## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Caution the patient about a rapid consumption of MCTs. If they are consumed too rapidly, hyperosmolar diarrhea may result. Abdominal discomfort, flatulence, diarrhea, or steatorrhea may indicate continued malabsorption; the physician should be contacted.
- Encourage several small, frequent meals throughout the day, avoiding fluids and foods that promote diarrhea. Monitor I & O of fluids, along with the number, color, and consistency of stools.

- Remember that a source of essential fatty acids may be needed if MCTs are used with a low-fat diet.

## Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to this individual who may be experiencing diarrhea and related discomfort.
- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# INFLAMMATORY BOWEL DISEASE: CROHN'S DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### Crohn disease

- Both large and small bowel involved
- Areas of normal bowel skipped

### Ulcerative colitis

- Small bowel not involved
- Continuous involvement—No skipped areas of normal bowel

Adapted from: Thomas H. McConnell, *The Nature Of Disease Pathology for the Health Professions*, Philadelphia: Lippincott Williams & Wilkins, 2007.

## DEFINITIONS AND BACKGROUND

Crohn's disease involves acute and chronic granulomatous, IBD with a cobblestone effect. Onset is generally between 15 and 30 years of age. Crohn's disease differs from UC by affecting mucosal tissue of GI tract from oral cavity to rectum. In 33%, only the ileum is involved; in 45%, both the ileum and the large intestine are affected.

As many as 1.4 million persons in the United States and 2.2 million persons in Europe suffer from with IBD. Macroscopic cobblestoning, segmental colitis, ileal stenosis and ulceration, perianal disease, and multiple granulomas in the small bowel or colon strongly suggest a diagnosis of CD. The causative antigen in IBD is the microflora in the intestinal lumen, facilitated by an impaired innate immune system; these provoke T helper 1 and T helper 17 responses in Crohn's disease and a T helper 2 response in UC, resulting in pro-inflammatory cytokines and interleukins (Festen et al, 2009). Increased numbers of mucosa-associated *E. coli* are observed (Willing et al, 2009). Patients with CD exhibit a profound systemic failure of the acute inflammatory response that results in markedly delayed clearance of bacteria from the tissues, leading to local chronic granulomatous inflammation and compensatory adaptive changes (Sewell et al, 2009).

Environmental triggers include smoking, northern geographic residence, allergic and autoimmune responses. Both passive and active smoke exposure in childhood predisposes children to IBD (Mahid et al, 2007). In addition, the pathways for amino acids, fatty acids, bile acids and AA are altered (Jansson et al, 2009).

The intestinal lumen decreases; peristalsis from food intake causes cramping pain, especially in the right lower quadrant. Only 25% of Crohn's disease cases present with the classic triad of abdominal pain, weight loss, and diarrhea (Beattie et al, 2006). Chronic watery diarrhea results from edema, bile salt malabsorption, bacterial overgrowth, and ulceration. Children may present with growth failure, inflammation, fever, pallor, and anemia. Stricture may precipitate bowel obstruction. Fever, weight loss, nausea, mouth sores, anal fissures, vomiting, abdominal pain, intestinal bleeding, arthritis, iritis or uveitis, conjunctivitis, jaundice, or pruritus may also be present. Elevated plasma tHcy is common. Nutritional therapy is an essential adjunctive treatment. In cases of short bowel syndrome (SBS), long-term CPN may be essential.

Anti-TNF alpha (anti-TNF $\alpha$ ) therapies have been used. Complications associated with Crohn's disease include arthritis, skin problems, inflammation in the eyes or mouth, kidney stones, gallstones, or other diseases of the hepatobiliary system. If medical management fails, surgery may be indicated for continuous bleeding; recurrent ileus, abscesses, or fistulae. After total proctocolectomy, patients have less morbidity and are more likely to be weaned off all Crohn's-related medications (Fichera et al, 2005).

Persons with Crohn's disease are at increased risk for colon cancer, obstruction, anorectal fistulas, and abscesses. Chronic inflammatory processes cause overproduction of reactive oxygen and nitrogen species, overproduction or activation of key AA metabolites and cytokines/growth factors, and immunity system dysfunction (Yang et al, 2009). Researchers are looking at genetically altering *Bacteroides ovatus*, naturally in the gut, to secrete human growth factor

KGF-2 protein when exposed to xylan sugar and to heal the damage caused by inflammation (Hamady et al, 2008).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Crohn's disease is associated with multiple mutations in the CARD15, the interleukin 23 receptor (IL23R) and autophagy-related 16-like 1 (ATG16L1) genes. The G allele of SNP rs2241880 confers strong risk for CD with a coding variant, threonine-to-alanine substitution at amino acid position 300 of the ATG16L1 protein (Grant et al, 2008).

<b>Clinical/History</b>	Abdominal CT Upper endoscopy	Transferrin, TIBC
Height	Colonoscopy with biopsies	N balance
Weight		Serum tHcy
BMI		Serum folate
Weight loss?		Serum B <sub>12</sub> and Schilling test
Stunted growth?	<b>Lab Work</b>	Ca <sup>++</sup> , Mg <sup>++</sup>
Diet history	WBC, ESR (increased)	Serum B <sub>12</sub>
BP (fever?)	Crohn's disease activity factor (CDAI)	Total protein
Temperature		BUN, Creat
Rectal bleeding		Serum carotene
Diarrhea		Serum zinc (decreased)
Number of bowel movements, frequency	CRP	TLC

	Serum Fe, ferritin (decreased)	Hydrogen breath test
	Na <sup>+</sup> , K <sup>+</sup>	
	Alb, transthyretin (low)	

## INTERVENTION

### OBJECTIVES

- Replace fluid and electrolytes lost through diarrhea and vomiting. Lessen mechanical irritation and promote rest, especially with diarrhea.
- Replenish nutrient reserves; correct malabsorption or anemia. Poor nutritional status may be related to decreased intake from anorexia, nausea or vomiting, abdominal pain, restrictive diets, side effects of medications, protein losses from ulcerated mucosal lesions, blood loss or wound-healing requirements, bacterial overgrowth, and malabsorption.
- Monitor lactose and gluten intolerances, which may be present.
- Promote healing; rest bowel from offending agents. Provide foods that contain short-chain fatty acids and glutamine to promote healing.
- Prevent peritonitis, obstruction, renal calculi, and fistulas.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Food and Nutrition Knowledge Deficit**

**Assessment:** Food diary, x-ray reports, biopsy.

**Nutrition Diagnosis (PES):** Food and nutrition-related knowledge deficit (NB 1.1) related to management of Crohn's as evidenced by new diagnosis and request for information from patient and family.

Altered GI function (NC 1.4) related to inflammation in newly diagnosed Crohn's disease as evidenced by diarrhea for 2 weeks; abdominal pain and cramping after meals.

Involuntary weight loss (NC 3.2) related to diarrhea and inability to consume and digest adequate daily kilocal as evidenced by weight loss of 15 lb in last 60 days.

**Interventions:** Food and Nutrient Delivery: ND 3.2.1 Multivitamin/mineral supplement. Clear liquids advancing to low residue diet prior to discharge.

Educate on low residue diet as needed, use of probiotic foods, and small frequent meals with lactose-free foods as needed.

Coordinate Care: Refer to gastroenterology dietitian specialist for outpatient follow-up.

**Monitoring and Evaluation:** Improved intake and type of foods; symptoms resolved or improved. Monitor Hgb, Alb, Na<sup>+</sup>, K<sup>+</sup> for improvements while inpatient; weight for maintenance and eventual regain to usual body weight; bowel health with regard to decreased cramping and diarrhea after meals.

- Promote weight gain or prevent losses from exudates or inadequate intake.
- Prepare for surgery if necessary after failed medical management, obstruction, fistula, or peritonitis. A total colectomy or a right-sided ileocelectomy may be necessary.
- In a child, promote growth. Growth spurts follow sustained weight gain.
- Reduce inflammatory process; fish oil intake may reduce severity of symptoms.
- Monitor mineral and trace element levels carefully to ensure adequacy. Iron tends to be low. Antioxidant intake should be increased.
- Prevent or correct metabolic bone disease (e.g., osteopenia, arthropathies) caused by disease itself, nutrient malabsorption, side effects of medications, or lifestyle factors.
- Because tHcy production within the intestinal mucosa may contribute to the inflammatory response and endothelial cell dysfunction, treat folate and vitamin B<sub>12</sub> deprivation as well as methylenetetrahydrofolate reductase (MTHFR) polymorphisms (Peyrin-Biroulet et al, 2007). Prevent thrombotic events.

**FOOD AND NUTRITION**

- For adult energy requirements, estimate needs according to current BMI. A low BMI (<15) may require

35–45 kcal/kg; a BMI of 15–19 may require 30–35 kcal/kg; a BMI of 20–29 may require 25–30 kcal/kg; and a high BMI (>30) may only require 15–25 kcal/kg. Estimate needs at the high end of normal for growth and repair in infants or children.

- With strictures or fistulas, use a low-fiber diet that is high in energy with a high protein content of 1–1.5 g/kg.
- For some patients, TF with added glutamine may be useful. Polymeric formulas are acceptable; elemental products are not required. Randomized controlled trials show that enteral nutrition is effective.
- Perioperative PN may reverse malnutrition and facilitate rehabilitation (Yao et al, 2005). If CPN is needed after total colectomy, use indirect calorimetry to estimate needs.
- A diet relatively high in fat may improve energy balance. Limit fat intake only if steatorrhea is present, in which case MCTs may be better tolerated. Omega-3 fatty acids may be indicated.
- Supplement the diet with multivitamins and minerals, especially thiamine, folacin, vitamin B<sub>12</sub>, vitamin E, zinc, vitamin D, calcium, magnesium, and iron. Vitamins A and K should be given every other day. With resection greater than 200 cm, selenium may become deficient; monitor carefully.
- Reduce lactose intake if not tolerated. Check for wheat and gluten tolerances.
- Monitor progress carefully; patients may be finicky. Small, frequent meals may be better tolerated.

**Common Drugs Used and Potential Side Effects**

- Therapies for CD typically include aminosalicylates and antibiotics (for mild mucosal disease), nutritional therapy (including elemental or polymeric formulas), corticosteroids (for moderate disease), and infliximab for corticosteroid-resistant or fistulizing disease (Rufo and Bousvaros, 2006). Standard treatments with 5-aminosalicylic acid, antibiotics, corticosteroids, and immunosuppressives have serious and potentially adverse events (Krygier et al, 2009).
- Anti-inflammation drugs are first-line treatments, with mesalamine in 5-ASA agents (Asacol, Canasa, Pentasa) or sulfasalazine (Azulfidine). Side effects include nausea, vomiting, heartburn, diarrhea, headache, folate depletion.
- Antibiotics reduce bacterial overgrowth and vitamin K may be needed for fistulas. Ampicillin, sulfonamide, cephalosporin, tetracycline, or metronidazole are common choices. Metronidazole may be used when there is anal involvement; nausea, vomiting, anorexia, or diarrhea may occur.
- Anti-diarrheal agents are needed, such as diphenoxylate, loperamide, and codeine.
- Corticosteroids such as Budesonide (Entocort) are used in large doses at first. They are most effective with colon involvement. Patients will need a diet that provides sodium restriction, with extra protein, calcium, and potassium. Corticosteroids are more effective than enteral nutrition (Zachos et al, 2007).

- Anti-TNF $\alpha$  therapy is beneficial. Infliximab (Remicade) was the first treatment approved specifically to reduce inflammation in Crohn's disease. The anti-TNF  $\alpha$  agents are effective in the induction and maintenance of remission in luminal and fistulizing Crohn's disease; early use with immunosuppressives may alter progression of the disease and prevent late complications (Krygier et al, 2009).
- Some neuroregulatory peptides act as endogenous immune factors with anti-inflammatory effects; selective peptide analogs are being developed as novel therapeutic strategies for IBD patients (Motilva et al, 2008).
- Retinoic acid and vitamin D are being studied for their possible effects in gut immunity and Crohn's disease (O'Sullivan, 2009).
- In MTHFR polymorphisms, use of L-methylfolate may be useful; Depkin is one prescription drug.

## Herbs, Botanicals, and Supplements

- Use of complementary medicine is common in this population (Langhorst et al, 2005). Omega-3 fatty acids help to reduce symptoms of Crohn's disease. Alpha linoleic acid (ALA) works better at decreasing bowel inflammation than EPA and DHA. Fish oil supplements can cause side effects such as flatulence and diarrhea.
- Phytochemicals such as turmeric (curcumin), red pepper (capsaicin), cloves (eugenol), ginger (gingerol), cumin, anise, and fennel (anethol), basil and rosemary (ursolic acid), garlic (diallyl sulfide, S-allylmercaptocysteine, ajoene), and pomegranate (ellagic acid) can suppress some inflammatory pathways (Aggarwal and Shishodia, 2004).
- Probiotics may be beneficial; clinical studies are needed to verify the specific bacteria to be recommended. Studies have been performed with a variety of antioxidants, glutamine, short-chain fatty acids and prebiotics.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage patient to eat. Discuss fiber, fluid, and supplements.
- Periodic assistance or reevaluation by a qualified dietitian may be helpful. Alleviate fears associated with mealtimes.
- Ensure that sources of potassium are increased during periods of diarrhea.
- Instruct patient to chew foods well and avoid swallowing air.
- Bone density should be monitored yearly (Sylvester et al, 2007). Highlight calcium and vitamin D and discuss alternate sources when milk cannot be used. Promote exercise as well.
- Nocturnal TFs have been useful to regain weight or to promote growth. Total enteral nutrition with a liquid formula can suppress gut inflammation and induce remission in active Crohn's disease (Johnson et al, 2006; Newby et al, 2005).

## Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual who may be experiencing diarrhea and related discomfort.
- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## INFLAMMATORY BOWEL DISEASE: ULCERATIVE COLITIS

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

UC is a chronic inflammatory disease of the mucosa of the colon. Complications can include arthritis, severe skin rashes, endocarditis, cirrhosis, splenomegaly, and stomatitis. Patients with UC may have histological features such as microscopic inflammation of the ileum, histological gastritis, periappendiceal inflammation, patchiness, and relative rectal sparing at the time of diagnosis (North American Society for Pediatric Gastroenterology, 2007).

UC usually begins in the rectum or sigmoid colon. When UC affects only the rectum, it is called **ulcerative proctitis**. If the disease affects only the left side of the colon, it is called **distal colitis**; and if it permeates the entire colon, it is termed **pancolitis**. The condition is often a relentless, continuous lesion of the colon with some involvement of the terminal ileum. It does not affect full thickness of the intestine and never affects the small intestine. UC may be acute, mild, or chronic. **Indeterminate colitis** may be diagnosed with features of both UC and Crohn's disease; this is called **colitis of uncertain type or etiology** (Geboes et al, 2008).

The pathogenesis is complex and involves environmental, genetic, microbial, and immune factors. Onset of UC is usually between 15 and 35 years of age. There is a second, lesser peak of onset between ages 50 and 70 years. Intestinal microvascular ischemia usually precedes the onset of UC (Ibrahim et al, 2009). Blood in the stool is the most common symptom (Beattie et al, 2006) but children who present with UC may also have growth failure. Remissions occur, and there may be long periods between exacerbations. Flares often involve non-GI symptoms such as arthritis, uveitis, and ankylosing spondylitis. Because increased risk of colon cancer exists for the more extensive disease, patients with UC should be enrolled in a colonoscopy surveillance program after 8–10 years of disease duration (Rufo and Bousvaros, 2006).

