mag-

nesium loss may represent a predisposing factor to the onset of alcohol-induced pathologies including stroke and cardiomyopathy (Romani, 2008). Rich sources of magnesium include nuts and seeds, soybeans, tofu, chocolate, dark-green vegetables, legumes, yogurt, wheat germ and dairy products. Although supplement use can help meet DRI levels for calcium, vitamin C and magnesium, supplementation may not work for potassium and may be too high for some other nutrients (Burnett-Hartman et al, 2009). In 2004, The Institute of Medicine of the National Academy of Sciences issued recommendations for intake of water and electrolytes that include the following suggestions:

- **CHLORIDE:** 2300 mg daily for adults to replace losses in perspiration.
- **POTASSIUM:** 4700 mg is needed to lower BP and reduce the risk of kidney stones and bone loss for most adults. No upper limit is set. African Americans may benefit. Natural sources are best.
- **SODIUM:** 1500 mg for adults aged 19–50; 1300 mg for adults aged 50–70; 1200 mg for adults aged 71 and over.

For a more specific list, Web site accessed July 7, 2009, at <http://www.nal.usda.gov/fnic/foodcomp/Data/SR17/wtrank/sr17w304.pdf>.

DASH Diet Principles	Food
Vegetables, choose 4–5 servings daily	Carrots, sweet potatoes, pumpkin, winter squash Green leafy vegetables (broccoli, kale, cabbage, etc.), green beans Tomato salsas, 6-oz servings of tomato juice or other vegetable juices
Fruits, choose 4–5 servings daily	Fresh fruits, including apples, bananas, cantaloupe, melons, berries Red or black grapes; grape juice (1 cup per day) Grapefruit, especially pink (40% more beta-carotene) Dried fruits, especially apricots, dates, prunes Pomegranates and other antioxidant juices (blueberry juice, red wine, orange juice, cranberry juice, green tea)
Protein-rich foods, choose 2 or less	Lean chicken and turkey breast Salmon and other fish Meats that are lean or have fat trimmed away
Low-fat dairy, 2–3 servings daily	Skim milk and yogurt (8 oz) Low-fat cheeses (1–1/2 oz per serving)
Low-fat foods	Tomato sauces with pasta Homemade pizza with low-fat toppings (chicken, vegetables, low-fat cheese)
Grains, choose 7–8 servings daily	Oatmeal, shredded wheat; high-fiber, low-sugar cereals Baked whole-wheat chips and tortillas Whole-grain breads and pastas, wheat germ
Nuts, seeds, and dry beans, 4–5 servings per week	Peanuts, walnuts, almonds, pistachios, other nuts in moderation Pumpkin seeds, sunflower seeds, sesame seeds Bean and chickpea dishes and dips
Oils, 2–3 servings	Olive oil and canola oil substituted for other oils Salad dressings and dips with nonfat sour cream or homemade yogurt

**NOTE:** Most of these foods are recommended in both the DASH and Mediterranean diets.

For more information, see Web site accessed July 7, 2009, at [http://www.nhlbi.nih.gov/health/public/heart/hbp/dash/new\\_dash.pdf](http://www.nhlbi.nih.gov/health/public/heart/hbp/dash/new_dash.pdf).

Highly active people may need more. If sodium sensitive, intake may need to be lower. Upper limit (UL) is set at 2.3 g sodium/d; over 95% of the American public consumes sodium above the UL level on a regular basis.

- **WATER:** 91 oz daily for women, 125 oz daily for men; more in hot climates or with physical activity. Drinking fluids with and between meals according to thirst is usually sufficient, although seniors may lose their thirst sensation. Beverages provide 80% of daily intake, 20% comes from food.

## ANGINA PECTORIS

### NUTRITIONAL ACUITY RANKING: LEVEL 1

#### DEFINITIONS AND BACKGROUND

Angina pectoris involves retrosternal chest pain or discomfort from decreased blood flow to the myocardium from decreased oxygen supply (often during exertion). Traditional risk factors include tobacco use, hypertension, diabetes mellitus, dyslipidemia, obesity, sedentary lifestyle, atherogenic diet; high-sensitivity C-reactive protein (hsCRP), lipoprotein (a), and elevated homocysteine (tHcy). Angina can also occur from anemia, hyperthyroidism, aortic stenosis, or vasospasm. In hypertrophic cardiomyopathy (HCM), an area of abnormally thick heart muscle impairs the heart's

pumping action and causes angina during or shortly after exercise.

Stable (classic) angina occurs after exertion and is relieved by rest and vasodilation; it lasts 3–5 minutes. Intractable (progressive) angina causes chronic chest pain that is not relieved by medical treatment. Variant angina is a mixed condition. If diagnosed early, the chance of living longer than 10–12 years is at least 50%. A very low-fat diet (i.e., 10% fat calories) has a substantial impact (Griel and Kris-Etherton, 2006). In addition, vitamin D provision through sun exposure or supplementation may be indicated when serum levels are below 20 ng/L (Kendrick et al, 2009).

An “ABCDE” approach is effective: “A” for antiplatelet therapy, anticoagulation, angiotensin-converting enzyme (ACE) inhibition, and angiotensin receptor blockade; “B” for beta-blockade and BP control; “C” for Chol treatment and cigarette-smoking cessation; “D” for diabetes management and diet; and “E” for exercise (Gluckman et al, 2005). Management of factors leading to the metabolic syndrome is also recommended (see Table 6-5). Cardiac rehabilitation helps to improve aerobic exercise capacity, physical functioning, and mental depression. Invasive treatments for chronic stable angina are only needed in a small number of patients (Kirwan et al, 2005). Currently, use of percutaneous coronary intervention (PCI) improves quality of life by relieving angina in patients with stable CAD (Brar and Stone, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** There are shared genetic pathways for angina pectoris (AP) and CHD death among both sexes; AP is important as a risk factor for CHD death (Zdravkovic et al, 2007).

<b>Clinical/History</b>	Electrocardiogram (ECG)	CoQ10 serum levels
Height	Radionucleotide imaging	Serum folate
Weight	Exercise stress test	Glucose (Gluc)
Body mass index (BMI)	Coronary angiography	Hemoglobin and hematocrit (H & H)
Waist circumference	<b>Lab Work</b>	Serum Fe, ferritin
Recent weight changes (e.g., gain)	Chol—LDL, HDL, total	Total iron-binding capacity (TIBC)
Diet history	Advanced lipid testing—	Aspartate aminotransferase (AST)
Chest pain	lipoprotein particle size	Alanine aminotransferase (ALT)
Shortness of breath	Triglycerides (TGs)	Transferrin
Sweating, nausea, vertigo	Lactate dehydrogenase (LDH)	Na <sup>+</sup> , K <sup>+</sup>
Ache in neck or jaw, earache	tHcy	Ca <sup>++</sup> , Mg <sup>++</sup>
Numbness or burning sensations	C-reactive protein (CRP)	Alkaline phosphatase (Alk phos)
Pulse (NL = 60–100 beats/min)		
BP		
Intake and output (I & O)		

**TABLE 6-5 Signs of the Metabolic Syndrome (Any Three of the Following)**

Risk Factor	Defining Level
Abdominal obesity <sup>a</sup>	Waist circumference <sup>b</sup>
Men	>102 cm (>40 in)
Women	>88 cm (>35 in)
Triglycerides	≥150 mg/dL
HDL cholesterol	
Men	<40 mg/dL
Women	<50 mg/dL
Blood pressure	≥130/≥85 mm Hg
Fasting glucose	≥110 mg/dL

From: National Heart, Lung, and Blood Institute. Web site accessed July 7, 2009, at <http://www.nhlbi.nih.gov/guidelines/cholesterol/atglance.htm#Step1>.

<sup>a</sup>Overweight and obesity are associated with insulin resistance and the metabolic syndrome. Abdominal obesity is more highly correlated with the metabolic risk factors than is an elevated BMI. Simple measure of waist circumference is recommended to identify the body weight component.

<sup>b</sup>Some male patients can develop multiple metabolic risk factors when the waist circumference is only marginally increased, e.g., 94–102 cm (37–39 in). Such patients may have a strong genetic contribution to insulin resistance. They should benefit from changes in life habits.

## INTERVENTION

### OBJECTIVES

- Relieve chest pain. Improve circulation to the heart.
- Increase activity as tolerated. Gradually increase exercise, especially through programs in cardiac rehabilitation.
- Maintain adequate rest periods.
- Maintain weight or lose weight if obese. A conventional dietetic intervention with weight loss helps to reduce pain frequency.
- Reduce symptoms of the metabolic syndrome where present (see Table 6-5).
- Avoid constipation with straining.
- Control BP and lower elevated serum Chol.

## FOOD AND NUTRITION

- Small, frequent feedings rather than three large meals are indicated.
- Increase fiber as tolerated; include an adequate fluid intake. Increase intake of fruits.
- Restrict saturated fats, dietary Chol, and sodium as necessary according to the individual profile. A very low-fat diet can be quite effective (Griel and Kris-Etherton, 2006).
- Limit stimulants such as caffeine to less than 5 cups of coffee or the equivalent daily. Energy drinks may contain 50–500 mg of caffeine.
- Promote calorie control if overweight; modify by age and sex.
- If tHcy levels are high, add more foods with folic acid, vitamins B<sub>6</sub> and B<sub>12</sub> to the diet.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Overweight

**Assessment Data:** BMI >90 percentile for age; complaints of heartburn and chest pain; diet hx shows intake of energy about 600 kcals extra per day and BMI 28.

**Nutrition Diagnoses (PES):** Overweight related to excessive energy intake as evidenced by BMI of 28 and limited physical activity.

**Interventions:** Education about the role of weight and heart disease, including angina. Counseling about desirable energy intake for age and activity level; ways to gradually increase physical activity.

**Monitoring and Evaluation:** BMI closer to desirable range; tolerance of physical activity; adequate drug therapy for angina.

- A Mediterranean diet that is rich in alpha linolenic acid (ALA) is effective (Estruch et al, 2006). It is prudent to increase intake of olive, soybean, and canola oils, seeds and nuts, including walnuts, almonds, macadamias, pecans, peanuts, and pistachios. Walnuts contain ALA; almonds are a good source of vitamin E. Nuts also contain flavonoids, phenols, phytosterols, saponins, elegendic acid, folic acid, magnesium, copper, potassium, and fiber. Pistachios, sunflower kernels, sesame seeds, and wheat germ are highest in phytosterols; use often.
- Beta-carotene supplements actually seem to increase angina. Dietary sources of carotenoids are a healthier choice.

### Common Drugs Used and Potential Side Effects

- Relief comes from use of tricyclic agents, beta-blockers, statins, or ACE inhibitors (Bugiardini and Bairey Mertz, 2005). Isosorbide (Isordil or Imdur) may cause nausea, vomiting, or dizziness; take on an empty stomach. Nadolol (Corgard) is a beta-blocker; it may cause weakness. Disopyramide (Norpace) may cause abdominal pain, nausea, or constipation.
- Antiplatelet therapy or anticoagulation therapy will be prescribed. Monitor for vitamin K intake with warfarin.
- Calcium channel blockers (verapamil [Calan], nifedipine, or diltiazem [Cardizem]) are used to dilate coronary arteries and slow down nerve impulses through the heart, thereby increasing blood flow. Nausea, edema, or constipation may be side effects. Take on an empty stomach. These drugs may also cause HF or dizziness; avoid taking with aloe, buckthorn bark and berry, cascara, and senna leaf. With nifedipine (Procardia), nausea, weakness, dizziness, and flatulence may occur; take after meals.

### Herbs, Botanicals, and Supplements

- The patient should not take herbals and botanicals without discussing with the physician. See Table 6-3.

#### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The patient will require stress management, activity, and education about proper eating habits.

- Discuss the role of nutrition in maintenance of wellness and in CVD. Discuss in particular: fiber, total fat intake, potassium and sodium, calcium and other nutrients, and caffeine.
- Discuss the importance of weight control in reduction of cardiovascular risks.
- Elevate the head of the bed 30–45° for greater comfort.
- Unstable angina is dangerous and should be treated as a potential emergency; new, worsening, or persistent chest discomfort should be evaluated in a hospital emergency department or “chest pain unit” and monitored carefully for acute MI (heart attack), severe cardiac arrhythmia, or cardiac arrest leading to sudden death. Dyspnea is a key factor and should be addressed (Arnold et al, 2009).

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## ARTERITIS

### NUTRITIONAL ACUITY RANKING: LEVEL 1

#### DEFINITIONS AND BACKGROUND

Arteritis involves inflammation of artery walls with decreased blood flow. **Cranial arteritis** (temporal or giant-cell arteritis) yields chronically inflamed temporal arteries

with a thickening of the lining and a reduction in blood flow; this condition is linked to polymyalgia rheumatica (PMR). Women older than 55 years of age are twice as likely to have the condition compared with other people. The greatest danger is permanent blindness or stroke.

**Buerger's disease** involves an arteritis that causes limb pain and numbness. **Periarteritis nodosa** is an autoimmune disease that can affect any artery in the body. A rare form, **Takayasu's arteritis**, affects the mesenteric artery and creates local ischemia; IL-8 may be involved. Patients with **giant cell arteritis** (GCA) are at risk for developing extra-cranial large vessel inflammation. GCA is a medical emergency with neuro-ophthalmic complications and permanent vision loss in up to a fifth of patients (Borg and Dasgupta, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Tumor necrosis factor appears to influence susceptibility and interleukin (IL)-1 receptor antagonist seems to play a role in the pathogenesis. Other genetic markers are being studied.

<b>Clinical/History</b>	Jaw pain	CoQ10 serum levels
Height	Muscular aches	Na <sup>+</sup> , K <sup>+</sup>
Weight	Abnormal arterial biopsy	Ca <sup>++</sup> , Mg <sup>++</sup>
BMI	(necrotizing vasculitis with	Gluc
Diet history	granulomatous proliferation)	Albumin (Alb) or transthyretin
BP	Ultrasonography	Creatinine kinase (CK)
Temperature (mild fever?)		Transferrin
Severe, throbbing headache (temples, back of the head)	<b>Lab Work</b>	Chol—total, HDL, LDL
Red, swollen, painful temporal artery	White blood cell count (WBC) (increased)	Trig
Anorexia, weight loss	Erythrocyte sedimentation rate (ESR) >50 mm/h	H & H (often decreased)
Scalp tenderness	CRP	Serum Fe, ferritin
Dysphagia		tHcy level
Hearing problems or vision changes		Serum folate and B <sub>12</sub>

## INTERVENTION

### OBJECTIVES

- Prevent stroke and blindness, which are potential complications.
- Reduce inflammation.
- Promote increased blood flow through the affected vessels.
- Modify intake according to requirements and coexisting problems such as hypertension.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Dysphagia

**Assessment Data:** Weight loss, dysphagia and jaw pain, throbbing headache.

**Nutrition Diagnoses (PES):** Dysphagia related to arteritis with jaw pain as evidenced by weight loss, complaints of difficulty swallowing solids, choking on thin liquids.

**Interventions:** Education about blending foods and simplifying meal planning to increase intake. Swallowing evaluation for determination of appropriate textures and thickening of liquids. Counseling on positioning at mealtime to reduce likelihood of aspiration.

**Monitoring and Evaluation:** Improved intake for meals and snacks; fewer complaints of difficulty swallowing. No further weight loss.

## FOOD AND NUTRITION

- Follow usual diet, with increased calories if patient is underweight or decreased calories if the patient is obese.
- Reduce excess sodium and total fat intake; monitor regularly. Increase intake of fruits.
- Patient may need to include carnitine in the diet. Although not yet proven, it may be reasonable to include in the diet more sources of vitamins E, B<sub>6</sub>, and B<sub>12</sub>, riboflavin, and folic acid or to use a multivitamin supplement that includes sufficient amounts.
- With steroids, decreased sodium intake with higher potassium intake may be needed. Adequate to high protein may also be necessary. Monitor for glucose intolerance.
- Omega-3 fatty acids may be used to reduce inflammation. Include salmon, tuna, sardines, mackerel, walnuts, and related foods.
- Treat with supplements of folic acid, vitamins B<sub>6</sub> and B<sub>12</sub> to reduce elevated tHcy concentrations.

## Common Drugs Used and Potential Side Effects

- The mainstay of therapy remains corticosteroids (Borg and Dasgupta, 2009). High-dose prednisone successfully controls the inflammatory process. Side effects include elevated glucose and decreased nitrogen levels, especially with long-term use.
- Methotrexate is being evaluated but more research is needed.
- Low-dose aspirin is sometimes recommended.

## Herbs, Botanicals, and Supplements

- The patient should not take herbals or botanicals without discussing with the physician. See Table 6-3.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of nutrition in the maintenance of health for CVD.

- Discuss the effects of medications on nutritional status and appetite.
- If dysphagia is present, discuss ways to alter texture or liquid consistencies.
- With long-term use of prednisone, monitor for osteoporosis, cataracts, easy bruising, elevated glucose levels.

#### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## ATHEROSCLEROSIS, CORONARY ARTERY DISEASE, DYSLIPIDEMIA

### NUTRITIONAL ACUITY RANKING: LEVEL 3

lations occur; the heart, brain, and leg arteries are most often affected. Metabolic syndrome is prevalent (see Table 6-5). Obesity leads to a proinflammatory and prothrombotic state that potentiates atherosclerosis (Moller and Kaufman, 2005). Vascular lipid accumulation and inflammation are hallmarks of atherosclerosis. As precursors to prostaglandins, thromboxanes, leukotrienes, lipoxins, and resolvins, essential fatty acids (EFAs) have significant clinical implications in hypertension, CHD and atherosclerosis (Das, 2006). The initial insult in adipose inflammation is mediated by macrophage recruitment and endogenous activation of Toll-like receptors, perpetuated through chemokine secretion, adipose retention of macrophages, and elaboration of pro-inflammatory adipocytokines (Shah et al, 2009). Then, paracrine and endocrine adipose inflammatory events induce a local and systemic inflammatory, insulin-resistant state promoting dyslipidemia and CVD (Shah et al, 2009).

**CAD** occurs when the coronary arteries that supply blood to the heart muscle become hardened and narrowed due to the buildup of plaque on the inner walls or lining of the arteries. Blood flow to the heart is reduced as plaque narrows the coronary arteries and diminishes oxygen supply to the heart muscle. CAD is common and is most often caused by smoking, high BP, low HDL Chol, family history of early CHD, and age (see Tables 6-1 and 6-2 for a long list of dietary and other relevant factors). Obesity, diabetes, and insulin resistance are also risks. Elevated plasma tHcy is an independent risk factor and a strong predictor of mortality in patients with CAD (Ntaios et al, 2010). Angioplasty is safe and as effective as bypass surgery for treatment of CAD.

**Ischemia** is a local and temporary deficiency of blood caused by obstruction, as from thrombosis. People with ischemic heart disease benefit from diets high in monounsaturated

#### DEFINITIONS AND BACKGROUND

**Atherosclerosis** involves progressive narrowing of the arterial tree, giving rise to collateral vessels. Fat-deposit accumu-

fatty acids (MUFA), omega-3 fatty acids, whole grains, vitamin E, wine, vegetables, and fruits.

**Dyslipidemia** involves hypertriglyceridemia and low levels of high-density lipoprotein Cholesterol. These imbalances in individual lipid components contribute to the increased risk of CAD. Serum lipid reductions decrease CAD risk; for each 1% reduction in serum Cholesterol, there is a 2% reduction in CAD risk.

Cholesterol screening is recommended, even for older adults. When treated, risks decrease significantly; therefore, early nutritional intervention is beneficial. In addition to BMI, use waist circumference or waist-to-hip ratio (WHR) to assess obesity and CVD risk since BMI alone is not a good predictor of CVD risk in persons over 65 years of age (ADA Evidence Analysis Library, 2009). In addition, correction of dyslipidemia in patients after coronary artery bypass graft (CABG) surgery prevents progression of atherosclerosis.

A therapeutic lifestyle modification program is effective. Nutrition and physical activity interventions have the potential to dramatically reduce the risks. Dietary counseling and education by a registered dietitian are associated with improved diet-related outcomes, and sufficient time to consult with a dietitian should be planned in cardiac rehabilitation (Locklin Holmes et al, 2005). Referral to a registered dietitian for medical nutrition therapy (MNT) is recommended whenever an individual has an abnormal lipid profile or CHD, with a planned initial visit lasting from 45–90 minutes and at least two to six planned follow-up visits of 30–60 minutes each (ADA Evidence Analysis Library, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Lipid alterations have a polygenic basis. Family history is the most significant independent risk factor for CAD. In the Multi-Ethnic Study of Atherosclerosis (MESA) the lipid-related HMG-CoA reductase (HMGCR) variations differed greatly among ethnicities (Chen et al, 2009). Another study identified 30 distinct loci with lipoprotein concentrations variants (Kathiresan et al, 2009). ApoE and lipoprotein lipase (LPL) genes have been known for some time. In addition, elevated plasma tHcy can result from genetic errors, including methylenetetrahydrofolate reductase (MTHFR) C677T and A1298C polymorphisms (Freitas et al, 2008). Genetic testing is needed in high-risk population groups (Olthof and Verhoef, 2005).

<b>Clinical/History</b>	Waist circumference >102 cm (40 in) in men and >88 cm (35 in) in women	Diet history BP Pancreatitis? Xanthomas?
Height		
Weight		
BMI		

## Lab Work

CRP	LDL Cholesterol: Goal <100 mg/dL	Serum B <sub>6</sub>
CoQ10 serum levels	Advanced lipid testing—small particle size	H & H
Trig: Goal below 150 mg/dL	tHcy: serum and urinary	Serum Fe
TC (often increased)	Serum and urinary folate	Na <sup>+</sup> , K <sup>+</sup>
HDL: Goal >40 mg/dL in men and >50 mg/dL in women	Serum and urinary B <sub>12</sub>	Ca <sup>++</sup> , Mg <sup>++</sup>
		Gluc
		AST, ALT
		Serum copper

## INTERVENTION

## OBJECTIVES

- Use a team approach to support the best possible outcomes: doctors, nurses, dietitians, other therapists.
- Improve LDL and HDL Cholesterol levels to prevent formation of new lesions. Lower elevated Cholesterol levels (>200 mg/dL) and Triglyceride levels (>200 mg/dL) using the TLC diet from the National Heart, Lung, and Blood Institute.
- Treat elevated TGs if over 150 mg/dL. Intensify weight management and increase physical activity. If TGs are ≥200 mg/dL after LDL goal is reached, set a secondary goal for non-HDL Cholesterol (total cholesterol minus HDL) 30 mg/dL higher than LDL goal.
- Treat metabolic syndrome. Address underlying causes (overweight/obesity and physical inactivity).

## SAMPLE NUTRITION CARE PROCESS STEPS

### Dyslipidemia

**Assessment Data:** Food frequency recall and intake records; computer nutrient analysis.

**Nutrition Diagnosis (PES):** Inappropriate intake of food fats related to food and nutrition-related knowledge deficit as evidenced by daily consumption of bacon, sausage, butter and ice cream, saturated fat intake of 15% of kilocal, TC 220 mg/dL, and LDL Cholesterol of 165 mg/dL and HDL Cholesterol of 30 mg/dL.

**Intervention:** Food and Nutrient Delivery: Clarify current diet order to include no fried foods, bacon, sausage, and creams/custards. Provide Cheerios or oatmeal for breakfast to help further lower Cholesterol. Add plant sterols or stanols.

Education: identify alternate sources of fats from meals and snacks that are more desirable.

**Monitoring and Evaluation:** Repeat lab values after 3–6 months; dietary recall. Goal = TC below 200 mg/dL.

- Initiate and maintain weight loss if overweight. Obesity with a high waist circumference is especially important to correct in both men and women.
- Moderate carbohydrate restriction and weight control can improve dyslipidemia.
- Correct elevated levels of tHcy ( $>6 \mu\text{mol/L}$ ).
- Use more flavonoids, phytochemicals, soy products, and fruits and vegetables.
- Treat hypertension; use aspirin for CAD patients to reduce prothrombotic state if appropriate.
- Monitor for effects of MTHFR genotype (Ilhan et al, 2008). This may be useful in predicting the development of premature coronary artery disease, especially in hypertensive adolescents (Koo et al, 2008) and those who have type 1 diabetes (Wiltshire et al, 2008).

## FOOD AND NUTRITION

- There is no “one size fits all” guideline; combine diet with exercise and other lifestyle changes. The Mediterranean diet tends to be quite acceptable to most people and works well in lowering coronary risk factors; it encourages use of olive oil, red wine, fish, fruits, and vegetables.
  - The Evidence Analysis Library of the American Dietetic Association recommends the “Therapeutic Lifestyle” diet consisting of 25–35% total fat,  $<7\%$  saturated and trans fat, and  $<200 \text{ mg}$  dietary Chol (NHLBI, 2009). To keep fat at about 3 g/100 kcal, examples include:
- | 25% of kilocal    | 30% of kilocal    | 35% of kilocal    |
|-------------------|-------------------|-------------------|
| 28 g in 1000 kcal | 33 g in 1000 kcal | 39 g in 1000 kcal |
| 33 g in 1200 kcal | 40 g in 1200 kcal | 47 g in 1200 kcal |
| 42 g in 1500 kcal | 50 g in 1500 kcal | 59 g in 1500 kcal |
| 50 g in 1800 kcal | 60 g in 1800 kcal | 70 g in 1800 kcal |
| 56 g in 2000 kcal | 67 g in 2000 kcal | 78 g in 2000 kcal |
| 67 g in 2400 kcal | 80 g in 2400 kcal | 93 g in 2400 kcal |
- Use isocaloric replacement of saturated fatty acids (SFA) with MUFA and polyunsaturated fatty acids (PUFA); include olive oil and canola oil in cooking and salad dressings.
  - A diet rich in fruits, vegetables, low-fat dairy products, and low in sodium and saturated fat can decrease BP, an effect that is enhanced by weight loss and increased physical activity.
  - Consume  $1/2$  cup of nuts daily or 5 oz per week with a diet low in saturated fat and Chol to decrease TC. Nuts contain flavonoids, phenols, sterols, saponins, elegendic acid, folic acid, magnesium, copper, potassium, and fiber. Almonds are a very good source of vitamin E; walnuts contain ALA.
  - Consume antioxidants from dietary sources. Vitamin E foods include asparagus, spinach, wheat germ, nuts, salad oils, and creamy salad dressings. Vitamin C foods should be consumed in amounts that meet DRI levels. Supplemental antioxidants alone or in combination with other antioxidants may act as pro-oxidants and have no protection for CVD events (ADA Evidence Analysis Library, 2009).
  - Use flavonoids from tea, blueberries, yellow onions, red wine, grape juice, apples, cocoa, dark chocolate, products such as CocoaVia. Pomegranate increases antioxidant consumption and lowers LDL Chol (Arias and Ramon-Laca, 2005). Cinnamon, cloves, licorice, and sage are recommended as well.
  - Consume a diet high in total fiber (17–30 g/d) and soluble fiber (7–13 g/d) as part of a diet low in saturated fat and Chol. Soluble fiber may include oatmeal, high fiber cereal, prunes, oat bran, corn bran, apples, and legumes as good sources. Risk factors associated with BP, lipoprotein subclasses and particle sizes, insulin resistance, postprandial glucose, fatal and non-fatal MI, or stroke are decreased as dietary fiber intake increases (ADA Evidence Analysis Library, 2009).
  - Consume 2–3 g of plant sterols and stanols (through margarine, low-fat yogurt, orange juice, breads, and cereals) daily to lower total and LDL Chol, even with statins. Stanol-containing margarines may be consumed for at least 3 weeks before reassessment. Consume one extra carotenoid-rich fruit or vegetable per day to maintain plasma carotenoid levels when consuming sterol-enriched spreads.
  - Pistachios, sunflower kernels, sesame seeds, and wheat germ are high in natural phytoosterols; use often.
  - Intake of approximately 1 g/d of EPA and DHA from a supplement or fish may decrease the risk of death from cardiac events in patients with heart disease. Regular consumption of an average of two servings of fatty fish per week (about 3.5 oz per serving) reduces risk of death from cardiac events. However, a low-to-moderate fat diet is also needed (Shah et al, 2009).
  - Diets containing soy are well tolerated but soy will produce varied results based on initial Chol level and conditions such as diabetes.
  - Use fewer animal proteins and more legumes or vegetable protein sources. Fish and shellfish may be used three to four times weekly, especially sources rich in omega-3 fatty acids. Remove chicken skin before cooking or just before serving. Lean beef and chicken are considered to be comparable.
  - Trans fatty acids should be avoided; read labels.
  - Provide chromium, copper, vitamin K in recommended amounts.
  - A diet rich in folic acid, vitamins B<sub>6</sub> and B<sub>12</sub>, betaine and choline might benefit cardiovascular health through a tHcy-lowering effect (da Costa et al, 2005; Olthof and Verhoef, 2005). Betaine is widely distributed in animals and plants, especially seafood, wheat germ, bran, and spinach; intake from foods is estimated at 0.5–2 g/d (Olthof and Verhoef, 2005).
  - The DASH diet is useful; see Table 6-4. This diet will include 9–12 servings of fruits and vegetables, 2–3 servings of low-fat dairy products, less than 2.3 g sodium, weight loss if necessary, and increased physical activity with moderate intensity three times per week (ADA Evidence Analysis Library, 2009).

## Common Drugs Used and Potential Side Effects

- Reduced progression of atherosclerosis is associated with intensive statin treatment which reduces both atherogenic lipoproteins and CRP (Nissen et al, 2005). Try “Diet First, Then Drugs”: see Table 6-6.
- If anticoagulants (warfarin) are used, limit vitamin K-containing foods to 1 per day. Foods high in vitamin K include mayonnaise, canola and soybean oils, Brussels sprouts, collards, endive, spinach, watercress, red bibb lettuce, cabbage, broccoli, kale, and parsley.
- Aspirin may decrease serum ferritin by increasing occult blood loss if used over a long time.
- Digitalis and digoxin (Lanoxin) require the patient to avoid excessive amounts of vitamin D, natural licorice, fiber, and potassium. Take these drugs 30 minutes before meals. Do not take with herbal teas, Siberian ginseng, milkweed, hawthorn, guar gum, or St. John’s wort.
- Gemfibrozil (Lopid) is used for elevated TGs when there is a risk of pancreatitis; taste changes or abdominal pain may occur. Probucol (Lorelco) may cause vomiting or anorexia.

- Statins reduce Chol production by the liver. They may lower coenzyme Q10 to the point of deficiency. Simvastatin may cause constipation; fluvastatin may cause nausea and abdominal cramps; pravastatin can elevate AST and ALT levels or cause nausea, vomiting, and diarrhea. Interestingly, statins support bone health. Increase omega-3 fatty acids and reduce the omega-6 to omega-3 ratio to allow statins to work more effectively.
- Thiazides, propranolol, estrogens, and oral contraceptives may increase lipid levels or may lower folate levels. Monitor for specific side effects.
- Colesevelam HCl (WelChol) can be used with statins; it is not absorbed into the bloodstream and has few side effects.

## Herbs, Botanicals, and Supplements

- In one small clinical trial, red yeast rice and TLC decreased LDL Chol level without increasing CPK levels; this may be a treatment option for dyslipidemic patients who cannot tolerate statin therapy (Becker et al, 2009).

**TABLE 6-6** Drugs Affecting Lipoprotein Metabolism

Drug Class	Agents and Daily Doses	Lipid/Lipoprotein Effects	Side Effects and Comments	Contraindications
Statins—HMG-CoA reductase inhibitors	Lovastatin (20–80 mg)	LDL-C, ↓18–55%	Muscle pain and tenderness; myopathy	Absolute:
	Pravastatin (20–40 mg)	HDL-C, →5–15%		Active or chronic liver disease
	Simvastatin (20–80 mg)	TG, ↓7–30%	Severe cases: rhabdomyolysis and release of myoglobin into the bloodstream	Relative:
	Fluvastatin (20–80 mg)		Increased liver enzymes	Concomitant use of certain drugs <sup>a</sup>
	Atorvastatin (10–80 mg)			
Bile acid sequestrant	Cerivastatin (0.4–0.8 mg)	LDL-C, ↓15–30%	GI distress	Absolute:
	Cholestyramine (4–16 g)	HDL-C, →3–5%	Constipation; use more fiber	Dysbetalipoproteinemia
	Colestipol (5–20 g)	TG, No change or increase	Decreased absorption of other drugs	TG >400 mg/dL
	Colesevelam (2.6–3.8 g)		Add folate and fat-soluble vitamins; mix with liquids	Relative: TG >200 mg/dL
Nicotinic acid (Nico-Bid, Nico-400)	Immediate-release (crystalline) nicotinic acid (1.5–3 g), extended-release nicotinic acid (Niaspan) (1–2 g), sustained-release nicotinic acid (1–2 g)	LDL-C, ↓5–25% HDL-C, →15–35% TG, ↓20–50%	Flushing Hyperglycemia Hyperuricemia (or gout) Upper GI distress Hepatotoxicity or altered LFTs Vomiting, diarrhea	Absolute: Chronic liver disease Severe gout Relative: Diabetes Hyperuricemia Peptic ulcer disease
Fibric acids	Gemfibrozil (600 mg BID)	LDL-C, ↓5–20% (may be increased in patients with high TG)	Dyspepsia	Absolute:
	Fenofibrate (200 mg)		Gallstones	Severe renal disease
	Clofibrate (1000 mg BID)	HDL-C, →10–20% TG, ↓20–50%	Myopathy Weight gain Diarrhea, nausea	Severe hepatic disease

HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; TG, triglycerides; LFT, liver function test; GI, gastrointestinal.

Adapted from National Heart, Lung, and Blood Institute. Web site accessed July 7, 2009, at <http://www.nhlbi.nih.gov/guidelines/cholesterol/atp3full.pdf>.

<sup>a</sup>Cyclosporine, macrolide antibiotics, various antifungal agents, and cytochrome P-450 inhibitors (fibrates and niacin should be used with appropriate caution).

- Folic acid lowers plasma tHcy by 25% maximally, because 5-methyltetrahydrofolate is a methyl donor in the remethylation of tHcy to methionine (Olthof and Verhoef, 2005). In the NORVIT trial, researchers concluded that folic acid supplements could cause more harm than good if given with B<sub>12</sub> supplements (Bonaa et al, 2006). However, betaine given in high doses (6 g/d and higher) acutely reduces increased tHcy after methionine loading by up to 50%, whereas folic acid has no effect (Olthof and Verhoef, 2005). This fact may have played a role in the outcome of recent folic acid trials where Albert et al (2008) and Ebbing (2008) and their colleagues reported that long-term studies for lowering tHcy with folic acid, B<sub>12</sub> and B<sub>6</sub> supplements failed to prevent cardiac events.
- Herbs and botanicals such as angelica, hawthorn, canola, cinchona, valerian, willow, grape, pigweed, and chicory have proven efficacy. Discuss herbs and botanicals with the physician; see Table 6-3.
- Encourage reading of food labels, including how to identify various ingredients such as “free, low, reduced” Chol.
- Aerobic exercise, weight loss, smoking cessation, and lifestyle changes are needed. Provide ideas, coping skills, motivational factors, and environmental barriers. Cardiac Rehabilitation programs that use a mind–body approach are useful.
- For individuals have MTHFR genetic allele, it is prudent to discuss dietary or supplemental measures (Klerk et al, 2002; Koo et al, 2008; Wiltshire et al, 2008). Sources of vitamin B<sub>6</sub> include eggs, meats, fish, vegetables, yeast, whole-wheat grains, and milk. Sources of vitamin B<sub>12</sub> include liver, meat, eggs, dairy products, and fish. See Table 6-4 for good sources of folate.
- Discuss low-fat cooking methods, such as baking, broiling, flame cooking, grilling, marinating, poaching, roasting, smoking, or steaming.
- Olestra, a fat substitute, decreases absorption of dietary fat. Use in moderate amounts to prevent diarrhea.
- Routine periodic fasting has been shown to have merit in reducing risk of CAD (Horne et al, 2008).
- Intensive lifestyle changes maintained for 5 years or longer may be needed. A strict low fat diet can help reverse atherosclerosis. Check serum lipids at least annually.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the roles of heredity, exercise, and lifestyle habits. BP, Chol, obesity, and diabetes are affected by dietary patterns; some control is possible.
- Adherence with the 2005 Dietary Guidelines for Americans (DGA) is significantly associated with slower atherosclerosis progression and less metabolic syndrome (Fogli-Cawley et al, 2007; Imamura et al, 2009).
- There is no Chol in foods of plant origin. Encourage use of a plant-based diet.
- Explain which foods are sources of saturated fats and trans fatty acids. Identify foods that are sources of polyunsaturated fats and monounsaturated fats (olive and peanut oils). An easy first step is changing to skim milk products instead of whole milk.
- Diets low in fat have different tastes and textures. If one changes diet too quickly, the diet may seem dry and unpalatable. Suggest changing gradually. Teach new ideas for moistening foods without adding excess fat (e.g., using applesauce instead of oil in some baked goods). Provide lists of resources such as cookbooks, newsletters, product samples, or coupons.
- Describe food sources of saturated MUFAs and PUFAs and Chol; discuss olive, soybean, walnut, and peanut oil uses. Help the patient make suitable substitutions. Although egg yolks contain Chol, they can be planned into the diet three to four times weekly.
- Use of red wine appears to be protective, but more studies are needed to verify effects on hemodynamics (Karatzis et al, 2009).
- Fish should be included several times weekly. Omega-3 fatty acids are found in fatter fish such as salmon, herring, tuna, mackerel, and other seafood.
- Sources of soluble fiber (guar gum, pectin) include apples, legumes, oat and corn brans. Include other whole-grain foods for insoluble fiber as both types of fiber are beneficial.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## CARDIAC CACHEXIA

### NUTRITIONAL ACUITY RANKING: LEVEL 4

## DEFINITIONS AND BACKGROUND

Cardiac cachexia is concurrent with HF of such severity that patients cannot eat adequately to maintain weight. It involves a loss of more than 10% of lean body mass and can clinically be defined as a body weight loss of 7.5% of previous dry body weight over 6 months or longer. The condition usually follows HF (moderate to severe), with some valvular heart disease. Nutritional insults generally affect the heart muscle severely, and the insult may be significant. While the pathophysiological alterations leading to cardiac cachexia are unclear, metabolic, neurohormonal and immune abnormalities may play a role. Cachectic HF patients show raised plasma levels of epinephrine, norepinephrine, cortisol, renin, and aldosterone. Patients with cardiac cachexia suffer from a general loss of fat tissue, lean tissue, and bone tissue. Lower, rather than higher, Chol levels are associated with poor clinical outcome in patients with chronic HF.