Probiotic bacterial mixtures provide relief in mild-to-moderate UC by reducing the number of “bad” bacteria, reducing the amount of inflammation, increasing the mucus layer of the gut, and increasing the number of anti-inflammatory molecules in the intestine (Bibioli et al, 2005). Researchers are looking at genetically altering *Bacteroides ovatus*, naturally in the gut, to secrete human growth factor KGF-2 protein when exposed to xylan sugar (Hamady et al, 2008). This may help to heal the damage caused by inflammation.

Both nutritional deficiencies and nutritional excesses impair GI responses and alter susceptibility to inflammation and other diseases. Enhancement of micronutrient nutrition is an important determinant of immunity and treatment of side effects in UC (Scrimgeour and Condlin, 2009).

Approximately 15% of patients with UC will develop a severe exacerbation requiring hospitalization (Doherty and Cheifetz, 2009). If medical management fails, surgical colectomy to remove the colon and rectum is curative. The ileocecal valve should be preserved where possible. Colectomy with creation of an ileal pouch anal anastomosis (J pouch) is standard for patients with severe or refractory colitis, resulting in an improved quality of life in most patients (Rufo and Bousvaros, 2006).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** IBD is associated with inheritance of several specific SNPs and gene variants that disrupt bacterial homeostasis mechanisms (Ferguson et al, 2007) and promote venous thrombosis (Bernstein et al, 2006). The ECM1 gene is found in UC (Jung and Hugit, 2009). Methionine synthase and MTHFR C677 T are also associated with extent of UC (Chen et al, 2008). Microflora in the intestinal lumen and an impaired innate immune system provoke a T helper 2 response, resulting in pro-inflammatory cytokines and interleukins (Festen et al, 2009). The IL-12-related cytokine, designated IL-23, establishes chronic inflammation and in the development of a Th cell subset producing IL-17, designated Th17 (Boniface et al, 2008; Shih and Targan, 2008).

<b>Clinical/History</b>	Temperature	Pus or mucus
Height	Stool sample	discharged
Weight	Bloody or explosive diarrhea	between stools
BMI	Crampy abdominal pain	Anemia, fatigue
Diet history		Anorexia

	N balance	WBC
		Hydrogen
		breath test
		Fecal fat study

## INTERVENTION

### OBJECTIVES

- In acute stages, allow the bowel to heal and use products that include short-chain fatty acids and glutamine to prevent a decline in nutritional status. Correct fluid and electrolyte imbalance.
- Develop an optimal regimen of pharmacologic therapies, nutritional management, psychologic support, and properly timed surgery (when necessary) to maintain disease remission, minimize disease and drug-induced adverse effects, and optimize growth and development (Rufo and Bousvaros, 2006).

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Nutrient Intake

**Assessment Data:** BMI 19, recent weight loss of 10 lb in 3 months, abdominal pain and bloody diarrhea at least once daily for 2 weeks. Diet hx reveals intolerance for high fiber fruits and vegetables and poor intake of protein-rich foods.

**Nutrition Diagnoses (PES):** Inadequate nutrient intake related to GI discomfort and maldigestion as evidenced by weight loss 10 lb in 3 months, intolerance of fruits and vegetables, poor intake of protein-rich foods.

**Interventions:** Food and nutrient delivery—change diet to low residue during flare. Educate about the role of diet in reducing inflammation; add omega-3 fatty acids and a multivitamin–mineral supplement once daily. Counsel about fiber-rich foods and when to avoid them (such as during times of GI distress). Discuss use of frequent small meals and intake of fruit and vegetable juices. Provide tips for adding protein and kilocalories into the diet to regain lost weight. Discuss the option of using probiotic food sources.

**Monitoring and Evaluation:** Weight status; diet hx revealing improved intake from all food groups; fewer incidents of GI distress with use of the low residue diet, omega-3 fatty acid supplements, and appropriate medicines.

- Replenish depleted stores and correct poor nutritional status. Poor nutritional status may be related to decreased intake from anorexia, nausea or vomiting, abdominal pain, restrictive diets, side effects of medications, protein losses from ulcerated mucosal lesions, blood loss or wound-healing requirements, bacterial overgrowth, or malabsorption.
- Avoid further irritation of the bowel by managing fiber intake. Large fecal volume distends the bowel and could create obstruction. Correct for diarrhea, steatorrhea, obstruction, and related anemias.
- Provide sufficient dietary antioxidants and omega-3 fatty acids, which play a role in inflammatory processes. UC patients may be able to reduce steroid doses and achieve good symptom control by drinking a nutritionally balanced cocktail of fish oil, soluble fiber, and antioxidants daily.
- Prolonged use of corticosteroids, calcium and vitamin D deficiency, and a low BMI are some of the possible contributing factors to bone disease. Replenish as needed.
- Production of tHcy within the intestinal mucosa can contribute to the inflammatory response and endothelial cell dysfunction; treat folate and vitamin B<sub>12</sub> deprivation as well as MTHFR polymorphisms, history of intestinal resection, or treatment with methotrexate (Peyrin-Biroulet et al, 2007). Prevent thrombotic events.

## FOOD AND NUTRITION

- For adult energy requirements, estimate needs according to current BMI. A low BMI (<15) may require 35–45 kcal/kg; a BMI of 15–19 may require 30–35 kcal/kg; a BMI of 20–29 may require 25–30 kcal/kg; and a high BMI (>30) may only require 15–25 kcal/kg.
- Estimate needs at the high end of normal for growth and tissue repair in infants or children.
- To treat the condition in its acute state, a low-fiber diet is needed to minimize fecal volume. A nutritional supplement that contains fish oil, soluble fiber, and antioxidants reduces reliance on traditional therapies and lessens the need to start on corticosteroid therapy (Seidner et al, 2005).
- Persons with this condition often have lactose, wheat, or gluten intolerance. Alter diet accordingly.
- Dietary changes that have been suggested include use of less red meat, dairy products, artificial sweeteners, and caffeine. Controlled trials are needed to confirm efficacy of these changes.
- Diet should limit nuts, seeds, legumes, and coarse whole grains during a flare. Fresh fruits and vegetables may not be tolerated if they are highly fibrous; monitor carefully. A low-residue diet is useful during exacerbations.
- CPN is useful when needed, often for 2 weeks or longer during acute stages. CPN may be needed in long term if there is short-gut syndrome.
- As the patient progresses, a high-protein diet (1–1.5 g/kg) with high energy intake, given in six small feedings, is recommended. Protein may have to be restricted in patients with renal disease.
- Vitamin–mineral supplementation may be needed. Supplement the diet with multivitamins and minerals,

especially zinc, thiamin, folic acid, vitamin B<sub>12</sub>, vitamin E, vitamin D, calcium, magnesium, and iron. Vitamins A and K can be given every other day. With resection greater than 200 cm, selenium may become deficient; monitor carefully.

- MCTs may be helpful. Use omega-3 fatty acid sources, such as salmon, mackerel, and tuna; supplements also may be beneficial.
- **After colectomy with ileostomy:** IV feeding should continue for 1–2 days. Diet should progress slowly to a low-fiber, high-protein regimen with high energy, vitamins, and minerals (especially sodium and potassium). The patient will need vitamin B<sub>12</sub> injections and adequate fluid. CPN may be needed if progress is slow. Once liberalized, foods are added one at a time. Avoid gas-forming foods that may cause increased peristalsis; products to reduce flatulence may be helpful.

### Common Drugs Used and Potential Side Effects

- The principal medical therapies used to induce disease remission in patients with UC are aminosaliclates for mild disease, corticosteroids for moderate disease, and cyclosporine for severe disease (Rufo and Bousvaros, 2006). Maintenance therapies that are used to prevent disease relapse include aminosaliclates, mercaptopurine, and azathioprine (Rufo and Bousvaros, 2006).
- Aminosaliclates (mesalamine, olsalazine, and sulfasalazine) contain 5-aminosalicylic acid (5-ASA) and reduce inflammation. Extra fluid intake is needed to avoid renal stone formation. anorexia, nausea, vomiting, and GI distress may occur. Folic acid supplements also may be required.
- Antibiotics such as metronidazole and ciprofloxacin reduce intestinal bacteria and directly suppress the intestine's immune system. They should be used with probiotics such as yogurt containing live and active cultures.
- Corticosteroids (prednisone, methylprednisolone, and budesonide) are used for patients with moderate-to-severe disease to reduce inflammation also. Although steroids can be quite effective for short-term control of acute episodes of colitis (flare-ups), they are not recommended for long-term use due to side effects. Negative nitrogen and calcium balances may result. Monitor the need for extra vitamins and minerals.
- Immunomodulatory medicines including azathioprine, 6-mercaptopurine (6-MP), 6-thioguanine (6-TG), and cyclosporine alter the immune cell interaction with the inflammatory process. They are used for patients when aminosaliclates and corticosteroids have been ineffective. Azathioprine and 6-MP may be useful in reducing dependence on corticosteroids and in maintaining remission in some patients. These medications take several months before their beneficial effects begin to work.
- Psyllium laxatives (Metamucil) can help with constipation and diarrhea. Long term use alters electrolytes. Flatulence or steatorrhea may occur.
- TNF-neutralizing agent infliximab (Remicade) appears to be an effective option for patients with UC that are not responding to conventional treatment.

- Therapies under investigation include tacrolimus and novel biologic drugs. However, there is the challenge of addressing potential safety issues, while more traditional drugs should be further developed to facilitate patient compliance (Pastroelli et al, 2009). The delivery system and frequency of medication administration should be resolved (Tindall, 2009).

### Herbs, Botanicals, and Supplements

- Probiotics may be beneficial. Inulin and oligofructose have been suggested to increase the number of natural intestinal flora.
- Use of complementary medicine is common in this population (Langhorst et al, 2005). Further study is needed to evaluate whether glutathione or coenzyme Q10 affects prevention or treatment of IBD.
- Herbs and botanical supplements should not be used without discussing with the physician. Onion, cat's claw, boswellia, honeysuckle, peppermint, valerian, and tea have been recommended for this condition, but no clinical trials have proven efficacy.
- Omega-3 fatty acids may help to reduce symptoms of UC. ALA works better at decreasing bowel inflammation than EPA and DHA. Fish oil supplements may cause flatulence and diarrhea.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Ensure that the patient avoids foods that are known to cause diarrhea. Avoid extremes in food or beverage temperatures.
- Pleasant mealtimes are an important part of treatment. Frequent, small meals may increase the total nutritional intake. Discontinue eating 2–3 hours before bedtime.
- Avoid iced or carbonated beverages, which may stimulate peristalsis in times of discomfort.
- Instruct the patient to eat slowly and chew foods well. Discuss fears related to eating.
- Frequent counseling by a dietitian may be helpful.
- It has been noted that women with IBD tend to be childless or have fewer children. However, fears should be discussed, as adverse reproductive problems are not common (Mountfield et al, 2009).

### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to this individual who may be experiencing diarrhea and related discomfort.
- Avoid excessive use of hand sanitizers, as a healthy gut contains some bacteria.
- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# INTESTINAL FISTULA

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

An intestinal fistula is an unwanted pathway from intestines to other organs (e.g., the bladder). External fistulas are between the small intestine and the outside (e.g., skin). Internal fistulas are between two internal organs. Most fistulas occur secondary to abdominal surgery, and a high proportion occurs in association with IBD, intestinal cancer, or trauma. In patients with a suspected fistula, CT followed by a colonoscopy helps to rule out malignancy.

Nutrition support may support spontaneous fistula closure. If spontaneous (nonoperative) closure does not occur in 5–6 weeks, it is unlikely to occur and an operation will be required (Osborn and Fischer, 2009).

GI cutaneous fistulas are among the more complex surgical conditions, with mortalities between 6% and 20%, and even up to 40% (Osborn and Fischer, 2009). Substantial morbidity is related to large fluid and electrolyte losses and metabolic disturbances; mortality is most often related to sepsis and malnutrition (Slater, 2009). Hypertriglyceridemia (266 mg/dL) is commonly observed with enterocutaneous fistulas; it is associated with sepsis, a high output small bowel fistula, nutrition by the parenteral route, and primary diseases with inflammatory etiology (Visschers et al, 2009).

Laparoscopic surgery may be a safe and effective procedure (Laurent et al, 2005), but surgery is performed only

after 4–6 months of medical therapy. Fistuloclysis is a procedure in which nutrition is provided via an enteral feeding tube placed directly into the distal lumen of a high output fistula (Slater, 2009). The primary determinant of mortality after enterocutaneous fistula (ECF) repair is a failed operation leading to recurrence of the fistula, especially with IBD, fistula located in the small intestine, an interval of 36 weeks or longer between diagnosis and operation, and resection with stapled anastomosis (Brenner et al, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** A fistula is acquired in most cases.

#### Clinical/History

Height  
Weight  
Weight loss

BMI  
Diet history  
Temperature  
(Fever?)

I & O  
Pain, tenderness  
Malaise  
CT scan

Fistulagram	Serum Fe, ferritin	RBP
Colonoscopy		BUN, Creat
Endosonography	Serum folate	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
	N balance	Transferrin
<b>Lab Work</b>	Alb,	Ca <sup>++</sup> , Mg <sup>++</sup>
H & H	transferritin	

## INTERVENTION

### OBJECTIVES

- Promote rest and healing, minimize drainage from fistula, and prevent organ failure from sepsis.
- Monitor the type of dietary regimen according to the location of the fistula and surgical or medical treatment. Adjunctive steps following the operation usually include a gastrostomy and a catheter jejunostomy (Osborn and Fischer, 2009).
- Replace fluid and electrolyte imbalances.
- Decrease malnutrition and infections through aggressive nutritional support. Promote positive nitrogen balance. Additional surgery may be needed to drain infection.

### FOOD AND NUTRITION

- A jejunostomy may help a duodenal fistula. A higher protein intake than usual may be needed. Use of an elemental formula diet also may be beneficial for an extended period of time to support GI tract recovery.
- Use CPN for jejunal fistulas. Monitor closely for hypertriglyceridemia.
- Progress to a low-residue, soft or normal diet as tolerated.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Excessive Parenteral Nutrition

**Assessment Data:** High output small bowel fistula, elevated triglycerides (>300 mg/dL), CPN for 10 days, 15 lb weight loss from Crohn's disease and poor intake over past year. BMI 19.

**Nutrition Diagnoses (PES):** Excessive intake from PN related to attempt to resolve high output small bowel fistula with CPN as evidenced by elevated triglycerides and use of CPN exceeding needs for 10 days.

**Interventions:** Calculation of current needs for protein, kilocalories, and lipids to lower TG level without compromising fistula repair.

**Monitoring and Evaluation:** Weights, lab values (especially glucose and TG), gradual healing of fistula over 4–6 weeks without surgery, BMI improving slowly.

## Common Drugs Used and Potential Side Effects

- Antibiotics commonly are used. Metronidazole and ciprofloxacin are useful.
- Infliximab has been used with some success for healing fistulas in IBD.
- Octreotide (somatostatin analog) inhibits endocrine/exocrine secretions and excessive GI motility. It is only used parenterally and can cause nausea, vomiting, abdominal pain, diarrhea, or flatulence.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Probiotic and prebiotic therapy may be useful.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Defined formula diets can help support spontaneous closure in approximately 4–6 weeks. If closure has not occurred, surgery is aided by better nutritional status.
- Instruct the patient regarding the fiber content of foods. Discuss how much to include during periods of flare-up and how to gradually increase fiber to achieve the goal set individually for that person.

### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to this individual.
- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# INTESTINAL LYMPHANGIECTASIA

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

Intestinal lymphangiectasia (IL) is a rare protein-losing enteropathy (PLE). It occurs most often in children, with 11 years as the average age of onset. IL can also occur secondary to conditions such as Crohn's disease, scleroderma, sclerosing mesenteritis, CD, lupus, lymphenteric fistula, constrictive pericarditis, or pancreatitis. IL is potentially fatal if not recognized and properly treated (McDonald and Bears, 2009). Increased intestinal lymphatic pressure with vessel dilatation occurs, discharging fluid into the bowel lumen. The fluid is then digested by intestinal enzymes and is reabsorbed. Massive fluid retention occurs from obstructed lymph vessels, especially in the abdomen and pleural cavities. While malabsorption and PLE occur, only marginal loss of protein occurs in most cases.

The main clinical features of this disorder include edema, fat malabsorption, lymphopenia, and hypoalbuminemia. Nausea, vomiting, nonbloody diarrhea, and abdominal pain result. Long-range problems may include lymphoma, osteomalacia or osteoporosis.

A low-fat diet associated with MCT supplementation is the cornerstone of medical management (Vignes and Bellanger, 2008). The need for dietary control appears to be permanent, because clinical and biochemical findings re-appear after low-fat diet withdrawal (Vignes and Bellanger, 2008).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Primary intestinal lymphangiectasia (PIL) is a rare disorder, generally diagnosed before 3 years of age; is it also called Waldman's disease (Vignes and Bellanger, 2008). Three genes, FLT4 (VEGFR3), FOXC2, and SOX18, cause varying forms of primary lymphedema (Finegold et al, 2008).

<b>Clinical/History</b>	Diarrhea	1 antitrypsin
Height	Chylous ascites?	(>56 cc/d
Weight	Double-contrast	with diarrhea)
BMI	radiographs	Jejunum biopsy
Weight loss,	of the small	(dilated lymphatic
inability to	bowel	lacteal
gain weight	Ultrasound or	vessels)
Stunting?	CT scans	Alb (decreased)
Diet history	Jejunum biopsy	Transthyretin
Fatigue		Serum 25-OH-
Abdominal pain	<b>Lab Work</b>	vitamin D and
Steatorrhea	Fecal concentra-	fat-soluble vita-
Peripheral edema	tion of alpha-	mins (low?)

Trace metal deficiency	Serum Fe, ferritin	Hypogammaglobulinemia
Chol (normal or low)	Transferrin (decreased)	Gluc
Trig	TLC (Lymphocytopenia)	Ca <sup>++</sup> (low)
Na <sup>+</sup> , K <sup>+</sup>		Mg <sup>++</sup>
H & H		BUN, Creat

### INTERVENTION

### OBJECTIVES

- Identify and correct the underlying cause (e.g., constrictive pericarditis).
- Decrease symptoms and promote recovery. Minimize peripheral edema.
- Decrease intake of long-chain fatty acids because they form chylomicrons and stimulate lymphatic flow into the gut. Use MCTs because they are more water-soluble and can be absorbed through the portal vein instead of the lymphatic system.
- Meet all nutritional needs for age and sex. Monitor absorption of fat-soluble vitamins; ensure adequacy from dietary or supplemental sources.

### FOOD AND NUTRITION

- Reduce intake of long-chain fatty acids. A formula or low-fat diet using a high concentration of MCTs is useful.
- Adequate protein and calories are needed, according to the individual's needs.
- Fat-soluble vitamins may be required in water-miscible form for adequate absorption.
- A calcium supplement may also be needed.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inappropriate Intake of Types of Fats

**Assessment Data:** Peripheral edema, weight loss, diarrhea, fecal alpha-1 antitrypsin >60 cc/d, low albumin (3.0 g/dL)

**Nutrition Diagnoses (PES):** Inappropriate intake of fatty acids (long-chain) related to intolerance of long-chain fatty acids and IL as evidenced by diarrhea, weight loss, altered labs (albumin, alpha-1 antitrypsin).

**Interventions:** Food-Nutrient Delivery—reduce intake of long-chain fatty acids and use MCTs instead. Education—teach diet principles. Counseling about the diet for managing the life-long condition.

**Monitoring and Evaluation:** Improvements in edema, lab values, and diarrhea after following the diet and taking appropriate medication.

## Common Drugs Used and Potential Side Effects

- Octreotide (Sandostatin) may be used. It is a potent inhibitor of growth hormone, glucagons, and insulin; it also suppresses gastrin, motilin, secretin, and pancreatic polypeptide.
- Over-the-counter remedies (bulking agents, drugs to control diarrhea) may be useful.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Supplements of vitamins and calcium are generally prescribed.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of fat in digestion, along with the need for MCT oils in the daily diet.
- Discuss fat-soluble vitamins and their sources in the diet.
- To minimize peripheral edema, elevation of extremities above the head may be recommended to decrease cel-

lulitis and lymphangitis. In addition, use of a recliner or elastic support stockings is suggested.

- It is not helpful to reduce salt intake or to use diuretics in this condition.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# INTESTINAL TRANSPLANTATION

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

Intestinal transplantation (ITx) represents a difficult life-saving intervention reserved for patients with irreversible intestinal failure (Varga et al, 2009). Intestinal failure leads to the inability to maintain protein energy, fluid, electrolyte, or micronutrient balance due to GI disease when on a normal diet. Transplantation is an effective therapy for the treatment of patients with end-stage intestine failure who cannot tolerate PN (Grant et al, 2005). The procedure should be considered before the development of PN failure (Matarese et al, 2007). PN-associated liver disease, recurrent catheter-related sepsis, and threatened loss of central venous access are the major reasons for transplantation. SBS, cancers, radiation enteritis, trauma, Crohn's disease, or other major intestinal diseases may also warrant ITx.

Transplantation of the small bowel restores quality of life for recipients who have functioning grafts. ITxs should be considered early in intestinal failure patients who develop liver injury to prevent irreversible liver disease that would mandate a simultaneous liver transplantation (Fryer, 2005). Medicare pays for ITx in patients who fail PN therapy in specific cases. Living-related donor transplantation is an option if a potential donor is available. The donor should have no history of liver disease or major intestinal pathology.

The carbohydrate and amino acid absorptive capacity of the transplanted intestine normalize within the first several months whereas fat absorption is impaired for several months. Morbidity and mortality following ITx are greater than that following liver or kidney transplantation, but long-term survival is improving. Infectious enteritis can occur in recipients after ITx; viral agents are the cause in most cases (Ziring et al, 2005). With newer immune-suppressive protocols, 1-year graft and patient survival rates have improved. Surgery and high-dose immunosuppression must be managed. Radiation to the small bowel before transplanting the organ, then administration of donor's bone marrow stem cells may reduce organ rejection. A loop ileostomy is often created for future endoscopy. Patients with ITx will require regular expert follow-up care and careful attention.

A serious complication of ITx is jejunal graft (JG) damage (Varga et al, 2009). Induction therapy, combined with advancements on surgical technique and clinical management, has improved patient and graft survival (Vianna and Mangus, 2009). An organized multidisciplinary approach is recommended for long-term follow-up.

Early and progressive enteral feeding using a complex polymeric formula is safe and effective after successful transplantation, eventually followed by unrestricted oral diet (Matarese et al, 2007). This modality of treatment is an alternative to PN, especially for those patients who have a poor quality of life as a result of PN (Middleton, 2007).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Transplantation is a surgical procedure for a variety of conditions, some of which may be genetic.

<b>Clinical/History</b>	Doppler ultrasonography	Na <sup>+</sup> , K <sup>+</sup> H & H Serum Fe, ferritin
Height	Liver biopsy	Serum folacin
Dry weight, present weight		BUN, Creat
BMI		Glomerular filtration rate (GFR)
Diet history	<b>Lab Work</b>	WBC, TLC
BP	Alb, transthyretin	Gluc
I & O	CRP	Chol, Trig
Temperature	CBC count	N balance
Wireless capsule endoscopy (CE)	Coagulation profile	Alk phos, phosphorus
Colonoscopy	Human leukocyte antigen (HLA) status	AST, ALT
CT scan to monitor for fistula or obstruction	Ca <sup>++</sup> , Mg <sup>++</sup>	Bilirubin
		Serum pH and lactate

## INTERVENTION

### OBJECTIVES

- Timely nutrition assessment and intervention may improve outcomes. Recovery of normal motility and absorptive capacity are the goals after surgery.
- Prevent infection and promote wound healing.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Altered GI Function

**Assessment Data:** Recent ITx following failure to tolerate PN; hx Crohn's disease; unintentional weight loss over past year.

**Nutrition Diagnoses (PES):** Altered GI function related to intestinal surgery as evidenced by intolerance of oral, enteral and PN with poor nutrition quality of life.

**Interventions:** Food and nutrient delivery—clear liquids, progressing slowly to enteral feedings that contain MCT. Progress gradually to oral diet. Educate about the transition period from enteral to oral diet. Counsel about potential problems, such as diarrhea, electrolyte depletion, vitamin and mineral deficiencies; teach about products or medications that may be needed.

**Monitoring and Evaluation:** Tolerance of enteral feedings post surgery. Resolution of diarrhea, high stomal output, abnormal labs. Achievement of desirable body weight range.

- Replenish lost nutrient stores as malnutrition compromises posttransplantation survival.
- Meet metabolic demands and support recovery.
- Control complications. Diarrhea and high stomal output are common problems and can lead to nutrient deficits, especially electrolytes.
- Supplement enteral feedings with MCTs for several months posttransplantation.
- Supplement the diet with IV fats and fat-soluble vitamins (vitamin D, E, A, and K) until the intestinal lymphatics are reestablished.

### FOOD AND NUTRITION

- When GI function is re-established, as indicated by decreasing G-tube returns and increasing gas and enteric contents in the ileostomy, a diet can be initiated. Advance as tolerated to provide full nutritional support. Monitor fluid status and adjust as needed.
- Daily intake of protein should be appropriate for age and sex; 1.5 g/kg while on steroids may be recommended. Calories should be calculated as 30–35 kcal/kg.
- Control CHO intake and encourage use of whole grains, vegetables, and fruits in cases of hyperglycemia.
- To avoid the development of chylous ascites, a no-fat or low-fat diet can be initially used. Gradually increase fat intake to 25–30% of total kilocal.
- Daily intake of sodium should be 2–4 g until the drug regimen is reduced. Adjust potassium levels as needed.
- Daily intake of calcium should be 1–1.5 times the DRI levels to offset poor absorption. Children especially need adequate calcium for growth. Daily intake of phosphorus should be equal to calcium intake.
- Supplement diet with vitamin D, magnesium, and thiamin if needed.
- Reduce gastric irritants as necessary if GI distress or reflux occurs.
- The special diet may be discontinued when drug therapy is reduced to maintenance levels. Encourage exercise and a weight control plan thereafter.

### Common Drugs Used and Potential Side Effects

- See Table 7-18.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Grapefruit juice decreases drug metabolism in the gut (via P450–CYP3A4 inhibition). One glass can affect medications up to 24 hours later. Avoid taking with cyclosporine and tacrolimus.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Indicate which foods are sources of protein, calcium, and other key nutrients in the diet.

**TABLE 7-18 Medications Used after Intestinal Transplantation**

Education	Description
Antibiotics	Broad-spectrum intravenous antibiotics are administered for about 1 week after the transplant.
Antiviral prophylaxis	Ganciclovir and/or cytomegalovirus (CMV) immunoglobulin (CytoGam) may be used.
Corticosteroids (prednisone or Solu-Cortef)	Corticosteroids such as prednisone and Solu-Cortef are used for immunosuppression. Side effects include increased catabolism of proteins, negative nitrogen balance, hyperphagia, ulcers, decreased glucose tolerance, sodium retention, fluid retention, and impaired calcium absorption and osteoporosis. Cushing's syndrome, obesity, muscle wasting, and increased gastric secretion may result. A higher protein intake and lower intake of simple CHO's may be needed.
Cyclosporine	Cyclosporine does not retain sodium as much as corticosteroids do. Intravenous doses are more effective than oral doses. Nausea, vomiting, and diarrhea are common side effects. Hyperlipidemia, hypertension, and hyperkalemia may also occur; decrease sodium and potassium as necessary. Elevated glucose and lipids may occur. The drug is also nephrotoxic; a controlled renal diet may be beneficial. Taking omega-3 fatty acids during cyclosporine therapy may reduce the toxic side effects (such as high blood pressure and kidney damage) associated with this medication in transplantation patients.
Immunosuppressants	Immunosuppressants such as muromonab (Orthoclone OKT3) and antithymocyte globulin (ATG) are less nephrotoxic than cyclosporine but can cause nausea, anorexia, diarrhea, and vomiting. Monitor carefully. Fever and stomatitis also may occur; alter diet as needed.
Induction Therapy	Monoclonal (alemtuzumab, basiliximab, daclizumab) or polyclonal (Thymoglobulin) antibody preparations are often administered intraoperatively or preoperatively.
Probiotics, Prebiotics	Although research is still preliminary, the use of probiotics and prebiotics may become common practice in the future.
Prostaglandin E <sub>1</sub>	Prostaglandin E <sub>1</sub> is given to improve the small bowel microcirculation.
Tacrolimus (Prograf, FK506)	Tacrolimus suppresses T-cell immunity; it is 100 times more potent than cyclosporine, thus requiring smaller doses. Side effects include GI distress, nausea, vomiting, hyperkalemia, and hyperglycemia.

- If the patient does not drink milk or use dairy products, discuss other sources of calcium.
- Alcohol should be avoided unless permitted by the doctor.
- Discuss control of hyperglycemia when appropriate. Discuss long-term problems such as obesity and dyslipidemia.
- Encourage moderation in diet; promote adequate exercise.
- Financial constraints can be a burden. Home care has evolved, but many disciplines are needed to keep everything in order.

#### **Patient Education—Foodborne Illness**

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual who may be experiencing graft–host rejection.
- Prevent infections from foodborne illness; patients who have undergone transplantation may be prone to increased risk more than other individuals.
- If home TF or CPN is needed, teach appropriate sanitation and food-handling procedures.

# IRRITABLE BOWEL SYNDROME

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

Irritable bowel syndrome (IBS) is a functional GI disorder affecting up to 3–15% of the general population in western countries (Camilleri and Andresen, 2009). The pathophysiology of IBS involves disturbances of the brain–gut axis (Camilleri and Andresen, 2009). Stimulated 5-HT<sub>3</sub> receptors promote intestinal motility, secretion, and sensation. Approximately one in ten patients with IBS believe their IBS began with an infectious illness (Spiller and Garsed, 2009). Prospective studies have shown that 3–36% of enteric infections lead to persistent new IBS symptoms; bacterial enteritis, protozoan, and helminth infections are often followed by prolonged postinfective IBS (Spiller and Garsed, 2009). Rome III Diagnostic criteria for IBS include at least 3 months of continuous or recurrent symptoms of abdominal pain or discomfort relieved with defecation or associated with change in frequency of stool or changed consistency of stool. Individuals with IBS often have had a prolonged initial illness, a toxic infecting bacterial strain, history of smoking, mucosal markers of inflammation, female gender, depression and adverse life events in the preceding 3 months (Spiller and Garsed, 2009).

Because 95% of the body's serotonin is located in the GI tract, it is important to note that people with IBS have diminished receptor activity. There are several subgroups of IBS: alternating bowel habits (IBS-A), constipation-predominant IBS (IBS-C), and diarrhea-predominant IBS (IBS-D). Signs that IBS patients require medical attention include anemia, fever, persistent diarrhea, rectal bleeding, weight loss, and nocturnal symptoms. In addition, a family history of IBD, CD, or colorectal cancer requires further diagnostic work-up.

Up to 65% of IBS patients attribute their symptoms to food allergies (Zar et al, 2005). However, this finding has not been confirmed (Brant et al, 2009). Some IBS sufferers may have a mild form of CD and should be tested for gluten

intolerance. Others may have lactose maldigestion. A food diary is useful to note symptoms and specific foods or practices that cause problems.

Therapies focus on specific GI dysfunctions (e.g., constipation, diarrhea, pain), and medications should only be used when nonprescription remedies do not work or when symptoms are severe. In some IBS patients, there is *H. pylori* infection; appropriate antibiotics may relieve symptoms. Therapies focus on nerve–gut communication dysfunction and antibiotics. Probiotics are another important therapy. Symptoms may also be improved by diets supplemented with probiotics such as hydrolyzed guar gum (Hadley and Gaardner, 2005) or bifidobacteria. Where carbohydrate malabsorption (lactose, fructose, or sorbitol) occurs, restrict the offending sugar(s). Overall, there is a reduction in quality of life (Brant et al, 2009). The American Dietetic Association has recommended three MNT visits for patients who have IBS.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Genetic modeling has identified a genetic link for IBS in twin studies (Lembo et al, 2007). However, the heritable components are poorly understood (Camilleri and Andresen, 2009).

Clinical/History	Change in form of stool	Lab Work
Height	Belching, flatulence, heartburn	tTG testing to rule out CD
Weight	Nausea	Hydrogen breath test
Weight changes	Mucus in stool?	for lactose tolerance
BMI	Polycystic ovarian syndrome?	CRP
Diet history	Urgency for defecation	H & H
Family history of GI disorders	Lower GI x-rays	Serum Fe, ferritin
Recurrent abdominal pain or discomfort	Colonoscopy or sigmoidoscopy	Alb, transthyretin
Change in frequency of stool		Gluc
		Na <sup>+</sup> , K <sup>+</sup>
		Ca <sup>++</sup> , Mg <sup>++</sup>

### INTERVENTION

#### OBJECTIVES

- Encourage regular eating patterns, regular bowel hygiene, adequate rest, and relaxation.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Undesirable Food Choices

**Assessment:** Diet history with analysis of fiber, caffeine, fluid, and CHOs; family history and medication/food allergies; bowel patterns.

**Nutrition Diagnosis (PES):** Undesirable food choices related to excessive intake of colas and coffee as evidenced by abdominal pain each day, symptoms of IBS-D, and poor nutritional quality of life.

**Intervention:** Educate about better fluid choices, probiotics, prebiotics, fiber, reduction in gas-forming foods.

**Monitoring and Evaluation:** Dietary and fluid intake changes; changes in abdominal pain, bowel patterns, frequency of diarrhea. Improved enjoyment of meals and a variety of foods and beverages.

- Avoid constipation by increasing physical activity and consuming adequate fluids and fiber (American Dietetic Association, 2008).
- Monitor for food intolerances to gluten in wheat, rye, barley; chocolate; lactose or milk products; caffeine; alcohol. Omit offending agents.
- Individualize diet management to the patient's symptoms. Alleviate pain, symptoms, and flatulence. Production of colonic gas, especially hydrogen, may be uncomfortable.
- Improve nutritional quality of life.

## FOOD AND NUTRITION

- Fiber is marginally beneficial; insoluble fiber may worsen symptoms but soluble fiber may help to alleviate constipation (Heizer et al, 2009). In acute phases, a low-fiber diet may be better tolerated. As treatment progresses, use adequate but not excessive fiber and ensure adequate fluid intake (30–35 mL/kg).
- Avoid high-fat foods, which may increase cholecystokinin release. Avoid high sugar intake, which increases osmolarity.
- Liberal amounts of fruits and vegetables are useful. Omit gas-forming oligosaccharides (beans, barley, Brussels sprouts, cabbage, nuts, figs, and soybeans), if not tolerated. Limit or omit spicy foods if poorly tolerated.
- A modified exclusion diet and stepwise reintroduction of foods or trials of eliminating classes of food may be useful (Heizer et al, 2009). Omit milk products if lactose is not tolerated; add calcium in other forms.
- In patients with CD, omit gluten and supplement with B-complex vitamins if needed.

## Common Drugs Used and Potential Side Effects

- 5-HT is a key modulator of GI sensorimotor function and this has led to the development of 5-HT(3) antagonists and 5-HT(4) agonists; alosetron (Lotronex), cilansetron,

and tegaserod are all effective in the treatment of IBS (Ford et al, 2009). If constipation results, a lower dose may be needed (Krause et al, 2007).

- Antidepressants, novel selective anticholinergics, alpha-adrenergic agonists, opioid agents, cholecystokinin-antagonists, neurokinin-antagonists, somatostatin receptor agonists, corticotropin releasing factor antagonists, chloride channel activators, guanylate cyclase-c agonists, melatonin, atypical benzodiazepines, antibiotics, immune modulators are under study (Camilleri and Andresen, 2009). Many of these have mixed reviews at the present time.
- Methylcellulose (Metamucil) and other bulking agents always must be taken with large amounts of water. Generally, 1 tablespoon is sufficient per day. Increased peristalsis occurs.

## Herbs, Botanicals, and Supplements

- Daily use of peppermint oil is effective in relieving IBS symptoms (Hadley and Gaardner, 2005; Heizer et al, 2009).
- The usefulness of probiotics in the form of foods such as live-culture yogurt and buttermilk for IBS symptoms is not established (Heizer et al, 2009). Two double-blind, randomized, placebo-controlled studies identified that *Bifidobacterium infantis* provides relief from IBS (Brenner and Chey, 2009; Spiller, 2005). Yogurt and other cultured foods may not be as effective as specific probiotics with high concentrations of microbes, but they are good sources of nutrients.
- To prevent intestinal gas from forming, try Beano and other products available on the market.
- Twice-weekly Acupuncture/Moxabustion treatment improves average daily abdominal pain and discomfort (Anastasi et al, 2009).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Slowly increase dietary fiber by 2–3 g/d to prevent discomfort and to promote soft, painless stools. Large servings of bran may aggravate IBS; assess individually.
- IBS does not harm the intestines and does not lead to cancer; it is unrelated to IBD.
- Drink six to eight glasses of water or fluids per day. Avoid carbonated beverages, chewing gum, or eating quickly, which may promote gas production.
- Regular times for bowel evacuation should be planned.
- Ensure the patient has adequate food intake and is not afraid to eat because of potential pain.
- A food diary may help to identify any food sensitivities.
- Large meals can cause cramping and diarrhea; smaller meals or smaller portions eaten more often may help IBS symptoms. Meals that are low in fat and high in carbohydrates such as pasta, rice, whole-grain breads and cereals (except with CD), fruits, and vegetables may help.
- Refer the patient for stress management. Patients with rapidly cycling symptoms may need further counseling and support (Tillisch et al, 2005). Cognitive behavioral therapy is beneficial.

- Family members may need to flexible and help to create regularity in the home. Avoid disorganization, overscheduling, lack of planning.
- Regular exercise is important, such as walking, swimming, or yoga. Adequate sleep is important as well.

### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual who may be experiencing diarrhea and related discomfort.

## LACTOSE MALDIGESTION

### NUTRITIONAL ACUITY RANKING: LEVEL 2–3

#### DEFINITIONS AND BACKGROUND

Lactose is a disaccharide (glucose-1 galactose) found in milk. If lactase enzyme is missing, lactose passes into the colon, where it is fermented to gases and organic acids by colonic bacteria, resulting in bloating, cramping, nausea, or diarrhea.

A limited proportion of the human adult population retains intestinal lactase-phlorizin hydrolase (LPH) activity during adulthood, the lactase persistence phenotype (Robayo-Torres and Nichols, 2007). Lactase persistence is an autosomal-dominant trait that is common in European-derived populations (Smith et al, 2009). A staggering 4000 million people cannot digest lactose properly (Campbell et al, 2005). As many as 75% of all African American, Jewish, Native American, and Mexican American adults and 90% of Asian American adults are lactose intolerant. A total of 95% of all adults have adult-type hypolactasia (ATH) and have difficulty digesting milk sugar (Robayo-Torres and Nichols, 2007). Table 7-19 describes the various types of this condition.

CD can lead to lactase deficiency (Ojetti et al, 2005). An increased prevalence of lactose intolerance is also seen in patients with IBS. In addition, fructose intolerance may be unrecognized, and testing should clarify which disaccharide

**TABLE 7-19** Types of Lactose Maldigestion

Type	Description	Incidence
Congenital, primary, or genetic	Rare, present at birth	Low incidence in children
Lactase “nonpersistence” or hypolactasia	Lactase decline, often to about 10% of neonatal values	Occurs after weaning; more common in adults
Secondary or acquired	From gastrointestinal disease, food allergy, antibiotics, or intestinal trauma	May occur in children after diarrhea or giardiasis. Common with HIV infection, inflammatory bowel disease.

is poorly tolerated. Children with suspected lactose intolerance can be assessed clinically by dietary lactose elimination or by tests including noninvasive hydrogen breath testing or invasive intestinal biopsy determination of lactase (and other disaccharidase) concentrations. (Heyman and Committee on Nutrition, 2006).

Lactose maldigesters can consume up to 1 cup (8 oz) of milk without experiencing symptoms; tolerance can be improved by consuming the milk with a meal, choosing yogurt or hard cheeses, or using products that aid in the digestion of lactose such as lactase supplements or lactose-reduced milks (Byers and Savaiano, 2005). Symptoms caused by lactose maldigestion need not hinder ingestion of a diet rich in dairy products that supplies around 1500 mg calcium daily (i.e., 2 cups of milk, 1 cup of yogurt, and several ounces of cheese). Bloating, abdominal pain, diarrhea, and overall symptom severity are often tolerable.

Pregnant women, children and teens who are lactose intolerant should be given appropriate counseling about intake of calcium from nonlactose sources. Individuals who are self-described as lactose intolerant may restrict dairy and calcium intake and are at greater risk of osteoporosis and bone fractures. The American Dietetic Association recommends at least three MNT visits for adults who have lactose maldigestion.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Congenital lactase deficiency (CLD) occurs because of an SNP upstream from the lactase (C-13910 > T) gene (Ingram 2009).

<b>Clinical/History</b>	Stool acidity test	Mg <sup>++</sup>
Height		Alk phos
Weight	<b>Lab Work</b>	Gluc
BMI	Alb,	H & H
Weight changes	transferrin	Serum Fe,
Lactose	BUN, Creat	ferritin
challenge test	Ca <sup>++</sup> (better	Na <sup>+</sup> , K <sup>+</sup>
Hydrogen	absorption	
breath test	can occur	
(3–5 hours)	over time)	

## INTERVENTION

### OBJECTIVES

- Manage pain and discomfort related to lactose ingestion that is caused by flatulence and bloating or diarrhea. Control lactose intake, which comprises 10% of the carbohydrate found in the American diet.
- Regular consumption of milk by lactase-deficient persons may improve colonic tolerance. Check for actual tolerance by monitoring intake.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Excessive Cho (Lactose) Intake

**Assessment:** Food diary and records with analysis of grams of lactose consumed on average day, stool frequency, and GI complaint reports.

**Nutrition Diagnosis (PES):** Excessive CHO (lactose) intake related to poor food choices as evidenced by frequent use of liquid dairy products, ice cream and milkshakes with resulting abdominal pain and diarrhea.

**Intervention:** Counseling on lactose-restricted diet, use of Lact-Aid and lactose-reduced products in meals and in cooking.

**Monitoring and Evaluation:** Food records and reports of GI distress or diarrhea after diet alterations have been implemented consistently for at least 7 days.

- Offer calcium and riboflavin from other foods and sources besides lactose-containing dairy products.

## FOOD AND NUTRITION

- Most people can tolerate up to 6 g of lactose, which is found in ½ cup (4 oz) of fluid milk. If small amounts are gradually added over approximately 3 months, most adults can ultimately adapt to 12 g lactose, equal to one 8-oz glass of regular milk.
- Dairy foods contain approximately 1–8% lactose by weight (milk, 4–5%; yogurt, 4%; ice cream, 3–4%; milk chocolate, 8%; cottage cheese, 1–2%). Because symptoms are related to dose, consume no more than 8 oz of lactose-containing milk at a time after other foods have been consumed to slow down transit time. See Table 7-20.
- Provide lactase enzyme supplements (e.g., Lactaid, Lactrase, Dairy Ease) 30 minutes before the consumption of a lactose-containing product. Two capsules provide enough lactase to hydrolyze the lactose in an 8-oz glass of whole milk. Lactose-hydrolyzed milk is generally tolerated. Note that not all preparations are equally effective.
- Persons on a lactose-free diet can use lactate, casein (curds), lactalbumin, and calcium. If the patient is highly sensitive, check labels of foods for fillers, whey protein, milk, whey solids, and milk solids; most people can tolerate small amounts in mashed potatoes, breads, and medications. Processed cheese or cheese foods may have nonfat dry milk solids; use in moderate amounts.
- Fermented products (buttermilk, natural or aged cheese, yogurt with live and active cultures, cottage cheese, or sour cream) may be better tolerated than milk by many individuals.
- Frozen yogurt has little or no lactase activity. It may be tolerated in small amounts.
- For infants with the condition, try milk-free formulas; gradually introduce foods that contain milk or lactose to test for tolerance. Distinguish milk allergy (usually early in life) from lactose maldigestion (more often in adults).
- Secondary lactase deficiency results from injury to the small intestine that occurs with severe diarrheal illness, CD, Crohn's disease, or chemotherapy; this is more common in infancy.

**TABLE 7-20 Lactose and Substitutes in Common Foods**

Food and Portion	Portion	Lactose (g)
Evaporated milk	1 cup	24
Sweetened condensed milk	½ cup	20
Milk, reduced fat	1 cup	11–14
Acidophilus Milk	1 cup	11
Yogurt, whole milk	1 cup	10–12
Buttermilk	1 cup	10
Ice cream	½ cup	6
Yogurt, plain, low fat	1 cup	5
Sour cream or light cream	½ cup	4
Cottage cheese	½ cup	3 creamed, 2 dry
Cheese, hard	1 oz	1–2
Swiss cheese	1 oz	1
Cream cheese	1 oz	1
Butter or margarine	1 tsp	Trace

**Recipe Substitutes for Dairy Products**

- 1 cup whole milk = mix ½ cup water with ½ cup nondairy cream or use 1 cup soy or rice milk
- 1 cup skim milk = ¼ cup nondairy cream plus ¾ cup water
- 1 cup evaporated milk = 1 cup nondairy cream or soy milk
- 1 cup buttermilk = ½ cup nondairy cream plus ½ cup water + 1 tbsp lemon juice or vinegar
- 1 cup whipped cream = 1 cup nondairy whipped topping
- 1 tbsp cream cheese = 1 tbsp mayonnaise
- ½ cup cottage cheese = ½ cup tofu
- 1 tbsp butter = 1 tbsp milk-free margarine or 1 tbsp vegetable oil
- 1 cup sour cream = ¼ cup cornstarch in ¾ cup water plus ¼ cup vinegar

**Common Drugs Used and Potential Side Effects**

- Many drugs contain lactose but seldom over 500 mg; most should be well tolerated. For example, some types of birth pills, as well as tablets for stomach acid and gas may contain lactose.
- Antidiarrheal agents such as loperamide (Imodium A-D) help reduce symptoms of lactose intolerance.