Chronic HF (CHF) is increasingly recognized as a multi-system disease with alterations in intestinal morphology, permeability, and absorption that lead to chronic inflammation (Sande et al, 2009). The wasting associated with chronic HF is an independent predictor of mortality. A loss of body weight or skeletal muscle mass is common in older persons and precedes a poor outcome; starvation results in a loss of body fat and nonfat mass due to inadequate intake of protein and energy and sarcopenia is associated with a reduction in muscle mass and strength (Thomas, 2007). Cardiac cachexia as a terminal stage of chronic HF carries a poor prognosis (von Haehling et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Ghrelin (the growth-hormone-releasing peptide in the stomach) may play a role in cachexia; more studies are needed. Tumor necrosis factor may be involved (Anker et al, 2004). In addition, adiponectin seems to have a role in the wasting process.

#### Clinical/History

Height  
Weight, current  
Dry weight  
BMI  
Waist circumference; ascites?  
Anorexia, weight loss?  
Edema  
BP  
Fatigue  
Shortness of breath (dyspnea)

Steatorrhea or diarrhea  
Loss of muscle mass  
Supraclavicular and temporal muscle wasting

#### Lab Work

Chol—total (low?)  
Trig  
CRP (elevated?)  
CoQ10 serum levels

Gluc  
Fecal fat (in steatorrhea)  
H & H  
Serum Fe, ferritin  
Liver function tests  
Thyroid-stimulating hormone (TSH)  
Total lymphocyte count (TLC)  
Serum insulin  
Alb, transthyretin  
Serum thiamin

## SAMPLE NUTRITION CARE PROCESS STEPS

### Unintentional Weight Loss

**Assessment Data:** BMI <18, HF and shortness of breath, weight loss of 20 lb in 12 months.

**Nutrition Diagnoses (PES):** Unintentional weight loss related to low oral intake as evidenced by weight loss of 20 lb in past year and BMI 17.5.

**Interventions:** Education about ways to enhance energy and nutrient density in meals and snacks.

**Monitoring and Evaluation:** BMI now >19 in 3 months; better intake of energy-dense foods and beverages.

Transferrin  
Na<sup>+</sup>, K<sup>+</sup>  
Ca<sup>++</sup>, Mg<sup>++</sup>  
tHcy

Serum folate and vitamin B<sub>12</sub>  
Blood urea nitrogen (BUN)

## INTERVENTION

### OBJECTIVES

- Improve hypoxic state and heart functioning.
- Correct malnutrition, wasting, malabsorption, and steatorrhea. Patients with HF have breathing difficulties, fatigue, nausea, loss of appetite, early feeling of fullness, or ascites that tend to decrease intake.
- Optimize heart function through balance of medications, antioxidants, fluids, and electrolytes.
- Reduce impact of inflammatory cytokines. Meet hypermetabolic state with adequate energy intake.
- Prevent infection or sepsis, especially if tracheostomy is required.
- Provide gradual repletion to prevent overloading in a severely depleted patient.
- Treat constipation or diarrhea as necessary.

## FOOD AND NUTRITION

- Energy needs may be calculated as high as 50% above basic needs.
- Protein should be estimated at a rate of 1.0–1.5 g/kg, increasing or decreasing depending on renal or hepatic status.
- Offer tube feeding (TF) or parenteral nutrition if appropriate. Sometimes, TFs are not well tolerated because of access to the thoracic cavity and reduced blood flow to the gastrointestinal (GI) tract. High-calorie, low-volume products have a high density of calories; they are appropriate for persons with a fluid limitation but must be monitored with renal or hepatic insufficiency.
- Provide small, frequent meals to prevent overloading with high glucose or fat. A diet high in saturated fat may actually be beneficial (Berthiaume et al, 2010).
- Provide as many preferred foods as feasible to improve appetite and intake.

- Antioxidants may benefit. Nutrient-dense foods containing omega-3 fatty acids can be safely recommended. Use more foods such as fish, fruits, cinnamon, cocoa, green tea, berries, nuts and foods that contain flavonols. Use the DASH diet as much as possible (Levitan et al, 2009).
- Sodium may need to be restricted to 1–2 g daily. In older patients, a more lenient 4–6 g may suffice. Modify potassium intake as appropriate. The DASH diet is useful.
- Diet may need to be high in folate, magnesium, zinc, iron (depending on serum levels), vitamins E, B<sub>6</sub>, and B<sub>12</sub>. Thiamin should be included to alleviate cardiac beri-beri, which is common.

### Common Drugs Used and Potential Side Effects

- Therapeutic approaches include appetite stimulants such as megestrol acetate, medroxyprogesterone acetate, and cannabinoids (von Haehling et al, 2009).

### Herbs, Botanicals, and Supplements

- Discuss herbs and botanicals with the physician. See Table 6-3.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Balance medications, fluid, and electrolytes carefully.
- Supplements may be beneficial between meals to improve total calorie intake (e.g., sherbet shakes).

- The importance of diet in cardiovascular health should be addressed, but rapid weight loss should be prevented. Patients with low BMI are at higher risk after cardiac surgery than obese patients.
- Exercise, with supervised guidance, can be beneficial to rebuild lean body mass.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## CARDIOMYOPATHIES

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Cardiomyopathies may be caused by many known diseases or have no specific known cause. They are progressive disorders that impair the structure or function of the muscular wall of the lower chambers of the heart. Echocardiography is useful in demonstrating cardiac abnormalities.

In **restrictive cardiomyopathy**, the heart chambers are unable to properly fill with blood because of stiffness in the heart. Amyloidosis or scleroderma are common causes.

**Dilated congestive cardiomyopathy (DCC)** is most commonly caused by CHD in the United States. DCC may also occur from a viral infection such as coxsackievirus B, from diabetes or thyroid disease, or from excessive alcohol, cocaine, or antidepressant use. Rarely, pregnancy or rheumatoid arthritis can also trigger DCC. Because prenatal dilated cardiomyopathy (DCM) can also be the presenting sign of cblC (cobalamin C deficiency) inborn errors of metabolism should be considered in view of the possible impact on treatment and future reproductive options (De Bie et al, 2009).

The first symptoms of DCC are shortness of breath on exertion and easy fatigability; sometimes, a fever and flu-like

symptoms occur if triggered by a virus. Calcium and potassium irregularities have been noted (Olson et al, 2005). Remaining heart muscle stretches to compensate for lost pumping action, and when the stretching no longer compensates, DCC occurs. Blood may pool in the swollen heart, and clots may form on the chamber walls. Seventy percent of patients with DCC die within 5 years of the beginning of their symptoms, and the prognosis worsens as the walls become thinner and the heart valves begin to leak. Because of this, DCC is the most common cause for heart transplantation.

**HCM** may occur as a birth defect or as a result of acromegaly (excessive growth hormone in the blood), a pheochromocytoma, or a neurofibromatosis. Glycogen storage disease may also present with some cardiomyopathy (Arad et al, 2005). Thickening of the heart wall causes high BP, pulmonary hypertension, and chronic shortness of breath. Faintness, chest pain, irregular heartbeats and palpitations, and HF with dyspnea will occur. Hyperhomocysteinemia chelates copper and impairs copper-dependent enzymes; therefore, copper supplementation may be needed (Hughes et al, 2008).

HCM is a possible cause of sudden death; it is largely confined to young people but can occur suddenly at any stage of life. Most patients with mild hypertrophy are at low risk. Treatment options for patients with obstructive HCM include medical therapy, pacemaker insertion, percutaneous transluminal septal myocardial ablation, mitral valve replacement, and surgical resection of the obstructing muscle. Nonsurgical septal reduction therapy is also an effective therapy for symptomatic patients with obstructive HCM. A heart transplant may be indicated.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** About 90% of cases of HCM are familial with mutations in the MYBPC3 gene, encoding cardiac myosin-binding protein C (van Dijk et al, 2009). Genetic factors also may be responsible for half of DCM cases.

## INTERVENTION

## OBJECTIVES

- Improve hypoxic state and heart functioning.
- Correct malnutrition, malabsorption, and steatorrhea.
- Growth failure is a significant clinical problem of children with cardiomyopathy; nearly one third of these children manifest some degree of growth failure (Miller et al, 2007).
- Optimize heart function through balance of medications, fluids, and electrolytes.
- Meet hypermetabolic state with adequate calories.
- Provide gradual repletion to prevent overloading in a severely depleted patient.
- Treat constipation or diarrhea as necessary.
- Prepare for surgery, if planned.

## FOOD AND NUTRITION

- Energy may be calculated as much as 50% above usual needs. Optimal intake of macronutrients and antioxidants that can protect against free radical damage are needed (Miller et al, 2007).
- Protein should be calculated at a rate of 1.0–1.5 g/kg, increasing or decreasing depending on renal or hepatic status.
- Provide small, frequent meals to prevent overloading with high glucose or with rapid fat infusion. Provide as

## SAMPLE NUTRITION CARE PROCESS STEPS

### Excessive Intake of Fluids

**Assessment Data:** Dietary intake records; I & O records. Presence of 1+ pitting edema. Signs of cardiac failure with lung crackles.

**Nutrition Diagnosis (PES):** Excessive intake of fluids related to food choices and preference for primarily soups and liquids on most days of the week as evidenced by edema, low BP and easy fatigue.

**Intervention:** Education and counseling about fluid limits using a food diary, fluid calculation chart, I & O records.

**Monitoring and Evaluation:** Weight maintenance versus fluctuations; improved intake records and food diaries reflecting successful management of fluid intake. Fewer symptoms of HF and improved breathing.

many preferred foods as feasible to improve appetite and intake.

- Follow TLC diet interventions. Pistachios, sunflower kernels, sesame seeds, and wheat germ are high in phytosterols; use often.
- The DASH diet is useful. Diet may need to be high in calcium and potassium (Olson et al, 2005); folate, magnesium, copper, zinc, and iron may also be needed, depending on serum levels. Increasing vitamins E, B<sub>6</sub>, and B<sub>12</sub> may be beneficial. Thiamin should also be included because of likelihood of cardiac beriberi.
- Sodium may need to be restricted to 2–4 g daily; modify potassium intake as appropriate for serum levels.
- Offer TF or parenteral nutrition if appropriate. Sometimes, TFs are not well tolerated because of proximity to the thoracic cavity and because of reduced blood flow to the GI tract. High-calorie, low-volume products are useful for their high density of calories. They are appropriate for persons with a fluid limitation but must be monitored in patients with renal or hepatic difficulty.

### Common Drugs Used and Potential Side Effects

- Anticoagulant therapy is needed to prevent clots from causing heart attacks, strokes, and other problems. With warfarin (Coumadin), use a controlled amount of vitamin K; check TF products and supplements. Limit foods high in vitamin K to 1 serving per day. Foods high in vitamin K include mayonnaise, canola and soybean oils, Brussels sprouts, collards, endive, spinach, watercress, red bibb lettuce, cabbage, broccoli, kale, and parsley.
- Blood-thinning medications: Omega-3 fatty acids may increase the blood-thinning effects of aspirin or warfarin. While the combination of aspirin and omega-3 fatty acids may actually be helpful under certain circumstances (such as heart disease), they should only be taken together under the guidance and supervision of a health care provider. Be wary of using supplements containing vitamins A and C with these drugs; side effects may be detrimental. Vitamin E should not be taken with warfarin because of the possibility of increased bleeding; avoid doses greater than 400 IU/d. Avoid taking with dong quai, fenugreek, feverfew, excessive garlic, ginger, ginkgo, and ginseng because of their effects.
- Beta-blockers and calcium channel blockers may be used to reduce the force of heart contractions.
- Diuretics: Side effects may include potassium depletion; review types used and alter diet accordingly. Some diuretics spare calcium and protect bone health.
- Digoxin: Monitor potassium intake or depletion carefully, especially when combining with diuretics. Avoid excessive intakes of fiber and wheat bran. Avoid use with hawthorn, milkweed, guar gum, and St. John's wort.
- Insulin may be needed if patient has diabetes or becomes hyperglycemic. Alter mealtimes accordingly.

### Herbs, Botanicals, and Supplements

- Table grape powder contains important phytochemicals; a diet with grape powder may reduce cardiac oxidative damage, increase cardiac glutathione, lower BP, improve cardiac function, reduce systemic inflammation, reduce cardiac hypertrophy and fibrosis (Seymour et al, 2008).
- Discuss herbs and botanicals with the physician. See Table 6-3. CoQ10 may be protective.
- Ephedra and adderol have been associated with cardiomyopathy and should be avoided.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Adequate rest is essential. Avoidance of stress is also important.
- Balance medications, fluid, and electrolytes carefully.
- Supplements may be beneficial between meals to improve total calorie intake (e.g., sherbet shakes).
- The importance of diet in cardiovascular health should be addressed. A moderate calorie restriction may be beneficial.
- Because of the high risk for sudden death in HCM patients, they should be advised against participation in highly competitive sports.
- For inherited forms of HCM, genetic counseling may be beneficial if planning a family.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# HEART FAILURE

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### • Heart Failure

Carbohydrates maintain sodium and fluid balance. A carbohydrate deficiency promotes loss of sodium and water, which can adversely affect blood pressure and cardiac function if not corrected.

### DEFINITIONS AND BACKGROUND

HF is the leading cause of CVD and related death, with nearly 5 million cases in the United States. HF results in reduced heart pumping efficiency in the lower two chambers, with less blood circulating to body tissues, congestion in lungs or body circulation, ankle swelling, abdominal pain, ascites, hepatic congestion, jugular vein distention, and breathing difficulty. The ability of mitochondria to oxidatively synthesize ATP from ADP and inorganic phosphate is compromised in the myocardium of HF patients.

Left ventricular failure will cause shortness of breath and fatigue; right ventricular failure causes peripheral and abdominal fluid accumulation. HF is a common diagnosis in hospitalized patients and four stages have been identified (Hunt et al, 2005):

- Stage A has mild symptoms and no limitation on physical activity.
- Stage B shows structural heart disease but no signs or symptoms of HF.
- Stage C demonstrates signs and symptoms of structural HF.
- Stage D shows refractory HF requiring specialized interventions.

HF can be caused by CHD, previous heart attack, history of cardiomyopathy, lung disease such as chronic obstructive pulmonary disease (COPD), severe anemia, excessive alcohol consumption, or low thyroid function. Male sex, lower education, physical inactivity, cigarette smoking, overweight, diabetes, hypertension, valvular heart disease, and CHD are all independent risk factors. The leading cause of HF in Western countries is ischemic heart disease. Therefore, aggressive therapy to halt progression of coronary atherosclerosis can have a major impact on controlling or curing HF.

B-type natriuretic peptide (BNP) is secreted by ventricles when pressure goes up in the heart. CoQ10 has been identified as a factor to consider. Patients with HF have low plasma levels of CoQ10, an essential cofactor for mitochondrial electron transport and myocardial energy supply (Molyneux et al, 2008). Low plasma TC concentrations have also been associated with higher mortality in HF; the relationship between CoQ10 and LDL-C levels may contribute to this association (Molyneux et al, 2008).

Decreased renal flow is common; BUN may be increased. Early adaptations to mild HF show susceptibility to sodium excess. Evidence suggests that advanced HF is a multifactor-

ial metabolic syndrome that can lead to cardiac cachexia, which then carries a very poor prognosis. The mechanisms underlying this association are poorly understood. Inflammatory cytokines may play a pathogenic role. HF is associated with elevated levels of angiotensin II in the blood, causing vessel contraction and high BP in addition to muscle wasting. Studies are reviewing the role of other factors.

Dairy nutrients (calcium, potassium and magnesium) have a BP lowering effect, as shown by studies showing the effectiveness of the DASH diet (Levitan et al, 2009). Low calcium increases intracellular calcium concentrations, thereby increasing 1,25-dihydroxyvitamin D(3) and parathyroid hormone (PTH), causing calcium influx into vascular smooth muscle cells and greater vascular resistance (Kris-Etherton et al, 2009). Dairy peptides may act as ACE inhibitors, thereby inhibiting the renin-angiotensin system with consequent vasodilation (Kris-Etherton et al, 2009). While sodium restriction and diuretics are basic treatments, treatment may also include implantation of a pacemaker or even cardiac transplantation. Joint efforts of cardiologists, endocrinologists, immunologists, and registered dietitians are required to develop effective therapeutic strategies. Referral to a registered dietitian is needed for MNT. For a person with HF, one planned initial visit and at least one to three planned follow-up visits can lead to improved dietary pattern and quality of life, decreased edema and fatigue, more optimal pharmacological management, and fewer hospitalizations (American Dietetic Association, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Nuclear factor kappa B (NF-kappaB) is chronically activated in cardiac myocytes; the NFKB1 -94 insertion/deletion ATTG polymorphism is associated with DCM (Zhou et al, 2009).

Clinical/History	Skin, cyanotic or pale	Pulmonary
Height	Abnormal	edema, rales,
Weight	breath	dyspnea (left-sided HF)
BMI	sounds	Glomerular
Waist-hip ratio	Increased heart	filtration
Weight changes?	rate; pulse	rate (GFR)
Diet history	>80	Oliguria
BP	beats/min	Confusion,
Shortness of breath	Temperature	impaired
Dry, hacking cough or wheezing	Pitting edema, fatigue (right-sided HF)	thinking
		Chest x-ray
		Echocardiography

ECG	Partial pressure of oxygen (pO <sub>2</sub> )	Ca <sup>++</sup> , Mg <sup>++</sup>
Cardiac catheterization	Specific gravity (increased)	Gluc
<b>Lab Work</b>	Chol—total, HDL, LDL	Serum zinc
CRP	Trig	Alk phos
Serum CoQ10	H & H	Alb, transthyretin
BNP or NT-pro-BNP levels	Serum Fe, ferritin	BUN, Creat
Uric acid	tHcy	PT or INR
Oximetry	Serum folate	LDH
Partial pressure of carbon dioxide (pCO <sub>2</sub> )	Serum B <sub>12</sub>	(increased)
	Na <sup>+</sup> , K <sup>+</sup>	Nitrogen (N) balance
		AST, ALT

## INTERVENTION

### OBJECTIVES

- Lessen demands on the heart and restore hemodynamic stability.
- Prevent cardiogenic shock, thromboembolism, and renal failure.
- Maintain BP <140/90 mm Hg in all patients or <130/80 mm Hg in those with diabetes or chronic kidney disease (Khan et al, 2009).
- Eliminate or reduce edema.
- Avoid distention and elevation of diaphragm, which reduces vital capacity. Avoid overfeeding in cachectic patients to prevent refeeding syndrome.
- Attain desirable BMI and WHR to decrease oxygen requirements and tissue nutrient demands. Replenish lean body mass (LBM) when needed.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Herb and Drug–Nutrient Interactions

**Assessment Data:** Food frequency recall and intake records; medical prescription for warfarin. Taking large doses of vitamin K supplement randomly, and St John's wort (300 mg BID) for "the blues."

**Nutrition Diagnosis (PES):** Excessive bioactive substance intake (N1–4.2) related to knowledge deficit as evidenced by subtherapeutic INR of 1.2.

**Intervention:** Education about supplement-drug interaction and effects of vitamin K while using warfarin. Counseling to discontinue use of St. John's wort and consider psychological counseling. Coordinate care and referral for counseling.

**Monitoring and Evaluation:** Repeat INR weekly until therapeutic dose is achieved. Assess compliance with discontinuation of St John's wort and random use of vitamin K supplements. Assess understanding of risks of use of herbs or supplements while taking warfarin.

- Prevent or correct cardiac cachexia, low BP, listlessness, weak pulse from potassium-depleting diuretics, anorexia, nausea and vomiting, and sepsis.
- Correct nutrient deficits. Assure adequate intake of dairy products, as tolerated (Kris-Etherton et al, 2009).
- Because anemia is associated with an increased risk of mortality in both systolic and diastolic HF, strategies to increase hemoglobin levels should be used when needed (Groenveld et al, 2008).
- Encourage use of omega-3 fatty acids with a low-to-moderate fat intake (Shah et al, 2009).
- Prevent pressure ulcers from reduced activity levels and poor circulation.
- Promote use of the DASH diet and whole grains (Levitan et al, 2009; Nettleton et al, 2009). In addition, promote weight reduction, physical activity, restriction of dietary sodium, and excessive alcohol intake as methods for lowering BP.

## FOOD AND NUTRITION

Evidence-based recommendations for Registered Dietitians (RDs) to follow in providing nutrition treatment for people with HF include (American Dietetic Association, 2009):

- Appropriate daily intake of protein for clinically stable patients; HF patients have significantly higher protein needs than those without HF.
- Fluid intake between 48 and 64 oz/d, depending on fatigue or shortness of breath.
- Sodium intake less than 2 g/d to improve clinical symptoms and quality of life.
- Consume folate through food and/or a combination of B<sub>6</sub>, B<sub>12</sub>, and folate supplementation.
- Promote the DASH diet, with adequate potassium, calcium, and magnesium (Gums, 2004). Table 6-7 lists the sodium content of common foods. Table 6-8 provides some alternative tips for lowering sodium in the diet. For TF, use a low-sodium product and increase volume gradually.
- With total parenteral nutrition, ensure adequate intake of all micronutrients as well as macronutrients.
- Provide antioxidants, such as vitamin E, at DRI levels; there is no evidence that more is better. It is safe to consume more pomegranate, blueberry, and grape products.
- If patient is obese, a calorie-controlled diet can be recommended. A vegan pattern may be helpful with five to six small meals daily.
- Limit caffeine only if needed. The evidence is not definitive in this area (Ahmed et al, 2009).
- Beans, cabbage, onions, cauliflower, and Brussels sprouts may cause heartburn or flatulence; avoid if needed.
- Whole grains cut the risk for HF while eggs and high-fat dairy products contribute to it, according to the ARIC study (Nettleton et al, 2009). Add soluble fiber to the diet from apples or oat bran.
- Pistachios, sunflower kernels, sesame seeds, and wheat germ are high in phytosterols; use often.
- Thiamin levels tend to be low. Cardiovascular problems may be associated with beri-beri.
- Limit alcohol intake; for women, 1 drink per day and for men, 2 drinks or less a day.

**TABLE 6-7 Sodium Content of Typical Food Items**

Food Item	Milligrams (mg)	Food Item	Milligrams (mg)
<b>Meat, poultry, and fish</b>		<b>Dairy products</b>	
Sirloin steak (3 oz)	53	Butter, salted (1 tbsp)	116
Baked salmon (3 oz)	55	Milk (1 cup)	122
Chicken breast (3 oz)	64	Sour cream (1 cup)	123
Ground beef patty (4 oz)	87	Margarine (1 tbsp)	134
Chicken leg, fried (2.5 oz)	194	Chocolate pudding (1 cup)	180
Tuna, canned (3 oz)	468	Baked custard (1 cup)	209
Hot dog (1)	504	Buttermilk (1 cup)	257
Salami (2 slices)	607	Parmesan cheese (1/4 cup)	465
Fast food hamburger (4 oz)	763	Cheddar cheese (1 cup)	701
Corned beef (3 oz)	802	Cottage cheese, creamy (1 cup)	911
Ham, canned (3 oz)	908	Cheese sauce, prepared from recipe (1 cup)	1198
Fast foods, shrimp, breaded and fried (6–8 shrimp)	1446	<b>Snacks, drinks, condiments, desserts</b>	
Submarine sandwich (one 6" roll, cold cuts)	1651	Orange juice (1 cup)	2
Smoked salmon (3 oz)	1700	Peanuts, unsalted (1 cup)	22
<b>Soups, Vegetables, Fruit</b>		Chocolate fudge (1 oz)	54
Apple (1)	0	Diet cola, with Saccharin	75
Banana (1)	1	Club soda (12 oz)	78
Mixed vegetables, frozen (1 cup)	64	Potato chips (10)	94
Mixed vegetables, canned (1 cup)	243	Mustard (1 tbsp)	129
Chicken noodle soup, canned (1 cup)	1106	Ketchup (1 tbsp)	156 (1 cup)
Tomato sauce, canned (1 cup)	1482	Hard pretzel (1)	258
Sauerkraut (1 cup)	1560	Shortbread cookies (2)	300
<b>Breads and grains</b>		Apple pie (1 slice)	476
Wheat bread (1 slice)	106	Peanuts, salted (1 cup)	626
Oatmeal, cooked (1 cup)	2	Vegetable juice (1 cup)	883
Italian bread (1 slice)	176	Dill pickle (1)	928
Bagel (1)	245	Pretzel twists (10)	966
English muffin (1)	378	Pie crust, 1 shell	976
Bread crumbs (1 cup)	3180	Beef bouillon (1 packet)	1019

## Common Drugs Used and Potential Side Effects

- Most patients with HF require combination therapy that includes a diuretic, an ACE inhibitor, an angiotensin II receptor blocker, beta-blockers, aldosterone antagonists, specialized implantable pacemakers. Once BP is controlled, acetylsalicylic acid therapy should be considered (Kahn et al, 2009).
- Nesiritide, a recombinant form of BNP may be used with acute HF (Waldo et al, 2008). Because obesity is associated with lower BNP levels in healthy individuals and patients with chronic congestive HF, use caution for interpretation of BNP levels (Krauser et al, 2005).
- Teach how to manage vitamin K intake if on warfarin. See Table 6-9.

**TABLE 6-9 Medications Used in Heart Failure**

Medication	Description	Medication	Description
<b>Angiotensin-converting enzyme (ACE) inhibitors</b>	ACE inhibitors block angiotensin II and decrease aldosterone output, thereby decreasing sodium and water retention. Monitor for hyperkalemia, nausea, vomiting, dizziness, and abdominal pain.	<b>Adrenergic system blockers</b>	Beta-adrenergic blockers reduce cardiac output in competing for available receptor sites; they decrease sympathetic stimulation of the heart. At first use, they may cause fatigue and fluid retention.
Benazepril ( <i>Lotensin</i> )		<b>Beta-blockers</b>	
Captopril ( <i>Capoten</i> )		Atenolol ( <i>Tenormin</i> )	
Enalapril ( <i>Vasotec</i> )		Bisoprolol ( <i>Zebeta</i> )	
Fosinopril ( <i>Monopril</i> )		Carvedilol ( <i>Coreg</i> )	
Lisinopril ( <i>Zestril/Prinivil</i> )		Metoprolol ( <i>Toprol XL</i> )	
Moexipril ( <i>Univasc</i> )		Propranolol ( <i>Inderal</i> )	
Perindopril ( <i>Aceon</i> )		<b>Cardiac glycosides</b>	Digitalis can deplete potassium, especially when taken with furosemide. Beware of excesses of wheat bran, which can decrease serum drug levels. Anorexia or nausea may occur.
Quinapril ( <i>Accupril</i> )		<b>Digitalis</b>	
Ramipril ( <i>Altace</i> )		Lanoxin (Digoxin)	
Trandolapril ( <i>Mavik</i> )			
<b>Angiotensin receptor blockers</b>	Common adverse effects include hypotension and dizziness, a concern when there is also blurred vision or worsening renal function.	<b>Diuretics</b>	Avoid use with fenugreek, ginkgo, and yohimbe. Some diuretics spare calcium and protect bone health.
Candesartan ( <i>Atacand</i> )		Hydrochlorothiazide ( <i>Microzide</i> );	
Eprosartan ( <i>Teveten</i> )		Eplerenone ( <i>Inspira</i> ); Furosemide ( <i>Lasix</i> ); Spironolactone ( <i>Aldactone</i> )	
Irbesartan ( <i>Avapro</i> )		<b>Loop diuretics</b>	Most loop diuretics deplete potassium and magnesium; calcium levels also decline. Glucose tolerance may be decreased; anorexia, nausea, or vomiting may occur. Use a low-sodium diet. Avoid use with Nonsteroidal anti-inflammatory drugs (NSAIDs).
Losartan ( <i>Cozaar</i> )		Bumetanide, Furosemide ( <i>Lasix</i> ), Torsemide	
Olmesartan ( <i>Benicar</i> )			
Telmisartan ( <i>Micardis</i> )			
Valsartan ( <i>Diovan</i> )			
<b>Aldosterone blockers</b>		<b>Thiazide diuretics</b>	Most thiazide diuretics deplete potassium, which must be replaced, either orally or by medication. Hyperkalemia can occur with use of potassium-sparing diuretics if lab values are not carefully monitored. Use potassium-rich foods and juices such as orange juice, bananas, potatoes. Monitor for signs of dehydration.
Eplerenone, Spironolactone		Hydrochlorothiazide ( <i>Microzide</i> )	
<b>Anticoagulants</b>	Consume foods high in vitamin K no more than once per day.	Chlorthalidone	
Warfarin (Coumadin)	Foods with high vitamin K content include: spinach, broccoli, Brussels sprouts, green raw cabbage, turnip greens, mustard greens, collard greens, parsley, green scallions, lettuce, endive, watercress, cucumber peels, kale, canola oil, soybean oil, raw chives, green onions, seaweed, green peas, liver, Swiss chard. Avoid taking with dong quai, fenugreek, feverfew, ginger, ginkgo, ginseng, excesses of ginger, aniseed, celery, cranberry juice, dandelion, licorice, onion, passion flower, or willow bark. Coenzyme Q10, green tea, goldenseal, St. John's wort, and yarrow will decrease the effectiveness of warfarin.	Indapamide	
		Metolazone	
		<b>Potassium-sparing diuretics</b>	No extra K <sup>+</sup> is needed.
		Amiloride	
		Spironolactone ( <i>Aldactone</i> )	
		Triamterene ( <i>Dyrenium</i> )	
		<b>Salt substitutes</b>	Salt substitutes generally contain KCl. Use could lead to hyperkalemia if potassium-sparing diuretics are part of treatment.
		<b>Statins</b>	Statins may be used if the underlying problem is related to coronary artery disease or dyslipidemia.

## Herbs, Botanicals, and Supplements

- The patient should not take herbals and botanicals without discussing with the physician. It is important to stress that no supplement or diet can cure HF. Taurine, hawthorn, magnesium, and other supplements have not been documented as effective at this time. See Tables 6-3 and 6-9 for more details.
- CoQ10 deficiency is detrimental to the long-term prognosis of HF (Molyneux et al, 2008). Supplementation of both CoQ10 and creatine may prove to be useful in HF; more controlled trials are needed.
- Supplementation with eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) from fish oil may prevent HF through lowering proinflammatory fatty acid arachidonic acid and urine thromboxane B<sub>2</sub>; high-fat diets (60% fat) block these effects in the chronically stressed myocardium.
- Pomegranate (*Punica granatum*) berries, grape and other antioxidant-rich juices can be safely consumed.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Identify the stage of readiness for change in the patient. The most difficult lifestyle changes include smoking cessation, weight loss, and restriction of dietary sodium (Paul and Sneed, 2004). Supervised nutrition intervention is of great importance (Colin Ramirez et al, 2004).
- Help patient plan fluid intake; usually 75% with meals and 25% with medications or between meals.
- A congested feeling may cause a poor appetite. Offer small, appetizing, frequent snacks, or meals. Use high-calorie, low-volume supplements to increase nutrient density when needed.
- Never force the patient to eat; rest before and after meals. Naps are good for heart health. Even bed rest may be required. To reduce congestion in the lungs, the patient's upper body should be elevated. For most patients, resting in an armchair is better than lying in bed. Relaxing and contracting leg muscles are important to prevent blood clots. As the patient improves, progressively more activity will be recommended.
- HF is associated with sleep apnea, in which tissues at the back of the throat periodically collapse and become blocked, causing the sleeper to gasp for air. Sleep apnea is associated with poorer survival in patients with HF. A continuous positive airway pressure (CPAP) device appears to improve ejection fraction; see Section 5.
- Teach label reading and tips for easy meal preparation. Choose items that state: sodium free, very low sodium, low sodium, reduced sodium, light in sodium, or unsalted. Avoid excessive use of canned soups, cured or smoked meats, and commercial sauces. Many frozen dinners are high in sodium; choose healthier brands.
- Check the water supply for use of softening agents. Monitor sodium-containing medications, toothpastes, and mouthwashes. Discuss spices and seasonings as salt alternatives.
- Freeze small meal portions to simplify meal preparation. Refer to local congregate meal programs or inquire about home-delivered meals if needed; many will provide low-sodium meals upon request.
- Implantation of circulatory assist devices as a permanent alternative to heart transplantation (destination therapy) is used with patients with HF who are not responding to medications. The HeartMate Left Ventricular Assist System is FDA-approved.

## Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## HEART TRANSPLANTATION OR HEART-LUNG TRANSPLANTATION

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

**Heart transplantation (HTx)** is usually performed for terminal HF, often with cardiomyopathy. Usually, the transplantation will be a Jarvik-7 or a live donor heart. Screening includes evaluations for chronic, coexisting illness, psychosocial stability, and normal or reversible cardiac status. The best candidates are younger than 55 years of age with normal hepatic and renal functioning and are free of diabetes mellitus and pulmonary problems, peptic ulcers, and peripheral heart disorders.

**Heart-lung transplantation** is rare, as for complex cases of cystic fibrosis, pulmonary fibrosis, emphysema, Eisenmenger's syndrome, and primary pulmonary hypertension. Graft-host resistance and sepsis are the major concerns.

Survival rates after transplantation are getting better. Pre-HTx diabetes, donor age, and incidences of infection and rejection within 2 years of HTx predict long-term (>10 years) survival (Radovancevic et al, 2005). Main causes of death early after transplantation are rejection, nonspecific graft failure, and right ventricular failure due to pulmonary hypertension (Bauer et al, 2005).

Implantation of circulatory assist devices as a permanent alternative to HTx is an option for patients who are not candidates for HTx (Lietz and Miller, 2005). Ventricular assist devices (VADs) are now quite common. More recently, cell-based cardiac repair using human embryonic stem cells (hESCs) represent an attractive source for obtaining cardiomyocytes (Zhu et al, 2009).

Traditional risk factors, high oxidative stress, and reduced antioxidant defenses play a role in the pathogenesis of atherosclerosis, especially in transplanted hearts. Dietary measures are important. Flavonoid-rich dark chocolate induces coronary vasodilation, improves coronary vascular function, and decreases platelet adhesion (Flammer et al, 2007). Omega-3 fatty acids lower Chol levels, improve endothelial function, and can reduce the risk of sudden death in HTx recipients (Harris et al, 2004; Wenke, 2004). Finally, obesity, dyslipidemia, hypertension, and diabetes mellitus are common after HTx. Therefore, dietary intervention to obtain weight and metabolic control after HTx is needed to decrease TC, TGs, glucose plasma level, and weight loss (Guida et al, 2009).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Cardiac transplantation may be required for idiopathic DCM, which is inherited in approximately one third of cases. In addition, recipient renin-angiotensin-aldosterone system (RAAS) polymorphisms are associated with a higher risk of rejection, graft cytokine expression, graft dysfunction, and a higher mortality after cardiac transplantation (Auerbach et al, 2009).

<b>Clinical/History</b>	Ultrasound of abdomen and blood vessels	BUN, Creat AST, ALT ECG
Height	Cardiac catheterization	pCO <sub>2</sub> , pO <sub>2</sub>
Weight		Alb,
BMI		transferrin
Waist circumference	<b>Lab Work</b>	Chol—HDL, LDL, total
Diet history	Urinary Na <sup>+</sup>	Trig
Edema	Na <sup>+</sup> , K <sup>+</sup>	Gluc
BP	Ca <sup>++</sup> , Mg <sup>++</sup>	tHcy
Stress test	CRP	Serum folate and B <sub>12</sub>
Chest x-ray	H & H	
ECG	Serum Fe	
Coronary angiogram	Transferrin	
Echocardiogram	Complete blood cell count (CBC)	
Cardiopulmonary test		

#### INTERVENTION

#### OBJECTIVES

- Promote adequate wound healing; prevent or correct wound dehiscence.
- Normalize heart functioning; prevent morbidity and death. Control infection and rejection during the first 2 years after HTx to improve survival.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Inadequate Intake of Bioactive Substances**

**Assessment Data:** Food frequency recall and intake records; computer nutrient analysis showing no intake of omega 3 fatty acid-rich foods or chocolate. Consumes meals only at fast food restaurants. Low HDL and elevated LDL levels. Recent HTx surgery for ASHD and hypertension.

**Nutrition Diagnosis (PES):** Inadequate intake of bioactive substances (flavonols) related to poor diet as evidenced by diet history and daily fast food intake.

**Intervention:** Education about the role of antioxidant-rich foods and omega-3 fatty acids in heart disease, especially after transplantation. Counseling about food choice options besides eating daily at fast food restaurants and how to include chocolate, cocoa, nuts and seeds as easy snack items.

**Monitoring and Evaluation:** Repeat lab values after 3–6 months; dietary recall indicating use of bioactive substances at least once daily and fewer meals at fast food restaurants.

- Control side effects of steroid and immunosuppressive therapy.
- Prevent complications such as hepatic or renal failure and diabetes mellitus.
- Maintain or improve nutritional status and fluid balance.

- Protect against posttransplantation hyperlipidemia, hypertension, and graft coronary vasculopathy (GCV). GCV is an accelerated form of atherosclerosis in transplanted hearts that is one of the most important late complications of HTx and is the single most limiting factor for long-term survival (Wenke, 2004).

## FOOD AND NUTRITION

*Pretransplantation*

- Control calories, protein, sodium, potassium, fat, and Chol as appropriate for specific underlying condition (see appropriate sections). Keep in mind the role of nutrients needed for wound healing, including adequate energy intake.
- Fluid overload must be avoided; limit to 1 L daily, using a nutrient-dense product if needed.
- Avoid alcohol, which can aggravate cardiomyopathies.
- Reduce cardiac stimulants (such as caffeine) until fully recovered.

*Posttransplantation*

- Increase diet as tolerated and as appropriate for status. Alter as needed. Include appropriate levels of calcium, magnesium, potassium, and fiber; the DASH diet is beneficial.
- Increase use of omega-3 fatty acids from fish and fish oils.
- Increase use of cardioprotective agents such as vitamins E, B<sub>6</sub>, and B<sub>12</sub> and folic acid. It is also prudent to use olive, soybean, and canola oils.

TABLE 6-10 Medications Used after Transplantation

Medication	Description
Analgesics	Analgesics are used to reduce pain. Long-term use may affect such nutrients as vitamin C and folacin; monitor carefully for each specific medication.
Cardiac medications	Antihypertensives, antilipemics, diuretics, and potassium supplements may be used. Monitor side effects accordingly. Some diuretics spare calcium and protect bone health.
Azathioprine (Imuran)	Azathioprine may cause leukopenia, thrombocytopenia, oral and esophageal sores, macrocytic anemia, pancreatitis, vomiting, diarrhea, and other complex side effects. Folate supplementation and other dietary modifications (liquid or soft diet, use of oral supplements) may be needed. The drug works by lowering the number of T cells; it is often prescribed along with prednisone for conventional immunosuppression.
Corticosteroids (prednisone, hydrocortisone [Solu-Cortef])	Corticosteroids such as prednisone and hydrocortisone are used for immunosuppression. Side effects include increased catabolism of proteins, negative nitrogen balance, hyperphagia, ulcers, decreased glucose tolerance, sodium retention, fluid retention, and impaired calcium absorption and osteoporosis. Cushing's syndrome, obesity, muscle wasting, and increased gastric secretion may result. A higher protein intake and lower intake of simple CHOs may be needed.
Cyclosporine	Cyclosporine does not retain sodium as much as corticosteroids do. Intravenous doses are more effective than oral doses. Nausea, vomiting, and diarrhea are common side effects. Hyperlipidemia, hypertension, and hyperkalemia may also occur; decrease sodium and potassium as necessary. Elevated glucose and lipids may occur. The drug is also nephrotoxic; a controlled renal diet may be beneficial. Taking omega-3 fatty acids during cyclosporine therapy may reduce the toxic side effects (such as high blood pressure and kidney damage) associated with this medication in transplantation patients.
Diuretics	Diuretics such as furosemide may cause hypokalemia. Aldactone actually spares potassium; monitor drug changes closely. In general, avoid use with fenugreek, yohimbe, and ginkgo.
Immunosuppressants	Immunosuppressants such as muromonab (Orthoclone OKT3) and antithymocyte globulin (ATG) are less nephrotoxic than cyclosporine but can cause nausea, anorexia, diarrhea, and vomiting. Monitor carefully. Fever and stomatitis also may occur; alter diet as needed.
Statins	Statins may be used to manage coronary artery disease or dyslipidemia.
Tacrolimus (Prograf, FK506)	Tacrolimus suppresses T-cell immunity; it is 100 times more potent than cyclosporine, thus requiring smaller doses. Side effects include GI distress, nausea, vomiting, hyperkalemia, and hyperglycemia.

- Nuts contain flavonoids, phenols, sterols, saponins, elagic acid, folic acid, magnesium, copper, potassium, and fiber. Walnuts contain ALA; almonds are a good source of vitamin E. Macadamias, pecans, and pistachios are also beneficial.
- Include chocolate and cocoa frequently.
- For TF, use a product low in sodium and advance gradually.

### Common Drugs Used and Potential Side Effects

- See Table 6-10.

### Herbs, Botanicals, and Supplements

- The patient should not take herbals and botanicals without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of nutrition in wound healing, immunocompetence, and cardiovascular health. Specify nutrients that are known to be protective.
- Discuss how exercise affects the use of calories.
- Discuss, as appropriate, fiber intake and sources of fat and Chol. Highlight the importance of maintaining an adequate diet to reduce risks of further heart disease and complications. Transplant CAD proceeds at an accelerated rate; this procedure is not a permanent cure.
- To improve quality of life in transplantation patients, web-based counseling and support may play a vital role in follow-up care and in patient and family adjustments

(Dew et al, 2004). This type of support is helpful, especially in rural areas where access to MNT is limited.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## HEART VALVE DISEASES

### NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

The heart has four valves (tricuspid, pulmonary, aortic, and mitral). Inflammation of any or several of these valves can cause stenosis with thickening (which narrows the opening) or incompetence (with distortion and inability to close fully). If the mitral valve is not functioning properly, due to injury or disease, blood leaks back into the left atrium (regurgitates) when the left ventricle contracts and backs up into the lungs. Because some of the blood being pumped by the left ventricle flows back into the left atrium, less blood is pumped into the aorta and throughout the body. The heart compensates for this by increasing the size of the left ventricle to increase the amount of blood it is pumping and to maintain an adequate forward flow of blood throughout the body. Unfortunately, compensation eventually leads to impairment of the left ventricle's ability to contract, which leads to further backup of blood into the lungs.

**Mitral valve prolapse** is the most common cause of severe mitral regurgitation in the United States. Overall prognosis of patients is excellent, but a small subset will develop serious complications, including infective endocarditis or sudden cardiac death (Hayek et al, 2005). Echocardiography is used for diagnosing this condition, and mitral valve repair is the treatment. With advancements in PCIs, some patients benefit from a hybrid approach involving initial planned PCI followed by valve surgery, rather than conventional CABG/valve surgery (Byrne et al, 2005).

**Mitral stenosis** (stiffening) can cause lung congestion, breathlessness after exercise or while lying down, hemoptysis, bronchial infections, chest pains, and right HF. Most people who have had rheumatic heart disease later have primarily mitral stenosis. **Aortic stenosis** can cause symptoms of angina, vertigo, fainting on exertion, and left HF. **Tricuspid stenosis** increases the risk of HF. **Pulmonary stenosis** is rare and occurs in only 2% of all valve disorders.

Patients at high risk for valvular disease should be screened for hyperhomocysteinemia; for prevention, a multivitamin supplement with vitamins B<sub>6</sub> and B<sub>12</sub> and folate should be taken.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Congenital heart defects are a cause of some valve disorders, but most are acquired.

<b>Clinical/History</b>	Cardiac catheterization	H & H Serum ferritin
Height	ECG	Chol—total, HDL, LDL
Weight	Vertigo	Trig
BMI	Fainting	BUN, Creat
Waist-hip ratio	Breathlessness	Na <sup>+</sup> , K <sup>+</sup>
Diet history	after exertion?	Ca <sup>++</sup> , Mg <sup>++</sup>
Weight changes	Heart palpitations	Gluc
Edema in belly, ankles, feet	Shortness of breath	tHcy
Pulse		Serum folate
Cool, moist skin		Serum B <sub>12</sub>
BP	<b>Lab Work</b>	
Urinary output (decreased)	CRP	
I & O	Alb, transthyretin	

## INTERVENTION

### OBJECTIVES

- Prevent HF (right- or left-sided), bacterial endocarditis, emboli or atrial fibrillation, and sudden death. Prevent stroke; mitral annular calcification is an independent predictor of stroke.
- Prepare, if necessary, for valve replacement surgery.
- Prevent or correct cardiogenic shock with tachycardia and other symptoms.
- Correct or manage atherosclerosis.

### FOOD AND NUTRITION

- Avoid excesses of calories, sodium, and fluid (as appropriate for the patient). In some patients with vertigo, fluid and sodium restrictions may actually be detrimental.
- If weight loss has taken place, add extra calories and snacks to return to a more desirable body weight.
- Use adequate vitamins E, B<sub>6</sub>, and B<sub>12</sub> and folic acid.
- The DASH diet is useful. Encourage use of flavonoids such as chocolate, cocoa, pomegranate, or grape juices, apples, onions, tea, or red wine when feasible. Flavonoids may help to reduce blood clot formation.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Excessive Vitamin K Intake

**Assessment Data:** Food intake records; computer nutrient analysis showing intake of vitamin K from multivitamin supplement and fortified nutritional beverages exceeding 150% of recommended levels while on warfarin; INR 1.0–1.5 range.

**Nutrition Diagnosis (PES):** Excessive vitamin K intake related to intake of oral supplements and multivitamin preparation as evidenced by low INR while on anticoagulant therapy.

**Intervention:** Educate patient and family about appropriate levels of vitamin K. Counsel about an appropriate supplement and oral beverage choice with less vitamin K content.

**Monitoring and Evaluation:** Intake from multivitamin and oral supplements in lower range of daily vitamin K requirements; improved INR and bleeding times.

- Ensure adequate intake of omega-3 fatty acids. However, avoid high fat diets as the benefits of omega-3 s are reduced with those diets (Shah et al, 2009).
- Control intake of vitamin K while on warfarin. Changes in dietary vitamin K (phyloquinone) intake may contribute to marked variations in the INR in patients receiving oral warfarin anticoagulant therapy, with potentially serious adverse outcomes (Couris et al, 2006).

## Common Drugs Used and Potential Side Effects

- Anticoagulants are commonly used. Monitor vitamin K-rich foods carefully; use no more than 1 per day (especially green leafy vegetables).
- If aspirin is used, monitor for GI side effects or occult blood loss if used for a long time.
- Diuretics may be used with fluid overload. Monitor potassium and sodium intake carefully. Some diuretics spare calcium and protect bone health.
- Because fenfluramine-phentermine (Fen-Phen) weight reduction drugs promoted valvular heart disease and pulmonary hypertension, they were removed from the market.
- Digoxin may be needed to strengthen the heart's pumping action after surgery. Monitor potassium intake or depletion carefully, especially when combining with diuretics. Avoid excessive intakes of fiber and wheat bran. Avoid use with hawthorn, milkweed, guar gum, and St. John's wort.
- Statins may be used to manage CAD or dyslipidemia. See Table 6-6.

## Herbs, Botanicals, and Supplements

- See Table 6-3 for details.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Careful use of all prescribed medications will be essential, with adequate return visits to the physician at appropriate intervals.
- Alternative food preparation methods may be suggested to reduce sodium or energy intake.

- Persons with a history of heart valve abnormalities may require antibiotic therapy to prevent infections, especially before surgery or dental work.
- After surgery, the patient should receive information about nutrition in wound healing. Some procedures are more invasive than others and will require longer healing time.

#### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## HYPERTENSION

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Asset provided by Anatomical Chart Co.

#### DEFINITIONS AND BACKGROUND

Hypertension is defined as having a sustained systolic and diastolic BP greater than 140 and 90 mm Hg, respectively. See Table 6-11. It affects about 600 million people worldwide and about 27% of the U.S. adult population.

Hypertension nearly doubles the risk for heart attack, stroke, and HF, especially for people over age 65. BP often increases with age and is highly prevalent in elderly individuals. Symptoms of hypertension include frequent headaches, impaired vision, shortness of breath, nose bleeds, chest pain, dizziness, failing memory, snoring and sleep apnea, and GI distress.

**TABLE 6-11** Categories for Blood Pressure Levels in Adults (Ages 18 years and Older)

Category	Blood Pressure Level (mm Hg)		
	Systolic		Diastolic
Normal	<120	and	<80
Prehypertension	120–139	or	80–89
High blood pressure:			
Stage 1 hypertension	140–159	or	90–99
Stage 2 hypertension	≥160	or	≥100

From: National Heart, Lung, and Blood Institute. Accessed July 16, 2009, at <http://www.nhlbi.nih.gov/hbp/detect/categ.htm>.

Identifiable causes of high BP include sleep apnea, drug-related causes, CKD, Cushing's syndrome, steroid therapy, pheochromocytoma, primary aldosteronism, thyroid and parathyroid diseases, and reno-vascular disease. Untreated hypertension can result in stroke, HF, renal failure, MI, accelerated bone loss and risk of fractures, and long-term memory problems. The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure, the JNC 7 Report (NHLBI, 2009) identified following priority concerns:

- In persons over age 50, systolic BP >140 mm Hg is a more important CVD risk factor than diastolic BP. Those who are normotensive at age 55 have a 90% lifetime risk of developing hypertension. Beginning at 115/75 mm Hg, CVD risk doubles for each increment of 20/10 mm Hg.
- Prehypertensive individuals (systolic BP of 120–139 mm Hg or diastolic BP of 80–89 mm Hg) require health-promoting lifestyle modifications to prevent the progressive rise in BP and CVD. However, patients must be motivated to stay on their treatment plans.

Endothelial activation, oxidative stress, and vascular smooth muscle dysfunction (hypertrophy, hyperplasia, remodeling) can promote inflammation and stiffened blood vessels (Houston, 2005). Elevated CRP is a marker of reduced production of nitric acid in the blood vessels. CRP over 3.5 represents endothelial dysfunction, the earliest event in atherosclerosis (Streppel et al, 2005). With endothelial dysfunction, diet greatly affects vascular reactivity.

Fish oil, antioxidants, folic acid, soy protein, and the Mediterranean diet (high consumption of vegetables, fish, and olive oil and moderate wine consumption) may have a positive effect. Increasing intake of fiber in populations where intake is far below recommended levels may help to prevent hypertension (Streppel et al, 2005). Weight loss is also important; abdominal adiposity promotes high CRP levels.

There is increasing evidence for use of nutrients such as omega-3 PUFA, vitamin C, folic acid, and potassium. The DASH eating plan is rich in fiber, vegetables, fruit, and non-fat dairy products and significantly lowers BP. The decreases are often comparable to those achieved with BP-lowering medication.

For patients with CKD who have hypertension; it is critical to control BP to reduce negative consequences. Current National Kidney Foundation guidelines recommend reducing sodium intake to less than 2.4 g/d; reducing potassium in patients with a GFR of <60 mL/min. Black populations benefit most from reduced salt intake, increased potassium intake, and the DASH diet (Appel et al, 2006).

Because nutrient–gene interactions determine a broad array of consequences such as vascular problems and hypertension, consuming optimal nutrition, nutraceuticals, vitamins, antioxidants, and minerals and moderately restricting alcohol may prevent, delay the onset, reduce the severity, treat, or control hypertension (Houston, 2005). For example, Vitamin D deficiency activates the rennin–angiotensin–aldosterone system and can predispose to hypertension and left ventricular hypertrophy; it can also increase parathyroid hormone that is associated with insulin resistance and hypertension (Lee et al, 2008).

Malignant hypertension, which occurs in only 1% of those with essential hypertension (EH), has medical urgency. In this condition, there is accelerated hypertension (systolic >220 mm Hg or diastolic >120 mm Hg) with no evidence of target organ damage. This differs from a medical emergency, such as a stroke, where it is important to lower elevated BP immediately. African Americans are at higher risk than individuals with European heritage.

Long-term sodium reductions of 400 mg in those with uncontrolled hypertension would eliminate about 1.5 million cases, potentially increasing productivity by \$2.5 billion annually and more aggressive diet changes of 1100 mg of sodium reductions yield potential productivity benefits of \$5.8 billion annually (Dall et al, 2009). Therefore, clinicians are encouraged to work closely with patients to agree on BP goals and develop a treatment plan. Reduced salt intake, weight loss, moderate alcohol consumption among those who drink, increased potassium intake, and use of the DASH diet are among the most effective strategies (Appel et al, 2006). The American Dietetic Association recommends at least three MNT visits for patients with hypertension.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** A genome-wide association study of systolic BP (SBP) and diastolic BP (DBP) and hypertension in the CHARGE Consortium, identified significance in four SNPs for SBP (ATP2B1, CYP17A1, PLEKHA7, SH2 B3), six for DBP (ATP2B1, CACNB2, CSK-ULK3, SH2 B3, TBX3-TBX5, ULK4), and one (ATP2B1) for hypertension (Levy et al, 2009). Severe mutations often result in the development of hypertension at a young age while subtle mutations may take decades to manifest. The MTHFR folate alleles are associated with EH because of their relationship with tHcy metabolism (Ilhan et al, 2008). Identifying genes associated with BP advances understanding of BP regulation and highlights potential drug targets for the prevention or treatment (Levy et al, 2009; Mein et al, 2004; Wang et al, 2009).

Clinical/History	I & O	CRP
Height	Renal arteriography	Alb,
Weight		transthyretin
BMI	Chest x-ray	Urinary Alb to
Waist circumference	Renal ultrasound	Creat ratio
BP pattern	Intravenous	(high levels
Diet history	pyelogram	impair
Headaches, dizziness	ECG	arterial dilatory capacity)
Snoring or sleep apnea?	<b>Lab Work</b>	Chol—HDL,
Polysomnogram	H & H	LDL
	Serum Fe, ferritin	Trig
		LDH

BUN	Parathormone	Serum folate
Creat, GFR	(PTH)	and B <sub>12</sub>
Uric acid	AST, ALT	Plasma ascorbic
Plasma renin	Alk phos	acid
Na <sup>+</sup> , K <sup>+</sup>	Serum vitamin D	Urinary Ca <sup>++</sup>
Chloride	PT or INR	Urinary cortisol
Serum Ca <sup>++</sup> , Mg <sup>++</sup>	Gluc tHcy	

## INTERVENTION

### OBJECTIVES

- Assess medical risk factors, comorbidities, and identifiable causes of the hypertension. For example, essential hypertension affects 1 billion people worldwide and has a genetic basis (Mein et al, 2004).
- Reduce cardiovascular (HF, stroke) and renal morbidity and mortality (ADA, 2009) by lowering high BP. The DASH dietary pattern reduces SBP by 8–14 mm Hg (ADA, 2009).
- For individuals with hypertension and diabetes or renal disease, maintain BP goal of <130/80 mm Hg (ADA, 2009).
- Increase vascular and lymphocyte beta-adrenergic responsiveness. Dietary sodium intake should be limited to no more than 2300 mg sodium (100 mmol) per day; this level can lower SBP by approximately 2–8 mm Hg (ADA, 2009).
- Achieve and maintain an optimal body weight (BMI 18.5–24.9); weight reduction lowers SBP by 5–20 mm Hg per 22 lb (10 kg) body weight loss (ADA, 2009).
- Increase magnesium, calcium, vitamins D, E, and K where serum levels or dietary intake is low.
- Encourage adequate intake of fluids unless contraindicated. Avoid excesses of alcohol that may increase BP.
- Dietitians should encourage individuals to engage in aerobic physical activity for at least 30 min/d on most days of

the week, as it reduces systolic BP by approximately 4–9 mm Hg (ADA, 2009).

## FOOD AND NUTRITION

- The DASH diet works within 14 days of initiation. This diet is rich in fruits, vegetables, and low-fat dairy foods; it is low in SFA and total fat. Adequate amounts of potassium from skim milk, baked potatoes, grapefruit, oranges, bananas, lima beans, and other fruits and vegetables should be planned daily.
- Tips on eating the DASH way: Start small; make gradual changes in eating habits. Organize meals around carbohydrates such as pasta, rice, beans, or vegetables. Carbohydrates such as beans, whole grains, oat bran, and fruits (apples, blueberries) and vegetables should make up 50% of the diet.
- Treat meat as one part of the whole meal, instead of the main focus. Use fruits or low-fat, low-calorie foods such as sugar-free gelatin for desserts and snacks.
- Increase fruits and vegetables (5–10 servings daily) for their flavonoid, phytochemical, potassium content and properties (ADA, 2009). Besides the DASH diet, Mediterranean and vegetarian diet patterns tend to lower BP and can be beneficial.
- Limit sodium intake. Only 20–50% of patients with hypertension are sodium sensitive. Patients with EH are more sodium sensitive than patients whose conditions are secondary to other disorders (Houben et al, 2005).
- Read labels carefully. If some thing is sodium free, it has 5 mg or less per serving. Something that is light in sodium has 50% less than the usual recipe. A food that is labeled low sodium must be 149 mg or less per serving. About 77% of salt in the diet comes from processed foods, 12% naturally, and the remainder is either added during cooking or at the table. Table 6-12 lists common salts, salt substitutes, and their content.
- Use an energy-controlled diet if weight loss is needed.
- Olive, soybean, and canola oils can be substituted for some saturated fats in cooking. Pistachios, sunflower kernels, sesame seeds, and wheat germ are good sources of phytosterols; use often.
- Limit alcoholic beverages to one drink for women and to two drinks for men.
- Use sources of omega-3 fatty acids, such as mackerel, haddock, sardines, and salmon, several times weekly. Tuna should be used less often because potential mercury content could elevate BP.
- Higher intake of dairy products seems to reduce serum uric acid levels; high uric acid levels are often correlated with BP and stroke (Choi et al, 2005).
- Increase food sources of folic acid, vitamins B<sub>12</sub>, and B<sub>6</sub> for overall cardiovascular health. Vitamin D is also important. Vitamin D deficiency is associated with increased risk of developing incident hypertension or sudden cardiac death in individuals with preexisting CVD (Judd and Tangpricha, 2009).
- Caffeine from habitual coffee intake is not problematic (Winkelmayer et al, 2005). Hibiscus tea, green tea, cocoa and chocolate should be encouraged.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Hypertension (HTN)

**Assessment:** Diet history and food records, BP records.

**Nutrition Diagnosis (PES):** Excessive intake of sodium related to high intake of commercially prepared and packaged foods as evidenced by BP s of 160/105 mm Hg and lack of knowledge about sources of sodium.

**Intervention:** Initial/brief nutrition education (E-1) to communicate the relationship between nutrition and HTN. Discuss lower sodium food choices, label reading, and options to reduce BP. Discuss choices for healthier meals and snacks. Promote use of BP monitoring records, easy preparation meals made from scratch, recipe alterations, shopping tips, tips for dining away from home.

**Monitoring and Evaluation:** BP reports, food records showing improved intake of sodium in daily diet.

**TABLE 6-12 Sodium and Potassium in Salt, Salt Substitutes, Herbal Seasonings**

Type	Milligrams (mg) of Sodium per $\frac{1}{4}$ tsp	Milligrams (mg) of Potassium per $\frac{1}{4}$ tsp
Morton's table salt	590	0
Morton sea salt	560	0
Morton's salt balance	440	200
Diamond crystal salt sense	390	0
Lawry's seasoned salt	380	0
Morton's lite salt	290	350
Papa dash	240	0
Baking soda	205	0
Monosodium glutamate	123	0
Sterling lo-salt mixture	115	150
Baking powder	85	0
Nu salt	0	795
Nosalt	0	650
Morton salt substitute	0	610
Also salt	0	300
Mrs. dash salt-free seasoning blends	0	5–15
Benson's gourmet salt free seasonings	<5	minimal
Durkee smart seasons	0	0–15
McCormick salt-free seasoning blends	1	20–40

Derived from: Edwards A. Salt, salt substitutes, and seasoning alternatives. *J Renal Nutr.* 18:e23, 2008.

### Common Drugs Used and Potential Side Effects

- Dietitians should assess food/nutrient-medication interactions in patients that are on pharmacologic therapy for hypertension, as many antihypertensive medications interact with food and nutrients (ADA, 2009). See Table 6-13.
- In uncomplicated stage 1 hypertension, dietary changes are the initial treatment, then drug therapy. In hypertensive patients already on drug therapy, lifestyle modification and reduced salt intake, can further lower BP (Appel et al, 2006).
- Use of a diuretic is part of the treatment plan in most patients. For stage 1, thiazide diuretics may suffice; in stage 2, two-drug combinations may be needed. Drug classes that have been shown to be effective in reducing hypertension's cardiovascular complications include ACE inhibitors, angiotensin receptor blockers, beta-blockers, and calcium channel blockers. Most persons will need multiple medications to lower BP to a desired level.
- Note that use of estrogens and oral contraceptives can increase BP.
- Antihypertensive therapy is challenging in the elderly because of metabolic and physiological alterations, comorbidities, polypharmacy, and biological variability. For example, ACE inhibitors and beta-blockers may

provide beneficial therapeutic effects to the EH patients by decreasing tHcy levels, while thiazide diuretics increase tHcy (Poduri et al, 2009).

### Herbs, Botanicals, and Supplements

- Green coffee bean extract, oolong, and moderate-strength green teas may be beneficial in lowering BP (Kozuma et al, 2005). Hibiscus tea may also be beneficial.
- While vitamin D supplementation is simple, safe, and inexpensive, large randomized controlled trials are needed to identify how much is needed to prevent hypertension (Lee et al, 2008).
- Use of 1000 mg of a specific olive leaf extract EFLA943 has been shown to lower BP in twins (Perrinjacquet-Moccetti et al, 2008). Larger population studies are suggested.
- See Table 6-3 for more information.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage patience; it takes 2 weeks to see the results while following the DASH diet.
- Remove the salt shaker from the table. Have the patient taste food before salting. Avoid excesses of processed and

**TABLE 6-13 Medications for Hypertension**

Medication	Description
<b>Angiotensin-converting enzyme (ACE) inhibitors</b> (benazepril/Lotensin, captopril/Capoten, enalapril/Vasotec, fosinopril/Monopril, lisinopril/Prinivil or Zestril, moexipril/Univasc, perindopril/Aceon, quinipril/Accupril, ramipril/Altace, trandolapril/Mavik)	ACE inhibitors prevent angiotensin I from conversion; they are useful in heart failure. Ramipril has been noted to prevent diabetes in hypertensive patients. Nausea, vomiting, and abdominal pain may occur; do not take with potassium supplements. Captopril (Capoten) can alter BUN/creatinine; take 1 hour before meals and reduce calories and sodium. Loss of taste can occur. Patients who take captopril and enalapril may develop zinc deficiency.
<b>Angiotensin II receptor antagonists</b> (candesartan/Atacand, eprosartan/Teveten, irbesartan/Avapro, losartan/Cozaar, olmesartan/Benicar, telmisartan/Micardis, valsartan/Diovan)	Use with low-sodium, low-calorie diet. GI distress can occur. Some are mixed with thiazide diuretics; monitor for potassium depletion.
<b>Direct renin inhibitors (DRIs)</b> (aliskiren/Tekturna)	
<b>Beta-blockers</b> (atenolol/Tenormin, pindolol/Visken, propranolol/Inderal, acebutolol/Sectral, bisoprolol/Zebeta, metoprolol/Lopressor, timolol/Blocadren, prazosin/Minipress)	Beta-blockers decrease the force and rate of heart contractions, thereby decreasing blood pressure. Dizziness and nausea are common side effects. Low-calorie, low-sodium diet may be useful. Metoprolol (Lopressor) should be taken with a low-calorie, low-sodium diet. Diarrhea, nausea, vomiting, or abdominal cramps may occur. Prazosin (Minipress) may cause nausea, weight gain, anorexia, diarrhea, or constipation.
<b>Calcium channel blockers</b> (amlodipine/Norvasc; diltiazem/Cardizem; felodipine/Plendil)	Use with low-sodium, low-calorie diet. Avoid natural licorice.
<b>Diuretics</b> Thiazides (furosemide/Lasix, indapamide/Lozol, chlorthalidone/Clorpres, hydrochlorothiazide/Hydrodiuril Microzide)	Thiazides deplete potassium and may require supplementation; diarrhea or GI bleeding can occur. Avoid natural licorice. Chlorthalidone may alter blood glucose or potassium levels; it may cause anorexia, vomiting, constipation, and nausea. In general, avoid use with fenugreek, yohimbe, and ginkgo.
<b>Diuretic-antihypertensives</b> (amiloride/Moduretic)	A low-calorie, low-sodium diet is important. Potassium loss is minimized. Avoid use with alcohol.
<b>Melatonin</b>	The nocturnal decline of blood pressure (BP) coincides with the elevation of melatonin, which may exert vasodilating and hypotensive effects; prolonged administration of melatonin may improve the day-night rhythm of BP.

canned foods. The normal adult needs only 1/2 teaspoon of sodium (200 mg) per day. Greater amounts of salt are required only in hot, humid conditions, during lactation, or with other salt-losing states. In such conditions, 2000 mg of salt is sufficient.

- Low fat dairy products have been linked with lower risk for hypertension; include often.
- Interesting food flavors are often hidden by salt. Discuss use of other seasonings and recipes. Monitor potassium in salt substitutes and medications to prevent hyperkalemia; read all labels carefully.
- Obesity leads to a proinflammatory and prothrombotic state that potentiates hypertension. Work on a weight loss program if needed.
- In children, an assessment of psychological and psychosocial factors that lead to obesity and hypertension should be undertaken (Kiessling et al, 2008).
- Increase physical activity when possible. Encourage use of pedometers for daily feedback.
- Omit or reduce alcohol intake severely, if needed.
- Assure adequate sleep; adverse changes to BP are noted with shorter duration.

#### **Patient Education—Foodborne Illness**

- Careful food handling will be important. Hand washing is key as well.

# MYOCARDIAL INFARCTION

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Cohen BJ, Wood DL. *Memmler's The Human Body in Health and Disease*. 9th ed. Philadelphia: Lippincott Williams & Wilkins, 2000.

## DEFINITIONS AND BACKGROUND

**MI** is necrosis in the heart muscle caused by prolonged inadequate blood supply or oxygen deficit. A **coronary occlusion** (heart attack) is the closing of a coronary artery feeding heart muscle by fatty deposits or a blood clot; it manifests with heavy squeezing pain radiating to the jaw or back, nausea, vomiting, diaphoresis, anxiety, and weakness. Abnormal lipids, smoking, hypertension, diabetes, abdominal obesity, psychosocial factors, inadequate consumption of fruits and vegetables, alcohol consumption, and lack of regular physical activity account for most of the risk factors for MI worldwide; Table 6-14 provides a complete list.

Women have symptoms of an MI that differ from men. Prodromal symptoms include unusual fatigue, shortness of breath, and pain in the shoulder blade/upper back; medical practitioners must develop an awareness of and a more comprehensive approach to treating women.

Stages after an MI include critical (first 48 hours), acute (3–14 days), and convalescent (15–90 days). Treatment with Chol-lowering medications and antioxidants may decrease MI and may reduce adverse coronary events. Table 6-15 lists potential complications after an MI. CVDs cause 12 million deaths worldwide, and MI is a significant problem.

**TABLE 6-14 Risk Factors for Myocardial Infarction**

- Family history of heart disease
- Patient history of heart disease
- Diabetes or elevated blood glucose, even in nondiabetics
- Hypertension
- Advanced age
- High lipoprotein (a) lipids
- African American ethnicity
- Stress, smoking, sedentary lifestyle, compulsive personality
- Poor diet (high sodium, high fat, high intake of alcohol; low intake of B-complex vitamins, calcium, magnesium, and potassium; low intake of fruits and vegetables)
- Obesity

Fruit and vegetable intake should be encouraged. Platelet aggregation is central in acute coronary syndromes, including MI and unstable angina. Effects of flavonoids on endothelial and platelet function might explain their protective benefits on cardiac risk (Vita, 2005). Studies relate wine/resveratrol with reduction in myocardial damage.

An **arrhythmia** is a variation from normal heartbeat rhythm. Among its many forms is a slowing of the heartbeat to less than 60 beats per minute (bradycardia), a speedup to more than 100 beats per minute (tachycardia), and premature or “skipped” beats. Post-MI patients will need to monitor themselves for arrhythmias.

On the basis of the ECG, a distinction is made between ST-elevation (where thrombolysis, PCI, angioplasty or stent insertion are used), versus non-ST elevation where medications suffice. In some cases, coronary artery bypass surgery (CABG) is an option.

**TABLE 6-15 Complications After Myocardial Infarction**

- Arrhythmias with risk of sudden death
- Cardiogenic shock
- Cardiac tamponade
- Cholesterol emboli due to cardiac catheterization or during CABG
- Heart failure with pulmonary edema
- Left ventricular free wall rupture
- Pericarditis
- Re-infarction
- Renal failure
- Splenic infarction with fever, tachycardia, left upper quadrant abdominal pain
- Thrombosis or CVA with ischemic bowel or renal infarct
- Valve insufficiency
- Ventricular septal defect

Incidence of systemic thromboembolic lesions in acute myocardial infarction. *Clin Cardiol.* 9:331, 1986; Prieto A, et al. Nonarrhythmic complications of acute MI. *Emerg Med Clin North Am.* 19:397, 2001.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Genetic factors and interactions between multiple genes and environmental factors indicate an association with MI or CHD of polymorphisms in MTHFR, LPL, APOE, and those in LTA and at chromosomal region 9p21.3 by genome-wide scans (Yamada et al, 2008).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Myocardial Infarction (MI)

**Assessment:** Diet history and food records, lipid profile, review of current and previous medications used for heart disease.

**Nutrition Diagnosis (PES):** Inappropriate intake of types of food fats due to nutrition-related knowledge deficit as evidenced by LDL Chol of 155 mg/dL and use of large meat portions at lunch and dinner meals.

**Intervention:** Easy meal preparation and recipe adaptations, shopping and dining away from home tips, one-on-one counseling and goal setting for making changes in choices of food fats.

**Monitoring and Evaluation:** Lipid profile, food diary and records, goal achievement.

## INTERVENTION

## OBJECTIVES

- Promote rest to reduce heart strain. Avoid the distention of heavy meals.
- Prevent arrhythmias by serving food at body temperature.
- Avoid both constipation and flatulence.
- Avoid excessive heart stimulation from caffeine. Energy drinks may contain 50–500 mg of caffeine.
- Reduce elevated levels of lipids: keep Chol below 200 mg/dL, TGs below 200 mg/dL, HDL between 40 and 60 mg/dL, and LDL between 100 and 129 mg/dL.
- Decrease energy required to chew, prepare meals, perform activities of daily living during convalescence.
- Identify modifiable risk factors and complications; reduce risks when possible (see Tables 6-14 and 6-15). For example, lose weight if obese.
- Consume more fish and a diet rich in ALA to reduce the risk of fatal heart attack.

## FOOD AND NUTRITION

- Initially, use liquids to promote rest while reducing the dangers of aspiration or vomiting. Reduce fluid and caffeine intake to that recommended by the physician. As treatment progresses, diet should include soft, easily digested foods that are low in saturated fats, Chol, and gas-forming foods.
- Limit diet to 2 g of sodium, or remove salt from the table. Schedule three to six small meals daily.
- If needed, use an energy-controlled diet to reduce the heart's workload.
- The DASH diet and Mediterranean diet are useful. Increase intake of fish, whole grains, and olive oil. Onions, tea, apples, grape juice, and pomegranate contain flavonoids and should be used often. Red wine is recommended, if approved by the physician.
- Adequate calcium, magnesium and potassium will be needed, but not in excess. Consuming micronutrients at levels exceeding those provided by a dietary pattern consistent with American Heart Association (AHA) Dietary Guidelines will not confer additional CVD risk reduction (Kris-Etherton et al, 2004).
- Decrease intake of whole-milk products, red meats, visible fat on meat/poultry, and commercial baked goods. Limit egg yolks to four to five times weekly if lipids are elevated.
- Increase food sources of vitamins E and K, folic acid, and vitamins B<sub>6</sub> and B<sub>12</sub>.
- Fiber is especially important; choose vegetables, fruits, and cereal grains.
- Include judicious use of nuts, such as walnuts, almonds, macadamias, pecans, and pistachios. Walnuts contain ALA; almonds are a good source of vitamin E. Nuts also contain flavonoids, phenols, sterols, saponins, elegendic acid, folic acid, magnesium, copper, potassium, and fiber.
- Pistachios, sunflower kernels, sesame seeds, and wheat germ are highest in phytosterols; use often.