**Herbs, Botanicals, and Supplements**

- Probiotics (such as lactobacilli and bifidobacteria) and prebiotics (nondigestible oligosaccharides) assist in alleviating lactose intolerance and improving calcium absorption (Doron and Gorbach, 2006).
- Take calcium supplements containing calcium carbonate with meals because stomach acid enhances absorption. Calcium citrate can be taken with meals or on an empty stomach. Take calcium in doses of 500 mg several times a day rather than all at once.
- Herbs and botanical supplements should not be used without discussing with the physician.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Identify foods that are lactose free and foods that are lactose-free sources of calcium.
- Reading labels is helpful. Store-bought cookies, cakes, bread, baked goods, cereals, instant potatoes, soups, margarine, lunch meat, salad dressings, pancakes, biscuits, nondairy creamers or whipped toppings, and candy may contain lactose.
- The patient must read labels, looking for and avoiding “milk,” “lactose,” butter, cheese, cream, milk solids, powdered milk, and whey.
- Home-cooked meals and lactose-free recipes are useful. Recipes are available for use of lactose-free formulas in products such as meat loaf. Advise that heating of milk does not change lactose.
- If dairy products are eliminated, other dietary sources of calcium or calcium supplements need to be provided, especially for infants, children, teens (Heyman and Committee on Nutrition, 2006), and pregnant women. Calcium-fortified soy milk, broccoli, leafy greens, canned salmon, almonds, oranges, certain kinds of tofu and soy milk, and calcium-fortified breads and juices can be used.
- Kosher foods are often acceptable if they are pareve (nonmilk, nonmeat).
- Discuss how to use LactAid drops to allow the enzyme to hydrolyze the lactose. Five to 15 drops per quart of milk will reduce lactose by 70–99%.
- Drink milk with meals rather than alone to decrease symptoms.

**Patient Education—Foodborne Illness**

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual who may be experiencing diarrhea and related discomfort.

## MEGACOLON

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Pillitteri, A. *Maternal and Child Nursing*, 4th ed. Philadelphia: Lippincott, Williams & Wilkins, 2003.

### DEFINITIONS AND BACKGROUND

Megacolon may come in three forms: acute (before age 1), chronic (after age 10), or toxic. Acquired megacolon is associated with chronic constipation. The enlarged bowel results from an abnormal colonic dilatation often reaching 8–10 cm in diameter. It may occur in elderly persons who have a long history of elimination problems created by laxative abuse or constipation. Persons with diabetes, hypothyroidism, scleroderma, spinal cord injury, Parkinson's, multiple sclerosis, electrolyte imbalances, tumor, strictures, and other conditions may be affected. Worldwide, infection with *Trypanosoma cruzi* (Chagas disease) is the major cause of megacolon.

Normal urges to defecate are affected by physical activity, neurological status, chemical/drug use, and bowel condition. Normal reflexes are needed for muscular and sphincter control. Family physicians must be alert for the presence of uncommon but serious megacolon (Biggs and Dery, 2006). Signs and symptoms of megacolon involve abdominal distention, flatus, absence of stool, smearing or bowel incontinence, nausea, anorexia, fatigue, and headache. Note that the colon provides reabsorption of water and electrolytes as well as elimination of waste and regulation of bacterial homeostasis; motility is crucial for these roles.

The ENS is the intrinsic segment of the GI tract that controls essential functions such as motility, secretion, and blood flow; it is organized into neurons and glial cells that are distributed throughout the entire length of the gut wall (Burns and Pachnis, 2009). Enteric nervous system stem cells (ENSSCs) provide potential tools to replenish absent ganglia in the congenital form of megacolon, Hirschsprung's disease (Metzger et al, 2009). IBD is associated with a host of intestinal disease-related complications including toxic megacolon (Scherer, 2009). Subtotal colectomy with ileostomy remains the procedure of choice (Ausch et al, 2006; Gladman et al, 2005). Colectomy is complicated by considerable morbidity, while rates have improved over the past several decades (Teeuwen et al, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Hirschsprung's disease is caused by a single gene mutation of the *RET* proto-oncogene on band 10q11.2. Megacolon can occur in multiple endocrine neoplasia type 2A (MEN 2A) or 2B (MEN 2B).

<b>Clinical/History</b>	Stool consistency	H & H
	Endoscopy	Serum Fe, ferritin
	Barium x-rays	Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup>
	Abdominal girth	Ca <sup>++</sup> , Mg <sup>++</sup>
Height		
Weight		
BMI		
Diet history		
BP		
I & O		
Stool pattern		
	<b>Lab Work</b>	Thyroid function
	BUN, Creat	Stool guaiac
	Gluc	

### INTERVENTION

### OBJECTIVES

- Prevent complications such as lung atelectasis from distention, sepsis, ulceration with hemorrhage or perforation, or sigmoid volvulus.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Inadequate Fluid Intake**

**Assessment Data:** Height, Weight, BMI normal. Hx chronic constipation and Parkinson's disease. Recent identification of megacolon. Minimal intake of fluids without prompting. Signs of early dementia.

**Nutrition Diagnoses (PES):** Inadequate fluid intake related to cognitive changes and forgetting to drink as evidenced by I & O records with chronic constipation and megacolon.

**Interventions:** Increase fluid intake to meet estimated needs (30 mL/kg). Offer beverages every 2 hours. Educate staff and family about cueing to drink and offering beverages often. Review effects of laxatives, stool softeners, and other prescribed medications on constipation.

**Monitoring and Evaluation:** Improvement in signs of chronic constipation; relief from megacolon. Improved fluid intake to meet estimated needs.

- Empty the bowel as needed, with osmotic laxatives, enemas, suppositories, cathartics, or digital disimpaction.
- Normalize bowel function as much as possible. Evaluate bowel pattern by history and at present, including drug use and laxative abuse. Exclude underlying cause if possible, such as calcium channel antagonists, narcotics, anticholinergics.
- Identify and correct any nutrient deficiencies, electrolyte imbalances, or protein-energy malnutrition.
- Assure adequate hydration.

## FOOD AND NUTRITION

- Use adequate fluid and fiber, pending status, and other conditions (such as heart failure). Prune juice added to hot cereal may help normalize bowel function. If raw fruits and vegetables are not tolerated at first, add over time. For some people, excessive bran will not be tolerated.
- Avoid excesses of refined foods and concentrated sweets to the exclusion of desirable foods.
- Fiber-rich TF may be needed for selected patients.

## Common Drugs Used and Potential Side Effects

- Osmotic agents, such as magnesium salts, sorbitol, or lactulose are often used; some may increase flatulence.
- Stimulant laxatives (senna and bisacodyl) may decrease the ability of the colon to evacuate; they are not as helpful in this condition.

- Suppositories and stool softeners may be used or may have been used excessively. Monitor specific medications accordingly and their side effects.
- Anticholinergics, opiates, and antidepressants may increase or aggravate constipation. Limit use.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Many patients take natural herbal laxatives that contain cascara.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of exercise in maintaining normal bowel function.
- Discuss the role of fluid and fiber in bowel regularity (American Dietetic Association, 2008). For example, drinking a cup of hot prune juice may be effective for some patients.
- Include probiotic foods such as yogurt with live and active cultures, lactobacilli and bifidobacteria, and prebiotics (nondigestible oligosaccharides) for gut integrity.

## Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## For More Information

# OSTOMY: COLOSTOMY

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

Adapted from: Neil O. Hardy. Westport, CT. *Stedman's Medical Dictionary*, 27th ed. Baltimore: Lippincott Williams & Wilkins, 2000, p. 383.

### DEFINITIONS AND BACKGROUND

The colon functions primarily to absorb water and sodium and to excrete potassium and bicarbonate. A colostomy is an artificial outlet for intestinal wastes created surgically by bringing a portion of the colon through the abdominal wall,

resulting in a stoma. Colostomy can be permanent or temporary. It may be indicated for intestinal cancer, diverticulitis, perforated bowel, radiation enteritis, obstruction, and Hirschsprung's disease. It may also be indicated for spinal cord-injured patients where bowel management (bowel care and defecation time) averages 6 hours/wk prior to stoma formation, but decreases to 1.5 hours/wk after a left colostomy, thus improving quality of life (Munck et al, 2009).

Abdominoperineal resection, with ileal colostomy, remains a standard treatment (Portier et al, 2005). With proper patient selection, laparoscopic colorectal surgery can be performed. Video-assisted, double barreled wet colostomy is minimally invasive. Table 7-21 lists the common types of colostomies.

Colostomy output is generally more formed than ileostomy output. Some colostomates can "irrigate," using a procedure similar to an enema to clean stool directly out of the colon through the stoma. This requires special irrigation appliances: an irrigation bag and a connecting tube (or catheter), a stoma cone, and an irrigation sleeve. A special lubricant is sometimes used on the stoma in preparation for irrigation. Following irrigation, some colostomates can use a stoma cap, a one- or two-piece system that simply covers and protects the stoma. This procedure is usually done to avoid the need to wear an appliance.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Colostomy is a surgical procedure, occasionally used for a congenital condition.

Clinical/History	Renal stones?	Alb,
Height		transferrin
Weight	<b>Lab Work</b>	Ca <sup>++</sup> , Mg <sup>++</sup>
BMI	H & H	Chol, Trig
Diet history	Serum Fe,	Transferrin,
I & O, hydration status	ferritin	TIBC
Diarrhea or constipation	Na <sup>+</sup> , K <sup>+</sup>	Serum B <sub>12</sub>
	Gluc	Serum folate
		PT or INR

**TABLE 7-21 Common Types of Colostomies**

Colostomy Type	Description
Temporary Colostomy	Allows the lower portion of the colon to rest or heal. It may have one or two openings (if two, one will discharge only mucus).
Permanent Colostomy	Usually involves the loss of part of the colon, most commonly the rectum. The end of the remaining portion of the colon is brought out to the abdominal wall to form the stoma.
Sigmoid or Descending Colostomy	The most common type of ostomy surgery, in which the end of the descending or sigmoid colon is brought to the surface of the abdomen. It is usually located on the lower left side of the abdomen.
Transverse Colostomy	The surgical opening created in the transverse colon resulting in one or two openings. It is located in the upper abdomen, middle or right side.
Loop Colostomy	Usually created in the transverse colon. This is one stoma with two openings; one discharges stool, the second discharges mucus.
Ascending Colostomy	A relatively rare opening in the ascending portion of the colon. It is located on the right side of the abdomen.

### INTERVENTION

### OBJECTIVES

- To avoid major problems of blockage, increased flatulence, and problems with certain foods, preoperative teaching and postoperative follow-up must include food selection guidance.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Poor Nutritional Quality of Life—Ostomy**

**Assessment:** I & O records or food diary; weight fluctuations. Complaints of abdominal discomfort and unplanned ostomy output of large quantity.

**Nutrition Diagnosis (PES):** Poor nutritional quality of life related to fear and frequent ostomy output as evidenced by weight fluctuations and reports of GI discomfort after meals.

**Intervention:** Educate about how to meet estimated nutritional needs using tolerated foods; how to track GI symptoms and food tolerances using a food diary.

**Monitoring and Evaluation:** Improved I & O records; stabilized weight. Fewer or no GI distress following meals when foods poorly tolerated are omitted from the diet. Ostomy output more predictable and normal.

- Speed wound healing and recovery.
- Correct weight loss or malnutrition from GI blood loss, anemia, protein malabsorption, steatorrhea.
- Prevent watery or unscheduled bowel movements. Correct or prevent dehydration.
- Individualize the diet: Eat regularly, avoid odor-causing foods, and monitor food preferences. Normalize nutritional quality of life as much as possible.
- Avoid infection and skin irritants.

## FOOD AND NUTRITION

- Early oral feeding in the patients undergoing colectomy is feasible, safe, and associated with reduced postoperative discomfort; it can accelerate the return of bowel function and improve rehabilitation (Zhou et al, 2006). Most people can resume oral diet 2 days after surgery.
- Progress from a liquid to a low-residue diet. To speed healing, the formula or diet should also be high in protein, energy, vitamins, and minerals.
- Diet should provide normal or increased salt intake. One to two quarts of fluid, taken between meals, should be ingested daily.
- Gradually introduce new foods; if done slowly, offending foods can be identified and obstruction can be controlled or prevented. Foods that may not be tolerated include:
  1. **Foods that may cause loose stools or diarrhea:** apple juice, prune juice, dried beans, chocolate, green beans, raw fruits and raw vegetables, fried foods, highly spiced foods, broccoli, and leafy green vegetables.
  2. **Gas or odor-causing foods:** alcohol (beer), beans, onions, cabbage, broccoli, cauliflower, Brussels sprouts, fish, eggs, asparagus, and garlic. Fresh parsley is a natural deodorizer.
  3. Foods that cause **urinary odor** include asparagus and seafood.
  4. Beets and red gelatin can cause **abnormal stool coloration**.

5. Avoid **high fiber foods:** granola, bean sprouts, bamboo shoots, bran, whole-kernel corn, mushrooms, celery, nuts, pineapple, popcorn, coleslaw, apple skins, seeds, or coconut.
  6. Foods **most often avoided** because of an ostomy include fresh fruits and vegetables such as cabbage, beans, onions, hot dogs, sausages and other meats with casings.
- Foods that thicken stool include applesauce, bananas, marshmallows, rice, pasta, peanut butter, tapioca, and yogurt.
  - Progress to a high-fiber diet with short-fibered foods.
  - If calcium oxalate stones develop after the colostomy, diet should provide a high-fluid intake. Restrict intake of oxalates from spinach, rhubarb, wild greens, coffee and tea, and chocolate.
  - Signs of blockage include: almost constant spurt of highly watery stool, bloating, cramping, swelling around stoma, strong odor of stool, nausea, vomiting, and pain. Avoid eating solid food, and do not take any laxatives or stool softeners. Drink a hot, caffeinated beverage; try a hot bath; gently massage the abdomen; and apply a pouch that has a larger opening.

## Common Drugs Used and Potential Side Effects

- Probiotics and prebiotics may be useful for return of gut immunity.
- Polyethylene glycol solution may be used as an alternative fluid regimen for colostomy irrigation.
- Patients with electrolyte concerns should be carefully monitored if sodium phosphate preparations (Osmoprep, Visicol) are used for colonoscopy preparation (Lichtenstein, 2009).
- Prednisone: Restrict excessive sodium intake. Monitor nitrogen, calcium, and potassium losses when used over a long period of time.
- Lomotil is a stool thickener and deodorizer; use plenty of fluids.
- Bulk-forming agents such psyllium (Metamucil) may be useful. Increased peristalsis occurs.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Approximately 6 weeks are required to acclimate the bowel to new procedures of irrigation. Enemas are used to wash the bowel up to the ileocecal valve (with 1000 mL of tap water). Constipation can occur with dehydration; therefore, adequate intake of fluid and fiber is important.
- Use of a commercial deodorant in the colostomy bag is preferred for eliminating highly flavored or nutrient-dense foods.