## Common Drugs Used and Potential Side Effects

- Appropriate drugs are provided according to needs established by the profile (elevated BP or lipids). Review specific drugs given to the patient and treat accordingly. Nitrates, beta-blockers, calcium channel blockers, statins, and related drugs are given according to the cause and risk factors for the patient.
- Anticoagulants such as warfarin (Coumadin) may be given where bleeding tendencies are not present. Limit to one vitamin K-rich food per day (green leafy vegetables such as kale, broccoli, spinach, and turnip greens). Avoid taking with dong quai, fenugreek, feverfew, excessive garlic, ginger, ginkgo, and ginseng.
- Aspirin is often recommended later to prevent recurrent MIs. Watch for GI bleeding or other side effects such as occult blood loss.
- Mexiletine (Mexitil) and propafenone (Rythmol) are used to treat arrhythmias. Nausea, vomiting, or constipation may occur. Procainamide (Procan) may result in a bitter taste, nausea, anorexia, or diarrhea.
- Morphine is used for relief of pain but should be given in minimal amounts to prevent hypotension and other side effects.

## Herbs, Botanicals, and Supplements

- Dietary supplementation with omega-3 fatty acids should be considered in the secondary prevention of cardiovascular events (Marik and Valon, 2009). Study of the associations between EPA and DHA intake and disease requires a valid biomarker of dietary intake; RBC delta(15)N as a biomarker of EPA and DHA intake is rapid and inexpensive (O'Brien et al, 2009).
- At this time, the scientific data do not justify the use of antioxidant vitamin supplements.
- See Table 6-3 for more guidance on herbs and botanical products.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Position patient and arrange utensils to avoid or lessen fatigue. Encourage relaxation, especially at mealtimes.
- If needed, use a weight-control diet.
- Discuss roles of fats, Chol, sodium, potassium, calcium, magnesium, and fiber in the diet. Encourage use of the DASH or Mediterranean diets (see Table 6-4). A vegetarian diet may also be beneficial (Craig et al, 2009).
- Monitor for changes in renal status. A GFR of <60 mL/min may indicate high risk for cardiac death in women (Kurth et al, 2009).
- Avoid excesses of carbohydrate and alcohol, especially with diabetes or elevated BP.
- Individuals continue to have multiple risk factors for CAD that place them at high risk for future events. Discuss convalescence and prevention of HF.
- The patient should stop smoking, follow the recommended diet, and manage other risk factors. A positive attitude toward the modified diet is essential for changing food behaviors.

- The reduction of exposure to second-hand smoke is also beneficial (Glantz et al, 2008; Pell et al, 2008).
- Management of anxiety is an important feature for recovery (Kuhl et al, 2009).
- Discuss a gradual increase in activity. Cardiac rehabilitation programs are very helpful (Lisspers et al, 2005). Aerobic physical activities, such as exercise or walking at work, seem to reduce the risk of MI, whereas anaerobic activities, such as heavy lifting, may increase risk of MI (Fransson et al, 2004).
- A comprehensive management plan uses the “ABCDE” approach: “A” for antiplatelet therapy, anticoagulation, ACE inhibition, and angiotensin receptor blockade; “B” for beta-blockade and BP control; “C” for Cholesterol treatment and cigarette smoking cessation; “D” for diabetes management and diet; and “E” for exercise (Gluckman et al, 2005).

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## PERICARDITIS AND CARDIAC TAMPONADE

### NUTRITIONAL ACUITY RANKING: LEVEL 2

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Pericarditis is inflammation of the pericardium due to human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), MI, rheumatic diseases, radiation

treatment, viral infection, trauma, neoplasm, chronic renal failure, or lupus. Bacterial pericarditis occurs by direct infection during trauma, thoracic surgery or catheter drainage, spread from *Staphylococcus*, *Streptococcus*, *Haemophilus*, and *Mycobacterium tuberculosis* (Pankuweit et al, 2005).

Severe substernal chest pain, dyspnea, shortness of breath, fever, chills, diaphoresis, nausea, fatigue, and anxiety are common in the acute stage. The chronic stage of pericarditis often results from tuberculosis and may involve ascites, edema of the extremities, HF, shrinkage of the pericardium, shortness of breath, coughing, fatigue, ascites, and leg edema.

Although pericarditis usually is not a life-threatening condition, other life-threatening conditions may cause chest pain and should be ruled out. These include MI, dissection of the aorta, pulmonary embolus, collapsed lung, and perforation or rupture of parts of the esophagus or stomach. Control of symptoms through diuretics is the usual treatment.

The most serious complication is **cardiac tamponade**, with accumulation of fluid or blood within the pericardial sac. If uncontrolled, this condition may lead to HF, arrest, or

shock (Meltzer and Karia, 2005). Decreased heart sounds, distended neck veins with inspiratory rise in venous pressure (Kussmaul's sign), decreased BP, and abdominal pain may occur. In children, cases of cardiac tamponade have occurred as a complication of malignancies, cardiac surgery, trauma, infections, central venous catheter placement, rheumatologic and autoimmune diseases (Cousineau and Savitsky, 2005). Pericardial effusions causing tamponade are rare in patients with lupus, but high-dose corticosteroids are often needed (Rosenbaum et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** A deficiency in the interleukin-1 receptor activated kinase 4 (IRAK-4) has recently been associated with severe recurrent, Gram-positive bacterial infections and related heart infections (Comeau et al, 2008). In addition, Familial Mediterranean fever is an autosomal recessive disease that presents with recurrent Peritonitis. More studies of the genetics of pericardial diseases are needed.

<b>Clinical/History</b>	Cyanosis?	Alb,
Height	Cough	transferrin
Weight	Dysphagia	BP
Weight changes (loss?)	Pericardial friction rub	BUN, Creat, GFR
BMI	ECG	H & H
Waist circumference	Cardiac catheterization	Serum Fe
Diet history	Magnetic resonance imaging (MRI)	Transferrin
Low-grade intermittent fever?	Computed tomography (CT)	Na <sup>+</sup> , K <sup>+</sup>
High fever?		Ca <sup>++</sup> , Mg <sup>++</sup>
I & O		WBC
Ascites or hepatomegaly?		tHcy
Tachypnea, dyspnea		Serum folate and B <sub>12</sub>
	<b>Lab Work</b>	
	CRP	
	Gluc	

## INTERVENTION

### OBJECTIVES

- It is critical for anyone who experiences chest pain to seek immediate medical attention to determine the cause and receive prompt, appropriate treatment to improve cardiac functioning.
- Maintain bed rest during acute stages.
- Prevent sepsis, HF, and shock, especially if cardiac tamponade occurs.
- Decrease fever and inflammation, which may last 10–14 days in the acute form.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Malnutrition

**Assessment Data:** Diet history and food records indicating intake of about 60% of usual intake; dyspnea, anorexia, nausea, recent fevers up to 103°F. BMI 17; usual BMI 20.

**Nutrition Diagnosis (PES):** Malnutrition related to pericarditis and chronically poor intake as evidenced by BMI of 17 and weight loss over the past year of 15 lb.

**Intervention:** Add protein powder to mixed dishes that are served. Educate about nutrient density and ways to add calories and protein. Review medications and suggest ways to increase appetite; discuss with medical team.

**Monitoring and Evaluation:** Improved intake and appetite; BMI closer to usual. Fewer complaints of fever, nausea, anorexia.

- Reduce nausea and anorexia.
- Prevent fluid overload if CPN is administered.

## FOOD AND NUTRITION

- Maintain an adequate diet as needed for any underlying conditions; increase protein and calories if tolerated and if needed to prevent loss of LBM.
- Alter sodium and fluids intake if necessary.
- Small, frequent feedings to reduce nausea may be indicated.
- Monitor diet and supplements adequately. Thiamin for the heart muscle and potassium may be especially necessary; vitamins B<sub>6</sub> and B<sub>12</sub> and folic acid may be needed if tHcy levels are elevated. It may also be prudent to increase vitamin E levels.
- The DASH diet, TLC diet, and Mediterranean diet are good choices.

## Common Drugs Used and Potential Side Effects

- Analgesics or nonsteroidal anti-inflammatory drugs (NSAIDs) may be used to relieve pain. Monitor for specific side effects.
- Antibiotics are needed for bacterial infections. Intravenous antibacterial therapy, such as vancomycin, ceftriaxone, or ciprofloxacin, is used in purulent pericarditis (Pankuweit et al, 2005). Monitor for side effects.
- Diuretics may be used. If a potassium-depleting diuretic is chosen, monitor serum potassium levels closely and manage dietary changes if needed.
- Treatment of tuberculous pericarditis includes isoniazid, rifampin, pyrazinamide, and ethambutol (Pankuweit et al, 2005). Prednisone is given and then progressively reduced in 6–8 weeks; GI distress, hyperglycemia, and calcium and nitrogen depletion may result.
- Some medications can trigger an immune response that causes pericarditis. These medications include isoniazid (Nydrazid), hydralazine (Apresoline), penicillin, antiarrhythmic agents such as procainamide (Procanbid or Pronestyl), and seizure medications such as phenytoin (Dilantin).

## Herbs, Botanicals, and Supplements

- See Table 6-3 for guidance.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the importance of avoiding fatigue.
- The patient should plan rest periods before and after activities and meals.
- Highlight the importance of nutrition in immunocompetence.
- Discuss any drug–nutrient interactions that are possible according to the treatment plan.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# PERIPHERAL ARTERY DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

**Peripheral vascular disease (PVD)** can affect the arteries, the veins, or the lymph vessels. The most common and important type of PVD is **peripheral artery disease (PAD)**. PAD, defined as atherosclerosis in the lower extremities, affects nearly 8.5 million people in the United States (Dobesh et al, 2009). Prevalence increases dramatically with age; by age 70, about 20% of the population has PAD. PAD disproportionately affects Mexican Americans and nonhispanic blacks. People with PAD face a six to seven times higher risk of heart attack or stroke. Occlusion of an artery occurs from a clot or by plaque buildup in the extremities, such as the hands and feet numbness, tingling in lower extremities, pain, difficult ambulation, gangrene with potential amputation. See Table 6-16.

Causes of PAD include heavy smoking, arterial embolism, obesity, diabetes mellitus, renal insufficiency, poor circulation, atherosclerosis, or exposure to heavy metals. Urinary cadmium, tungsten, and possibly antimony have been associated with PAD (Navas-Acien et al, 2005). Modifiable risk factors such as smoking, dyslipidemia, hypertension, and diabetes should be addressed (Aronow, 2005; Nijm et al, 2005).

Elevated levels of fibrinogen and CRP may indicate that there is inflammation. PAD is a red flag that the same

process may be going on elsewhere; PAD is often associated with other life-threatening vascular diseases. Exercise is the first-line treatment for intermittent claudication with symptoms of aching pain, numbness, weakness, or fatigue (Dobesh et al, 2009).

**TABLE 6-16 Sites Where Peripheral Arterial Disease Produces Symptoms**

Arteries supplying blood to the brain	Stroke is a serious complication.
Arteries supplying blood to the kidneys	Renal artery stenosis is one of the causes of high blood pressure and renal failure.
Arteries supplying blood to the legs	Diminished ability to walk can occur; worst-case scenario leads to amputation.
Arteries supplying blood to the intestines	Mesenteric arterial disease is less frequent but can cause severe pain, weight loss, and death from intestinal gangrene.

Endothelial dysfunction may reduce functional capacity via attenuations in peripheral blood flow; dietary docosahexaenoic acid (DHA) may improve this dysfunction (Stebbens et al, 2008). When National Health and Nutrition Examination Survey (NHANES) data were evaluated to determine specific nutrients that are associated with PAD, it was found that higher consumption of antioxidants (vitamin A, C, and E), vitamin B<sub>6</sub>, fiber, folate, and omega-3 fatty acids have a significant protective effect (Lane et al, 2008). Because hypovitaminosis D is more common in blacks than Hispanics or whites, check serum levels of serum 25-hydroxyvitamin D (25[OH]D) and supplement as needed (Reis et al, 2008). Dietary supplementation may protect against PAD (Lane et al, 2008).

Angioplasty may be needed to clear obstruction, relieve symptoms, heal ulcers, and prevent amputation. Indications for lower extremity angioplasty, preferably with stenting, or bypass surgery are (1) incapacitating claudication in persons that interferes with work or lifestyle; (2) limb salvage in persons with limb-threatening ischemia as manifested by rest pain, nonhealing ulcers, and/or infection or gangrene; and (3) vasculogenic impotence (Aronow, 2005). If the limb cannot be salvaged, amputation would be needed.

**Buerger's disease** is the obstruction of small- and medium-sized arteries by inflammation triggered by smoking and is usually found among men aged 20–40 years. Skin ulcers or gangrene may result if smoking is not discontinued. Walking is beneficial, unless the person has gangrene, sores, or pain at rest.

**Raynaud's syndrome** allows small arterioles in the fingers and toes to go into spasm, and the skin turns pale or patchy red to blue. Sometimes the underlying cause is not known. Approximately 60–90% of cases occur in young women. Scleroderma, rheumatoid arthritis, atherosclerosis, nerve disorders, hypothyroidism, injury, and reactions to certain drugs are causes. Some people also have migraine headaches and pulmonary hypertension. These individuals must protect their extremities from the cold or take mild sedatives for pain.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Adipokine angiopoietin-like 4 gene (ANGPTL4[E40K]) variant appears to confer reduced genetic risk for CHD and other conditions, including PAD (Folsom et al, 2008). These common alleles are correlated with low TG and high HDL-C (Nettleton et al, 2009). Dietary fat intake modifies relations between HDL-C and polymorphisms in hepatic lipase (LIPC-514 C→T), cholesteryl ester transfer protein (CETP TaqIB), and lipoprotein lipase (LPL S447X) genes (Nettleton et al, 2007).

<b>Clinical/History</b>	BMI	BP
Height	Waist–hip ratio	Smoking history
Weight	Diet history	

Ankle brachial index (ABI) test <0.9	<b>Lab Work</b>	Gluc
Exercise tolerance, stress testing	CRP	Serum insulin
Ulcerations	Chol—total, HDL, LDL	Na <sup>+</sup> , K <sup>+</sup>
Gangrene	Trig	Ca <sup>++</sup> , Mg <sup>++</sup>
ECG	BUN, Creat	Serum 25-hydroxyvitamin D (25[OH]D)
Cardiac catheterization	Uric acid	
MRI or CT scan	tHcy	
	Serum folate and B <sub>12</sub>	

## INTERVENTION

### OBJECTIVES

- Treatment goals are aimed at decreasing cardiovascular risk, as well as improving quality of life (Dobesh et al, 2009). Reduce complications such as angina, HF, heart attack, stroke, renal failure, ulcerative disease, gangrene of lower extremities or toes.
- Prevent sepsis, pressure ulcers, or the need for amputation.
- Correct high levels of tHcy.
- Attain desired body weight if obese.
- Reduce the inflammatory process, as possible. CRP and other inflammatory markers offer risk prediction (Haugen et al, 2007).
- Modify carbohydrate and fat intakes (Nettleton, 2009).
- Correct hypovitaminosis D if needed.

### FOOD AND NUTRITION

- If patient is obese, use a low-calorie diet with high fiber.
- Diet should provide adequate protein intake for wound healing with ulcers or surgery.
- Vitamin E in almonds, filberts, avocados, sunflower seeds, vegetable oils, margarine, mayonnaise, and wheat germ are the best sources. Pistachios, sunflower kernels, sesame seeds, and wheat germ are high in phytosterols and should be used frequently.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Intake of Fatty Acids

**Assessment:** Diet history and food records, BP records. Labs with elevated LDL Chol.

**Nutrition Diagnosis (PES):** Inadequate intake of omega-3 fatty acids related to poor diet and peripheral circulation as evidenced by elevated LDL Chol intake.

**Intervention:** Education about the role of omega-3 fatty acids in cardiovascular health and reduction of inflammation.

**Monitoring and Evaluation:** Improved dietary records showing use of omega-3 fatty acids from diet and supplements.

- Increase folic acid, riboflavin, and vitamins B<sub>6</sub> and B<sub>12</sub> if serum tHcy levels are elevated.
- The DASH, TLC, and Mediterranean diet patterns are useful.
- Olive oil consumption along with a dietary supplement of fish oil may be helpful in the management of PVD. Avoid use of butter and saturated fats.
- Correct vitamin D deficiency as needed.

### Common Drugs Used and Potential Side Effects

- Antiplatelet drugs such as aspirin or clopidogrel may be helpful.
- Antibiotics may be used to control infections.
- ACE inhibitors are an important risk-reduction therapy for patients with PAD. Beta-blockers should be given if CAD is present (Aronow, 2005).
- Anticoagulants such as warfarin may be used. Use no more than one high-vitamin K food source daily. Avoid taking with dong quai, fenugreek, feverfew, excessive garlic, ginger, ginkgo, or ginseng because of their effects.
- Isoxsuprine (Vasodilan) may be used to dilate the vessels. If niacin is used as a vasodilator, do not use large doses without monitoring by a physician.
- Pentoxifylline (Trental) improves blood flow. GI distress, nausea, and anorexia may occur; take with meals.
- Statins reduce the incidence of intermittent claudication and improve exercise duration (Aronow, 2005).

### Herbs, Botanicals, and Supplements

- Coenzyme Q10, ginger, purslane, and ginkgo have been recommended for PAD, but no clinical trials have proven efficacy. Use a vitamin D supplement if serum levels are low.
- See Table 6-3 for more information.

#### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Emphasize the importance of weight control and exercise.
- Reduce excess alcohol consumption if TGs are elevated.
- Fish and meatless meals should be used three to four times weekly.

- Hyperbaric oxygen treatments may be needed to heal lesions. Here, oxygen permeates the flesh, and anaerobic bacteria cannot survive.
- Encourage a smoking cessation program.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

## THROMBOPHLEBITIS

### NUTRITIONAL ACUITY RANKING: LEVEL 1

#### DEFINITIONS AND BACKGROUND

Phlebitis is inflammation of a vein that usually is caused by infection or injury. Blood flow may be disturbed, with blood clots (thrombi) adhering to the wall of the inflamed vein. This condition usually occurs in leg veins, especially in vari-

cose veins. Blood clots in the thigh veins are usually more serious than those in the lower leg and are usually deep vein thromboses (DVTs).

Fatty acids have been implicated in the etiology of thrombophlebitis, but there is no clearly demonstrated mechanism. Blood tHcy levels are an important, independent,

**TABLE 6-17 Causes of Thrombophlebitis**

- Age: Over age 60 is more common, but it can occur any time
- Cancer and its treatment; especially in recently diagnosed patients, patients with cancer that has spread to distant sites (metastases), and those with certain genetic mutations (Blom et al, 2005)
- Central venous catheters
- Inherited conditions that cause increased risk for clotting; factor V Leiden, the genetic defect underlying resistance to activated protein C, is one factor that causes inherited thrombophilia
- Low blood flow in a deep vein due to injury, surgery, or immobilization
- Obesity or overweight
- Oral contraceptives or hormone replacement therapy; both estrogen and progesterone affect the condition
- Pregnancy and postpartum, especially the first 6 weeks after giving birth
- Sitting for a long period of time (long trips in a car or airplane)
- Varicose veins, which are enlarged, twisted, painful superficial veins resulting from poorly functioning valves, usually in the legs. They affect women more commonly than men.

and frequent risk factor for venous thrombosis. The VITRO (Vitamins and ThROMbosis) trial was the first multicenter, randomized, double-blind and placebo-controlled study to evaluate the effect of tHcy-lowering therapy by means of 5 mg folic acid, 0.4 mg vitamin B<sub>12</sub> and 50 mg vitamin B<sub>6</sub>; it did not prevent recurrences (den Heijer et al, 2007).

Venous thromboembolism (VTE) is a major cause of morbidity and mortality worldwide, and the annual incidence of VTE is 1 per 1000 (Bramlage et al, 2005). Table 6-17 lists common causes of thrombophlebitis.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Venous thrombosis is one of the leading causes of maternal morbidity and mortality; it is highly increased in carriers of factor V Leiden or the prothrombin 20210 A mutation (Pomp et al, 2008). It has also been noted with folate MTHFR alleles.

Clinical/History	BP	Duplex ultrasound
Height	Pain, redness,	Doppler study
Weight	warmth, tenderness, itching	Ankle BP measurements
BMI	Hard or cord-like swelling	
Waist-hip ratio	along the affected vein	
Diet history		
Recent weight changes		
Temperature

Alb, transferrin Chol—total, HDL, LDL Trig BUN, Creat Uric acid WBC	H & H Gluc TLC Na <sup>+</sup> , K <sup>+</sup> Ca <sup>++</sup> , Mg <sup>++</sup> tHcy Serum folate and B <sub>12</sub>	Sex hormone-binding globulin (SHBG)—for oral contraceptive users
--	--	--

## INTERVENTION

### OBJECTIVES

- Stop the clot from getting bigger.
- Reduce inflammation and swelling.
- Prevent septicemia, pulmonary embolism (with chest pain and shortness of breath), and related complications.
- Lower elevated plasma tHcy, which increases the risk of VTE.

## FOOD AND NUTRITION

- Weight control diet may be needed if the patient is obese. The DASH, TLC, and Mediterranean diets may be beneficial.
- Sodium restriction may be beneficial for persons with a generally high salt or sodium intake. Monitor carefully.
- For general cardiovascular health, adequate vitamins B<sub>6</sub> and B<sub>12</sub> and folic acid intakes should be included. Intake of B vitamins through diet, supplementation, and fortified foods effectively reduces tHcy concentration and thus may reduce the risk.
- Thiamin and vitamin E are also beneficial for heart health at levels meeting but not exceeding daily requirements.
- Encourage use of omega-3 fatty acids from fish and other foods.
- Pistachios, sunflower kernels, sesame seeds, and wheat germ are high in phytosterols; use often.
- Flavonoids (including tannins, quercetin, and phenols) in grapes, strawberries, blueberries, apples, kale, broccoli, onions, garlic tea, beer, and red wine may reduce platelet activity and prevent clots.

### SAMPLE NUTRITION CARE PROCESS STEPS

**Assessment:** Diet history and food records, BP records.

**Nutrition Diagnosis (PES):** Inadequate intake of types of fat

**Intervention:** Nutrition education about food and supplemental sources of EPA and DHA.

**Monitoring and Evaluation:** No clotting problems. BP improved or controlled.

- Foods that contain vitamin K can change how well warfarin (Coumadin) will work. Eat a balanced diet that does not vary in usual content of these vitamin K-rich foods so that the medication can be regulated.

### Common Drugs Used and Potential Side Effects

- The anticoagulant warfarin (Coumadin) may be used, with side effects that alter use of vitamin K. Monitor intake carefully. Avoid supplements that are high in vitamins E, C, or A during use. Avoid taking with dong quai, fenugreek, feverfew, excessive garlic, ginger, ginkgo, and ginseng because of their effects.
- Another anticoagulant drug, ximelagatran (Exanta), may be useful as well (O'Brien and Gage, 2005). It is an oral direct thrombin inhibitor (DTI) that binds noncovalently and reversibly to both fibrin-bound and freely circulating thrombin (Petersen, 2005).
- Antibiotics are used in bacterial infections.
- Aspirin or acetaminophen may be used to reduce fever or pain. Chronic use of aspirin may decrease serum ferritin by increasing occult blood loss.
- Thrombolytics may be given to quickly dissolve blood clots that cause symptoms during life-threatening situations. Thrombin inhibitors may be used to interfere with the clotting process.

### Herbs, Botanicals, and Supplements

- See Table 6-3 for guidance.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Bedrest may be important during acute stages of DVT. Leg and foot elevation may be required. Monitor side effects of immobility if patient will be immobilized for a long period of time.
- Zinc ointment may relieve itching.

- The DASH diet plan should be taught. Discuss flavonoids and other nutrients.
- For overall improvement of venous health, encourage patient to stop smoking, increase exercise, lower elevated lipids, and wear compression stockings if needed.
- Discuss sources of the B vitamins, and suggest a supplement if appropriate, especially for individuals with MTHFR mutations (Varga et al, 2005).

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is key as well.

# Gastrointestinal Disorders

## CHIEF ASSESSMENT FACTORS

- Abdominal Pain or Distention
- Appetite, Anorexia
- Ascites, Jaundice
- Bezoars (Undigested Foreign Matter, Usually in Stomach)
- Change in Eating or Bowel Habits
- Change in Stools, Consistency, and Frequency; Fecal Incontinence
- Constipation
- Dentition
- Diarrhea (bloody, explosive)
- Dysphagia
- Easy Fatigue
- Edema of Extremities
- Feeding Method for Digestive or Absorptive Problems
- Hemorrhoids, Rectal Bleeding or Polyps
- Indigestion, Heartburn, Reflux
- Nausea, Vomiting, Regurgitation
- Painful or Cramping Abdomen, Flatulence
- Painful Oral Tissues, Tongue
- Use of Antacids, Stool Softeners, Diuretics, Laxatives, Histamine Blockers
- Weight Loss

## INTRODUCTION AND BACKGROUND FOR GASTROINTESTINAL DISORDERS

### Digestion

Digestion is a process that physically and chemically breaks down food in preparation for absorption. It begins with mastication and mixing of food with salivary fluid and enzymes (oral phase). In the gastric phase, pepsin and gastric acid begin to work. Chyme is then delivered to the small intestine for mixing with pancreatic and biliary juices. The pancreatic phase involves pancreatic amylase and lipase, proteases, and phospholipase. The intestinal phase involves disaccharidases (maltase, lactase, and sucrase), peptidases, and cholecystokinin for bile salts. *Maldigestion* involves the interference at any of these stages, including abnormal emptying of the stomach and pancreatic insufficiency.

### Absorption

Passage of molecular nutrients into the bloodstream from the intestinal cells, starts primarily in the duodenum, with monosaccharides, amino acids and small peptides, mono-glycerides, and free fatty acids. Water is also absorbed to maintain isotonicity of blood and cells. Bile and fat are needed to absorb fat-soluble vitamins A, D, E, and K. Water-soluble vitamins C and B-complex are usually absorbed in the intestinal mucosa with some storage in the liver. *Malabsorption* can result from dysfunction from any of the above steps.

### Small Intestine

It is approximately 3.8 cm in diameter and 4.8-m long, covered with villi projections to increase absorptive surface. Villi cells have a rapid turnover rate of 2–5 days. Fecal fat is a valuable test of lipid digestion/absorption.

### Large Intestine

It is approximately 5 cm in diameter and 1.5-m long, with two sections (colon and rectum) forming a frame around a highly convoluted small intestine. A diet high in whole and unrefined foods (whole grains, dark green and yellow/orange vegetables and fruits, legumes, nuts, and seeds) is high in antioxidant phenolic compounds, fibers, and other phytochemicals, all of which are beneficial.

### Rectum

It is approximately 12-cm long. The area is susceptible to polyps and tumors.

The entire process of digestion/absorption takes about 24 hours, with large variations among individuals.

Digestive problems such as abdominal pain, diarrhea, nausea, and vomiting result in approximately millions of physician visits, billions in direct U.S. medical costs annually, and frequent use of prescription medications. Table 7-1 lists gastrointestinal (GI) conditions that may lead to malnutri-

**TABLE 7-1 Gastrointestinal Conditions That May Lead to Malnutrition**

#### *Malabsorption*

Celiac disease	Pancreatic insufficiency
Crohn's disease	Short bowel syndrome
Disaccharidase deficiencies	Ulcerative colitis
Dumping syndrome	
HIV infection or AIDS	

#### *Mechanical Function*

Achalasia or esophageal hypomotility	Esophageal obstruction
Adynamic ileus	Hirschsprung's disease
Bezoar formation after gastric surgery	Pyloric stenosis
Bowel obstruction	Tracheoesophageal fistula
Esophageal stricture	

#### *Conditions that May Cause Fear of Eating*

Aspiration risk	Crohn's disease
Bloating/obstruction/distension/pain	Dental disease
Cholelithiasis and other biliary diseases	Diarrhea
Diverticulitis	Irritable bowel syndrome
Dumping syndrome	Lactose intolerance
Dysphagia	Pancreatitis (acute or chronic)

Flatulence	Proctitis
Food allergies	Rectal fissures
Gastritis	Reflux esophagitis
Ill-fitting dentures	Ulcerative colitis

tion. The enteric nervous system (ENS) consists of many different types of enteric neurons forming complex reflex circuits that underlie or regulate many gut functions (Young, 2008). The identification of the genetic, molecular, and cellular mechanisms responsible for the colonization of the gut by enteric neuron precursors provides an exciting future management for GI disorders.

The GI tract does not respond well to inflammation where digestion, absorption, and gut barrier protection is impaired (Tappenden, 2008). Arachidonic acid (AA) is the precursor of inflammatory eicosanoids-like prostaglandin E(2) and leukotriene B(4); the n-3 PUFAs eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) are anti-inflammatory. Fish oil supplementation in patients with inflammatory bowel diseases (IBD) results in n-3 PUFA incorporation into gut mucosal tissue with the potential for modified inflammation, improved gut histology, decreased disease activity, reduced use of corticosteroids (Calder, 2008), and decreased risk of colorectal cancer (Habermann et al, 2009). Glutamine (an amino acid needed in stress or

**TABLE 7-2 Enteral Nutrition, Prebiotics, Probiotics, and Synbiotics in Gastrointestinal Tract Function**

When an oral diet is not feasible, **enteral nutrition (EN)** is needed to avoid prolonged starvation, to prevent deterioration of intestinal integrity, and to avoid translocation of gut bacteria. One or two basic formulas can meet most patients' needs.

**Prebiotics:** Low-digestible carbohydrates that are not digested in the upper GI tract become fermented in the large intestine. They have physiological benefits similar to those of dietary fiber. Short-chain fatty acids (SCFAs) are produced from fermentation of fiber; the SCFAs are fuel for mucosal cells, so they benefit the gut tissue. Fermentation leads to the selective stimulation and growth of beneficial gut bacteria such as *bifidobacteria* (prebiotics). Carbohydrates that offer desirable physiological properties are resistant starch (RS), oligofructose, and polydextrose.

**Probiotics** are live microbial food supplements; they support balance in the intestinal tract. Probiotics have the ability to modify gut pH, antagonize pathogens, produce lactase, and stimulate immunomodulatory cells. Functional foods such as yogurt with live cultures may decrease the incidence of cancer, allergic reactions, and lactose intolerance. Probiotics also have immunomodulating properties and enhance the mucosal barrier in inflammatory bowel disease, pancreatitis, liver transplantation, and diarrhea (Jenkins et al, 2005).

**Synbiotics** are combinations of prebiotics and probiotics. By combining specific prebiotics and plant fibers into multifiber synbiotics, immunosupportive effects are possible (Bengmark and Martindale, 2005). The use of these products may become common practice in intensive care and GI units. Crohn's disease and ulcerative colitis are caused by overly aggressive immune responses to a nonpathogenic enteric bacteria in genetically predisposed individuals; administration of probiotics, prebiotics, or synbiotics can restore a predominance of beneficial *Lactobacillus* and *Bifidobacterium*. They may be protective against colon cancer as well (Pool-Zobel, 2005).

sepsis) requires GI processing to become effective; this is likely true for other nutrients. Threonine is an essential amino acid that is abundantly present in intestinally produced glycoproteins; studies in infants suggest a high obligatory visceral need for it in protein synthesis (van der Schoor et al, 2007). Lysine, arginine, and other amino acids are also used in intestinal health, providing support for early enteral feeding whenever possible. Table 7-2 gives details about the role of enteral nutrition, prebiotics, probiotics, and synbiotics in GI health. The right product and the right ingredients can make a big difference. Therefore, it is beneficial to employ a nutrition support specialist or team in facilities where many patients need enteral or parenteral support. Table 7-3 lists GI conditions that may benefit from nutritional enhancements and Table 7-4 describes the role of dietitians in the GI specialty area.

**TABLE 7-4 Knowledge and Skills of Dietitians in Gastrointestinal Specialty**

#### The GI dietetics practitioner:

- Knows sites of digestion and absorption of macronutrients and micronutrients
- Understands normal digestion, nutrient secretion, and absorption
- Identifies key nutritional screening factors for persons with GI disease
- Explains the association between diet and other therapies in treating GI disorders
- Knows the value and limitations of enteral and parenteral nutrition formulas and common functional food ingredients
- Knows how to handle complex GI problems in conditions as diverse as cystic fibrosis (Mascarenhas, 2003) and celiac disease (Niewinski, 2008)
- Recognizes extremes of dietary intake and the effects of diet on GI function and symptoms
- Understands how GI dysfunction, surgical resections, and diseases affect nutritional status
- Understands how other diseases and conditions can affect GI function, such as diabetes and gastroparesis, postanesthetic ileus, neurological injury, and hormonal changes
- Understands the consequences of eating patterns in both healthy persons and in those who have GI disease

**UPPER GI: ESOPHAGUS****DYSPHAGIA****NUTRITIONAL ACUITY RANKING: LEVEL 3–4**

**TABLE 7-5 Standard Questions in the Evaluation of Dysphagia**

Describe any difficulty swallowing that you have.  
 Is the swallowing difficulty greater for solids or liquids?  
 How long have you had this swallowing difficulty?  
 Do you have heartburn along with this difficulty swallowing?  
 Is swallowing painful?  
 Do you get chest pain?  
 Does food get stuck when you swallow?  
 Do you choke or cough with swallowing?  
 Do you have temperature sensitivity (especially cold foods and beverages)?  
 Has there been any weight loss?

Adapted from: <http://www.ncbi.nlm.nih.gov/bookshelf/br.fcgi?book=cm&part=A2747>, accessed July 25, 2009.

## DEFINITIONS AND BACKGROUND

Anatomic or physiological swallowing problems of dysphagia create a disturbance in the normal transfer of food from the oral cavity to the stomach. Swallowing requires 5–10 seconds and three phases for completion—oral phase, pharyngeal phase, and esophageal phase. All must be adequate to prevent choking and/or aspiration into the lung. Signs of possible dysphagia include coughing with meals, choking, drooling, or pocketing of foods. Consult speech therapist for a full evaluation; a barium swallow may reveal silent aspiration. Videofluoroscopy (VF) is the gold standard. Questions to ask about swallowing difficulty are listed in Table 7-5.

Progress diet when possible, under guidance of the therapist. Inadequate dietary intake, weight loss, nutrient deficiencies, protein-energy malnutrition, and dehydration may result from prolonged dysphagia. In children with developmental disabilities, diagnosis-specific treatment of feeding disorders results in significantly improved energy consumption and nutritional status.

Dysphagia is classified into oropharyngeal dysphagia due to malfunction of the pharynx and upper esophageal sphincter, or esophageal dysphagia due to malfunction of the esophagus. Common causes of dysphagia are listed in Table 7-6.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutations in the PABPN1 gene can cause an oculopharyngeal muscular dystrophy.

#### Clinical/History

Height  
Weight  
Body mass index (BMI)

Weight changes  
Diet history and swallowing problems—current, history, duration

Fiberoptic endoscopic evaluation of swallowing (FEES)

Videofluoroscopic swallowing study	Wet, gurgly voice after drinking or eating	Upper GI bleeding Blood pressure (BP)
Esophagoscopy	Slurred speech	<b>Lab Work</b>
Barium swallow	Poor tongue control or excessive movement	Hemoglobin and hematocrit (H & H)
Cookie swallow test	Hoarseness, breathy voice	Blood urea nitrogen (BUN)
Pocketing of food under tongue or in cheeks	Recurrent pneumonia	Albumin (Alb)
Spitting food out of mouth	Mealtime resistance—clenching teeth or throat	C-reactive protein (CRP)
Facial weakness	Regurgitation of food through nose or mouth	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup> Ca <sup>++</sup> , Mg <sup>++</sup>
Slow oral transit time		Other labs specific for the disorder
Choking		
Coughing before, during, or after swallowing		
Excessive eating time		

**TABLE 7-6 Common Causes of Dysphagia**

Achalasia	Head trauma
Aging	Hiatal hernia
Alzheimer's disease	Huntington's disease
Amyotrophic lateral sclerosis	Lung cancer
Cerebral palsy	Meningitis
Cerebrovascular accident (stroke)	Multiple sclerosis
Chronic obstructive lung disease	Muscular dystrophy
Cleft lip or palate	Myasthenia gravis
Closed head injury	Myotonic dystonia
Dehydration from medications	Parkinson's disease
Diabetes, type 1 (long term)	Pneumonia with aspiration history
Encephalopathy	Poliomyelitis
Esophageal inflammation	Prematurity
Esophageal fistula	Pulmonary disorders
Esophageal obstruction or stricture	Radiation treatment to head/neck
Esophageal trauma	Sjögren's disease
Gastroparesis	Spinal cord injury
Gastroesophageal reflux (GERD)	Throat cancer or injury
Goiter	Tongue cancer
Guillain-Barré syndrome	Tracheoesophageal fistula
Head or neck cancer	Zenker's diverticulum

## SAMPLE NUTRITION CARE PROCESS STEPS

**Dysphagia**

**Assessment Data:** Weight loss, dysphagia and jaw pain, throbbing headache

**Nutrition Diagnoses (PES):** Dysphagia related to progression of Parkinson's disease as evidenced by weight loss, difficulty swallowing solids, and choking on thin liquids.

**Interventions:** Education about blending foods and simplifying meal planning to increase intake. Swallowing evaluation for determination of appropriate textures and thickening of liquids. Counseling on positioning at mealtime to reduce likelihood of aspiration.

**Monitoring and Evaluation:** Improved intake for meals and snacks; fewer complaints of difficulty swallowing. No further weight loss.

## INTERVENTION

## OBJECTIVES

- Prevent choking and aspiration of foods and beverages.
- Promote weight maintenance or gain if losses have occurred. In head and neck cancer patients, anorexia and dysphagia are factors that adversely affect outcome of treatments (Kubrak et al, 2010).
- Individualize diet based on patient needs and preferences. Refer to speech therapist, who will help to determine the level of consistency that is required (e.g., nectar or syrup, honey, pudding). Monitor for pocketing of food.
- For some patients, thin liquids may be needed. Modify levels of dysphagia diets as impairment level changes; upgrade when and if safe for the patient.
- Support independence in eating whenever possible. Provide foods that stimulate the swallowing reflex.
- For persons who have viscous oral secretions or dry mouth, liquefy foods before serving by adding broth, juice, or water. Provide moistened foods or thickened beverages for adequate hydration.
- Correct any nutrient deficits. Prevent pressure ulcers, if relevant.

## FOOD AND NUTRITION

- The patient may be fed enterally if needed. Results from the FOOD (Feed or Ordinary Food) Collaboration Trials showed that nasogastric (NG) tube feeding (TF) was favored over percutaneous endoscopic gastrostomy (PEG) as the early route of feeding in dysphagic stroke patients (Prosser-Loose and Paterson, 2006).
- If needed, jejunostomy feedings may be more appropriate for the patient's condition. Home TF may be needed,

depending on the medical condition and cause of dysphagia.

- If central parenteral nutrition (CPN) is needed, monitor closely for ability to progress back to TF or oral diet.
- Following a protocol, clinical guideline, or algorithms improves dysphagia management.
- Calculate needs at 30–35 kcal/kg. Use a 1- to 1.5-g protein intake per kilogram to assure adequacy and to prevent loss of lean body mass. Monitor cardiac, hepatic, and renal status accordingly.
- Prevent aspiration by careful selection of foods and beverages, such as thick, soft, pureed foods instead of thin liquids. Thickening may be at honey, nectar, or pudding consistency; the label on the thickener will indicate the amount required for the differing levels. When a thickened liquid diet is ordered, foods such as gelatin should not be used because they liquefy at body temperature. Thicken foods and beverages with special products such as Thick-It, Thicken-Up, and Thick 'n Easy; these products use thickeners to make semisolids out of coffee, soup, beverages, juices, and shakes.
- It is possible to use mashed potato flakes to thicken some meat and casserole dishes. Baby rice cereal is an inexpensive thickener as well. Fruit purees are also helpful in thickening juices and some desserts.
- Progress over time to a soft diet.
- With a decreased saliva production, moisten foods with small amounts of liquid and use extra fats, mild sauces, and gravies.
- Monitor for deficiencies in fiber, vitamins A and C if whole grains, fruits, and vegetables are not consumed.
- Avoid alcoholic and extremely hot or cold liquids and beverages.
- Avoid foods that cause choking or are hard to manage: tart juices and foods, dry or crisp foods such as crackers and chips, bony fish, chewy meats such as steak, sticky foods such as peanut butter or bananas, thinly pureed foods that are easily aspirated, foods with varying consistency, excessively sweet drinks that aggravate drooling, carbonated beverages, dry bread in sandwiches.
- Avoid foods that are easily aspirated: popcorn, bran cereals, nuts, dry mashed potatoes, cottage cheese, corn, celery, pineapple, other fruits or vegetables with skins or fibrous pulp.
- Where there is reduced oral sensation, position food in the most sensitive area and use cold foods.
- To form a more cohesive bolus of food in the mouth, serve semisolid consistencies.
- For a severely sore mouth, avoid acidic foods and use soft foods at moderate temperatures.
- For delayed or absent swallowing reflex, temperature extremes and spicy foods may help excite the nerves necessary to function better. Some thickened liquids may actually be beneficial. Use cohesive foods that do not fall apart.
- Finely crushed bran on cereal, powdered fiber, or high-fiber tube-feeding products can help alleviate constipation.
- An interdisciplinary care plan is available for use.

# INTERDISCIPLINARY NUTRITION CARE PLAN

## Dysphagia

Client Name: \_\_\_\_\_ #: \_\_\_\_\_ Initiated by: \_\_\_\_\_ Date: \_\_\_\_\_

### SCREEN

Nutrition Screen diagnosis: Dysphagia

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

### GOALS (Check any/all):

- ☐ Safely eat and drink without risk in \_\_\_\_ (goal time).
  - ☐ Swallow efficiently to maintain nutrition and hydration in \_\_\_\_ (goal time).
  - ☐ Advance to normal texture of food in \_\_\_\_ (goal time).
- Weight ☐ maintained, or ☐ loss/ ☐ gain of \_\_\_\_ lb in \_\_\_\_ (goal time).

### ASSESS (Check any/all)

☐ Food/liquid texture modification

**Weight/BMI**

- ☐ Weight loss >3 lb/wk or >5%/mo or >10%/6 mo
- ☐ BMI <20 (High risk)
- ☐ BMI <27

☐ Medications

☐ Infection (e.g., pneumonia)

☐ Pressure ulcers/wounds

**Poor oral intake symptoms**

- ☐ Complex diet order
- ☐ Nausea/vomiting
- ☐ Poor appetite/early satiety
- ☐ Problems chewing/swallowing
- ☐ Depression/anxiety
- ☐ GI distress

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

### MODERATE RISK INTERVENTIONS (Check any/all)

- ☐ Foods that are easy to swallow provided and explained
- ☐ Food record provided and explained
- Obtain Dr. orders as needed:**
  - ☐ RD chart consult
  - ☐ SLP chart consult
  - ☐ OT chart consult
  - ☐ Monitor weight q: \_\_\_\_\_
  - ☐ Monitor I & O q: \_\_\_\_\_
  - ☐ BID/TID supplements
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

### HIGH-RISK INTERVENTIONS (Check any/all)

- ☐ Foods that are easy to swallow provided and explained
- ☐ Food record provided and explained
- Obtain Dr. orders as needed:**
  - ☐ RD referral for home visit(s)
  - ☐ SLP referral for home visit(s)
  - ☐ OT referral for home visit(s)
  - ☐ Monitor weight q: \_\_\_\_\_
  - ☐ Monitor I & O q: \_\_\_\_\_
  - ☐ BID/TID supplements
- ☐ Medication adjustment
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

### ASSESS RESPONSE (Check any/all)

- ☐ Further food/liquid texture modification required
- ☐ Weight change not appropriate per goal
- ☐ Dehydration
- ☐ Onset of pulmonary infection
- ☐ Exhibiting Poor Oral Intake Symptoms
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

### OUTCOMES ACHIEVED

- ☐ Food/liquid texture advanced toward normal
- ☐ Weight maintained or improved
- ☐ Hydration status maintained or improved
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Risk Screen in \_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

### ASSESS RESPONSE (Check any/all)

- ☐ Further food/liquid texture modification required
- ☐ Continued poor oral intake symptoms
- ☐ Weight change not appropriate per goal
- ☐ Dehydration
- ☐ Onset of pulmonary infection
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

### OUTCOMES ACHIEVED

- ☐ Food/liquid texture advanced toward normal
- ☐ Weight maintained or improved
- ☐ Hydration status maintained or improved
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Risk Screen in \_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

### OUTCOMES NOT ACHIEVED

Reassess/evaluate need for EN/PN (refer to Tube Feeding Nutrition Care Plan). Document on Nutrition Variance Tracking form.

## Common Drugs Used and Potential Side Effects

- For thick saliva and gagging, artificial saliva such as lemon glycerin may be useful.
- Papain or citrus juices may be useful for thinning secretions.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- It is important to stress that no supplement or diet can cure dysphagia.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Follow meals by brushing teeth to reduce dental caries; encourage optimal mouth care.
- Offer suggestions for specific changes in food preparation (e.g., adding moistening sauces, gravies, etc.) and cutting or mincing foods to increase control of the swallowing process.

- Encourage regular review of changes in swallowing abilities to identify early decline or to lessen restrictions when possible.
- Monitor for quality of life factors and adjust where possible.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# ESOPHAGEAL STRICTURE OR SPASM, ACHALASIA, OR ZENKER'S DIVERTICULUM

## NUTRITIONAL ACUITY RANKING: LEVEL 3, STRICTURE; LEVEL 2 ACHALASIA

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

**Esophageal stricture** is caused by injury or chemical ingestion (such as lye), sliding hiatal hernia, esophageal cancer, reflux esophagitis (RE), peptic ulcer disease, or prolonged use of an NG tube. Another cause is eosinophilic esophagitis, with solid food dysphagia on presentation. Scar tissue builds up and prevents normal swallowing.

In **esophageal spasm**, segmented, concentric contractions occur simultaneously in the lower two thirds of the esophagus. Barium and manometric studies are useful in the evaluation. Achalasia and diffuse esophageal spasm are associated with hypertrophy of circular and longitudinal muscle layers (Mittal et al, 2005). Chemical denervation with *Clostridium botulinum* toxin (Botox) is effective in relieving spasm.

**Achalasia** is failure of the cardiac sphincter to relax, with obstruction of food passage into the stomach. In addition, the esophagus does not demonstrate normal waves of contraction after swallowing. The mechanisms remain poorly understood (Kraichely and Farrugia, 2006; Sonnenberg, 2009). Esophageal dilatation or surgical myotomy is common. Laparoscopic procedures are preferred (Pastor et al, 2009).

**Zenker's diverticulum** (ZD, or pharyngeal pouch) generally presents after 60 years of age, but patients may have years of dysphagia symptoms. Regurgitation of undigested food when patient bends over or lies down may occur. Serious complications include aspiration and malnutrition (Ferreira et al, 2008). Diagnosis is by barium swallow, and treatment is open surgical diverticulectomy. Minimally invasive (endoscopic stapling) devices are often used. Oral feeding is usually possible the day after surgery as general anesthesia is not needed.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Achalasia is usually of idiopathic origin but may be secondary to cancer or mast cell disorders.

Esophageal stricture secondary to radiation treatment may show signs of altered interleukin or tumor necrosis factor (TNF).

Clinical/History		Lab Work
Height	Regurgitation, halitosis	Glucose (Gluc)
Weight	Heartburn or	Alb
Weight loss?	other specific	CRP
BMI	symptoms	Gastrin
Diet history	Endoscopy	H & H
Intake and output (I & O)	Esophageal manometry	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
Dysphagia	Esophagoscopy	Ca <sup>++</sup> , Mg <sup>++</sup>
Substernal pain after meals	Cineesophagography	
	BP	

## INTERVENTION

### OBJECTIVES

- **Esophageal stricture:** Avoid large boluses of food. Provide adequate nutrition. Prevent weight loss. Remove cause or dilate, if necessary.
- **Esophageal spasm:** Avoid either very cold or very hot foods or beverages. Monitor dysphagia.
- **Achalasia:** Individualize diet according to patient tolerances and preferences. Monitor chronic dysphagia. Avoid aspiration.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Dysphagia and Esophageal Stricture

**Assessment Data:** Weight loss, choking after swallowing, regurgitation, heartburn and chest pain after eating.

**Nutrition Diagnoses (PES):** Dysphagia related to altered GI function and esophageal stricture as evidenced by difficulty swallowing, abnormal barium swallow, and weight loss of 10 lb in last month.

**Interventions:** Education about blending foods and simplifying meal planning to increase intake. Swallowing evaluation for determination of appropriate textures and thickening of liquids. Counseling on positioning at mealtime; preparation for surgery

**Monitoring and Evaluation:** Improved intake of meals and snacks. Resolution of esophageal structure after surgery with no further weight loss.

## FOOD AND NUTRITION

- **Esophageal stricture:** Begin with liquid diet and progress to soft diet as tolerance increases. Adequate calories are needed. Gastrostomy may be needed. Antireflux regimen (no alcohol, weight loss) may be helpful. Avoid sticky and dry foods. Use thin liquids and pureed or soft foods.
- **Esophageal spasm:** Use diet as tolerated with modified temperatures for foods and beverages.
- **Achalasia:** Patients should take smaller bites of food, chew well, and eat slowly. Provide large volumes of fluids with each meal, unless dysphagia prevents appropriate swallowing of liquids. Tube feed if needed; may need to use gastrostomy TF.

### Common Drugs Used and Potential Side Effects

- Antacids: Check the label for aluminum, calcium, magnesium, or sodium if other medical problems exist. Beware of long-term side effects.
- Isosorbide dinitrate and calcium channel blockers such as nifedipine may be needed 30 minutes before meals.
- Nitroglycerin often helps spasm. Headache is one possible side effect.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Emphasize the importance of spacing meals and achieving relaxation. Recommend intake of food at moderate temperature only.
- Elevate head of bed for 30–45 minutes after meals and at bedtime.
- Encourage fluids at mealtimes.
- Avoid foods that aggravate dysphagia.
- Bland foods are not clearly beneficial and not required.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### DEFINITIONS AND BACKGROUND

Esophageal trauma is a major traumatic condition that affects the esophagus; it is often caused by chemical burns, ingestion of foreign bodies, or injury. Diagnosis of penetrating pharyngeal and esophageal injuries is difficult when the patient has severe facial injuries, is obese, intubated, or hemodynamically unstable (Ahmed et al, 2009).

**Boerhaave syndrome** involves complete laceration of the esophagus, sometimes spontaneously from alcohol abuse with retching or secondary to endoscopy or vagotomy. **Mallory–Weiss syndrome** involves a mucosal gastric tear that can occur at the gastroesophageal (GE) junction or proximal stomach; it is also associated with retching or alcohol abuse.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Esophageal trauma is acquired, not genetic.

<b>Clinical/History</b>	Respiratory distress	Na <sup>+</sup> , K <sup>+</sup>
Height	Esophageal perforation?	TLC
Weight	Dysphagia	H & H
BMI	Temperature	Serum Fe, ferritin, ferritin
Weight changes		Alb or transthyretin
Videoendoscopy		Transferrin
I & O	<b>Lab Work</b>	Ca <sup>++</sup> , Mg <sup>++</sup>
Nausea, vomiting	Gluc	
Loss of consciousness	BUN, creatinine (Creat)	

## INTERVENTION

### OBJECTIVES

- Emergency care, such as adequate ventilation, is given as needed.

- Allow the esophagus to rest and heal. Prepare for esophageal surgery if necessary.
- Keep the patient adequately hydrated.
- Improve swallowing capacity as rapidly as possible; prevent aspiration.
- Prevent malnutrition, weight loss, sepsis, constipation, fluid loss from exudates, and other complications.
- For serious injuries with permanent damage, it may be necessary for a gastrostomy TF to be used.

### FOOD AND NUTRITION

- Nothing by mouth (NPO) as needed. Provide CPN, gastrostomy, or jejunostomy feedings as appropriate for the patient's condition.
- Calculate needs with extra protein, if applicable. Monitor cardiac, hepatic, and renal status.
- Progress over time to a soft diet. Avoid alcoholic beverages, extremely hot liquids and beverages, caffeine, and spicy foods if not tolerated.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Unintentional Weight Loss

**Assessment:** Prior gunshot wound to the neck that required esophageal repair. Loss of 10 lb this year even though eating "a lot."

**Nutrition Diagnosis (PES):** Inability to digest/absorb nutrients (NC-1.4) related to surgical alteration in GI anatomical structure as evidenced by weight loss, albumin indicative of malnutrition.

**Interventions:** Food and Nutrient Delivery: ND 1.2—Alter diet as tolerated. ND 32.3 and 32.4—Initiate vitamin and mineral supplementation.

Education: E-1.2—Discuss ways to increase energy and nutrient density in food choices.

Counseling: C-2.3—Keep a food diary for 1 month. C-2.2—Set goal of only nutrient and energy-dense meals for 1 month if tolerated.

**Monitoring and Evaluation:** Review food diary after 1 month. Monitor weight for resolution of unintentional weight loss; goal is gain of 1–2 lb weekly.

- Provide adequate fluids but avoid overhydration.
- When able to eat orally, monitor for signs of dysphagia. Work with a speech therapist for proper consistency evaluations. Use appropriately thickened or thinned liquids and pureed foods until swallowing ability returns.
- Home TF may be needed, for which either a gastrostomy or jejunostomy will be used, depending on location and extent of injury and surgical repair.

### Common Drugs Used and Potential Side Effects

- Liquid topical anesthetizing agents (such as lidocaine) may be used before meals to reduce pain.
- Antibiotics may be used in bacterial infections.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- When the patient can swallow, discuss the need to chew well and swallow carefully. The patient should also learn to eat slowly to prevent aspiration.
- Discuss the appropriate food textures for different stages of progress. This plan will be developed in accordance with the speech therapist and the physician.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

### For More Information

- Esophageal trauma  
<http://emedicine.medscape.com/article/775165-overview>

### ESOPHAGEAL TRAUMA—CITED REFERENCES

Ahmed N, et al. Diagnosis of penetrating injuries of the pharynx and esophagus in the severely injured patient. *J Trauma*. 67:152, 2009.

## ESOPHAGEAL VARICES

### NUTRITIONAL ACUITY RANKING: LEVEL 2–3

### DEFINITIONS AND BACKGROUND

Acute bleeding from esophageal varices due to portal hypertension is a frequent and severe complication of liver cirrhosis (Lata et al, 2006). Esophageal varices occur in about half of all people with alcoholic cirrhosis and one third of these will experience variceal hemorrhage, a life-threatening event (Smith, 2010). Portal hypertension is defined as a portal pressure gradient exceeding 5 mm Hg where porto-systemic collaterals decompress the portal circulation and give rise to varices (Toubia and Sanyal, 2008). Small esophageal veins become distended and may rupture due to increased pressure in the portal system. Thrombocytopenia and splenomegaly are independent predictors of large esophageal varices.

All cirrhotic patients should undergo endoscopic screening to detect varices. Severe fibrosis and esophageal varices may be diagnosed through a prothrombin index of less than 60%, alkaline phosphatase activity greater than 110 IU/L, and hyaluronate greater than 100 g/L in alcoholic patients (Vanbiervliet et al, 2005). Maintenance of a good renal function is essential in these patients (Lata et al, 2006). Fortunately, great strides have been made because of noninvasive imaging and pressure measurement. Mortality has been substantially reduced. Band ligation is the first-line endoscopic treatment. If this fails, the more invasive surgical shunt may be needed.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Cirrhotic patients have an increased risk for thrombosis because of portal blood flow stasis; known risk factors include G20210 A mutation of prothrombin or factor V Leiden (Amitrano et al, 2007).

Clinical/History	Lab Work	
Height	Confusion	Transferrin
Weight	Abdominal distention,	Bilirubin
BMI	Jaundice or	(>20 mg/dL)
Diet history	hepatic coma	Platelet count
Weight changes		(<200,000/mm <sup>3</sup> )
Esophagoscopy		Prothrombin index
Edema	H & H	(<60%)
Melena	Serum Fe, ferritin	Hyaluronate
Upper GI bleeding	Ammonia (NH <sub>3</sub> )	(>100 g/L)
BP	BUN	Alkaline phosphatase
Respiratory distress	Alb (<4.0 g/dL)	(Alk phos)
Aspiration of emesis	Ascites	(>110 IU/L)
	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>	
	Ca <sup>++</sup> , Mg <sup>++</sup>	

## SAMPLE NUTRITION CARE PROCESS STEPS

**Excessive Alcohol Intake**

**Assessment:** Intake history revealing poor intake of nutrient-dense foods and frequent meal skipping with use of one fifth of rum daily for 12+ years. Lab results showing elevated ammonia level, blood in stool, low H & H with documented anemia.

**Nutrition Diagnoses (PES):** Excessive alcohol intake related to intake of rum instead of meals as evidenced by bleeding and varices, diet history, altered hepatic labs.

**Interventions:** Enhance oral intake, or offer PEG TF as needed. Remove access to alcohol and coordinate care for referral to rehabilitation center when feasible.

**Monitoring and Evaluation:** No rebleeding. Adequate intake from TF and slow progression back to oral diet. Improved intake of all macro- and micronutrients, and improvement in labs. Corrected anemia.

## INTERVENTION

## OBJECTIVES

- Promote healing and recovery.
- Prevent variceal rebleeding, which is a very frequent and severe complication in cirrhotic patients (Kravetz, 2007).
- Avoid constipation or straining with stool.
- Prevent or correct hepatic encephalopathy or coma; see Section 8.

## FOOD AND NUTRITION

- Generally, unless comatose, the patient can tolerate five to six small meals of soft foods. Avoid foods such as tacos, tortilla chips, or large pieces of raw fruits and vegetables.
- Alter carbohydrate, protein, and fat intake according to hepatic function and state of consciousness. Monitor micronutrient needs, such as iron if patient is anemic.
- Provide adequate fluid as allowed or controlled.
- To prevent constipation and straining, use foods such as prune juice or formulas with added fiber.
- Consider use of branched-chain amino acid formula for cirrhosis.

## Common Drugs Used and Potential Side Effects

- Antacids may be beneficial to buffer gastric acidity. Extended use can cause problems with pH, altered mineral and nutrient use, and other imbalances.

- Beta-blockers; propranolol reduces the risk of bleeding, especially in cirrhosis (Suzuki et al, 2005). However, the combination of beta-blockers with mononitrate of isosorbide is superior to beta-blockade alone (Kravetz, 2007).
- Vasoactive agents, such as somatostatin analog and terlipressin, are useful.
- Vitamin K may be needed to help with clotting.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The importance of good nutrition with proper consistency should be addressed. Avoid rough or crunchy foods that are fibrous or sharp; chew all foods well before swallowing.
- If gastrostomy is needed, discuss how to manage the process.
- If relevant, discuss the role of alcohol in contributing to the disease process with the patient and family. Advise the patient to avoid mouthwashes, cough syrups, and other products that contain alcohol.

## Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# ESOPHAGITIS, GASTROESOPHAGEAL REFLUX DISEASE AND HIATAL HERNIA

NUTRITIONAL ACUITY RANKING: LEVEL 2–3

Asset provided by Anatomical Chart Co.

## DEFINITIONS AND BACKGROUND

**Esophagitis** results from gastric juice being forced into the esophagus from the stomach. Pill-induced esophageal injury may occur from use of aspirin, tetracycline, vitamin C, ferrous sulfate, potassium chloride, or nonsteroidal anti-inflammatory drugs (NSAIDs). Take these with plenty of liquid.

**Eosinophilic esophagitis (EoE or EE)** is a disorder characterized by a severe, isolated eosinophilic infiltration of the esophagus that is unresponsive to aggressive acid blockade but responsive to the removal of dietary antigens (Liacouras et al, 2005). Adult patients usually present with dysphagia, food impaction and reflux-like symptoms (Gupte and Draganov, 2009). Known causes of tissue eosinophilia include GE reflux disease (GERD), infections, malignancy, collagen vascular diseases, hypersensitivity, and IBD (Gupte and Draganov, 2009). It is highly associated with atopic disease.

**Barrett's esophagus** is a condition that affects men more than women, and length of impact is greater in men than in women (Falk et al, 2005). It is also more common in Caucasians and in persons older than age 50. Symptoms are similar to GERD, but Barrett's esophagus is more likely to precede esophageal adenocarcinoma. Upper endoscopy and surveillance biopsies may be needed (Liu and Saltzman, 2006). Antioxidants (vitamins C, E, and beta-carotene) are important protective factors (Kubo et al, 2008), whereas obesity and the western diet may be promoters of cancer.

**GERD** and peptic ulcer disease are common in elderly individuals. GERD affects approximately 19 million Americans; prevalence is as high as 80% among asthma patients. There is a significantly higher prevalence of RE in an *Helicobacter pylori*-infected individuals of any age or sex (Moon et al, 2009). Distal esophageal cancer is associated with symptomatic GI reflux disease and Barrett's esophagus; surveillance programs are identifying patients early for curable esophageal adenocarcinoma (Demeester, 2006).

GERD may occur in infants but usually resolves by 6–12 months of age. Management involves thickened feedings and positioning. The recommended approach for infants with uncomplicated regurgitation is the reassurance of the parents about the physiological nature of excessive regurgitation and dietary recommendations for formula feeding. Symptoms of pediatric GERD include colic, inconsolable crying, frequent spitting up or vomiting, food refusal, failure to thrive, heartburn, stomach pains, chronic sore throat, chronic respiratory problems, asthma, and apnea. GERD diagnosis in older children warrants review for upper GI tract disorders, cow's milk allergy, or metabolic, infectious, renal, or central nervous system diseases.

Treatment guidelines address lifestyle changes, patient-directed (over the counter) therapy, acid suppression, pro-motility therapy, maintenance therapy, and antireflux surgery (DeVault and Castell, 2005). Intractable GERD may require minor surgery to strengthen a weak sphincter. Laparoscopic antireflux surgery is highly effective as a long-term treatment for severe GERD.

**Hiatal hernia** is caused by protrusion of part of the stomach through the diaphragm muscle, which separates the chest from the abdomen. This causes an enlarged diaphragm opening (hiatus) through which the esophagus passes to join the stomach. An increase in BMI is associated with the increased prevalence of hiatal hernia, esophageal mucosal injury, and complications because of increased intragastric pressure and increased GE pressure gradient (Fass, 2008). Hiatal hernia may show no symptoms or may contribute to heartburn, swallowing difficulty, reflux, or vomiting. Hiatal hernia surgery has evolved from anatomic repair to physiological restoration (Stylopoulos and Rattner, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Proton pump inhibitors (PPIs), such as omeprazole, lansoprazole, and rabeprazole are metabolized by CYP2C19 in the liver; there are genetic differences in the activity of this enzyme (Furuta et al, 2010). These genotypic differences influence the healing and eradication rates for GERD and *H. pylori* infection (Furuta et al, 2010). The pathogenesis of EE involves multiple tissues, cell types, and genes, and derives from complex genetic and environmental factors (Blanchard and Rothenberg, 2008).

Clinical/History	Reactive airway disease or nocturnal asthma	<i>H. pylori</i> infection?
Height		Cholesterol (Chol)
Weight		Triglycerides (Trig)
BMI	Choking attacks	Transferrin
Diet history	Dental erosion or caries	Total iron-binding capacity (TIBC)
Weight changes		Bernstein test:
Upper GI endoscopy	<b>Lab Work</b>	HCl solution is dripped into the distal esophagus; positive test mimics patient symptoms
Esophagoscopy	H & H	
PillCAM (noninvasive visualization)	Mean cell volume (MCV)	
Manometry	Na <sup>+</sup> , K <sup>+</sup>	
Feeding difficulties in children	Ca <sup>++</sup> , Mg <sup>++</sup>	
Recurrent vomiting	Gluc	
	Gastrin	
	Alb, transthyretin	
	CRP	

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Gastroesophageal Reflux Disease (GERD)

**Assessment:** Knowledge about the role of diet in GERD; food diary; timing of meals and related symptoms. Use of antacids with every meal and at bedtime.

**Nutrition Diagnosis (PES):** Undesirable food choices related to lack of knowledge regarding role of diet in GERD symptoms and complications as evidenced by frequent consumption of large, high-fat meals and alcoholic beverages.

**Intervention:** Teach about dietary changes that will alleviate GERD symptoms and possibly prevent complications. Counsel about lifestyle changes, such as weight loss, loose clothing, and upright posture during and after eating.

**Monitoring and Evaluation:** Report of relief from symptoms. No complications from GERD. Gradual reduction in need for antacids and medication.

## INTERVENTION

### OBJECTIVES

- In stage 1, simple lifestyle modifications may be successful: elevate head of the bed, decrease fat intake, stop smoking, lose excess weight, avoid eating large meals, and do not eat 3 hours before lying down. Large meals increase gastric pressure and alter pressure on the lower esophageal sphincter (LES), thereby allowing reflux or aspiration to occur. Avoid tightly fitted garments around the abdomen.
- In stage 2, add pharmacological treatments, such as histamine-receptor blockers or antacids.
- In stage 3 with erosive esophagitis, it may be necessary to add a PPI as first-line therapy.
- In stage 4, maintenance therapy, use the lowest possible dose of medications to manage symptoms.
- In severe stage 5, surgery may be needed. This may include laparoscopic Nissan fundoplication.

### FOOD AND NUTRITION

- Provide an individual diet reflecting patient needs. Assess intake of fat, alcohol, spices, and caffeine.
- If needed, a reduced-energy diet should be used to promote weight loss.
- During acute episodes, provide small, frequent feedings of soft foods.
- Diet should be high in protein to stimulate gastrin secretion and to increase LES pressure. Avoid foods that decrease LES pressure, including chocolate, peppermint, onions, garlic, and spearmint.
- Use fewer fried foods, cream sauces, gravies, fatty meats, pastries, nuts, potato chips, butter, and margarine.
- Dietary fiber and physical exercise may be protective. Increased fiber intake benefits a number of GI disorders including GERD (Anderson et al, 2009). Dietary fiber intakes for children and adults should be calculated as 14 g/1000 kcal.
- Avoid foods that may irritate the esophagus, such as citrus juices, tomatoes, and tomato sauce. Other spicy foods are to be eliminated according to individual experience.
- If there is EoE, try a dietary elimination diet and add back foods one at a time to identify potential allergens (Liacouras et al, 2005).
- Fluids can be taken between meals to reduce abdominal distention and discomfort.
- Preterm infants may benefit from transpyloric feedings if they show signs suggestive of reflux and apnea (Malcolm et al, 2009).

### Common Drugs Used and Potential Side Effects

- Antacids neutralize gastric contents. They destroy thiamin and may provide excess sodium for the body; check labels carefully. If the antacid contains calcium (e.g., Tums, which contains calcium carbonate), excess calcium may decrease levels of magnesium and phosphorus. Aluminum hydroxide (Maalox) depletes phosphorus, which is acceptable for patients with certain types of renal diseases, but otherwise this is not desirable for the long term. When

used as an antacid, sodium bicarbonate can decrease iron absorption and causes sodium retention; use with caution.

- Calcium glycerophosphate (Prelief) is somewhat useful for relief of heartburn by neutralizing the acid in foods; it is available over the counter.
- PPIs, such as lansoprazole (Prevacid), omeprazole (Prilosec), and esomeprazole (Nexium) are popular treatments. When clarithromycin-resistant *H. pylori* (CRHP) occur, PPIs tend to inhibit the growth and motility of CRHP. Omeprazole is useful for refractory RE. Because CYP2C19 genotypes affect the recurrence rate of GERD symptoms during PPI maintenance therapy, genotype-based tailored therapy is needed (Furuta et al, 2010; Saitoh et al, 2009).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Chamomile, fennel, cardamom, cinnamon, dill, and licorice have been recommended for this condition, but no clinical trials have proven efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage the patient to avoid late evening meals and snacks and to avoid lying down or sleeping or swimming soon after a meal to guard against reflux.
- Teach the proper measures for controlling weight, including small, frequent feedings.
- Instruct the patient about lifestyle modifications listed in the Objectives. Patients with heartburn probably should not sleep in a waterbed.
- Chewing sugarless gum after meals may reduce reflux somewhat because of the saliva production.
- More effective communication and consumer education is required to enhance fiber consumption from foods or supplements (Anderson et al, 2009).

## Patient Education—Foodborne Illness

- Careful food handling and washing hands before eating are useful recommendations.

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## STOMACH

# DYSPEPSIA/INDIGESTION OR BEZOAR FORMATION

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

## DEFINITIONS AND BACKGROUND

Indigestion (dyspepsia) may be secondary to other systemic disorders such as atherosclerotic heart disease, hypertension, liver disease, or renal disease. It may have psychogenic causes as well, such as during periods of anxiety. Symptoms may be graded from mild to severe for the individual patient. Gastric hypersensitivity is an important factor.

In rare cases, a patient may exhibit signs of **bezoar formation**, such as after gastric surgery or chronic use of medications that do not dissolve easily for that individual. A bezoar (foreign matter accumulation) may be made of plant material, medications, or swallowed foreign objects. The patient complains of vague abdominal pain or indigestion and may experience nausea or vomiting. An x-ray of the GI tract may be useful for a clarifying diagnosis.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Genetic factors in indigestion would be related to the primary disorder.

Clinical/History		Lab Work
Height	Anorexia	Gluc
Weight	Nausea or vomiting	<i>H. pylori</i>
Weight changes	Epigastric pain or burning	infection
BMI	Postprandial fullness, early satiation	H & H
Diet history	Gastric burning sensation	Serum Fe, ferritin
Bloating, heartburn, nausea	Gastric barostat tests	MCV
Burping, vomiting	Endoscopy	Alb, transthyretin
Early satiety, postprandial fullness	I & O	CRP
	Bezoar formation?	BUN, Creat
		Na <sup>+</sup> , K <sup>+</sup>
		Ca <sup>++</sup> , Mg <sup>++</sup>

## INTERVENTION

### OBJECTIVES

- Determine whether the problem is psychogenic or organic in etiology. Do not oversimplify the patient's discomfort.
- If the patient has a bezoar, alter food and beverage consistencies.
- If the patient has irritable bowel or other GI condition, work closely with the medical team to manage dietary changes and reduce excessive use of medications.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Dyspepsia

**Assessment Data:** Weight, BMI; recent GI surgery for extensive peptic ulcer disease; positive hx of *H. pylori* infection; heartburn with every meal and complaints of indigestion.

**Nutrition Diagnoses (PES):** Inadequate oral food and beverage intake related to frequent bouts of indigestion after GI surgery as evidenced by unplanned weight loss, reports of heartburn and indigestion with meals.

**Interventions:** Alter foods served to decrease use of acidic foods or stimulants such as caffeine and alcoholic beverages. Educate about simplifying meals and small snacks to increase intake. Counseling on food choices and lifestyle changes to improve intake and decrease discomfort.

**Monitoring and Evaluation:** Improved intake for meals and snacks. Fewer complaints of dyspepsia. No further weight loss. Reduced need for use of antacids for heartburn.

## FOOD AND NUTRITION

- Diet should make use of well-cooked foods that are adequate in amount but not overly seasoned.
- Evaluate for any undetected food allergies and manage accordingly.
- A relaxed atmosphere is helpful, and small meals may be better tolerated.
- If the dyspepsia is organic in etiology, a soft, low-fat diet may be helpful.
- If there is irritable bowel as well, discuss fiber from fruits and vegetables (American Dietetic Association, 2008). Bran is not always well tolerated.
- If the patient has an obstruction or bezoar, a liquid diet may be useful until resolved.

### Common Drugs Used and Potential Side Effects

- Antacids: Beware of nutritional side effects resulting from chronic use or dependency.
- Antisecretory drugs are useful (Suzuki et al, 2006). PPIs may be used, especially if reflux also exists. Lansoprazole (Prevacid), omeprazole (Prilosec), and esomeprazole (Nexium) are commonly used.
- NSAIDs are nonselective cyclooxygenase-1 (COX-1) and COX-2 inhibitors and may be associated with dyspepsia. Other anti-inflammatory medicines such as ibuprofen, aspirin, and naproxen (Aleve) can irritate the stomach. Acetaminophen (Tylenol) is a better choice for pain.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Ginger is often used as an antiemetic. Do not use large doses with warfarin, aspirin, other antiplatelet drugs, antihypertensive drugs, and hypoglycemic drugs. Additive effects can cause unpredictable changes in BP and decreases in blood glucose levels and may decrease platelet aggregation and thus increase bleeding. Ginger ale has few side effects.
- Chamomile, peppermint, red pepper, angelica, and coriander have been recommended, but no clinical trials have proven efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage the patient to eat in a relaxed atmosphere.
- Yoga and other stress-relieving lifestyle changes may be beneficial.
- Discuss the role of fiber in maintaining bowel regularity.
- Discuss tips for preparing meals that are lower in acid, stimulants, or other irritants.

**Patient Education—Food Safety**

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the diet of the individual. Preparation and storage techniques are also essential.
- If home TF is needed, teach appropriate sanitation and food handling procedures.

**For More Information**

# GASTRECTOMY AND VAGOTOMY

**NUTRITIONAL ACUITY RANKING: LEVEL 3–4**

Adapted from: Nettina, Sandra M., MSN, RN, CS, ANP, *The Lippincott Manual of Nursing Practice*, 7th ed. Lippincott, Williams & Wilkins, 2001.