- Instruct the patient to eat slowly, chew foods well, and avoid swallowing air.
- Irrigations should not be performed when there is vomiting or diarrhea. Working with an enterostomal therapist can be helpful for more suggestions.
- Regular mealtimes should be encouraged.
- Reassurance is needed, without misleading the patient. Some colostomies are permanent (Riansuwan et al, 2009). Quality of life may decrease after the procedure (Yau et al, 2009).
- If a temporary colostomy is performed, a patient may be evaluated for a reversal of the colostomy where the remaining colon and rectum must be examined for normalcy.

#### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual who may be experiencing diarrhea and related discomfort.
- Proper ostomy care requires careful and constant hand washing.
- If home TF or CPN is needed, teach appropriate sanitation and food-handling procedures.

## OSTOMY: ILEOSTOMY

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Life ART image copyright © 2010 Lippincott Williams & Wilkins. All rights reserved.

#### DEFINITIONS AND BACKGROUND

Used to treat intractable cases of ulcerative disease, Crohn's disease, polyposis, and colon cancer, an ileostomy is a surgical procedure (stoma/opening formation) that brings the ileum through the abdominal wall. It may be temporary or permanent. This procedure causes a decrease in fat, bile acid, and vitamin B<sub>12</sub> absorption, as well as greater losses of sodium and potassium.

Patients will be incontinent of gas and stool. Ideally, the ileocecal valve can be kept to decrease bacterial influx into the small intestine. Of these patients, 50–70% will have recurrent disease. Effective ostomy management is important and involves establishment of an effective system for managing altered dietary and fluid intake, maintaining fluid and electrolyte balance, and preventing food blockage (Doughty, 2005).

Subtotal colectomy with ileostomy is a safe and effective treatment for patients requiring urgent surgery (Hyman et al, 2005). Interval ileal pouch–anal anastomosis reconstruction without a stoma after colectomy equals the more traditional protocol in terms of clinical outcome but yields lower hospital costs and probably a shorter length of hospital stay (Swenson et al, 2005). Table 7-22 describes the procedures for ileostomy.

**TABLE 7-22 Ileostomy Procedures**

Procedure	Description
Ileoanal Anastomosis	This is now the most common alternative to the conventional ileostomy. Technically, it is not an ostomy since there is no stoma. In this procedure, the colon and most of the rectum are surgically removed, and an internal pouch is formed out of the terminal portion of the ileum. An opening at the bottom of this pouch is attached to the anus such that the existing anal sphincter muscles can be used for continence. This procedure should only be performed on patients with ulcerative colitis or familial polyposis and who have not previously lost their rectum or anus. It is also called J-pouch, pull-thru, endorectal pullthrough, pelvic pouch, or a combination of these terms.
Continent Ileostomy	This surgical variation of the ileostomy is also called a <b>Kock pouch</b> . A reservoir pouch is created inside the abdomen with a portion of the terminal ileum. A valve is constructed in the pouch, and a stoma is brought through the abdominal wall. A catheter or tube is inserted into the pouch several times a day to drain feces from the reservoir. This procedure has generally been replaced in popularity by the ileoanal pouch. A modified version of this procedure called the Barnett continent ileal reservoir is performed at a limited number of facilities.

Source: United Ostomy Association, Inc. What is ostomy? at [http://www.uoa.org/ostomy\\_main.htm](http://www.uoa.org/ostomy_main.htm), accessed March 31, 2005.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Ileostomy is a surgical procedure, occasionally used for a congenital condition.

Clinical/History	Lab Work	
Height	H & H	Transferrin
Weight	Serum Fe,	TIBC
BMI	ferritin	Gluc
Diet history	BUN, Creat	WBC
Stool (occult blood)	Na <sup>+</sup> , K <sup>+</sup>	Ca <sup>++</sup> , Mg <sup>++</sup>
BP	Alb,	Serum B <sub>12</sub>
	transferrin	Schilling test if needed
		Serum folate

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Fluid Intake

**Assessment Data:** I & O, weight changes, signs of dehydration, high output from ileostomy.

**Nutrition Diagnoses (PES):** Inadequate fluid intake related to losses from ileostomy and insufficient intake as evidenced by I & O records (intake 1200 mL, output 1600 mL/d).

**Interventions:** Food and nutrient delivery: Calculate needs, provide extra liquids with meals, offer a beverage every few hours. Educate: Discuss the need for extra fluids when ileostomal losses are increased, during febrile periods, when there is vomiting.

**Monitoring and Evaluation:** I & O records, weight records, fewer signs of dehydration (poor skin turgor, sunken eyeballs, etc).

## INTERVENTION

### OBJECTIVES

- Modify the diet to counteract malabsorption of nutrients secondary to diarrhea, protein, and fluid losses, negative nitrogen balance from nutrient loss, and anorexia.
- Correct any anemia caused by inadequate intake or blood losses.
- Counteract weakness and muscle cramping from potassium losses.
- Provide increased energy intake during periods of fever or infection.
- Replenish calcium to reverse losses caused by steatorrhea and bone density loss if steroid therapy is used.
- Prevent gallstones, renal oxalate stones, bacterial overgrowth, and fatty acid malabsorption.

### FOOD AND NUTRITION

- **Preoperatively:** Fiber and lactose intolerances are common; alter diet accordingly. With strictures, avoid popcorn, nuts, seeds, mushrooms, celery, fruit skins, and vegetable skins. Have the patient chew thoroughly.
- **Postoperatively:** Provide a high-energy, high-protein diet for wound healing that is low in excess insoluble fiber. Avoid the high-fiber foods suggested for preoperative care for about 4 weeks. Pectin in apples and oligosaccharides in oatmeal may be beneficial to add back first. Spinach or parsley are natural intestinal deodorizers, but beware of excesses of oxalate-rich foods.
- The patient needs an adequate intake of protein (provided by low-fat sources such as lean meats and egg white), vitamin B<sub>12</sub> (provided by liver, fish, and eggs), folacin, calcium, magnesium, iron, sodium, vitamin C, and potassium.
- Diet should provide an adequate amount of fluids, especially in hot weather. Add salt if needed.
- Apple juice has chemoprotective properties for human colon cells. Intake of apple juice results in bioavailable polyphenols in the gut lumen, which could contribute

- to reduced genotoxicity, enhanced antigenotoxicity and favorable modulation of GSTT2 gene expression (Veeriah et al, 2008).
- Since obesity can cause more discomfort, a weight management plan may be useful.

### Common Drugs Used and Potential Side Effects

- Corticosteroids:** With prednisone, restrict excessive sodium intake and monitor nitrogen and calcium losses. The corticosteroid budesonide (Entocort) may be administered to increase the absorptive capacity of the intestinal mucosa in patients with ileostomies (Ecker et al, 2005). Side effects may include increased appetite and weight gain, hypokalemia, and elevated CRP.
- Lomotil** is a stool thickener and deodorizer. Plenty of fluids should be used.
- Probiotics** and prebiotics may be useful to help with recovery of gut immunity. Research is underway for the use of a special form of *Bacteroides ovatus* (Hamady et al, 2008).
- Psyllium** (Metamucil) is used as a bulk-forming agent. Increased peristalsis will occur.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Use of fish oil may be beneficial during periods of inflammation.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain which foods are common sources of the needed nutrients in a diet or suggest supplementation with multivitamins and minerals. Encourage use of apple juice and other protective foods as tolerated.
- Monitor individual tolerance to offending foods such as gas-forming or fried foods, highly seasoned foods, nuts, raisins, and pineapple. Foods that may cause rapid intestinal transit or discomfort may include dried fruits, prune juice, fresh strawberries or peaches, coconut, nuts, seeds, cabbage, celery, bamboo shoots, corn, and milk.
- An enterostomal therapist may be of assistance.
- Discuss replacement of fluid and sodium, especially during hot weather.

- Eating before bedtime should be avoided to lessen discomfort.
- More than half of patients operated with proctocolectomy will need surgical intervention within 20 years; the failure rate is more than 10% and complications must be addressed (Wasmuth et al, 2009).

### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual who may be experiencing diarrhea and related discomfort.
- Proper ostomy care requires careful and constant hand washing.
- If home TF or PN is needed, teach appropriate sanitation and food-handling procedures.

## PERITONITIS

### NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

In peritonitis, inflammation of the peritoneal cavity due to infiltration of intestinal contents occurs. Contents from

such conditions as ruptured appendix, gastric or intestinal perforation such as in diverticulitis, trauma, fistula, anastomotic leaks, or failed peritoneal dialysis (PD) may initiate the problem.

Bacterial peritonitis is a major cause of morbidity in pediatric PD patients and can lead to catheter removal, hospitalizations, peritoneal membrane dysfunction, and sepsis (Chand et al, 2009). Spontaneous bacterial peritonitis is also common in patients with cirrhosis and ascites because of bacterial translocation. The diagnostic evaluation of ascites involves an assessment of its cause by determining the serum-ascites albumin gradient and the exclusion spontaneous bacterial peritonitis (Hou and Sanyal, 2009). Peritonitis in liver transplant patients may suggest organ rejection (Macedo et al, 2005). Prophylactic antibiotics and omentectomy at catheter insertion are useful (Chand, 2009). Aggressive nutritional supplementation pre- and postoperatively is suggested (De Frietas et al, 2008). It is important to avoid refeeding syndrome.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Peritonitis is the result of infection and not genetic origins.

<b>Clinical/History</b>	Ileus	BUN, Creat
Height	Sepsis?	Gluc
Weight	X-rays	Alb,
BMI	Paracentesis	transthyretin
Diet history	(>250 poly-	CRP
Abdominal pain,	morphonu-	Na <sup>+</sup> , K <sup>+</sup>
tenderness	cleate cells)	Ca <sup>++</sup> , Mg <sup>++</sup>
Abdominal	Laparoscopy	TLC
rigidity	<b>Lab Work</b>	
(washboard	H & H	
appearance)	Serum Fe,	
Fever?	ferritin	
BP	WBC	
I & O		

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Energy Intake

**Assessment Data:** I & O records, weight, severe abdominal pain, intake <25% in past 24 hours, fever 102°F.

**Nutrition Diagnoses (PES):** Inadequate energy intake related to inability to eat orally and abdominal pain as evidenced by intake <25% in past day and fever demands about 21% higher energy needs than normal.

**Interventions:** IV fluids with dextrose until able to eat orally. Monitor for readiness to eat again, based on drop in fever, return of bowel sounds, tolerance for soft or bland foods.

**Monitoring and Evaluation:** Gradual return to oral diet with improved I & O records; weight returning to usual. No fever or signs of abdominal pain or peritonitis. No signs of refeeding.

## INTERVENTION

## OBJECTIVES

- Correct fluid/electrolyte imbalances when present. Vigorous IV rehydration is needed.
- Provide bowel rest and recovery. PN may be better than NG feeding but further studies into dualenteral nutrition and PN are needed (De Frietas et al, 2008).
- Improve nutritional status, especially if patient has been malnourished over a period of time or if there is anorexia or ileus.
- Avoid high risk for refeeding syndrome (De Frietas et al, 2008).

## FOOD AND NUTRITION

- Patient generally is NPO with IV feedings for at least 24 hours. Progress as tolerated to a soft or general diet appropriate for the condition that caused the peritonitis originally.
- Increase protein intake to correct catabolic state. Increase calories because basal energy expenditure is generally elevated by 10–17%.

## Common Drugs Used and Potential Side Effects

- Ciprofloxacin is effective in the treatment. Other antibiotics may be used for bacterial peritonitis. Monitor for specific side effects.
- Probiotics may be useful; research continues in this area.
- PPIs suppress gastric acid secretion, allowing bacterial colonization of the upper GI tract, this may predispose to bacterial overgrowth, translocation and peritonitis (Bajaj et al, 2009). Research is needed in this area.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- With patients on CAPD, diet may need to be altered similar to the diet typical for renal patients.
- Discuss diet appropriate for the illness of origin (such as diabetes, hypertension, toxemia, or renal disease).

## Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual.
- If home TF or CPN is needed, teach appropriate sanitation and food-handling procedures.

# SHORT BOWEL SYNDROME

**NUTRITIONAL ACUITY RANKING: LEVEL 4****DEFINITIONS AND BACKGROUND**

SBS is the predominant cause of intestinal failure, with a high degree of morbidity and mortality. Intestinal failure involves reduction of gut mass below the minimal amount needed for nutrient absorption. SBS involves surgical resection of a portion of the small bowel, compromising the absorptive surface and resulting in malabsorption (especially if more than 50% of the small intestine has been removed). Malnutrition from maldigestion, malabsorption diarrhea, and steatorrhea may result.

A bowel resection that results in SBS may be due to Crohn's disease, intestinal cancer, scleroderma, or fistula in adults; or it may be due to necrotizing enterocolitis, intestinal atresia, or mesentery artery occlusion in infants. If only 30% of the small intestine remains in an adult (or <30 cm in infants), the resulting malabsorption may be life threatening. Problems are significant when more than 70% of the bowel is resected, unless the terminal ileum and ileocecal valve remain. Every attempt should be made to keep the ileocecal valve to prevent contamination of the small intestine. See Table 7-23 regarding the implications of bowel resections.

Normal bowel length is about 600 cm. SBS generally leaves less than 150 cm of small intestine. A total of 100 cm is necessary to completely absorb bile salts; 50–70 cm of jejunum–ileum maintains minimal intestinal autonomy. The minimal length of functional bowel needed for enteral feeding is over 100 cm in the absence of an intact colon and over 60 cm in continuity with the colon.

Patients with SBS require long-term PN. After massive intestinal resection, the intestine undergoes adaptation, and nutritional autonomy may be obtained if the adaptive process is supported by both nutritive and nonnutritive factors (Weale et al, 2005). Length of small intestine remaining after resection is the best predictor of the final success in terminating PN. Home PN may cost between \$400+ a day; most insurance companies cover up to \$1 million, about 10 years of reimbursement.

Aggressive nutritional intervention is necessary for resolution of nutritional deficits and recovery of health. Early oral feeding after colorectal surgery is safe. Bowel adaptation takes about 1 year. Assessment must include oral intake, stool and urine output, serum electrolytes and visceral proteins, and body weight (DiBaise et al, 2006). Diarrhea and high stomal output are common problems and can lead to dehydration; hypokalemia; deficiencies of calcium, magnesium, and zinc; carbohydrate and lactose malabsorption; protein malabsorption; renal oxalate stone formation; cholesterol biliary stones; gastric acid hypersecretion; vitamin B<sub>12</sub> or iron deficiency; fat-soluble vitamin deficiency; and diarrhea. See Table 7-24 for malabsorption concerns in SBS.

Patient education and motivation are key factors in successful weaning from PN, where possible (DiBaise et al, 2006).

**TABLE 7-23 Implications of Bowel Resections**

**Loss of jejunum.** Ileum undergoes hyperplasia; length and absorption per centimeter increases.

**Loss of ileum.** This is more serious than loss of jejunum because vitamin B<sub>12</sub> and bile salts will be reabsorbed poorly as a result. The ileocecal valve keeps colonic bacteria out of the small intestine and regulates chyme flow. Some colonic adaptation occurs during the next 2–5 years.

**Loss of colon.** Overall, with removal of the colon versus the small intestine, fewer malabsorption problems occur. Loss of electrolyte and water-absorbing capacity occurs, as well as loss of salvage absorption of CHO and other nutrients. Most oxalate absorption occurs here.