**DEFINITIONS AND BACKGROUND**

**Gastrectomy** and **vagotomy** are surgical procedures that are used for gastric cancer, when medical management for peptic ulcer has failed, or for perforation. The frequency with which elective gastric surgeries are performed has decreased in the past 20 years as drugs have become increasingly effective in treating ulcers. Laparoscopic-assisted gastrectomy is an increasingly common procedure for gastric cancer, with fewer side effects (Mochiki et al, 2005).

Billroth I (gastroduodenostomy) is an anastomosis between the stomach and duodenum after removal of the distal portion of the stomach. Billroth II (gastrojejunostomy) is an anastomosis between the stomach and jejunum after removal of two thirds to three fourths of the stomach; iron loss can occur. While the Billroth I and Billroth II operations have been used for reconstruction after a distal gastrectomy for gastric cancer, a Roux-en-Y reconstruction is increasingly performed to prevent duodenogastric reflux (Hoya et al, 2009).

Vagotomy is a procedure in which the vagus nerve is cut to reduce pain; much less nutritional intervention is required. Gastrectomy or vagotomy may lead to reactive hypoglycemia, which may drop plasma glucose levels to as low as 30–40 mg/dL due to rapid digestion and absorption of food, especially carbohydrates. Gastric emptying rate for solids may increase in some patients. In most of them, however, there is a normal to decreased emptying rate.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Gastrectomy and vagotomy are surgical procedures. Any genetic relationships would be from the original problem.

Clinical/History	Lab Work	
Height	H & H	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
Weight	Serum Fe, ferritin	Blood guaiac
BMI		Urine acetone
Diet history	Gluc	White blood cell (WBC) count
BP	Glucose	BUN
Temperature, fever	tolerance test (GTT)	Alb,
Electrogastrogram (EGG)	Chol, Trig	transthyretin
Dual-energy x-ray absorptiometry (DEXA) scan	Pro-time (PT) or International Normalized Ratio (INR)	Serum amylase
		Serum B <sub>12</sub>
		Ca <sup>++</sup> , Mg <sup>++</sup>
		Serum folate
		TIBC

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inconsistent Carbohydrate Intake

**Assessment Data:** Weight loss, frequent emesis after meals, irregular blood glucose levels with reactive hypoglycemia several times weekly.

**Nutrition Diagnoses (PES):** Inconsistent carbohydrate intake related to lack of knowledge about nutrition after gastrectomy as evidenced by weight loss, complaints of profuse sweating, diarrhea, and vomiting after meals high in carbohydrate, and blood glucose levels that vary with bouts of reactive hypoglycemia.

**Interventions:** (ND-1) Order diet that is low fat, high protein, no concentrated sweets (NCS). Educate about foods that are high in simple carbohydrate and those that are complex. Counsel on eating slowly and drinking beverages between meals.

**Monitoring and Evaluation:** Improved intake for meals and snacks; fewer complaints of dumping syndrome. No further weight loss.

## INTERVENTION

### OBJECTIVES

#### Preoperative

- Empty the stomach and upper intestines.
- Ensure high-calorie intake for glycogen stores and weight maintenance or weight gain if needed. Ensure adequate nutrient storage to promote postoperative wound healing.
- Maintain normal fluid and electrolyte balance.

#### Postoperative

- Prevent distention and pain. Reduce the likelihood of the dumping syndrome: nausea, vomiting, abdominal distention, diarrhea, malaise, profuse sweating, hypoglycemia, hypotension, increased bowel sounds, and vertigo. Additional use of soy and fermentable fiber may be useful; liquid pectin may prolong gastric emptying time and reduce the onset of dumping.
- Compensate for loss of storage/holding space and lessen dumping of large amounts of chyme into the duodenum/jejunum at one time. Overcome effects of decreased hormonal output (secretin, pancreaticozymin, and cholecystokinin).
- Overcome negative nitrogen balance after surgery; restore healthy nutritional status.
- Prevent or correct iron malabsorption; steatorrhea, calcium malabsorption, and vitamin B<sub>12</sub> or folacin anemias.
- Prevent or treat metabolic bone disease, which can occur over time.
- Prevent or treat problems such as bezoars, gastric stasis, or gastroparesis.

### FOOD AND NUTRITION

#### Preoperative

- Use a soft diet that is high in calories with adequate protein and vitamins C and K.
- Regress to soft diet with full liquids and then NPO about 8 hours before surgery.

#### Postoperative

- Within a total quantity limit, intake of complex carbohydrates such as bread, rice, and vegetables should be liberal (50–60%). To lessen the hyperosmolar load, use only 0–15% of diet from foods made with sucrose, fructose, and glucose. Initial diet may need to be 20 mL of liquid nutritional supplement every few hours, progressing as tolerated. Gastrectomy patients will be limited by the size of the remaining stomach as well.
- A protein-rich food should be consumed with each meal. Include eggs, cheese, dried beans or peas, tender meat or poultry, boneless fish, yogurt, peanut butter, nuts, tofu, and cottage cheese.
- Lactose intolerance is common in patients with these conditions; use less milk or omit if needed. Monitor calcium intake carefully.
- Use a moderate fat intake (about one third of energy intake). If needed, medium-chain triglycerides (MCTs) may be beneficial with fat maldigestion, and pancreatic enzymes may also be needed in some cases.

- The diet should also provide adequate chromium, vitamin B<sub>12</sub>, riboflavin, iron, folacin, calcium, and vitamin D. A liquid multivitamin–mineral supplement may be needed.
- If weight loss becomes a problem, a liquid supplemental beverage may be useful between meals and can be sipped throughout the day and evening.
- Diet should provide a moderate sodium intake; excess salt draws fluid into the duodenum. If there is diarrhea, losses of sodium in the stool may occur.
- Fluids should be taken 1 hour before or after meals, rather than with meals; assure adequate fluid intake overall.
- Sit upright while eating. Encourage slow eating and adequate chewing for all meals and snacks.
- Diet should provide frequent, small meals. Avoid extremes in food temperature.

### Common Drugs Used and Potential Side Effects

- Antibiotics may be used to control bacterial overgrowth.
- Antidiarrheals such as Kaopectate and loperamide may be useful. Dry mouth, nausea, vomiting, and bloating may occur. Use plenty of fluids.
- For reactive hypoglycemia, use of an alpha-glucosidase inhibitor, acarbose, may be beneficial. GI side effects are common.
- Pancreatic enzymes may be useful; the usual dose provides two to three capsules with meals.
- If vitamin B<sub>12</sub> deficiency occurs, shots may be needed.
- If bone density loss occurs, the use of calcium, vitamin D, or bisphosphonates may be prescribed, and these should be taken as directed.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Stress the importance of self-care and optimal functioning—what to do for illness, episodes of vomiting, eating away from home, and how to read labels for carbohydrate (CHO) content.
- Discuss the use of artificial sweeteners.
- Instruct the patient to eat slowly in an upright position and to remain upright for awhile after meals.
- Help the patient to overcome reluctance and the fear of eating. Discuss the dumping syndrome and its effects on nutrient absorption if untreated.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## GASTRITIS AND GASTROENTERITIS

### NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

**Gastritis** involves inflammation of the stomach. Types of gastritis include bacterial (from *H. pylori*), autoimmune gastritis with pernicious anemia, erosive gastritis (from aspirin or NSAID use), alcohol-induced gastritis, bile reflux gastritis, or atrophic gastritis. The treatment of gastritis will depend on its cause; reduction of stomach acid by medication is often most helpful.

*Helicobacter pylori* infects half the world's population, causing **chronic gastritis** (Shanks and El-Omar, 2009). Bacterial, environmental and host genetic factors combine to define the degree of gastric damage in gastritis (Shanks and El-Omar, 2009). **Hemorrhagic gastritis** may result from chronic intake of alcohol or medications, Crohn's disease or HIV

infection. **Atrophic gastritis** is chronic inflammation of the gastric mucosa without erosion but with hypochlorhydria or achlorhydria; it is important to monitor vitamin B<sub>12</sub>, calcium, and ferric iron intake.

**Gastroenteritis (GE)** is an inflammation of the stomach and intestinal lining that may occur from eating chemical toxins in food (such as seafood, mushrooms, arsenic, or lead), drinking excessive alcohol, foodborne illness and viruses, cathartics or other drugs. GE produces malaise, nausea, vomiting, intestinal rumbles, diarrhea with or without blood and mucus, fever and prostration.

Viral gastroenteritis is contagious. Many different viruses can cause gastroenteritis, including rotaviruses or adenoviruses. Norovirus infection is associated with 90% of nonbacterial acute gastroenteritis (Sala et al, 2005).

Contaminated shellfish and raw oysters are major contributors. People who get viral gastroenteritis almost always recover completely if they consume adequate fluids to replace what they lose through vomiting or diarrhea.

Because the intestinal epithelium constitutes the largest and most important barrier against intraluminal toxins, antigens, and enteric flora, its dysfunction is a major factor contributing to the predisposition to inflammatory diseases (Groschwitz and Hogan, 2009). Post-infectious irritable bowel syndrome (PI-IBS) is a disorder where symptoms begin after an episode of acute GE with persistent subclinical inflammation, changes in intestinal permeability and alteration of gut flora (Thabane and Marshall, 2009). Some children acquire functional GI disorders after an episode of acute bacterial gastroenteritis (AGE) from *Salmonella* (54%), *Campylobacter*, or *Shigella* (Saps et al, 2008). Other issues related to intestinal dysfunction include food allergy, IBD, and celiac disease (Groschwitz and Hogan, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Gastroenteritis is acquired and not genetic. Host genetic factors define the severity and extent of *Helicobacter*-induced gastritis; interleukin-1 and TNF- $\alpha$  gene clusters are involved (Shanks and El-Omar, 2009).

Clinical/History	Barium swallow study	MCV
Height	Upper GI endoscopy	Serum folate
Weight	Gastric biopsy	Serum B <sub>12</sub>
BMI	Diarrhea	Gluc
Diet history	Stool culture	Alb,
Anorexia, nausea	Blood in stool?	transferrin
Upset stomach		Ca <sup>++</sup> , Mg <sup>++</sup>
Hiccups		Hydrogen
I & O		breath test
Signs of dehydration?	<b>Lab Work</b>	BUN, creatinine
Fever?	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>	
Esophageal manometry	H & H	
	Serum Fe, ferritin	

## INTERVENTION

### OBJECTIVES

- Prevent or correct dehydration, shock, hypokalemia, and hyponatremia.
- If hemorrhage occurs, consider a medical emergency.
- Allow the stomach and GI tract to rest. Empty stomach to permit mucous lining to heal.
- Omit lactose if not tolerated during bouts of gastroenteritis.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Abnormal GI Function—Diarrhea

**Assessment Data:** Diarrhea, GI pain, slight fever; recent intake of undercooked beef and sushi while traveling.

**Nutrition Diagnoses (PES):** Altered GI function (NC-1.4) with foodborne illness as evidenced by diarrhea, slight fever (100°F) for 7 days and stool culture positive for *Escherichia coli* O157:H7.

**Interventions:** Alter diet as tolerated; soft diet or liquids may be accepted. Provide oral rehydration products. Educate about foodborne illness related to *E. coli* O157:H7 including food sources. Counseling about safe food-handling procedures and better choices at restaurants while traveling.

**Monitoring and Evaluation:** Resolution of diarrhea. Stool cultures free from *E. coli* O157:H7. Improved knowledge about food safety as documented by correct responses to questions.

## FOOD AND NUTRITION

- **Gastritis:** Omit foods that are poorly tolerated. Provide adequate hydration. If chronic, mucosal atrophy can lead to nutritional deficits (e.g., pernicious anemia, achlorhydria). Alter diet accordingly.
- **Acute gastroenteritis:** Patient will be NPO or on partial parenteral nutrition (PPN) for the first 24–48 hours to rest stomach. Use crushed ice to relieve thirst. Oral rehydration therapy may be useful. Progress to a soft diet, if desired. Alcohol is prohibited. Omit lactose if needed. Gradually add fiber-containing foods as tolerance improves. Rehydration solutions may be effective.
- **Chronic gastritis:** Use small, frequent feedings of easily tolerated foods. Progress with larger amounts and greater variety of foods, as tolerated. Restrict fat intake, which depresses food motility, and alcohol intake. Monitor lactose intolerance. Add fiber-containing foods as tolerated.

## Common Drugs Used and Potential Side Effects

- Antacids: Watch for constipation caused by aluminum and calcium agents. Watch for diarrhea caused by magnesium agents.
- Antibiotics are used for infection. If used in excess over a long period of time, they may cause or aggravate gastroenteritis. Monitor carefully and suggest use of probiotics such as yogurt with live and active cultures.
- Sucralfate may be useful. Take separately from calcium or magnesium supplements by 30 minutes. Constipation may occur.
- Early postoperative medication with a PPI is effective in preventing gastritis after open-heart surgery (Hata et al, 2005). Lansoprazole (Prevacid), omeprazole (Prilosec), and esomeprazole (Nexium) are commonly used.
- Eliminate use of aspirin and other agents that may aggravate gastritis.
- If the gastritis is caused by pernicious anemia, B<sub>12</sub> vitamin shots will be given.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. Products such as ginger and ginger ale may alleviate some nausea.
- The Polynesian traditional food, poi, is a starchy paste made from taro plants (Brown et al, 2005). It may be useful as a probiotic.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Omit offenders in chronic conditions: alcohol, caffeine, and aspirin.
- Patients with chronic gastritis should be assessed for folate and vitamin B<sub>12</sub> status. Atrophy of the stomach and intestinal lining interferes with folate and vitamin B<sub>12</sub> absorption.
- Discuss calcium and riboflavin food sources if dairy products must be omitted.
- Discuss the role of fiber in achieving or maintaining bowel integrity.
- Discuss foodborne illness and its prevention (e.g., avoiding raw shellfish).
- Oral rehydration therapy (ORT) is recommended as first-line therapy for both mildly and moderately dehydrated children with gastroenteritis (Spandorfer et al, 2005).

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

- Careful food handling will be important. To prevent gastroenteritis, cook all foods to proper temperatures; wash all produce before cutting or eating; use careful hand washing.

# GASTROPARESIS AND GASTRIC RETENTION

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

Etiologies of Gastroparesis

## DEFINITIONS AND BACKGROUND

Phases of normal digestion include: phase I (45–60 minutes of inactivity), phase II (30–45 minutes of intermittent peristaltic contractions), phase III (10 minutes of intense, regular contractions), and phase IV (brief transition between cycles). **Gastric retention** is caused by a partial obstruction at the outlet of the stomach into the small bowel. Gastric retention may result from diabetes, prolonged hyperglycemia, vagal autonomic neuropathy, scleroderma, Parkinson's disease, hypothyroidism, postviral syndromes, gastric surgery, or vascular insufficiencies.

**Gastroparesis** is a chronic disorder of gastric motility that is characterized by delayed emptying of either solids or liquids from the stomach in the absence of any mechanical obstruction; diabetes mellitus and postsurgical states cause the majority of these problems. Complications include ketoacidosis, infection, and bezoar formation (Feigenbaum, 2006). Bezoars further obstruct the flow from the stomach to the small intestine. Gastroparesis may occur as a

complication of end-stage liver disease and portal hypertension. Idiopathic gastroparesis is characterized by severely delayed gastric emptying of solids without obvious underlying organic cause (Karamanolis et al, 2007).

Because ghrelin is produced by enteroendocrine cells in the gastric mucosa, vagal function and regulation of ghrelin are impaired in gastroparesis (Gaddipati et al, 2006; Levin et al, 2006). Severe gastroparesis can result in recurrent hospitalizations, malnutrition, and even death (McKenna et al, 2008).

Gastroparesis can be difficult to treat. Prokinetic drugs are commonly used. Treatment may involve use of an implantable gastric electrical stimulation (GES) device or endoscopic botulinum toxin injection (Gumaste and Baum, 2008; Monnikes and van der Voort, 2006; Vittal and Pasricha, 2006). The surgical procedure has been found to be effective in reducing symptoms within 6 weeks (McKenna et al, 2008).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** No specific genetic disorder predicts the onset of gastric retention or gastroparesis.

<b>Clinical/History</b>	Flatulence	H & H
Height	Early satiety	BUN, Creat
Weight	Gastric x-rays–	Alb,
Weight changes	EGG	transferrin
BMI	Gastric emptying	CRP
Diet history	test (slow	Gastrin
I & O	emptying of	Ghrelin levels
Nausea,	liquids	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
vomiting	and/or solids)	Ca <sup>++</sup> , Mg <sup>++</sup>
Abdominal pain	<b>Lab Work</b>	Serum folate
after eating		and B <sub>12</sub>
Heartburn	Gluc (poorly con-	
Belching,	trolled, over	
bloating	200 mg/dL?)	

## INTERVENTION

### OBJECTIVES

- Decrease volume of meals served. Use liquids or foods that liquefy at body temperature so they are able to pass by a partial obstruction before or during digestion. Bypass or correct obstruction or other causes of retention.
- If diabetes is present, manage control of blood glucose. Differentiate from ketoacidosis, which has similar symptoms of nausea and vomiting. Pernicious vomiting may occur; distinguish from bulimia.
- Correct dehydration and electrolyte abnormalities.
- Reduce or control pain, diarrhea, or bouts of constipation.
- Ensure adequate intake of diet as prescribed to prevent weight loss and control malnutrition.
- Prevent or correct bezoar formation of indigestible solids.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Phytobezoar

**Assessment Data:** Weight loss. Abdominal pain. Swallowing evaluation showing gastroparesis and GI obstruction from phytobezoar.

**Nutrition Diagnoses (PES):** Altered GI function (NC-1.4) related to phytobezoar as evidenced by delayed gastric emptying, abdominal pain and vomiting, and labs showing glucose levels of 250–300 mg/dL.

**Interventions:** Food and Nutrient Delivery: Use a liquid, low residue diet until bezoar is resolved. Educate: Blending foods to improve intake. Coordinate care: insulin as needed to improve serum glucose control; try doses of coca cola to dissolve phytobezoar.

**Monitoring and Evaluation:** Improved intake for meals and snacks. Improved glucose management. No further abdominal pain or vomiting. Resolution of phytobezoar.

- Monitor use of, or avoid where possible, medications that cause gastric stasis.

## FOOD AND NUTRITION

- A soft-to-liquid diet lower in fat may be useful to prevent delay in gastric emptying. Isotonic liquids empty more quickly than hypertonic liquids.
- Six small meals may be better tolerated than large meals.
- Calculate protein and energy requirements according to underlying medical condition(s).
- Alter fiber intake according to needs (more to alleviate diarrhea, constipation; less with a history of bezoar formation).
- If patient complains of dry mouth, add extra fluids and moisten foods with broth or allowed sauces or gravies.
- For patients with a lesser obstruction of the stomach, progress to a mechanical soft diet.
- For patients with greater obstruction of the stomach, use a low-fiber diet or tube feed, checking residuals frequently.
- A jejunostomy TF may be indicated for persistent problems, even temporarily if needed to correct malnutrition. Consider if there is a history of significant weight loss, cyclical nausea and vomiting, or repeated hospitalizations for gastroparesis.
- Ensure that the patient sits upright during meals.

## Common Drugs Used and Potential Side Effects

- Medications that may cause or aggravate gastric emptying include: alcohol, antacids containing aluminum, anticholinergics, calcitonin, calcium channel blockers, glucagon, interleukin-1, levodopa, lithium, octreotide, narcotics, nicotine, potassium salts, progesterone, sucralfate, tricyclic antidepressants, selective serotonin reuptake inhibitors (SSRIs) including Celexa, Paxil, Prozac, and Zoloft.
- Dopamine antagonists, such as metoclopramide and domperidone, and the motilin receptor agonist erythromycin have been the cornerstones in drug treatment of severe gastroparesis for more than a decade (Abrahamsson, 2007).

These drugs are less than ideal (Gumaste and Baum, 2008). Give metoclopramide (Reglan) 30 minutes before meals to increase gastric contractions and to relax the pyloric sphincter. Dry mouth, sleepiness, anxiety, and nausea can be side effects.

- If there is hyperglycemia, oral agents or insulin may be needed.
- Ghrelin receptor agonists may have a role as prokinetic agents (Levin et al, 2006).

### Herbs, Botanicals, and Supplements

- Products such as ginger and ginger ale may alleviate some nausea. Use of herbal remedies is common in the Hispanic population. Herbs and botanical supplements should not be used without discussing with the physician.
- *Cuminum cyminum* is widely used in Ayurvedic medicine for the treatment of dyspepsia.
- Adolph's Meat Tenderizer (1 teaspoonful in 8 oz of water before each meal for 7 days) provides papain, a proteolytic enzyme that is a safe treatment for bezoars (Baker et al, 2007). Other studies suggest the use of coca cola.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help the patient determine a specific dietary regimen. If there is diabetes, optimize glycemic control.
- Discuss methods for liquefying foods as needed.
- Bezoar formation may occur after eating oranges, coconuts, green beans, apples, figs, potato skins, Brussels sprouts, broccoli, and sauerkraut in a vulnerable individual.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## GIANT HYPERTROPHIC GASTRITIS AND MÉNÉTRIÉ'S DISEASE

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Ronald L. Eisenberg, *An Atlas of Differential Diagnosis*. 4th ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

### DEFINITIONS AND BACKGROUND

**Giant hypertrophic gastritis (GHG)** is a pathological condition with increased loss of plasma proteins, resulting in hydrolysis by the proteolytic enzymes of the gut. The hydrolyzed proteins are then reabsorbed as amino acids. Ascites or edema occur if the liver cannot produce sufficient albumin rapidly enough. The condition may precede stomach cancer. The disease is rare and diagnosed in patients with giant gastric folds, dyspeptic symptoms, and hypoalbuminemia due to GI protein loss.

**Ménétrier's disease** is a form of hyperplastic gastropathy and not a form of gastritis because inflammation is minimal. Overexpression of transforming growth factor (TGF)-alpha results in selective expansion of surface mucous cells in the body and fundus of the stomach. Ménétrier's disease is often associated with *H. pylori* infection. Most patients with

Ménétrier's disease are treated nonoperatively with nutritional support, antacids, and pain medications (Sanchez et al, 2007). Gastric resection provides permanent relief if needed.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The *H. pylori* strain with Ménétrier's disease has high hepatocyte growth factor (HGF) and TNF-alpha mRNA expressions from gastric fibroblasts (Ishikawa et al, 2008).

<b>Clinical/History</b>	Fecal occult blood test	CRP
Height	Stearrhea	Gluc
Weight	Generalized edema	Na <sup>+</sup> , K <sup>+</sup>
BMI	Stomach ulcers?	Ca <sup>++</sup> , Mg <sup>++</sup>
Diet history		Nitrogen (N) balance
Weight changes		Transferrin
Abdominal pain	<b>Lab Work</b>	H & H
Blood in vomit	Pepsin levels	Serum Fe, ferritin
Gastroscopy	<i>H. pylori</i> bacteria	Serum folate and B <sub>12</sub>
Gastric biopsy	Alb, transthyretin	BUN, Creat
Abdominal ultrasound	Globulin	
	A:G ratio	

## INTERVENTION

### OBJECTIVES

- Replace protein; maintain adequate nitrogen balance.
- Reduce edema.
- Spare protein for tissue synthesis and repair.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Protein Intake

**Assessment Data:** Diagnosis of GHG with giant gastric folds, dyspepsia, hypoalbuminemia (serum levels <2.0).

**Nutrition Diagnoses (PES):** Inadequate protein intake (NI-52.1) related to GI protein loss as evidenced by serum albumin <2.0 g/dL.

**Interventions:** Alter diet to increase protein intake orally, or tube feed if necessary. Educate patient and family about the role of protein in alleviating edema and correcting low albumin levels.

**Monitoring and Evaluation:** Improvements in serum albumin from diet or transfusion (if needed). Transthyretin levels showing improvement over several weeks. Resolution of edema and improved quality of life.

- Promote normal dietary intake with a return to wellness.
- Delay or prevent onset of stomach cancer if possible.

## FOOD AND NUTRITION

- Use a high-protein/high-calorie diet. The protein level should be approximately 20% of total kilocal unless contraindicated for renal or hepatic problems.
- Omit any food intolerances.
- Include adequate sources of micronutrients in the diet; a basic supplement may be warranted.

### Common Drugs Used and Potential Side Effects

- Ménétrier disease patients have been effectively treated with a specific blocking monoclonal antibody (Coffey et al, 2007). This reduces the frequency of nausea and vomiting, improves serum albumin concentration, and improves abnormalities of the stomach.
- For eradication of *H. pylori*, 2 weeks of treatment with an acid-suppressing drug (one time daily), Pepto-Bismol (four times daily), and antibiotics (three to four times daily) are prescribed. This therapy often must be used more than once. Other combinations may include the antibiotics omeprazole, clarithromycin, and ranitidine bismuth (Tritec).
- Lansoprazole (Prevacid), omeprazole (Prilosec), and esomeprazole (Nexium) may be prescribed.
- If prednisone is used for a long period of time, monitor for changes in glucose levels.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Eliminate aggravating foods specific to the patient.
- Teach the patient about use of high biological value (HBV) proteins to replenish protein levels from GI losses.
- During recovery, the use of probiotics such as yogurt with live and active cultures may be helpful.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

### For More Information

- Giant hypertrophic gastritis

# PEPTIC ULCER DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Thomas H. McConnell, *The Nature Of Disease Pathology for the Health Professions*, Philadelphia: Lippincott Williams & Wilkins, 2007.

## DEFINITIONS AND BACKGROUND

A peptic ulcer suggests an imbalance between digestive fluids in the stomach and duodenum, with erosion by gastric acid and pepsin and exposed nerves. Most ulcers are duodenal, within the first 25–30 cm.

One of 10 Americans suffers from peptic ulcer disease. *H. pylori* bacteria play a role in the etiology of 75% or more of peptic ulcers. *Helicobacter pylori* can be transmitted from person to person through close contact, exposure to vomit, or fecal–oral contamination. It can also be found in well water. Because the bacterium is one of the most genetically diverse bacterial species, more than half of the world population in both developed and developing countries are infected (Dube et al, 2009). It has been implicated in stomach cancer.

Hand washing is an important preventive measure. In addition, sulforaphane (SF) from broccoli is a powerful bactericidal agent against *H. pylori* (Yanaka et al, 2009) and intake of soy products may help reduce the effects of inflammation-related IL-10 genetic polymorphisms (Ko et al, 2009).

Individuals who have cirrhosis, chronic obstructive pulmonary disease, renal failure, and organ transplantation

tend to have a higher risk for peptic ulcer disease (PUD). Bland diets neither heal ulcers nor cause a decrease in gastric acid secretion. Drug therapy is most effective in preventing ulcer recurrence and primarily consists of antibiotics and antacids. A vaccine to prevent *H. pylori* infection is being developed. In the meantime, vitamin B<sub>12</sub> tends to be lower in patients who have peptic ulcers; anemia should be monitored.

The decline in duodenal ulcer disease and the established relation of peptic ulcer to *H. pylori* have eliminated the need for elective ulcer surgery. Options for refractory and complicated PUD include vagotomy and pyloroplasty, vagotomy and antrectomy with gastroduodenal reconstruction (Billroth I) or gastrojejunal reconstruction (Billroth II).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** *H. pylori* infection tends to run in families. This pathogen has been shown to follow the routes of human migration; the global *H. pylori* population has been divided into six ancestral populations, three from Africa, two from Asia, and one from Europe (Tay et al, 2009). In addition, the interleukin 1B gene has been identified as a factor, especially inflammation-related IL-10 genetic polymorphisms.

### Clinical/History

Height  
Weight  
BMI  
Diet history  
Weight and appetite changes  
Sharp and sudden abdominal pain  
Burning or gnawing pain (better with meals but returns)

### GI bleeding or

black, tarry stools  
Nausea, vomiting  
Frequent bloating  
Chronic idiopathic urticaria or atopic dermatitis  
Stool test for *H. pylori*  
Endoscopy

### Lab Work

Red blood cell (RBC) count  
Anti-*H. pylori* immunoglobulin G antibody titer  
C-Urea breath test for *H. pylori*  
Chol, Trig  
BUN, Creat  
Alb, transthyretin

Alanine amino-transferase (ALT)	perforated ulcers)	Serum folate PT or INR
Aspartate aminotransferase (AST)	Serum gastrin (increased)	Transferrin
Blood guaiac	Alk phos (increased)	Ca <sup>++</sup> , Mg <sup>++</sup>
Amylase (increased in	H & H	Serum B <sub>12</sub>
	Serum Fe, ferritin	TIBC
		Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
		Ca <sup>++</sup> , Mg <sup>++</sup>

## INTERVENTION

### OBJECTIVES

- Eradicate any *H. pylori* infection where present. Take medications as directed. Rest during healing stages.
- Reduce pain. Avoid distention from large meals.
- Dilute stomach contents and provide buffering action.
- Correct anemia, if present. Vitamin B<sub>12</sub> deficiency may be corrected after effective *H. pylori* treatment.
- Monitor and prevent steatorrhea, bone disease, dumping syndrome, and complications such as perforation and obstruction.

### FOOD AND NUTRITION

- Use small feedings, frequently if preferred. Include high-protein foods and vitamin C to speed healing.
- Avoid personal intolerances. Citrus and acidic juices may cause pain during exacerbations. If a particular food bothers an individual, it should be avoided.
- Use broccoli and cruciferous vegetables often to enhance chemoprotection of the gastric mucosa against *H. pylori*-induced oxidative stress (Yanaka et al, 2009).
- Encourage soybean intake (Ko et al, 2009).
- Limit gastric stimulants if not tolerated, such as caffeine, alcohol, peppermint, black pepper, garlic, cloves, and chili powder. This is a “liberal bland” diet. See Table 7-7 regarding caffeine in beverages and medications.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Undesirable Food Choices

**Assessment:** Food and symptoms diary. Positive stool guaiac test. Altered GI lab results. No *H. pylori* present.

**Nutrition Diagnosis (PES):** Undesirable food choices related to chronic alcohol intake (beer and wine, 10 drinks/wk) as evidenced by nausea, sharp stomach pains, abdominal discomfort, black tarry stools and altered GI labs.

**Intervention:** Teach about role of alcohol in GI mucosal damage. Counsel about alternative lifestyle changes that will help alleviate GI pain. Encourage intake of broccoli for its chemoprotective effects.

**Monitoring and Evaluation:** Report of decreased alcohol consumption and less GI discomfort and pain. Resolution of peptic ulcer symptoms; improved lab results. No further tarry stools.

**TABLE 7-7 Typical Caffeine Content of Beverages and Medications**

Beverages/Medications	Measure	Caffeine (mg)
Coffee, brewed	5 oz	65–120 (average, 85)
Coffee, instant	5 oz	60–85 (average, 75)
Coffee, Starbucks Frappuccino	8 oz	83
Espresso coffee	1 oz	30–50 (average, 40)
Decaffeinated coffee	5 oz	2–4
Black tea, brewed (most U.S. brands)	5 oz	20–50
Black tea, brewed (imported)	5 oz	25–60
Tea, instant	6 oz	28–30
Mountain Dew	12 oz	54
Cola drinks	12 oz	36–47
Coffee ice cream	4 oz	28
Baker's chocolate	1 oz	26
Dark chocolate	1 oz	5–35 (average, 20)
Milk chocolate	1 oz	1–15 (average, 6)
Cocoa beverage	8 oz	3–32 (average, 6)
Chocolate milk	8 oz	2–7 (average, 5)
Analgesic	1 tablet	30–66
Cold preparation	1 tablet	30
Chocolate syrup	1 oz	4
7-Up or Sprite	12 oz	0
Ovaltine	8 oz	0

Data from Leonard T, et al. The effects of caffeine on various body systems: a review. *J Am Diet Assoc.* 87:1048, 1987.

- Use fewer saturated fats and more polyunsaturated fats if increased lipid levels are found. AA metabolites may play a role in peptic ulcer disease.
- Monitor water supply as a potential source of *H. pylori*.

## Common Drugs Used and Potential Side Effects (see Table 7-8)

- Most patients with PUD should avoid NSAIDs. Analgesics and corticosteroids, when taken over a long time, may cause GI bleeding and ulceration and should be taken with food. High doses of Advil or Motrin (ibuprofen), even for a few days, can significantly increase the risk of GI bleeding.
- For eradication of *H. pylori*, 2 weeks of treatment with an acid-suppressing drug (once daily), Pepto-Bismol (four times daily), and antibiotics (three to four times daily) are prescribed. A 1- to 2-week course of *H. pylori* eradication therapy is an effective treatment (Ford et al, 2006); triple therapy often must be used more than once. Quadruple therapy is also being tested (Feng et al, 2005). Some FDA-approved combinations include the antibiotics omeprazole, clarithromycin, and ranitidine bismuth (Tritec). Other antibiotics include amoxicillin, metronidazole, and tetracycline. Suggest use of probiotics, such as yogurt with live and active cultures.

**TABLE 7-8 Medications Used in Peptic Ulcer Disease**

Medication Type	Description	Specific Drugs
Antacids	<p>Aluminum-containing and magnesium-containing antacids can be helpful in relieving symptoms of gastritis by neutralizing gastric acids. These agents are inexpensive and safe.</p> <p>Aluminum ions inhibit smooth muscle contraction, thus inhibiting gastric emptying. Use aluminum-containing antacids cautiously with upper GI hemorrhage.</p> <p>Magnesium and aluminum antacid mixtures are used to avoid bowel function changes.</p>	<p>Gaviscon contains magnesium as well as aluminum and may decrease absorption of thiamine, phosphate, and vitamin A.</p> <p>Gelusil contains magnesium, aluminum, and simethicone; it may have side effects similar to those of Gaviscon.</p> <p>Mylanta and Amphogel (aluminum hydroxide) may cause nausea, vomiting, and lowered vitamin A, calcium, and phosphate absorption. Take between meals, followed by water.</p> <p>Milk of magnesia (magnesium hydroxide) is a laxative-antacid and can deplete phosphorus and calcium over time.</p> <p>Magaldrate (Riopan) decreases serum vitamin A but can be used on a low-sodium diet.</p>
H <sub>2</sub> -receptor antagonists	<p>These drugs inhibit the action of histamine on the parietal cell, which inhibits acid secretion. The drugs in this class are all equally effective and are available over the counter in half prescription strength for heartburn treatment.</p> <p>Histamine H<sub>2</sub> blockers should be taken with food.</p> <p>Since acid secretion and ulcer pain are most prevalent at night, taking Zantac or Tagamet before bed may be helpful.</p> <p>These drugs can elevate AST/ALT and creatinine, cause confusion in elderly individuals, and cause diarrhea, constipation, or urticaria.</p>	<p>Cimetidine (Tagamet) inhibits histamine at H<sub>2</sub> receptors of the gastric parietal cells, resulting in reduced gastric acid secretion, gastric volume, and hydrogen ion concentrations.</p> <p>Famotidine (Pepcid) competitively inhibits histamine at the H<sub>2</sub> receptor of the gastric parietal cells, resulting in reduced gastric acid secretion, gastric volume, and reduced hydrogen concentrations.</p> <p>Nizatidine (Axid) competitively inhibits histamine at H<sub>2</sub> receptors of gastric parietal cells, resulting in reduced gastric acid secretion, gastric volume, and reduced hydrogen concentrations.</p> <p>Ranitidine (Zantac) competitively inhibits histamine at the H<sub>2</sub> receptors of gastric parietal cells, resulting in reduced gastric acid secretion, gastric volume, and hydrogen concentrations. Ranitidine can cause nausea, constipation, and vitamin B<sub>12</sub> malabsorption; may alter serum levels of serum iron.</p>
Proton pump inhibitors (PPIs)	<p>PPIs bind to the proton pump of parietal cell, inhibiting secretion of hydrogen ions into gastric lumen.</p> <p>PPIs relieve pain and heal peptic ulcers more rapidly than H<sub>2</sub> antagonists do. Drugs in this class are equally effective.</p> <p>All PPIs decrease serum concentrations of drugs that require gastric acidity for absorption, such as ketoconazole or itraconazole.</p> <p>PPIs are used for up to 4 weeks to treat and relieve symptoms of active duodenal ulcers. Physicians may prescribe for up to 8 weeks to treat all grades of erosive esophagitis.</p>	<p>Lansoprazole (Prevacid) decreases gastric acid secretion by inhibiting the parietal cell H<sup>+</sup>/K<sup>+</sup> ATP pump.</p> <p>Omeprazole (Prilosec) decreases gastric acid secretion by inhibiting the parietal cell H<sup>+</sup>/K<sup>+</sup> ATP pump. Omeprazole is now available over the counter.</p> <p>Esomeprazole (Nexium) is the S-isomer of omeprazole. It decreases gastric acid secretion by inhibiting the parietal cell H<sup>+</sup>/K<sup>+</sup> ATP pump. May increase absorption of digoxin; may decrease absorption of iron.</p> <p>Rabeprazole (Aciphex, Alfence, Pariet) decreases gastric acid secretion by inhibiting the parietal cell H<sup>+</sup>/K<sup>+</sup> ATP pump. It is used for short-term (4–8 weeks) treatment and symptomatic relief of gastritis.</p> <p>Pantoprazole (Protonix) decreases gastric acid secretion by inhibiting the parietal cell H<sup>+</sup>/K<sup>+</sup> ATP pump. It is used for short-term (4–8 weeks) treatment and symptomatic relief of gastritis.</p>
Gastrointestinal agents	<p>These agents are effective in the treatment of peptic ulcers and in preventing relapse. Their mechanism of action is not clear. Multiple doses are required, and they are not as effective as the other options.</p>	<p>Sucralfate (Carafate) binds with positively charged proteins in exudates and forms a viscous adhesive substance that protects the GI lining against pepsin, peptic acid, and bile salts. Used for short-term management of ulcers. Sucralfate may cause constipation as one side effect.</p>
Stomach acid protector	<p>Bismuth subsalicylate</p>	<p>Bismuth is a component of Pepto-Bismol and is used to protect the stomach lining from acid; it kills <i>Helicobacter pylori</i>.</p>

Adapted from: Shayne P. Gastritis and peptic ulcer disease, <http://www.emedicine.com/emerg/topic820.htm>, accessed February 28, 2005.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Ginger may be used as an antinauseant. Do not use large doses with warfarin, aspirin, or other antiplatelet drugs, antihypertensive drugs, and hypoglycemic drugs. Additive effects can cause unpredictable changes in BP and decreases in blood glucose levels and may decrease platelet aggregation and thus increase bleeding. Ginger ale is commonly used with few side effects.
- Licorice root may be recommended for gastric and duodenal ulcers. Do not take with digoxin, because it may cause potassium loss and digoxin toxicity. Licorice root may potentiate the effects of steroids, especially hydrocortisone, progesterone, and estrogens. Also avoid taking with thiazide diuretics and antihypertensive medications because of increased sodium and water retention, along with potential hypokalemia; spironolactone is especially antagonized by licorice root.
- Banana, garlic, cabbage, and yellow root have no clinical trials proving efficacy. Broccoli and soy products may be beneficial.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- As needed by the individual, offer guidance about dietary alterations that may be useful.
- Discuss the need to complete treatments for eradication of *H. pylori* bacteria, where present. One treatment is usually not sufficient. Suggest increasing intake of broccoli and soy products.
- Reduce intake of alcoholic beverages; stop smoking; and monitor any family history of ulcer disease to address it as quickly as possible.