**In short bowel syndrome (SBS),** short-chain triglycerides have a precursor in pectin; oligosaccharides increase O<sub>2</sub> uptake in the colon, thereby maintaining gut integrity. Early refeeding (i.e., free fatty acids, sugars, proteins) stimulates mucosal growth. Hyperphagia can increase enterocyte production. Adaptation requires adequate nutrition, intraluminal nutrients, and bile and pancreatic secretions. Enhancers of the adaptive process seem to include gastrin, glutamine, growth hormone, insulin, short-chain fatty acids, fats, some dietary fibers, cholecystokinin (CCK), glucagon, insulin-like growth factor I, neurotensin, and glucose.

**TABLE 7-24 Malabsorption Concerns in Short Bowel Syndrome**

Bacterial overgrowth, if ileocecal valve is absent
Decreased bile acid concentration (with loss of ileum and bacterial overgrowth)
Decreased surface area and lessened fluid reabsorption
Dumping syndrome from rapid transit and reduced bowel length
Gastric acid oversecretion with resulting damage to duodenal cells and altered pH, thus affecting pancreatic enzyme and bile activity
Maladaptive remaining small bowel, especially from original bowel disease, lactase deficiency
Pancreatic enzyme activity loss from duodenum, with malnutrition

The use of trophic substances may increase the absorptive function of the remaining gut. Glucagon-like peptide 2 (GLP-2) has been shown to improve intestinal absorption in SBS patients; it reduces fecal weight and enables SBS patients to maintain their intestinal fluid and electrolyte absorption at lower oral intakes (Jeppesen et al, 2009). Current guidelines, however, suggest that the use of growth hormone, glutamine and GLP-2 should not be recommended in patients with short bowel syndrome (Van Gossum et al, 2009).

Serial transverse enteroplasty (STEP) procedure is a safe way to lengthen the small bowel in patients with SBS (Ehrlich et al, 2007). Surgical bowel lengthening should be considered in any chronically PN-dependent patient when there is substantial bowel dilation, regardless of remnant bowel length (Thompson and Sudan, 2008). ITx may also restore quality of life by recovery of normal motility and absorptive capacity. While high-dose immunosuppression is a potential problem, advances in transplantation hold promise as an alternative to intestinal failure and chronic dependence on CPN.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** SBS is a surgical procedure.

Clinical/History	Lab Work	
Height	H & H	Alk phos
Weight	Serum Fe,	Na <sup>+</sup> (serum,
BMI	ferritin	urine, stool)
Diet history	Transferrin	K <sup>+</sup> (serum,
Weight changes	CRP, ESR	urine, stool)
I & O	D-xylose	Fecal nitrogen
Steatorrhea	absorption	GTT
Stool output	Serum gastrin	Gluc
Dehydration?	(increased)	RBP
Urinary output	Ca <sup>++</sup> , Mg <sup>++</sup>	N balance
DEXA bone	25-hydroxyvita-	Serum oxalate
density scan	min D level	Alb,
		transthyretin

Barium follow-through (BaFT) examination	Serum amylase, lipase	Lactose tolerance test
Schilling test	Serum copper	Hydrogen breath test
Serum B <sub>12</sub>	Bile acid breath test	Fecal fat test

### INTERVENTION

### OBJECTIVES

- Determine the location and amount of the intestine that was resected to predict likelihood of diarrhea, malabsorption, and malnutrition (see Table 7-24). Provide nutrient replacements, dependent on area of resection (proximal jejunum—calcium, iron, magnesium, protein, CHO, and fat; terminal ileum—bile acids and intrinsic factor-bound vitamin B<sub>12</sub>).
- Manage post surgical phases. The first phase lasts 1–3 months, massive diarrhea and limited absorption; the second phase: 4–12 months where weight gain begins and absorption improves. In the last phase between 13 and 24 months, maximal adaptation occurs, with possible discontinuation of PN when fluid is >7 L daily and when energy intake is sufficient for desired weight goal.
- Support hyperphagia, in which the amount of protein absorbed increases relative to the amount of remnant small bowel length. Try weaning off PN without trophic factors. If this is unsuccessful, a trophic factors should be attempted (Steiger et al, 2006).
- Prevent and correct fluid and electrolyte imbalances and dehydration. Oral intake could aggravate already massive losses of fluid (3–10 L/d is common). Immediately post-operatively, NPO with IV fluid replacement is likely. Eventually switch to oral intake as tolerated.
- Use remaining bowel surface and maximize efficacy. Prevent atrophy of small bowel mucosa, catheter sepsis, metabolic bone disease, and liver disease with long-term use of CPN. Carefully monitor for signs and symptoms of these problems and manage accordingly.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Parenteral Infusion

**Assessment Data:** Calculations of energy needs showing PN infusion at a rate exceeding goal by 25%; hypophosphatemia, hypokalemia and signs of refeeding syndrome.

**Nutrition Diagnoses (PES):** Excessive parenteral infusion (NI 2.4) related to order for CPN solution that exceeds estimated needs by 25% (200 kcal/d) as evidenced by signs of refeeding syndrome with hypophosphatemia and hypokalemia.

**Interventions:** Reduction in CPN infusion to meet rather than exceed requirements Intervention code.

**Monitoring and Evaluation:** Consistent monitoring of labs until resolution of refeeding syndrome; tolerance of CPN solution with no further complications.

- Correct symptoms of deficiency and malabsorption, when possible, for vitamins B<sub>12</sub>, A, D, E, and K and for the minerals zinc, potassium, and magnesium.
- Minimize weight loss (approximately 10 lb monthly until adaptation occurs). Maximize energy intake from fats and carbohydrates without worsening the diarrhea.
- Omit lactose if not tolerated; provide adequate calcium replacements.
- Decrease oxalate from the diet to reduce renal stone formation. Excess bile in the colon from decreased ileal absorption enhances absorption of free oxalate (normally only 10–15% is absorbed).
- Control or prevent gallstone formation (increased risk of two to three times normal), anemia, PLE, peptic ulcer from increased gastric acid secretion, and liver disease (often from home CPN). Parenteral fish-oil lipid or olive-oil emulsions are now more available.
- Allow remaining intestine to compensate over time by hypertrophy of villi and increased diameter. Home CPN is expensive but can be lifesaving for months or years. Transitional feedings may be needed over several months from PN to oral diet. For care of colostomy or ileostomy, see appropriate entries.

## FOOD AND NUTRITION

- **First Postoperative Phase:** IV nutrition or CPN may be appropriate immediately before and approximately 5 days after surgery to allow rest. Determine whether the patient has problems with bloating. The first phase involves extensive diarrhea greater than 2 L daily; advance CPN slowly to avoid refeeding syndrome. At the end of this time, if diarrhea continues to be greater than 2 L, CPN may be lifelong.
- **Second Postoperative Phase:** Diarrhea is lessened and intestinal adaptation begins; CPN may be slowly reduced and polymeric TF started at a slow, continuous rate according to stomal output or stool output. Provide 40–60 kcal/kg and 1.2–1.5 g protein/kg. Providing patients with enteral nutrition, glutamine, dietary fiber, and r-hGH during bowel rehabilitation therapy allows weaning from CPN. If weight loss is greater than 1 kg/wk, CPN may need to be restarted.
- Nocturnal enteral rehydration is an intervention using ORS through PEG tubes at night; this allows for earlier discontinuation of CPN and improved fluid absorption.
- **Third Postoperative Phase:** Complete bowel adaptation begins as TF is tolerated and oral diet is slowly resumed (from 2 months to 1 year). Six small feedings that are high CHO and low fat may be tolerated (60% CHO, 20% protein, 20% fat, with a limit on MCT of 40 g/d). With no colon, the jejunostomy feeding may need to be 40–50% CHO, 20% protein, 30–40% fat. PN reductions can be made by either decreasing the days of PN infusion per week or decreasing the PN infusion volume equally across all days of the week.
- Supplemental zinc, potassium, liquid magnesium, oral calcium (600–1000 mg), manganese, iron, vitamin C, selenium, B-complex vitamins (especially folic acid), and other nutrients may be needed. Determine needs based on site of resection and signs of malnutrition.
- Monitor for needs for vitamins A, E, and D; use water-miscible forms. Patients with SBS are depleted in diet-derived carotenoids despite oral and IV multivitamin supplementation; reduction of PN lipid infusion may improve serum alpha-tocopherol concentrations (Luo et al, 2009). With antibiotic use, the patient will need extra vitamin K.
- Lactose-restricted and oxalate-restricted diets may be needed for an extended period of time. Rhubarb, spinach, beets, cocoa and chocolate, sweet potatoes, strawberries, celery, and peanuts are high-oxalate foods. Nuts and nut butters, berries, Concord grapes, sweet potatoes and potatoes, and most vegetables have smaller amounts.
- Omit alcoholic beverages and caffeine unless physician permits small quantities.
- Taking fluids between instead of with meals may be helpful to reduce dumping. Restrict at first to 1500 mL; progress as tolerated.
- With osmotic diarrhea, a reduction in simple carbohydrates and an increase in complex carbohydrates may be needed. Sorbitol, mannitol, and xylitol are usually poorly absorbed.
- Restricted foods such as lactose may be attempted and added back to the diet if they are tolerated. Bowel adaptation occurs over time and may eventually lead the patient back to an unrestricted diet.

## Common Drugs Used and Potential Side Effects (see Table 7-25)

- **Note: Most oral medications are poorly tolerated in this condition!** Accelerated intestinal luminal transit time causes a reduction in absorption of certain antimicrobial agents, digoxin, hydrochlorothiazide, cyclosporine, cimetidine, mesalazine (5-aminosalicylic acid), oral contraceptives, and levothyroxine.
- Dietary glutamine (GLN) or oral antibiotics (ABX) can blunt gut barrier dysfunction (Tian et al, 2009). Antibacterial drugs, antimotility drugs, antidiarrheal agents, H<sub>2</sub> antagonists and PPIs, pancreatic enzymes, somatostatin analogs, antimicrobials, and trophic factors have been quite helpful in addition to nutritional therapy (Matarese and Steiger, 2006).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Probiotics and foods such as acidophilus or yogurt are useful aids in bowel adaptation phases. Not all probiotic bacteria have similar therapeutic effects. Research is available for probiotic supplementation for children with SBS (Wallace, 2009).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Importance of nutrition and supplementation must be discussed to prevent or correct malnutrition and

**TABLE 7-25 Medications Used in Short Bowel Syndrome**

Medication	Description
Antibiotics	Tetracycline, Flagyl, Septra, or Cipro may be needed for bacterial overgrowth. Monitor hydrogen breath tests (especially with blind loop).
Antidiarrheals	Antidiarrheals such as Lomotil, Imodium, and codeine are useful. Liquid preparations often are better tolerated. If dehydration occurs, use oral rehydration therapy but not sports drinks, which do not have the adequate electrolyte replacements.
Bile salt replacements	Cholylsarcosine (CS) is a semisynthetic bile salt that may be useful in bile salt replacement therapy of short bowel syndrome (Furst et al, 2005).
Calcium supplements	Oral calcium supplements (OsCal or Tums four times daily) often are used to bind oxalate excesses and to decrease diarrhea. Do not take with a bulk-forming laxative or with an iron supplement. Increase water intake.
Cholestyramine	Cholestyramine may be used for choleraic diarrhea when less than 100 cm is resected and when the colon is in continuity; prevent excessive use. Take before meals. Nausea, vomiting, or constipation may occur.
Cimetidine or omeprazole	Cimetidine and omeprazole may be needed to decrease gastric hypersecretion; parenteral administration may be needed. Serum gastrin levels should be monitored. A dose two to three times higher than normal may be needed because of gastric hypersecretion; lack of sufficient time with intestinal mucosa leads to insufficient absorption. Vitamin B <sub>12</sub> absorption decreases with use of these medications.
Clonidine	Clonidine can effectively reduce intestinal fluid and electrolyte losses and should be considered in patients with short bowel syndrome.
Growth hormone	Growth hormone increases water/sodium transport. It is useful in combination with glutamine and a modified diet, but results have been mixed.
Minerals	Liquid potassium and intravenous or intramuscular magnesium may be needed.
Pancreatic enzymes	Pancrelipase may improve fat and protein absorption after jejunal resection; results are variable.
Peptides	Glucagon-like peptide-2 (GLP-2) is an enteroendocrine peptide that is released in response to luminal nutrients; it seems to help support the adaptive response to resection (Martin et al, 2005).
Probiotics and prebiotics (synbiotics)	This type of therapy might be a potent modulator of intestinal flora and a promising strategy to treat short bowel patients with enterocolitis.
Vitamins	Vitamins that are chewable or in liquid form may be better tolerated. Parenteral vitamin B <sub>12</sub> may be necessary. Add extra fat-soluble vitamins A, E, D, and K if deficiency occurs. Do not use vitamin C in excessively large quantities; some links with oxalate stones have been noted.

malabsorption. After adaptation, significant energy intakes will be needed to maintain desired weight.

- Provide recipes or food-preparation tips to support the specific dietary regimen and to evaluate tolerances over time.
- Progression in diet is allowed when the small intestine adapts over several months. Use yogurt with live and active cultures.
- Discuss the need for free water.
- The use of home CPN is beneficial in many cases. Judicious use of home CPN in this setting requires careful clinical assessment on a patient-by-patient basis (Hoda et al, 2005). A supportive attitude from family and caregivers is essential.
- There are potential benefits of a multidisciplinary intestinal rehabilitation program. Interventions can help decrease incidence and economic impact of intestinal failure.
- Exercise, such as resistance training, can help regenerate lean body mass.

#### **Patient Education—Foodborne Illness**

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual.

- If home TF or CPN is needed, teach appropriate sanitation and food-handling procedures.

## TROPICAL SPRUE

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

Tropical sprue is an acquired disorder that presents with chronic diarrhea, anorexia, weight loss, megaloblastic anemia (folic acid deficiency), light-colored stools, diarrhea, weight loss, pallor, sore tongue (vitamin B<sub>12</sub> deficiency), and easy bruising (vitamin K deficiency). Etiology is often bacterial, viral, or parasitic infection or toxins in spoiled food. *Giardia intestinalis* is a common culprit. Tropical sprue may occur after traveling to the Caribbean, southern India, and Southeast Asia.

Tropical sprue causes progressive villus atrophy in the small intestine, similar to CD ("nontropical" sprue). Villi of the small intestinal mucosa become blunted, or obliterated. Treatment of tropical sprue includes folic acid and vitamin B<sub>12</sub> replacement. However, even prolonged treatment fails to resolve malabsorption. While tropical sprue is less common than it was decades ago (Nath, 2005), sporadic tropical sprue is still an important cause of malabsorption in adults and in children in South Asia (Ramakrishna, 2007).

Biomarker (13)C-sucrose breath test (SBT) to measure enterocyte sucrose activity can be used as a marker of small intestinal villus integrity and function (Ritchie et al, 2009). Enhanced magnification endoscopy can help identify patchy areas of partial mucosal atrophy, potentially reducing the need for blind biopsies (Lo et al, 2007).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** An infectious cause is suspected in tropical sprue.