- As a preventive measure, recommend endoscopy early in patients older than 45–50 years who have dysphagia, recurrent vomiting, weight loss, or bleeding.

### Patient Education—Foodborne Illness

- Careful food handling will be important. Hand washing is important to reduce the spread of *H. pylori*. Always wash hands after using the bathroom and before eating.
- If home TF is needed, teach appropriate sanitation and food handling procedures.

# VOMITING, PERNICIOUS

## NUTRITIONAL ACUITY RANKING: LEVEL 3 (LONGER THAN 7 DAYS)

### DEFINITIONS AND BACKGROUND

Pernicious, uncontrolled vomiting may occur in any of several disorders, including concussion or brain trauma, meningitis or encephalitis, intestinal blockage, migraine headaches, brain tumor or other forms of cancer, foodborne illness, gastroparesis, and pregnancy (hyperemesis gravidarum, see Pregnancy in Section 1). Hyperemesis gravidarum involves pregnancy-induced hormonal changes, often associated with concurrent *H. pylori* infection. The presence of weight loss, GI bleeding, persistent fever,

chronic severe diarrhea, and significant vomiting is associated with a higher prevalence of organic disease in children and should be carefully assessed (American Academy of Pediatrics, 2005).

The biggest immediate risk with pernicious vomiting is dehydration, where losses of water, potassium, and sodium can affect the brain, kidneys, and heart. Watch for signs such as dry mouth membranes, dry lips, sunken eyes, rapid but weak pulse, rapid breathing, cold hands and feet, confusion, and difficulty with arousal. Nutritional deficits are possible when the vomiting is prolonged.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Pernicious vomiting in itself is a symptom of an underlying condition and is not genetic.

<b>Clinical/History</b>	Orthostatic hypotension?	N balance
Height	GI bleeding?	Gluc
Weight		H & H
Weight changes		Serum Fe,
BMI	<b>Lab Work</b>	ferritin
Diet history	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>	Serum folate or
Temperature	Ca <sup>++</sup> , Mg <sup>++</sup>	B <sub>12</sub>
(fever?)	Alb, transthyretin	Gastric emptying
Dehydration?	BUN, Creat	tests

## INTERVENTION

### OBJECTIVES

- Correct electrolyte and fluid imbalances and unintentional weight loss
- Modify oral intake until vomiting resolves.
- Distinguish symptoms that could be related to bulimia nervosa.
- If there is hyperglycemia or diabetes, return to normal blood glucose levels as quickly as possible; insulin may be needed.
- For cancer patients, depending on the type of treatment (either curative or palliative) and on the patient's nutritional status, provide patient-tailored nutritional intervention such as oral supplementation, enteral or total PN (Marin Caro et al, 2007).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal GI Function—Vomiting

**Assessment:** Food records, I & O reports, chemotherapy schedule and frequency. Uncontrollable vomiting three to four times daily for past week. Signs of dehydration.

**Nutrition Diagnosis (PES):** Inadequate food and beverage intake related to intolerance to oral diet and chemotherapy treatment as evidenced by dehydration and vomiting after meals, with weight loss of 5 lb over past week.

**Intervention:** Coordinate care: Alter meal pattern according to chemotherapy medications and timing, review timing of fluid intake related to meals. Offer sips of fluid every 1–2 hours while awake.

**Monitoring and Evaluation:** Food records, I & O reports, weight recovery. Resolution of vomiting episodes.

## FOOD AND NUTRITION

- For patients with an acute condition, NPO for 24 hours with intravenous (IV) glucose is common. Oral rehydration solution may be needed. (See Diarrhea entry.)
- When tolerated, gastrostomy TF or jejunostomy may be warranted. An isotonic formula is desirable to reduce imbalances between solute and solvent. CPN may also be a consideration if the condition is prolonged.
- As the patient progresses to an oral diet, clear liquids such as cranberry juice or boullion may be helpful. Gradually add toast, crackers, jelly, and simple carbohydrates in small, frequent meals.
- Give fluids between meals (a “dry diet”). Avoid acidic fruit and vegetable juices if not tolerated.
- Consider avoiding foods that delay gastric emptying (high-fat, hypertonic, or highly fibrous foods).
- Gradually have the patient resume a normal diet. Decrease fatty foods if not tolerated.

### Common Drugs Used and Potential Side Effects

- Anti-emetic agents may be indicated for some conditions. Meclizine or cyclizine may be prescribed; they are antihistamines and powerful antinausea agents.
- Selective serotonin 5-hydroxytryptamine-3 (5-HT<sub>3</sub>) receptor antagonists have proven to be safe and effective for post-operative nausea and vomiting; these include dolasetron, granisetron, ondansetron, and tropisetron, which bind to 5-HT<sub>3</sub> receptors, blocking serotonin binding at vagal afferents in the gut and in the regions of the CNS involved in emesis (Gan, 2005).
- Insulin or oral agents may be needed if diabetes is also present.
- Peristaltic agents may be used in cases of gastroparesis.
- Chronic use of cannabinoids can lead to hyperemesis; this includes oral use of marijuana for cancer, multiple sclerosis, or social purposes.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Ginger is often used as an antiemetic. Do not use large doses with warfarin, aspirin, other antiplatelet drugs, antihypertensive drugs, and hypoglycemic drugs. Additive effects can cause unpredictable changes in BP, blood glucose levels, platelet aggregation, and bleeding.
- Ginger ale has few side effects and may help.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain why fluids should be taken between meals. Identify adequate amounts of fluids to be consumed every day. Sips of 1–2 oz every few hours can be tolerated; this may include water, sports drinks, gelatin, and clear broth.
- There are many suitable oral rehydration products available from a pharmacy; discuss appropriate products with

the pharmacist. If needed, share the ingredient recipe if it is to be made at home.

- Do not force eating. Eat and drink slowly; stop when full. Make up lost calories at another time.
- Eat meals in a well-ventilated area free from odors.
- Do not lie down for 2 hours after eating. Do not overeat.
- Discuss the role of carbohydrates and fiber in maintaining blood glucose levels.
- Discuss reasons to seek immediate medical attention, including severe abdominal pain, severe headache, stiff neck, fever over 101°F, vomiting of blood, rapid breathing or pulse.
- In palliative care, nutritional support aims at improving patient's quality of life by controlling symptoms such as nausea, vomiting, and pain related to food intake (Marin Caro et al, 2007).

#### Patient Education—Food Safety

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the diet of the individual.

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## LOWER GI: INTESTINAL DISORDERS

# CARCINOID SYNDROME

### NUTRITIONAL ACUITY RANKING: LEVEL 3

#### DEFINITIONS AND BACKGROUND

Carcinoid tumors are part of a group of GI and pancreatic endocrine tumors that secrete hormones, 5-HT, tachykinins, and other mediators (Druce et al, 2009). The rare neuroendocrine growth develops in the wall of the intestine and is usually discovered in x-rays or during surgery performed for other reasons. GI carcinoid tumors are difficult to diagnose (Gore et al, 2005). Carcinoid cancer patients often have elevated levels of serotonin or its precursor 5-hydroxytryptophan (Shah et al, 2005). Octreotide scanning has a sensitivity of primary tumor detection of 90% (Northrup and Lee, 2007). GI carcinoids comprise 90% of all carcinoid tumors and all carcinoids have malignant potential (Northrup and Lee, 2007). Sometimes, the growth occurs in the appendix area. The growths can be large enough to cause intestinal obstruction. Some growths metastasize to the liver, creating hormone-producing tumors with flushing of the head and neck (usually triggered by alcohol or exercise). Flushing symptoms can last for several hours from the release of vasoactive serotonin, histamine, and prostaglandins.

Other symptoms include swollen or watery eyes, explosive diarrhea, abdominal cramps, wheezing, breathlessness, and symptoms similar to heart failure. Cardiac lesions are also seen; up to one third of patients develop cardiac valvulopathy. Patients may benefit from a valve replacement. If liver involvement occurs, liver resection or transplantation may be needed.

Diversion of tryptophan to 5-HT synthesis occurs, resulting in less tryptophan for protein and nicotinamide synthesis. Pellagra and psychiatric symptoms result from depletion of tryptophan, which is consumed by the tumor for serotonin

synthesis (van der Horst-Schrivers et al, 2004). Psychiatric symptoms should be evaluated carefully.

The malignant carcinoid syndrome is caused by circulating neuroendocrine mediators produced by the tumor and occurs in less than 10% of patients (Bell et al, 2005). Surgery is combined with continuous biotherapy with long-acting somatostatin analogs and interferon, which may alleviate symptoms and slow the disease progression (Akerstrom et al, 2005). Survival ranges from 3 to 20 years after diagnosis.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Carcinoid tumor fibrosis is a CTGF/TGFβ-mediated stellate cell-driven fibrotic response (Kidd et al, 2007).

Clinical/History	(carcinoid syndrome)	Octreotide scanning
Height	Breathlessness	X-rays of GI tract
Weight	Number of stools, consistency	Skin changes (scleroderma, pellagra)?
BMI	Biopsy	Psychiatric symptoms?
Diet history	Endoscopy	
Diarrhea, flushing, wheezing		

Magnetic resonance imaging (MRI)	Serum histamine	TLC
	Serum serotonin (elevated)	H & H
	Alb, transthyretin	Serum Fe, ferritin
	Transferrin	Na <sup>+</sup> , K <sup>+</sup>
		Ca <sup>++</sup> , Mg <sup>++</sup>

**Lab Work**

5-HIAA test  
(urine  
S-HIAA)

**INTERVENTION****OBJECTIVES**

- Ease symptoms of secretory diarrhea and reduce any pain.
- Slow progression of the disease, which is not cured by surgery.
- Control side effects of medications.
- Replenish electrolyte and fluid losses.
- Correct niacin deficiency. Biochemical niacin deficiency is prevalent among newly diagnosed carcinoid syndrome patients (Shah et al, 2005).

**FOOD AND NUTRITION**

- Decrease fiber intake during acute stages of diarrhea. Add pectin and ensure adequate fluid intake during those periods.
- Avoid alcoholic beverages. Limit caffeine intake to a controlled amount.
- During testing, omit foods that contain 5-HIAA: avocados, pineapple, bananas, kiwi fruit, plums, eggplant, walnuts, hickory nuts, and pecans.
- Omega-3 fatty acids may be used for their role in reduction of inflammation; include fish such as salmon, sardines, tuna, and herring often.
- Since tryptophan is not adequately converted to niacin, a daily supplement with DRI levels may be suggested. Avoid excesses.

**SAMPLE NUTRITION CARE PROCESS STEPS****Altered GI Function**

**Assessment Data:** Explosive diarrhea, flushing, fear of eating.

**Nutrition Diagnoses (PES):** Altered GI function related to release of vasoactive substances as evidenced by explosive diarrhea and altered labs with diagnosis of carcinoid syndrome.

**Interventions:** Education about foods or alcohol that may aggravate symptoms. Counseling about postsurgical wound healing, if required. Discuss use of probiotics, adequate fluid, omega-3 fatty acid sources. Avoid alcohol if symptoms are aggravated by intake.

**Monitoring and Evaluation:** Fewer complaints of diarrhea, flushing, GI discomfort, and fear of eating.

**Common Drugs Used and Potential Side Effects**

- Subcutaneous injections of the somatostatin analog octreotide are used. This is expensive, and treatment may be for many years. Newer somatostatin analogs (such as lanreotide) are being tested. Vasoconstricting interleukin or cytotoxic drugs may control side effects.
- If kaolin (Kaopectate) and other medications are used to control diarrhea, constipation is a possible side effect.
- Bronchodilators may be used to control wheezing. Evaluate for potential side effects.

**Herbs, Botanicals, and Supplements**

- Herbs and botanical supplements should not be used without discussing with the physician.
- Monitor side effects if large doses of niacin are taken.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Discuss measures specifically designed for the patient's status and tolerance levels.
- Suggest ways to make meals more appetizing if appetite is poor.
- Describe techniques for management of diarrhea, abdominal pain, or cramping by reducing fiber and fat intake during those times of flare.
- Probiotics such as acidophilus milk and yogurt with live and active cultures may be useful in the diet.

**Patient Education—Foodborne Illness**

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# CELIAC DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 4

## DEFINITIONS AND BACKGROUND

Celiac disease (CD) is a common, lifelong, genetically based autoimmune disorder that causes inflammation of the proximal small intestine (See and Murray, 2006). CD is characterized by inappropriate T cell-mediated immune response to ingested gluten from wheat, rye, and barley that leads to inflammation, villous atrophy, and crypt hyperplasia in the small intestine. Intestinal villi decrease in number, with less absorptive surface and fewer enzymes. Crypts are markedly elongated, causing mucosal malabsorption.

Other names for this disorder include celiac sprue, gluten enteropathy, or nontropical sprue. A major consensus panel determined that 1% of Caucasians (upwards of 3 million people) may have CD (See and Murray, 2006). While screening suggests that one in 133 people have it, the frequency may be closer to one in 100; undiagnosed CD seems to have increased dramatically in the United States during the past 50 years (Rubio-Tapia et al, 2009).

Diagnosis can occur at any age (infancy through old age) and often occurs after stress, pregnancy, or viral infections. Infants may present with impaired growth, diarrhea, pica, abdominal distention, pallor, edema, or vomiting. Children may have frequent, strong-smelling stools that are pale and foamy, diarrhea, irritability, a distended abdomen, easy fatigue, pallor, weight loss, vomiting, and anemia.

Increased intestinal permeability plays a pathogenic role in various autoimmune diseases including CD and type 1 diabetes (T1D) (Visser et al, 2009). Gliadin may also be involved in the pathogenesis of T1D (Visser et al, 2009). All persons with GI symptoms should be tested for CD, as should individuals with type 1 diabetes (T1D), unexplained iron deficiency anemia, elevated levels of transaminases, thyroid disorders, short stature, delayed puberty, fetal loss, and in relatives of patients who have CD (Thompson, 2005). Screening studies have revealed that CD may be asymptomatic in adults (Niewinski, 2008), or they may have episodic or nocturnal diarrhea, flatulence, intestinal bloating that mimics IBS, steatorrhea, weight loss, recurrent stomatitis, anemias or peripheral neuropathy.

Tissue transglutaminase is the main antigen for the antiendomysial antibodies used to diagnose CD. Deamidated gliadin antibodies (DGP) have shown promising results as serological markers for CD (Setty et al, 2008). False-negative test results can occur in children under age 2 years or in patients who have followed a gluten-free (GF) diet for a month or longer. The diagnostic criteria for CD need re-evaluation; endomysial antibody positivity without atrophy belongs to the spectrum of genetic gluten intolerance, and warrants dietary treatment (Kurppa J, et al. 2010).

Early diagnosis and treatment, together with regular follow-up visits with a dietitian, are necessary to ensure nutritional adequacy and to prevent malnutrition while adhering to the GF diet for life (Niewinski, 2008). Longer duration of exposure to gluten can increase the risk of other autoimmune diseases, including non-Hodgkin's or intestinal lymphoma,

squamous cell cancer of the esophagus, type 1 diabetes, autoimmune thyroid disease, Addison's disease, lupus, primary biliary cirrhosis, osteoporosis, psoriasis, Sjogren's syndrome, and rheumatoid arthritis (National Institutes of Health, 2004).

Dermatitis herpetiformis (DH) is the skin manifestation, with intensely pruritic lesions that occur over the surface of the elbows, knees, legs, buttocks, trunk, neck, or scalp. Abnormal biopsy is evident, but GI symptoms are not always present. There may be immunoglobulin (IgA) deposits around the lesions, and large intake of iodine may trigger flares of DH.

When wheat, rye, and barley grains are consumed, they damage the mucosa of the small intestine, eventually leading to nutrient malabsorption. Moderate amounts of pure oats can be consumed. However, since much of the commercially available oat flour may be contaminated with wheat gluten, caution is advised for new patients.

Response to GF diets in children with autism may be related to amelioration of nutritional deficiency resulting from undiagnosed gluten sensitivity. Therefore, it is recommended that all children with neurodevelopmental problems be assessed for CD (Genius and Bouchard, 2009). Children and adolescents with symptoms of or an increased risk for CD should have the blood test for antibody to tissue transglutaminase (TTG). Those with an elevated TTG should be referred to a pediatric gastroenterologist for an intestinal biopsy. If tests prove positive, a GF diet is needed. Then, a gastroenterologist should follow all patients with CD.

Because oxidative stress plays an important role in the inflammatory process of CD, increased use of lycopene, quercetin, and tyrosol can be recommended (DeStefano et al, 2007). New forms of treatment propose the use of gluten-degrading enzymes to be ingested with meals, the development of GF grains by genetic modification, the use of substrates regulating intestinal permeability to prevent gluten entry across the epithelium, and different forms of immunotherapy (Setty et al, 2008).

Since the defect is permanent, the GF diet is curative and must be a permanent change. Surface cells of the mucosa are replaced within 5 days; swelling is reduced within 14 days; and villi improve within 6 months or up to 5 years. Consultation with a dietetics professional knowledgeable in CD is essential. An individualized, team approach is best because symptoms change over time.

Single-nucleotide polymorphisms (SNPs) in the chromosome 4q27 region containing IL2 and IL21 are associated with CD; this is similar to other autoimmune diseases such as rheumatoid arthritis, type 1 diabetes, Graves' disease, psoriatic arthritis, and ulcerative colitis (UC, Glas et al, 2009).

Clinical/History	Multiple small bowel biopsies showing flat villi	Macrocytic anemia (low vitamin B <sub>12</sub> or folate?)
Height		
Weight		
BMI		
Diet history	Abdominal computed tomography (CT) or MRI scan	Serum homocysteine (tHcy)
Failure to thrive or weight loss		Serum carotene for vitamin A
Aphthous stomatitis	Capsule endoscopy	Serum vitamins D, E, and K
Fatigue, lassitude, depression	Small bowel biopsy	Serum copper (decreased)
Recurrent abdominal pain, bloating		Serum phosphorus (decreased)
Strong-smelling stools that are pale and foamy	<b>Lab Work</b>	Serum zinc (decreased)
Distended abdomen	Anti-TTG antibodies (tTG)—IgA and IgG (95–100% sensitive and specific)	Ca <sup>++</sup> (often low)
Irritability, pallor		Na <sup>+</sup> , K <sup>+</sup>
Steatorrhea, chronic diarrhea	Anti-endomysium antibodies—IgA (EMA)—100% specificity, >90% sensitivity	Mg <sup>++</sup>
DH		Alb, transthyretin
Enamel defects of permanent teeth	HLA-DQ2 and HLA-DQ8 haplotype	CRP
Headaches?	H & H	Transferrin, TIBC
Osteopenia, bone pain?	Serum Fe, ferritin (anemia is common)	Lactic acid dehydrogenase (increased)
Infertility, frequent miscarriages?		Xylose absorption
Short stature?		DEXA scan
		Fecal chymotrypsin level
		Fecal fat study
		Liver function tests (mildly abnormal)

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Like an IBD, gliadin peptides are presented on the Human Leukocyte Antigen DQ2 or DQ-8 molecules of antigen-presenting cells to T helper cells, provoking a T helper 1 response that leads to damage by pro-inflammatory cytokines and interleukins (Festen et al, 2009; Visser et al, 2009). CD is more common among people with other genetic disorders including Down syndrome.

## INTERVENTION

## OBJECTIVES

There are six elements required for the management of CD (Thompson, 2005):

1. Consult a skilled dietetics professional. Medical nutrition therapy (MNT) to promote provided by a registered dietitian is strongly recommended improved self-management (American Dietetic Association, 2009).
2. Educate about the disease.
3. Adhere to a GF diet. Remove the offending protein (gliadin fraction) from the diet; glutenin is harmless. Improvement is noted within 4–5 days.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Altered Nutrient Utilization—Celiac Disease**

**Assessment Data:** Weight loss over the past year. I & O records; stool patterns and frequency; abdominal distention and bloating; DH. GI biopsies reveal CD; positive tTG test.

**Nutrition Diagnosis (PES):** Altered nutrient utilization related to flattened intestinal villi from CD as evidenced by positive biopsies and tTG test, presence of DH, frequent bouts of abdominal distention, bloating, diarrhea and weight loss.

**Intervention:** Education about the sources of gluten from diet and food and nonfood products. Provision of recipes for managing the GF diet. Supplier sources of GF foods and flours or grain products. Counseling about fluid sources and ways to incorporate fluids into meals and nourishments. Meal planning tips for the family.

**Monitoring and Evaluation:** Improved I & O records and weight gain. Normalized stool patterns and frequency. Fewer complaints of GI distress, bloating and diarrhea associated with meals. No signs of protein-energy malnutrition.

## 4. Identify and treat nutritional deficiencies:

- Deficiencies of iron, folate, calcium, and vitamin D may be found.
- Replace nutrients lost from diarrhea and steatorrhea.
- Reverse bone demineralization, hypoalbuminemia, and hypoproteorubinemia where present.
- Whole-body protein breakdown is common in CD, contributing to a high level of protein-calorie malnutrition.
- Glutamine is an important fuel for the health of intestinal epithelial cells. Replenish as needed.

## 5. Provide access to an advocacy group. A local celiac support chapter is most helpful.

## 6. Provide continuous long-term follow-up care by a multidisciplinary team.

## FOOD AND NUTRITION

- A GF diet excludes wheat, rye, and barley. Avoid products such as breadings, stuffing, croutons, graham, bulgur, matzo, broth, breadings or coating mixes, communion wafers, pastas, cracked wheat, semolina, farina, malt, malt flavoring, brown rice syrup, commercial soups, imitation bacon, imitation seafood, marinades, processed meats, roux, sauces, seasonings, self-basting poultry, soups and soup bases, thickeners, vegetarian meat substitutes, and commercial potato and rice mixes. Soy sauce, white or nonmalt vinegars, and wheat starch must be pure; read labels.
- Plan a diet that includes acceptable grains and starches; see Table 7-9.
- A Greek-Mediterranean dietary pattern with olive oil, nuts, fruits, and vegetable intake can be recommended. Lycopene, quercetin, and tyrosol may control the pro-inflammatory genes involved in CD (DeStefano et al, 2007). Tyrosol is found in wine and extra virgin olive oil;

**TABLE 7-9 Grains and Starches to Use Freely in Celiac Disease**

Amaranth	Nut flours
Arrowroot	Quinoa
Beans (black, garbanzo, kidney, northern, pinto)	Poha flakes
Black-eyed peas, lentils, split peas	Potato
Buckwheat	Potato starch, potato flour
Cassava	Rice
Corn, corn bran, hasa marina	Sorghum
Gluten-free bread	Soy
Hominy, grits	Tapioca
Indian rice grass	Tef
Montina	Wild rice

lycopene in tomato products, watermelon, pink grapefruit; quercetin in apples, citrus fruit, tea, capers, buckwheat, red grapes, broccoli, and red onions. Buckwheat contains rutin (quercetin-3-O-rutinoside) which produces a catabolite (3,4-dihydroxyphenylacetic acid) with significant reducing power, free-radical scavenging activity and enhanced antioxidant capacity of the colonic lumen (Jaganath et al, 2009).

- Because oats are sometimes contaminated with wheat during processing, avoid in initial stages of treatment. Include small-to-moderate amounts if tolerated after the first few months.
- Diet for adults should provide 1–2 g of protein/kg body weight from fresh meat, fresh fish, milk, cheese, and eggs. Examine processed items carefully since there is often gluten added.
- Diet should provide 35–40 kcal/kg body weight for adults.
- For infants with diarrhea, provide fluids, electrolytes, and a formula that is not high in fat content. Infants may tolerate banana powder; adults and children can eat starchy-type carbohydrates, bananas, lean meats, and fish. Rehydrate with oral rehydration solution or other fluids.
- Initially, the diet should include low amounts of fiber because of flattened mucosal villi; increase as tolerated. Fruits and vegetables are naturally low in gluten and should be included regularly.
- If TF is used, a glutamine-enriched product may be useful. Monitor ingredients carefully to avoid gluten.
- Lactose intolerance may be either temporary or permanent. Initially, dairy products (primarily milk and products made with milk) should be avoided. After 3–6 months of treatment, dairy products may be gradually reintroduced.
- GF products are often low in B vitamins, calcium, vitamin D, iron, zinc, magnesium, and fiber. Few GF products are enriched or fortified, adding to the risk of nutrient deficiencies. Correction of vitamin and mineral deficiencies is important. Supplements to the diet should include water-miscible vitamins A, D, E, and K, iron, calcium,

folic acid, vitamin B<sub>12</sub>, thiamine, and other B-complex vitamins.

- Products containing MCTs are often used when fat malabsorption is present, especially in adults.
- Foods that often are not allowed include commercial cream soups, creamed vegetables, ice cream (labels should be checked for thickening agents), cakes, cookies, and breads unless made with rice, corn, or potato flours. For toddlers, mixed infant dinners and junior dinners that contain flour thickeners, spaghetti, macaroni, and other pastas should not be used.

### Common Drugs Used and Potential Side Effects

- No drug therapy has been proven to suppress the disease.
- Check all labels *each time* for gluten-containing ingredients. GF laxatives include psyllium seed laxatives (Metamucil, Naturacil), docusate sodium (Surfak), and bisacodyl (Dulcolax). Gliadins are often impurities in medications, including acetaminophen; check carefully.
- Corticosteroids may be used with numerous side effects. Take with food. Monitor for negative nitrogen or calcium balances, and for weight gain.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Avoid aloe, cascara, senna, and yellow dock because of enhancing effects when using bisacodyl.
- A B-complex supplement may be warranted if serum tHcy levels are elevated (Hadiithi et al, 2009; Hallert et al, 2009). A general multivitamin–mineral supplement may be beneficial.
- With antibiotics, quercetin may interfere with fluoroquinolones. Advise the physician if used in large amounts.
- Studies are ongoing about the need for carnitine supplementation in CD.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- **Strict lifelong elimination of gluten** and dietary adherence are essential (Chand and Mihas, 2006). If strictly followed, improvement will occur in most patients within 2 weeks. If results are not seen after 6–9 months of diet therapy, a new diagnosis should be sought.
- Endomysial antibodies are specific in predicting villous atrophy; patients with endomysial antibodies benefit from a GFD regardless of the degree of enteropathy (Kurppa et al, 2010).
- Intense expert dietary counseling is needed for all patients with CD because the diet is complex (American Dietetic Association, 2009; Niewinski, 2008). An effective plan requires extensive, repeated counseling and instruction of the patient by a skilled dietitian.
- Instruct the patient or family to read food labels *each time* for cereal, starch, flour, thickening agents, emulsifiers,

gluten, stabilizers, hydrolyzed vegetable proteins, semolina, durum, triticale, bulgur, farina, couscous, broth, caramel coloring and monosodium glutamate (MSG).

- The Food Allergen Labeling and Consumer Protection Act (FALCPA) requires food labels to clearly identify wheat and other common food allergens in the list of ingredients. A GF symbol is now widely used by food manufacturers. Contact the manufacturer if there are questionable ingredients.
- “Wheat free” is not the same as gluten free; products may contain rye or barley.
- Because of possible contamination with wheat, oats should be avoided in new patients.
- “Wheat starch” is acceptable because the gliadin/gluten has been removed.
- Toothpaste, mouthwash, lipstick or chapstick, glue on envelopes or teabags, boxed candy, chewing gum wrappers, utensils in buffet lines, toasters, bulk food bins, jars used for various purposes, and other related items should be checked carefully and avoided if gluten is present.
- A Greek–Mediterranean dietary pattern high in olive oil, nuts, fruits and vegetable may be recommended.
- For children at school, it may be necessary to educate the staff, nurses and teachers about the GF diet to enhance compliance.
- Quality of life improves for most individuals with CD who follow the GF diet for at least a year (American Dietetic Association, 2009).

### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual who may be experiencing diarrhea and related GI discomfort.
- If home TF is needed, teach appropriate sanitation and food handling procedures.

## CONSTIPATION

### NUTRITIONAL ACUITY RANKING: LEVEL 1–2

#### DEFINITIONS AND BACKGROUND

Constipation occurs when the fecal mass remains in the colon longer than the normal 24–72 hours after meal ingestion or when the patient strains to defecate. Stool type and frequency could be used to determine another problem, such as IBS. Constipation and fecal incontinence are common symptoms in patients with cerebral palsy, traumatic spinal cord injuries, spina bifida, multiple sclerosis, diabetic polyneuropathy, Parkinson's disease, and stroke. Intestinal obstruction, tumors and diverticulosis may narrow the intestine, which can also lead to constipation.

**Atonic constipation** ("lazy bowel") occurs when musculature of the bowel no longer functions properly, sometimes from laxative overuse or poor bowel habits. **Spastic constipation** entails increased narrowing of the colon with small, ribbon-like stools caused by inactivity, immobility, or obstruction; increasing physical activity may be useful. **TF constipation** occurs with use of low-fiber products, medications, or other products.

In infants and children, chronic constipation is a concern, with **encopresis** from poor bowel habits and poor fiber intake. There may be food allergies, such as to milk or wheat, which should also be addressed.

Treatment modalities for constipation include prokinetic agents, enemas administered through the enema continence catheter, and biofeedback. For chronic problems, bowel retraining may be necessary.

There is limited evidence that constipation can successfully be treated by increasing fluid intake unless there is dehydration (Muller-Lissner et al, 2005). Increasing physical activity may be helpful (Muller-Lissner et al, 2005). Some patients may be helped by a fiber-rich diet (American Dietetic Association, 2008). Water-soluble fibers (e.g., pectins, gums, mucilages, and some hemicelluloses) slow down intestinal transit while insoluble fibers from lignin, cellulose, and hemicellulose accelerate intestinal transit. Patients with more severe constipation may get increased bloating or distention when increasing dietary fiber intake; proceed slowly when making a change in fiber intake. Fiber supplements may also help.

Conservative therapies focus on a holistic approach in tandem with evolving drug therapies that target intestinal secretion and transit (Chatoor and Emmanuel, 2009). Chronic constipation decreases quality of life. A Constipation-Related Quality of Life measure is available but should be validated with different treatment methods used for chronic constipation (Wang et al, 2009). Surgical correction of rectocele and intussusception benefit those with anatomical symptoms; for those with predominantly functional features, surgery is best avoided (Chatoor and Emmanuel, 2009).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Chronic constipation may have a genetic basis; research is underway.

Clinical/History	Bowel habits	Gas pain, flatulence
Height	Stool color and number	Heartburn, indigestion
Weight	Hard, lumpy stools	Straining at stool
Recent weight changes	I & O	Feeling of obstruction or incomplete evacuation
BMI	BP	
Diet history	Headaches	
Defecation longer than every 3 days	Abdominal distention, pain, spasms	

Colorectal transit study	Constipation Severity Index	H & H Serum Fe, ferritin
Anorectal function test	<b>Lab Work</b>	Gluc Na <sup>+</sup> , K <sup>+</sup>
Colonoscopy or sigmoidoscopy	Alb, transthyretin BUN, Creat	Ca <sup>++</sup> , Mg <sup>++</sup> Stool guaiac

## INTERVENTION

### OBJECTIVES

- **Atonic constipation (“lazy bowel”):** Stimulate peristalsis, provide bulk, and retain water in the feces.
- **Spastic constipation:** Undue distention and stimulation of the bowel should be prevented during exacerbations. After the patient is well, fiber should be increased.
- **TF constipation:** Check for obstruction (nausea, vomiting, distention, and dehydration). Record I & O, along with activity levels.
- **Pediatric constipation and encopresis:** Provide laxatives and lubricants initially, followed by improved fiber and fluid intakes.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Altered GI Function—Constipation

**Assessment Data:** Fluid intake records (I & O), medication history and recent changes, stool patterns and frequency. No food allergies or intolerances noted. Limited fluid intake recently.

**Nutrition Diagnosis (PES):** Altered GI function related to very low fluid intake and use of constipating medications as evidenced by patient complaints of hard, dry, infrequent stools, low intake of fluids, and poor nutritional quality of life.

**Intervention:** Food-Nutrient Delivery: Incorporate more fluids into meals and nourishments, discussion of fluid tracking with staff or family as well as patient. Offer hot or caffeinated beverages, such as coffee or hot tea. Try prune juice mixed with bran and applesauce, especially for the elderly.

**Education:** Discuss role of fiber, fluid and physical activity in maintenance of normal bowel activity.

**Counseling:** Discuss food sources and ways to increase fiber content in recipes and meals.

**Coordination of Care:** Discuss need for stool softener with doctor or nursing staff. Avoid mineral oil that interferes with nutrient absorption.

**Monitoring and Evaluation:** Fluid intake records, stool patterns and frequency records. Review medication changes or addition of stool softener. Note fewer complaints of incidents of hard, dry, and infrequent stools or straining. Note more GI comfort and improved nutritional quality of life.

## FOOD AND NUTRITION

- In general, it may be helpful to consume more fruits and vegetables and more servings from the bread/cereal group each day, especially whole grains, root vegetables such as carrots or potatoes, stewed dried fruit, and cabbage. Gradually increase fiber, maintain an adequate fluid intake, and exercise regularly.
- **Atonic constipation:** The diet should contain 20–35 g of fiber, with liberal use of whole grains, fruits, and vegetables. Adding a few carrots and whole-grain breads and cereal may be an easy solution. Use adequate fluid (30–35 mL/Kg).
- **Spastic constipation:** Decrease fiber during painful episodes. Then, increase use of prune juice, dried fruits, raw fruits and vegetables, nuts, and whole grains. If wheat allergy is a concern for a patient, do not promote use of bran.
- **TF constipation:** Use a fiber-containing formula if appropriate. Use adequate flushes.
- **Pediatric constipation and encopresis:** Add more fruits and vegetables to the diet; increase whole-grain fiber and fluid intake.

## Common Drugs Used and Potential Side Effects

- There is limited evidence about efficacy of treatments used for constipation. Good evidence supports the use of polyethylene glycol and tegaserod. Moderate evidence supports the use of psyllium and lactulose. Limited-quality data exist for milk of magnesia, senna, bisacodyl, and stool softeners (Kamm et al, 2005; Ramkumar and Rao, 2005).
- Discourage overuse or dependence on laxatives and cathartics; see Table 7-10.
- Prescription medications that may cause constipation include opiates, anticholinergics, tricyclic antidepressants, calcium channel blockers, antiparkinsonian drugs, antipsychotics, diuretics and antihistamines.
- Over the counter drugs that can cause constipation include calcium-containing antacids, calcium supplements, iron supplements, NSAIDs, and antidiarrheal agents.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Flax, aloe (anthraquinones), fenugreek, and rhubarb have been recommended for constipation, but no clinical trials have proven efficacy.
- With use of bisacodyl, avoid aloe, cascara, senna, and yellow dock because of enhancing effects.
- A herbal tea (Smooth Move) increases bowel movements naturally (Bub et al, 2006).
- More studies on probiotic products are needed, but they have possibility.

**TABLE 7-10 Medications for Constipation**

Medication	Description
<b>Bulking agents</b> Psyllium (Metamucil, Effersyllium, Perdiem Fiber), Benefiber (with guar gum), methylcellulose (Citrucel), calcium polycarbophil (FiberCon), Fiberall, Fiber-Lax, Equilactin, Konsyl, Serutan	Fiber supplements that retain water and are safe choices. Take with plenty of water or juice (8 oz per teaspoonful). Results may require 1–4 teaspoons of the product.
<b>Chloride channel activators</b> Lubiprostone (Amitiza)	Activators increase intestinal motility and fluid to ease passage of stool. Not recommended for use longer than 12 months without doctor's evaluation.
<b>Lubricant laxatives</b> (Fleet Mineral Oil, Zymenol)	Lubricant laxatives coat the intestinal lining to allow easier passage of stool but may also interfere with absorption of calcium and fat-soluble vitamins.
<b>Osmotic or Hyperosmolar laxatives</b> (Cephulac, Fleet Phospho-Soda, Milk of Magnesia or MOM, Kristalose) or Lactulose (Chronulac) or Polyethylene Glycol 3350 (Miralax, Glycolax)	Osmotics and saline laxatives draw fluid, cause bowel distention, and may be useful for idiopathic constipation. "The wetter the better." Take with plenty of fluid. Monitor for electrolyte imbalances. Use caution in diabetes. Miralax is safe and effective in pediatrics and pregnancy.
<b>Prebiotics and probiotics</b>	Use of probiotics such as yogurt with active cultures, lactobacilli and bifidobacteria, and prebiotics (nondigestible oligosaccharides) may be beneficial for gut integrity.
<b>Stimulant laxatives</b> Bisacodyl (Fleet Stimulant Laxative, Correctol, Dulcolax) Ex-Lax or Senokot (with senna) Herbal Authority Aloe Vera, Purge, Feen-a-Mint. Prunes (dried plums) are a natural stimulant laxative.	Stimulant laxatives irritate the intestine, causing bowel contractions. They can cause severe cramping, diarrhea, nausea, and electrolyte imbalances. Avoid using bisacodyl (Dulcolax) with dairy products; take with a high-fiber diet. Not recommended for daily or regular use as they can deplete vitamin D and calcium.
<b>Stool softeners (Emollient laxatives)</b> Docusate sodium (Colace, Fleet Sof-lax, Peri-Colace, Surfak)	Stool softeners are short-term solutions; they allow more water to penetrate stool and to facilitate elimination. Docusate sodium (Colace) should be taken with milk or juice. Long-term use can deplete electrolytes.
<b>Tegaserod (Zelnorm)</b>	Tegaserod was removed from the market in 2007.

See also: Drug Class Review on constipation Drugs at <http://www.ncbi.nlm.nih.gov/books/bv.fcgi?rid=constip>, accessed August 11, 2009.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain that proper diet can produce relief but cannot cure the condition. A normal bowel routine is needed, but daily fecal evacuation is not needed by everyone.
- Specifically identify foods that have a laxative effect for the patient. Explain why fiber should be increased on a gradual basis only and that items such as prune juice may help. For every gram of cereal fiber, stool weight increases by 3–9 g. For some, a cup of hot prune juice may be useful.
- Have the patient drink 8–10 glasses of water daily, as permitted. Warm fluids are especially useful.
- Exercise may be beneficial in maintaining regularity, especially abdominal-strengthening exercises.
- Discuss foods that have caused constipation, flatus, and GI distress; offer relevant suggestions.
- Medical assistance is needed for diarrhea, bleeding, infection, or other changes in bowel habits.
- Bowel retraining programs may be helpful and may include increasing exercise, including more fiber in the diet, drinking more liquids, and setting aside 15 minutes to spend on the toilet after breakfast. Regular practices may help reestablish a healthy pattern.

- In a pediatric population, dietary changes, corn syrup, or both may resolve constipation in 25% of children. Laxatives such as milk of magnesia and polyethylene glycol are efficient and safe for almost all cases (Loening-Baucke, 2005).

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.
- Hand washing is extremely important after toileting.

# DIARRHEA, DYSENTERY, AND TRAVELER'S DIARRHEA

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Diarrhea (acute enteritis) is a symptom of many disorders in which there is usually an increased peristalsis with decreased transit time through the GI tract. In Table 7-11, etiologies and comments related to diarrhea are given. Reduced reabsorption of water and watery stools result; see Table 7-12.

**Bacterial diarrhea** is caused from food or water contaminated with *Campylobacter*, *Salmonella*, *Shigella*, and *E. coli*. Chronic diarrhea involves production of loose stools with or without increased frequency for more than a month. An individualized approach, knowledge of GI physiology, and awareness of the physiological effects of foods or medications are best used to design an effective dietary plan

(Schiller, 2006). Dehydration is a common problem; watch for decreased skin turgor, dry mucous membranes, thirst, 2% weight loss or more, low BP, postural hypotension, increased BUN and hematocrit, and decreased urinary output.

**Early childhood diarrhea** can come from or lead to malnutrition. Diarrhea is the leading cause of death in children younger than 5 years of age, especially in developing countries. Early rehydration may prevent many deaths in high-risk infants if mothers seek medical attention and offer proper rehydration solutions as soon as diarrhea begins. Oral rehydration solutions (ORS) are well tolerated and shorten illness and decrease fluid losses. Diarrhea can be prevented by breastfeeding, by immunizing all children

**TABLE 7-11** Diarrhea: Etiologies, Comments and Bristol Stool Chart

Diarrhea Type	Cause	Comments
Antibiotic-induced	<i>Clostridium difficile</i> is the gram-positive anaerobic bacterium most often responsible.	Clindamycin or cephalosporin often causes diarrhea.
Chronic diarrhea	Celiac disease, cow's milk allergy, bacterial and parasitic factors, cystic fibrosis, or post-infectious gastroenteritis	Manage the underlying condition and often the diarrhea resolves. Celiac disease or food allergy should be considered.
Dysentery	<b>Dysentery is from poor sanitation; causes range from contact with feces to contamination by houseflies.</b>	<b>Dysentery may involve diarrhea, with blood and mucus, intestinal rumbling, cramps, fever, and pus in stools.</b>
Functional	From irritation or stress	Often resolves on its own
Organic	From intestinal lesion	May require further medical evaluation
Osmotic	From carbohydrate intolerance	Lactose, fructose, or sorbitol malabsorption may be a cause
Secretory	From bacteria, viruses, bile acids, laxatives, or hormones	This is typically a more serious condition. <i>Rotavirus</i> and <i>Norwalk virus</i> commonly affect infants and school-aged children; vomiting and watery diarrhea may occur. Norwalk-like viruses may also affect the frail elderly.
Traveler's diarrhea (TD)	TD is from contaminated food or water.	TD is usually caused by enterotoxigenic bacteria ( <i>E. coli</i> , <i>Campylobacter</i> , <i>Shigella</i> , <i>Salmonella</i> , or <i>Yersinia</i> ) or viruses or protozoa, <i>Giardia</i> is less common.

**TABLE 7-12 Bristol Stool Scale<sup>a</sup>**

Type 1		Separate hard lumps, like nuts (hard to pass)
Type 2		Sausage-shaped but lumpy
Type 3		Like a sausage but with cracks on its surface
Type 4		Like a sausage or snake, smooth and soft
Type 5		Soft blobs with clear-cut edges (passed easily)
Type 6		Fluffy pieces with ragged edges, a mushy stool
Type 7		Watery, no solid pieces. <b>Entirely Liquid</b>

<sup>a</sup>This medical aid was designed to classify feces into seven groups, developed by Heaton and Lewis at the University of Bristol, and first published in the *Scandinavian Journal of Gastroenterology* in 1997. The form of the stool depends on the time it spends in the colon. For more information, see [www.continence.org.au](http://www.continence.org.au). Accessed August 1, 2009.

against measles, by keeping food safe and water clean, and by washing hands before touching food.

**Clostridium difficile infection (CDI)** diarrhea can be caused by use of most antibiotics. There may be profuse watery diarrhea that may be foul smelling; abdominal pain, cramping, and tenderness; stools that may be guaiac positive and grossly bloody; and fever or WBC count of 12,000–20,000/ $\mu$ L. In severe cases, toxic megacolon, colonic perforation, peritonitis, hypovolemic shock, sepsis, and hemorrhage might occur. Symptoms may develop within a few days or even 6–10 weeks after antibiotic therapy is completed. Because *C. difficile* may be a normal bowel organism (especially in children), simply culturing the organism does not mean that diarrhea is caused by *C. difficile*. In mild cases, symptoms will usually resolve spontaneously once the causative antibiotic is withdrawn. More severe cases warrant therapy with vancomycin and metronidazole for 10 days. Tapered-dose oral vancomycin followed by a pulsed-dose regimen, probiotic approaches, restoration of the normal flora, immunological approaches, toxin-binding approaches, and serial therapy with vancomycin followed by rifaximin may be needed for recurrent infections (Johnson, 2009). See Section 15 for more information.

**Dysentery** involves severe diarrhea containing mucus or blood. Vomiting of blood occurs. If left untreated, it may be fatal. Oral rehydration therapy is needed, and medication to treat any parasitic or bacterial infection.

For **traveler's diarrhea (TD)**, high-risk destinations include most countries in Latin America, Africa, the Middle East, and Asia. Both cooked and uncooked foods are a concern if they have been improperly handled. Risky foods include raw or undercooked meat and seafood and raw

fruits and vegetables. Tap water, ice, and unpasteurized milk and dairy products can be associated with increased risk. Daily doses of rifaximin (Xifaxan) appear to significantly decrease the incidence of TD from *E. coli*.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Diarrhea is a symptom rather than a disease. Identify the cause and whether or not there is a genetic origin.

Clinical/History	I & O; dehydration?	Lactose tolerance test
Height	Temperature	Hydrogen breath test
Weight	Abdominal pain	Stool culture
Weight changes		such as for <i>C. difficile</i>
BMI	<b>Lab Work</b>	BUN:Creat ratio
Diet history	Na <sup>+</sup> (decreased)	Gluc
Number of stools daily	K <sup>+</sup> , Cl <sup>-</sup>	Alb, transthyretin
Stool consistency (see Stool Chart)	Ca <sup>++</sup> , Mg <sup>++</sup>	CRP
BP	H & H	Serum copper
	Serum Fe, ferritin	N balance

## SAMPLE NUTRITION CARE PROCESS STEPS

**Altered GI Function with Diarrhea**

**Assessment:** Food diary, bowel patterns. Medical history or genetic etiology of diarrheal disorders.

**Nutrition Diagnosis (PES):** Altered GI function related to excessive intake of poorly absorbed CHO as evidenced by frequent intake of apple juice and sorbitol-containing dietetic products with cramping and loose stools.

**Intervention:** Food and Nutrient Delivery: change diet as needed. Educate about impact of poorly absorbed CHO on bowel function.

**Monitoring/Evaluation:** Reports of less abdominal cramping and loose stools.

## INTERVENTION

## OBJECTIVES

- Determine cause and apply an appropriate treatment.
- Prevent or alleviate dehydration, electrolyte imbalances, anemia, weight loss, and hypoglycemia.
- Avoid refeeding syndrome. CPN may lead to reduction in nutrient intake and atrophy of the gut.
- Restore normal bowel motility. Alter stool consistency and quantity; up to 200 g of stool per day is normal.
- Avoid extremes in food and beverage temperatures, which may stimulate extra colonic activity.
- Correct intolerances for CHO and protein. Ensure adequate fat intake. Short-chain fatty acids enhance sodium reabsorption; include adequate fiber (American Dietetic Association, 2008).
- Probiotic foods may be useful, such as yogurt with live and active cultures.

## FOOD AND NUTRITION

- It may be useful to hold food for 12 hours with use of IV fluids and electrolytes. Start oral fluids as soon as allowed. Use oral rehydration therapy, shown in Table 7-13, or prepared products such as CeraLyte.
- **Infants:** Use rehydration solutions if allowed. Breastfeeding may be continued, or return to lactose-containing

formula when feasible. Cut back on use of sorbitol (as in apple juice).

- **Adults:** Start with broth, tea, toast, and gradually add foods to a normal diet as tolerance progresses. Three to four small meals may be better tolerated. Products such as Gatorade may be useful. Banana flakes may be a safe, cost-effective treatment for diarrhea in critically ill patients on TFs. Use products containing probiotics. For potassium, include bananas, orange juice, fruits, and vegetables in the diet. Cocoa beans contain a large amount of flavonoids; dark chocolate may offer mild relief from diarrhea (Schuier et al, 2005).
- If TF is used, check tube placement and medications, presence of bloody stools, and endoscopic exams. Treatment includes changing medications, decreasing rate of feeding, changing to a high formula, antibiotic therapy, or using antidiarrheal medications. A jejunal placement may be too far for some patients and may actually cause some diarrhea.
- Use CPN only for intractable diarrhea. Osmotic diarrhea abates with NPO. Short-chain fatty acids from high-fiber sources may be useful.
- Use multivitamin–mineral supplements to replace vitamins A and C, zinc, iron, and other nutrients.

## Common Drugs Used and Potential Side Effects

- Every patient should receive a careful medication review. Magnesium-containing antacids, digoxin, broad-spectrum antibiotics, antifungal agents, colchicine, thiazide diuretics and other antihypertensives, Azulfidine, methotrexate and other anticancer agents, cholinergic stimulants, antiemetics such as metoclopramide, and laxatives such as mineral oil or methylcellulose may cause drug-induced diarrhea. Sorbitol may cause diarrhea; it is found in many medications. Megadoses of vitamin C (>1 g daily) may cause diarrhea.
- Antibiotics are used if shigellae or amoebae are causing the problem. Suggest use of probiotics with antibiotic therapy. Intestinal flora modifiers (e.g., *Lactobacillus acidophilus*, Lactinex, Bacid) also help recolonize normal intestinal flora. A common prescription is three to four packages every day for 3 days in adults. Modifiers may be mixed with water for tube-fed patients.
- Antidiarrheal drugs are used to slow peristalsis or thicken stools. Kaolin (Kaopectate) has no major side effects but

TABLE 7-13 UNICEF/WHO Oral Rehydration Therapy<sup>a</sup>

Ingredients	Original ORS	New Reduced Osmolarity ORS
Sodium chloride	3.5 g/L	2.6 g/L
Potassium chloride	1.5 g	1.5 g/L
Sodium	2.5 g sodium bicarbonate	2.9 g/L trisodium citrate
Glucose	20 g /L of clean drinking water	13.5 g/L of clean drinking water

<sup>a</sup>Where ORS is not available, home-prepared solutions may use 1 teaspoon of salt, 8 teaspoons of sugar, and 4 oz of orange juice mixed into 1 L of water. From WHO Rehydration Project. Accessed August 1, 2009, at [http://www.rehydrate.org/ors/ort\\_how\\_it\\_works.htm](http://www.rehydrate.org/ors/ort_how_it_works.htm).

is not useful with infants. Lomotil should be taken with food; it may cause bloating, constipation, dry mouth, swollen gums, dizziness, nausea, and vomiting. Avoid using it with alcohol. Psyllium ingestion reduces stool looseness.

- Cholestyramine (Questran) may be used for bile acid diarrhea. Nausea, belching, or constipation may result. Replace fat-soluble vitamins.
- Ciprofloxacin is used for TD; one dose is often sufficient. It is a quinolone-class antibiotic. Avoid milk or yogurt. Nausea is one side effect.
- Vancomycin is used for treating *C. difficile*. Anorexia, GI distress, diarrhea, and nausea may result.
- Daily doses of rifaximin (Xifaxan) may significantly decrease TD from *E. coli*. It is not known yet if this same treatment is effective against TD from *Salmonella* and other bacteria.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. Apple, carrot, blackberry, carob, bilberry, and tea have been recommended, but no clinical trials have proven efficacy.
- Probiotic medications may be helpful: for children, *Lactobacillus* GG or Culturelle; and for adults, *Saccharomyces boulardii*. Probiotics in foods can help to maintain good bacteria in the GI tract of those taking antibiotics. Yogurt may help to reculture the GI tract; check labels for live and active cultures. Acidophilus milk is also useful.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Describe the effects of pectin as a thickening agent (as in apples and bananas), and inform about yogurt or acidophilus milk or other specific probiotic foods/supplements.
- Avoid sweetened carbonated beverages because their electrolyte content is low and osmolality is high. Caffeine, apple juice, and milk can aggravate diarrhea; omit until resolved.
- Limit fruit juice to 6 oz daily in children.
- Partially hydrolyzed guar gum (Benefiber) added to a diet ferments in the colon and produces short-chain fatty acids. This improves intestinal function, including colonic salt and water absorption (Alam et al, 2005). It may be a useful addition until diarrhea resolves.
- Newly formulated oral rehydration salts contain lower concentrations of glucose, and salt and zinc supplementation can drastically reduce the number of child deaths.
- Teach about the prevention and treatment of dehydration with appropriate fluids, breastfeeding of infants, and selective use of antibiotics to reduce the duration and severity of diarrheal episodes.
- Signs of dehydration include increased thirst, dark urine, light headedness, dry skin and less-frequent urination. Children may have no tears when crying, dry mouth and tongue, sunken abdomen or eyes.

## Patient Education—Foodborne Illness

- The World Health Organization (2009) states the following facts:  
A total of 1.8 million people die every year from diarrheal diseases (including cholera); 90% are children under 5 who live in developing countries.  
Nearly all diarrheal disease is attributed to unsafe water supply, inadequate sanitation, and poor hygiene.  
Improved water supply reduces diarrhea morbidity by 21%, improved sanitation by 37.5%.  
Simply washing hands at critical times can reduce diarrheal cases by up to 35%. Improvement of drinking water quality, such as point of use disinfection, would lead to a reduction of diarrheal episodes by half.
- To prevent TD, follow these guidelines:  
Use safe, bottled water for drinking and brushing teeth.  
Wash hands before eating, using antiseptic gel or hand wipes.  
Avoid ice in drinks.  
Do not eat raw vegetables or salads, raw fruits, or unpasteurized dairy products.  
Avoid swimming in streams and lakes.  
Use only cooked foods and bottled beverages (e.g., water, juices, beer, etc.).  
Brush teeth with bottled water only.  
Use caution with fresh foods that may have been washed in contaminated water and foods prepared with unheated water (e.g., jello) or ice cubes made with contaminated water.  
If symptoms persist, medical attention should be sought.

## DIVERTICULAR DISEASES

### NUTRITIONAL ACUITY RANKING: LEVEL 2–3

#### DEFINITIONS AND BACKGROUND

Diverticular disease results from formation of small pouches (diverticula) in the colon wall and lining due to chronic constipation. Diverticular disease occurs in Westernized countries because of low-fiber diets but is rare in societies that subscribe to high-fiber patterns. Lower GI bleeding from diverticulosis is a common reason for hospital admission, particularly in the elderly (Strate, 2005).

A high-fiber diet is the mainstay of management for diverticulosis (American Dietetic Association, 2008). Diverticulitis (inflammation) develops when bacteria or other irritants are trapped in the pouches, causing spasm and pain in the lower left side of the abdomen, as well as distention, nausea, vomiting, constipation or diarrhea, chills, and fever. Bowel cancer has been associated with the presence of diverticular disease.

Serotonin is widely distributed throughout the gut in both the enteric nerves and enterochromaffin cells, where they act as signal transducers and respond to bacterial or dietary substances with an inflammatory response and associated diarrheal symptoms respond well to 5-HT(3) receptor antagonists (Spiller, 2008). Probiotics and prebiotics are being tested for relief of pain and inflammation. Prebiotics such as guar gum are fermented into short chain fatty acids in the colon, where they stimulate water and sodium absorption. Probiotics are used to prevent or treat diarrhea; they are live organisms that eliminate toxins and inhibit proliferation of pathogens.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Altered motility is an important feature of the pathogenesis of diverticular disease, and serotonin (5-HT) release is a primary trigger of gut motility (Costedio et al, 2008).

#### Clinical/History

Height  
Weight  
BMI

Diet history

Obesity?

Physical inactivity?

CT scan	CRP	WBC
Barium enema	Erythrocyte sedimentation rate (increased)	(increased)
<b>Lab Work</b>		
H & H	Alb,	
Serum Fe, ferritin	transferrin	

#### INTERVENTION

#### OBJECTIVES

##### *Diverticulitis (Inflamed State)*

- Allow complete bowel rest to prevent perforation by avoiding the laxative effect of excess fiber.
- Eliminate food particles that accumulate in sacs as they may cause bacterial contamination.

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### **Inadequate Fiber Intake**

**Assessment:** Dietary recall of food intake with calculation of average fiber intake <8 g based on 24-hour recall and food frequency.

**Nutrition Diagnoses (PES):** Inadequate fiber intake (NI 5.8.5) related to nutrition-related knowledge deficit as evidenced by inability to list five foods high in fiber and average daily fiber intake less than 3 g/d. Altered GI function (NC 1.4) related to diarrhea for 3 days, frequent pain, and increased flatus over 3 months.

**Interventions:** Food-Nutrient Delivery—ND 1.2—soft diet, low-fiber foods until pain subsides.

Education—E 2.2—current diet order for soft, low fiber. Education on gradual introduction of fiber to diet to goal daily amount of 25–35 g; adequate fluid intake; increasing physical activity if possible. Provide list of high-fiber foods for inclusion in the diet, discuss the importance of fiber in diverticulosis.

Counseling: Discuss foods to avoid when there is discomfort.

**Monitoring and Evaluation:** Reassess dietary intake of fiber at next visit in 3 months; goal is to increase intake to 25–35 g/d. Evaluate daily dietary fiber intake using food recall/diary. Fewer complaints of pain, flatus, or diarrhea.

- Prevent peritonitis and abscess.
- Correct any GI bleeding, hypoalbuminemia, or anemia.
- Each person differs in the amounts and types of foods they can eat; keep a food diary to identify any foods that may cause symptoms or discomfort.

#### *Diverticulosis (Convalescent State)*

- Improve stool quality and increase volume, mostly from fiber.
- Relieve intraluminal pressure; decrease the contractions of colonic circular smooth muscle.
- Distend the bowel wall to prevent development of high-pressure segments and inflammation.
- Elimination of specific foods is not necessary.

### FOOD AND NUTRITION

#### *Diverticulitis (Inflamed State)*

- As treatment begins, use a soft diet with low fiber. Gradually add fiber as inflammation and pain decrease.
- Ensure adequate intake of protein and iron sources.
- A low-fat diet may be better tolerated.

#### *Diverticulosis (Convalescent State)*

- Diet should be high in fiber; 25–35 g/d is desirable. Whole grains, stewed or dried fruits, potato skins, raw carrots, or celery may be used; see Table 7-14. No evidence supports the common advice to avoid nuts and seeds (Strate et al, 2008). Eating nuts, corn, and popcorn does not increase the risk; in fact, nuts and popcorn may have a protective effect (Weisberger and Jamieson, 2009). Increase fiber gradually; avoid large excesses of fiber that may interfere with mineral absorption. Seeds in fruits or vegetables, and sunflower, pumpkin, caraway, poppy and sesame seeds do not enter, block, or irritate the diverticula and may be consumed.
- Adequate fluid is recommended.
- A vegetarian, plant-based diet is beneficial (Leitzmann, 2005) and a low-fat diet may reduce intracolonic pressure.

**TABLE 7-14** How to Eat More Fiber

- To get adequate fiber in the diet, follow the U.S. Department of Agriculture Food Guidance System (MyPyramid), which recommends eating 2–4 servings of fruit, 3–5 servings of vegetables, and 6–11 servings of cereal and grain foods each day.
  1. Be smart by eating a whole-grain cereal that contains at least 5 g of fiber per serving. 1/2 cup of bran cereal contains 10 g of fiber.
  2. Beans, peas, and lentils contain 6–9 g per 1/2 cup portion. Add them to soups, stews, and salads.
  3. Eat raw vegetables as much as possible because cooking may reduce fiber content. A baked potato with skin, broccoli, shredded carrots, and cauliflower are great choices.
  4. Eat the peel on fruits (such as apples, pears), and vegetables (such as cucumbers) because much of the fiber is found in the skin.
  5. Eat fresh and dried fruits as snacks. Pears, apples, oranges, strawberries, other berries, prunes, bananas, and figs are all good choices.
  6. Read food labels. Select foods that contain fiber whenever possible.

Sources: U.S. Department of Agriculture Nutrient Database, Release 17, 2004; and Medline Plus. Dietary fiber. 2009. Accessed at <http://www.nlm.nih.gov/medlineplus/dietaryfiber.html>

### Common Drugs Used and Potential Side Effects

- Antibiotics: For patients with severe and complicated diverticulitis, ampicillin, gentamicin, metronidazole, piperacillin, and tazobactam are used. Ciprofloxacin, metronidazole, and rifaximin are used for uncomplicated diverticular disease. Side effects may include nausea, vomiting, stomatitis, and other GI effects.
- There is not enough evidence to recommend the anti-inflammatory drug mesalamine or a polybacterial lysate for immunostimulation (Weisberger and Jamieson, 2009).
- Pain medicine may be needed when cramping or bloating is significant.
- Overusing laxatives may result in dependence on them.
- Probiotics seem to be beneficial.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Flax, wheat, wild yam, slippery elm, and chamomile have been recommended for this condition, but no clinical trials have proven efficacy.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Instruct patient concerning dietary fiber:
  - Some ingested plant material is not digested by GI enzymes, including cellulose, pectin, lignin, and hemicelluloses.
  - Some dietary fibers (whole grains) resist intestinal disintegration, whereas others (fruits and vegetables) are more or less disintegrated. In general, increased fiber increases stool volume, frequency, and transit rate and decreases intracolonic pressure (American Dietetic Association, 2008).
  - Increased stool volume and decreased intracolonic pressure improve transit time.
  - Take a fiber product such as methylcellulose (Citrucel) or psyllium (Metamucil) one to three times a day with at least 8 oz of water.
- Instruct patient to chew slowly and to avoid constipation and straining.
- If flatulence is a problem, advise that approximately 6 weeks will be needed to allow bacterial flora to adapt to increased fiber intakes.
- Adequate physical activity is beneficial.

### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual who may be experiencing diarrhea and related discomfort.
- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## FAT MALABSORPTION SYNDROME

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Rubin E MD and Farber JL MD. *Pathology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 1999.

**TABLE 7-15 Altered Stools and Related Disorders**

Characteristic	Disorder
Yellow or silver color	Fat malabsorption
Pale, foamy, mushy, or floating	Pan malabsorption
Formed in morning	Diarrhea
Formed in evening	Bile salt malabsorption

## DEFINITIONS AND BACKGROUND

Fat malabsorption syndrome is caused by functional or organic causes. There may be fatigue, weight changes, steatorrhea, abdominal distention with cramps and gas, explosive diarrhea with foul-smelling stools, malnutrition and weight loss, and biochemical abnormalities. Exocrine pancreatic insufficiency is the principal cause. Other causes may include: postgastrectomy, blind loop syndrome, Crohn's disease, small bowel resection; cystic fibrosis, chronic pancreatitis, pancreatic cancer, pancreatectomy; biliary atresia or steatorrhea; CD, lipoprotein deficiency, or HIV infection.

The individual with malabsorption syndrome must be monitored for dehydration (dry tongue, mouth, and skin; increased thirst; low, concentrated urine output; weakness or dizziness when standing). Signs of nutrient depletion include nausea, vomiting, fissures at corner of mouth, fatigue, weakness, and dry, pluckable hair. Long-term nutritional monitoring is necessary after operations for morbid obesity, which can lead to fat malabsorption and vitamin deficiencies for vitamins A, D, and K (Malinowski, 2006). Malabsorption can have severe clinical consequences, including a decline in bone health.

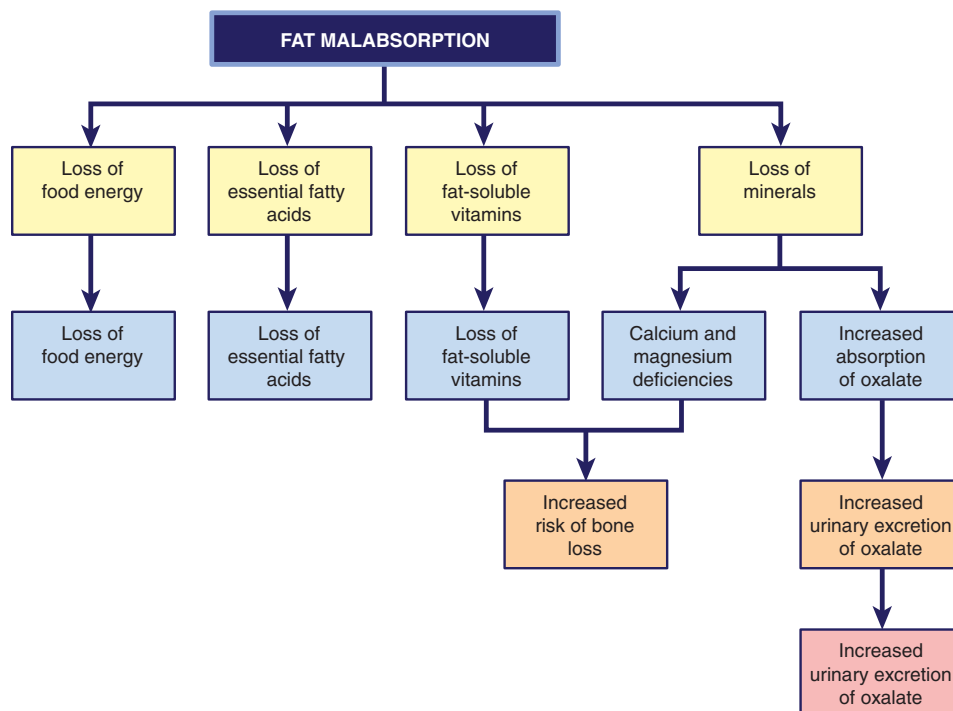

**TABLE 7-16 Fecal Fat Study**

Fat absorption is tested by quantitative measurement of total fat in the stool.	
Preparation:	Consume 100 g of long-chain triglycerides (LCT) over 3 days
Normal excretion:	Less than 7 g (5% of a 60–100 g intake)
Mild malabsorption:	7–25 g (defects in micelle formation)
Moderate malabsorption:	25–30 g (intestinal mucosal disease)
Severe malabsorption:	More than 40 g (massive ileal resection or pancreatic disease)

Adapted from Hermann-Zaidins M. Malabsorption. *J Am Diet Assoc.* 86:1171, 1986.

To avoid nutritional deterioration, early screening for fat malabsorption should be recommended. Low total cholesterol (<120 mg/dL) or low serum carotene levels may be typical of fat malabsorption but are not necessarily diagnostic. Altered stools characterize different types of malabsorption, as shown in Table 7-15. In patients with bile acid malabsorption, a larger amount of bile acids is spilled into the colon, where the acids stimulate electrolyte and water secretion, which results in loose to watery stools (Westergaard, 2007). Patients with more severe bile acid malabsorption have both diarrhea and steatorrhea; these patients are best treated with a low-fat diet supplemented with MCTs (Westergaard, 2007). A fecal fat study, though now uncommon, may be ordered; see Table 7-16.

Enteric hyperoxaluria is the major risk factor for fat malabsorption, especially with IBD. In UC after restorative proctocolectomy, an increase of serum AA occurs with lower utilization for inflammatory processes, and reduced LDL cholesterol occurs as an index of malabsorption (Scarpa et al, 2008). Probiotics are being studied.

Adapted from: Merck Manual. Malabsorption syndromes. [http://www.merck.com/media/mmpe/pdf/Figure\\_017-1.pdf](http://www.merck.com/media/mmpe/pdf/Figure_017-1.pdf). Website accessed 9/1/09.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Fat malabsorption is typically a symptom of an underlying disorder that may be either genetic or acquired.

Clinical/History	Lab Work	
Height	Tryptophan load	D-xylose test
Weight	test for	(decreased
BMI	vitamin B <sub>6</sub>	excretion?)
Diet history	Fecal Ca <sup>++</sup>	Serum vitamin E
BP (may be low)	Acid steatorrit	Schilling test for
Signs of	Malabsorption	vitamin B <sub>12</sub>
dehydration?	blood test	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup> (may
Failure to thrive	<sup>14</sup> C-triolein	be low from
in children	breath test	diarrhea)
Perianal itching	Fecal fat study:	Ca <sup>++</sup> , Mg <sup>++</sup>
or soreness	72-hour stool	(may be low)
Frequent, foul-	collection	Chol (may be
smelling stools	Labeled carbon	decreased)
Small intestine	breath test	Trig
biopsy	Sudan stain test	H & H
CT scan or MRI	Serum carotene,	Serum Fe, ferritin
Barium enema	vitamin A	Gluc
or x-rays	(may be low)	Alb, transthyretin
		(may be low)
		CRP

## INTERVENTION

### OBJECTIVES

- Monitor for malabsorption of fat-soluble vitamins (A, D, E, and K). Long-term consequences of vitamin deficiency results if fat malabsorption is not corrected.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal Nutrient (FAT) Utilization

**Assessment:** I & O, abnormal nutritional labs for cholesterol, albumin, electrolytes. Fecal fat test results showing excesses of 20 g fat in stool; stools of yellowish hue. Abdominal pain.

**Nutrition Diagnoses (PES):** Abnormal fat utilization related to malabsorption as evidenced by fecal fat study showing fat in stool of >20 g/d, yellowish stools, and abdominal pain.

**Interventions:** Food and nutrient delivery: alter diet to include products containing MCT oil until condition can be resolved.

Education: Discuss how fat malabsorption affects metabolism and absorption of nutrients. Counseling: Inclusion of water-miscible forms of fat-soluble vitamins, more calcium and water-soluble vitamins.

**Monitoring and Evaluation:** Improvement in nutritional labs; fewer yellowish or abnormal stools. Fecal fat study showing less than 7 g fat. Less abdominal discomfort.

**TABLE 7-17 Medium-Chain Triglycerides (MCTs)**

- Many products now contain MCTs as the primary fat source.
- MCTs use portal (albumin-free fatty acids) rather than lymphatic system transport and absorption (using less lipase and bile).
- MCTs have an 8- to 10-carbon source of fat and are useful when longer chain fatty acids (16–18 carbons) cannot be efficiently digested or absorbed.
- MCTs have concentrated calories made from coconut oil for adjunct therapy.
- MCT oil has 230 kcal/30 mL (6–7 kcal/g). Use instead of vegetable oil in recipes.

- Prevent calcium oxalate stone formation, or correct where present.
- Correct all other nutrient deficiencies.
- Alleviate steatorrhea and reduce intake of fat sources that are not tolerated. MCTs are useful. See Table 7-17.

## FOOD AND NUTRITION

- Initial treatment should consist of parenteral solutions or liquid formulas that contain MCT. MCTs alleviate steatorrhea in some cases; start with 20–60 g and increase gradually in an adult.
- For mild cases, oral feeding is preferred because it stimulates brush-border activity. For moderate-to-severe cases, tube feed if necessary (50 mL/hr full strength initially; advance gradually).
- Dietary fat may be limited to one egg and 4–6 oz of meat, poultry, or fish. Gradually check tolerance for long-chain triglycerides (LCTs) and work up to 30–40 g.
- Increase intake of protein, which may be in the form of skim milk, egg white, cereals, or legumes.
- Complex carbohydrates may be better tolerated than simple sugars. Lactose may not be tolerated.
- A multivitamin–mineral supplement may be necessary to offset fecal losses of nutrients, vitamins, and water in patients with malabsorption syndromes—especially zinc, folate, vitamin B<sub>12</sub>, calcium, magnesium, iron, and fat-soluble vitamins (A, D, E, and K).
- Monitor or decrease dietary oxalate intake to prevent renal stones. Use of probiotics may be helpful.

## Common Drugs Used and Potential Side Effects

- Antibiotics are used for bacterial overgrowth. Suggest use of yogurt with live and active cultures with antibiotic therapy. Intestinal flora modifiers (e.g., *Lactobacillus acidophilus*, Lactinex, Bacid) also help recolonize normal intestinal flora, perhaps three to four packages every day for 3 days in adults. They may be mixed with water for TFs.
- Antidiarrheals may be used, such as kaolin (Kaopectate). Cholestyramine may be needed for bile salt diarrhea; fat-soluble vitamins can be depleted.
- Cholylsarcosine (CS) is a semisynthetic bile salt replacement. If used properly, no side effects occur.
- Orlistat inhibits pancreatic lipase and blocks the absorption of 30% of ingested fat in patients seeking weight loss.

By its nature, it has the potential to create fat malabsorption syndrome, and use should be carefully monitored to assure that nutrient deficiencies do not occur.

- Pancreatic enzymes may be needed if there is pancreatic insufficiency.
- Patients with mild-to-moderate bile acid malabsorption present with watery diarrhea and generally respond very well to treatment with bile acid binders such as cholestyramine (Westergaard, 2007).