<b>Clinical/History</b>	Diet history	Malabsorption,
Height	Weight loss?	especially for
Weight	I & O; dehydration?	xylose
BMI		Glossitis
		Cramps, nausea

Gas, indigestion	Na <sup>+</sup> , K <sup>+</sup>	Ca <sup>++</sup>
Paleness	H & H, Serum	(decreased)
Biopsy	Fe, ferritin	Mg <sup>++</sup>
Enhanced magnification endoscopy (EME)	(decreased)	PT or INR
	Alb,	(altered)
	transferrin	
	(decreased)	
	Serum B <sub>12</sub>	
	(decreased)	
<b>Lab Work</b>	Serum folate	
Gluc	(decreased)	
SBT		

#### INTERVENTION

#### OBJECTIVES

- Provide fluids and electrolytes.
- Differentiate between tropical sprue and CD. Control diarrhea, which leads to malabsorption and malnutrition over time.
- Improve or correct folic acid, vitamin B<sub>12</sub>, and vitamin K deficiencies. Treat tropical sprue with folate and vitamin B<sub>12</sub> cures the macrocytic anemia and the accompanying glossitis.
- Avoid fatty foods that can cause oily, foul-smelling stools.

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### Abnormal GI Function

**Assessment Data:** Diarrhea, fever, macrocytic anemia, biopsy showing flattened villi and diagnosis of tropical sprue.

**Nutrition Diagnoses (PES):** Abnormal GI function related to infectious process as evidenced by diarrhea, macrocytic anemia, and flattened villi on biopsy.

**Interventions:** Provide folic acid and vitamin B<sub>12</sub> in supplemental form along with antibiotic therapy; extra fluids, sodium and potassium as needed. Progress to low-fat diet.

**Monitoring and Evaluation:** Improvement in macrocytic anemia; resolution of diarrhea.

## FOOD AND NUTRITION

- Use a regular diet with supplements of vitamin B<sub>12</sub> and folic acid. Good sources of folacin include liver, kidney, yeast, leafy greens, lean beef, and eggs. Good sources of vitamin B<sub>12</sub> include meat, poultry, fish, dairy products, and eggs.
- Avoid meals with fatty foods.
- Diet should provide sufficient amounts of energy intake, protein, calcium, iron, and vitamins.
- Extra fluid may be needed for dehydration.
- No gluten restriction is needed.

## Common Drugs Used and Potential Side Effects

- Tetracycline may be used; do not take within 2 hours of a calcium-containing supplement or meal as calcium makes the drug less effective.
- Vitamin supplements are required, especially for vitamin B<sub>12</sub>, folate, and vitamin K. Calcium may also be needed. Avoid excesses of any single nutrient for an extended time period.
- Suggest use of probiotics such as yogurt with live and active cultures during antibiotic therapy. Intestinal flora modifiers (e.g., *Lactobacillus acidophilus*, Lactinex, Bacid) also help recolonize normal intestinal flora in people on antibiotics. A common order is three to four packages every day for 3 days in adults. They may be mixed with water for TFs.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain to the patient which foods are good sources of folic acid and vitamin B<sub>12</sub>.
- Describe good sources of protein and calories from the diet.
- Describe how to follow a low-fat diet and how to use MCT oil in cooking.

## Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual.
- If home TF or CPN is needed, teach appropriate sanitation and food-handling procedures.

# WHIPPLE'S DISEASE (INTESTINAL LIPODYSTROPHY)

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

## DEFINITIONS AND BACKGROUND

Whipple's disease is a chronic systemic inflammatory disease caused by *Tropheryma whipplei*. The hallmark of Whipple's disease is invasion of the intestinal mucosa with macrophages incompetent to degrade *T. whipplei* (Moos et al, 2010). This condition presents with weight loss, arthralgias, and diarrhea that involves infiltration of the small intestine with glycoprotein-laden macrophages in varying body tissues (Muller et al, 2005). Endocarditis and heart murmur are common. Infection may spread to the central nervous system, which may lead to loss of memory, confusion, or disturbed gait. Treatment is antibiotic therapy.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Decreased production of Interleukin (IL)-12, IL-2 and Interferon (IFN)- $\gamma$  accompanied by an increased secretion of IL-4 may predispose patients for an infection with *T. whipplei* (Deriban and Marth, 2006).

<b>Clinical/History</b>	Lymphadenopathy	CRP (elevated?)
Height	Confusion, memory loss	Acid-Schiff (PAS)-positive
Weight	Edema?	foamy macrophages
BMI	Duodenal biopsy; villous blunting	<i>T. whipplei</i> DNA—polymerase chain reaction (PCR) assays
Weight loss?	Skin biopsy	H & H (decreased)
Wasting?		Serum Fe, ferritin
Diet history		Transferrin
Fever		
I & O	<b>Lab Work</b>	
Malabsorption, cholestasis	Alk phos	
Gray to brown skin pigmentation	Na <sup>+</sup> , K <sup>+</sup>	
	Ca <sup>++</sup> , Mg <sup>++</sup>	
	Alb (decreased)	

## INTERVENTION

### OBJECTIVES

- Reduce fever and inflammatory processes.
- Correct malnutrition and malabsorption.
- Correct anemia, iron overloading, or hypoproteinemia when present.
- Prevent or correct dehydration and electrolyte imbalances.

### FOOD AND NUTRITION

- Use a high-protein/high-calorie diet appropriate for the patient's age and sex.
- Ensure that the diet includes sufficient vitamins and minerals, especially for vitamin D and calcium, when steatorrhea is a problem. Vitamins A, B-complex, and K may also be needed.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Weight Loss

**Assessment Data:** I & O, weight loss, BMI, fever; low albumin, elevated CRP

**Nutrition Diagnoses (PES):** Involuntary weight loss (NC-3.2) related to fever and infection as evidenced by BMI below usual range and inflammatory process with elevated CRP.

**Interventions:** Offer frequent small meals and snacks with nutrient dense, calorie-rich foods. Educate about the role of nutrition in maintaining healthy immune system.

**Monitoring and Evaluation:** Weight gain back to usual weight; no further fever or weight loss. Maintain adequate hydration.

- Provide adequate fluid intake to reduce fever and replenish tissues.
- If edema is a problem, control excess sodium.

## Common Drugs Used and Potential Side Effects

- Antibiotic treatment is mandatory and leads to a rapid clinical improvement and remission in most patients: 2-week parenteral cephalosporins followed by long-term therapy with trimethoprim-sulfamethoxazole. Trimethoprim-sulfamethoxazole (Bactrim) combinations may have numerous side effects; monitor closely for anorexia, nausea, vomiting, and diarrhea.

## Herbs, Botanicals, and Supplements

- Use probiotic or prebiotic foods when possible to replenish "good" gut bacteria.
- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss inclusion of high-quality proteins in the diet. Frequent snacks may be beneficial if large meals are not tolerated.
- Provide lists for nutrient-dense foods rich in specific and needed nutrients (e.g., iron, calcium, etc).

## Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual.
- If home TF or CPN is needed, teach appropriate sanitation and food-handling procedures.

## RECTAL DISORDERS

## FECAL INCONTINENCE

## NUTRITIONAL ACUITY RANKING: LEVEL 1

## DEFINITIONS AND BACKGROUND

Fecal incontinence is the inability to control bowel movements, and stool may leak from the rectum unexpectedly. More than 5.5 million Americans have fecal incontinence, affecting both children and adults, especially seniors. Fecal incontinence is more common in women than in men (Novi and Mulvihill, 2005); see Table 7-26. Fecal incontinence affects up to 20% of community-dwelling adults and more than 50% of nursing home residents, and is one of the major risk factors for elderly persons in the nursing home (Leung and Rao, 2009).

Bowel training helps some people relearn how to control their bowels. In some cases, it involves strengthening muscles; in others, it means training the bowels to empty at a specific time of day. Biofeedback and sacral nerve stimulation may be useful in refractory patients and should be considered before colostomy (Leung and Rao, 2009; Jarrett et al, 2005). Biofeedback helps strengthen and coordinate the muscles. Kegel exercises may be used to strengthen the muscles in the pelvic floor, including those involved in controlling stool. This condition is often correlated with the presence of stroke and diabetes, or use of certain psychoactive medications (Quander

et al, 2005). Treatment depends on the cause and severity of fecal incontinence; it may include dietary changes, medication, bowel training, and/or surgery. Surgery may be needed if fecal incontinence occurs in severe cases where injury has taken place. In patients with functional bowel disorders not responding to maximal medical treatment, bowel lavage or biofeedback therapy, can nowadays be treated by sacral nerve neuromodulation (Govaert et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

## Clinical/History

Height  
Weight

BMI  
Diet history  
I & O

BP  
History of  
diarrhea

TABLE 7-26 Fecal Incontinence: Causes and Comments

Cause	Comments
Constipation	One of the most common causes of fecal incontinence, constipation causes large, hard stools to become lodged in the rectum. Watery stool can then leak out around the hardened stool. Constipation also causes the muscles of the rectum to stretch, which weakens the muscles so they cannot hold stool in the rectum long enough for a person to reach a bathroom. In children, early toilet training or some developmental disorders can cause or aggravate constipation. Consult the doctor for specific management techniques.
Damage to the anal sphincter muscles	Fecal incontinence can be caused by injury to one or both of the ring-like muscles at the end of the rectum called the anal internal and/or external sphincters. The sphincters keep stool inside. When damaged, the muscles are not strong enough to do their job, and stool can leak out. In women, the damage often happens when giving birth. The risk of injury is greatest if the doctor uses forceps to help deliver the baby or does an episiotomy, which is a cut in the vaginal area to prevent it from tearing during birth. Hemorrhoid surgery can damage the sphincters as well.
Damage to the nerves of the anal sphincter muscles or the rectum	Fecal incontinence can also be caused by damage to the nerves that control the anal sphincters or to the nerves that sense stool in the rectum. If the nerves that control the sphincters are injured, the muscle does not work properly, and incontinence can occur. If the sensory nerves are damaged, they do not sense that stool is in the rectum. The individual will not feel the need to use the bathroom until stool has leaked out. Nerve damage can be caused by childbirth, a long-term habit of straining to pass stool, stroke, and diseases that affect the nerves, such as diabetes and multiple sclerosis.
Loss of storage capacity in the rectum	Normally, the rectum stretches to hold stool until a person can get to a bathroom. But rectal surgery, radiation treatment, and inflammatory bowel disease can cause scarring that makes the walls of the rectum stiff and less elastic. The rectum then cannot stretch as much and cannot hold stool, and fecal incontinence results. Inflammatory bowel disease also can make rectal walls very irritated and thereby unable to contain stool.
Diarrhea	Diarrhea, or loose stool, is more difficult to control than solid stool that is formed. Even people who do not have fecal incontinence can have an accident when they have diarrhea.
Pelvic floor dysfunction	Abnormalities of the pelvic floor can lead to fecal incontinence. Examples of some abnormalities are decreased perception of rectal sensation, decreased anal canal pressures, decreased squeeze pressure of the anal canal, impaired anal sensation, a dropping down of the rectum (rectal prolapse), protrusion of the rectum through the vagina (rectocele), and/or generalized weakness and sagging of the pelvic floor. Often the cause of pelvic floor dysfunction is childbirth, and incontinence does not show up until the midforties or later (Bharucha et al, 2005).

Constipation	<b>Lab Work</b>	Stool (occult blood)
Anal manometry	H & H	Na <sup>+</sup> , K <sup>+</sup>
Anorectal ultrasonography	Serum Fe, ferritin	Ca <sup>++</sup> , Mg <sup>++</sup>
Proctography	BUN	
Proctosigmoidoscopy	Transferrin, TIBC	
Anal electromyography tests for nerve damage	PT	
	Alb, transthyretin	

## INTERVENTION

### OBJECTIVES

- Timely assessment and intervention are needed to manage constipation and incontinence of stool. Maintain a food diary to determine when incontinence occurs and to identify changes that may be helpful.
- Establish a bowel training regimen to develop a regular pattern of bowel movements; some people train themselves to have bowel movements at specific times during the day, such as after every meal.
- Identify and treat underlying causes, such as diet- or medication-induced diarrhea, constipation, and fecal impaction (Leung and Rao, 2009).
- Prepare for surgery if needed.

### FOOD AND NUTRITION

- Daily intake of protein should be appropriate for age and sex. Calories should be calculated as 30–35 kcal/kg.
- Foods that may make the problem worse are drinks containing caffeine, such as coffee, tea, and chocolate, which relax the internal anal sphincter muscle. Other foods that have been implicated are cured or smoked meats

such as sausage, ham, or turkey; spicy foods; alcohol; dairy products such as milk, cheese, and ice cream; fruits such as apples, peaches, or pears; fatty and greasy foods; sweeteners, such as sorbitol, xylitol, mannitol, and fructose, which are found in diet drinks, sugarless gum and candy, chocolate, and fruit juices.

- Serve smaller meals more frequently.
- Since liquid helps move food through the digestive system, drink half an hour before or after meals.
- Foods that contain soluble, digestible fiber slow the emptying of the bowels. Bananas, rice, tapioca, bread, potatoes, applesauce, cheese, smooth peanut butter, yogurt, pasta, and oatmeal may be helpful.
- High-fiber foods will add bulk and make stool easier to control. Fiber is found in fruits, vegetables, and grains. 20–30 g of fiber a day is needed; add it slowly.
- Too much fiber all at once can cause bloating, gas, or even diarrhea. If fiber intake makes diarrhea worse, cut back to two servings each of fruits and vegetables and remove skins and seeds. Increase fluid intake when fiber intake is increased to prevent fecal obstruction.

## Common Drugs Used and Potential Side Effects

- If diarrhea is causing the incontinence, medication may help. Sometimes doctors recommend using bulk laxatives to help people develop a more regular bowel pattern. Antidiarrheal medicines, such as loperamide or diphenoxylate, may be used to slow down the bowel activity.
- Use of probiotic or prebiotic therapy is under study for this condition.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### Inadequate Physical Activity

**Assessment Data:** I & O, constipation and fecal incontinence, bedridden with no transfer from bed to chair; no walking.

**Nutrition Diagnoses (PES):** Inadequate physical activity related to nonambulatory status as evidenced by being bedridden for 5 months after hip replacement leading to fecal incontinence.

**Interventions:** Ensure adequate fluid and fiber intake; prune juice once daily as tolerated. Coordinate with physical therapy to enhance strengthening exercises; with nursing to offer bowel training.

**Monitoring and Evaluation:** Improvement in fecal continence; resident more compliant with bed exercises for strengthening lean body mass.

- The key to a successful bowel management program rests in tailoring the type of enema, medication, and diet to the specific type of colon (Bischoff et al, 2009).
- The skin around the anus is delicate and sensitive. Constipation and diarrhea or contact between skin and stool can cause pain or itching. To relieve discomfort, wash the area with water, but not soap, after a bowel movement; wash in the shower with lukewarm water or use a sitz bath. Premoistened, alcohol-free towelettes are a better choice than toilet paper. Let the area air dry after washing. Use a moisture-barrier cream. Wear loose clothing, absorbent pads and special undergarments (Leung and Rao, 2009).
- Ensure that the patient adequately exercises, rests, and maintains regular bowel habits.
- Indicate which foods are sources of fiber and other key nutrients in the diet. See Table 7-27.

**TABLE 7-27 Fiber Content of Common Foods**

Fruits	Amount	Grams of Fiber	Fruits	Amount	Grams of Fiber
Figs	2 dried	4.6	<b>Grains</b>		
Pear	1 pear	4.0	All Bran	1/2 cup	9.6
Raspberries	1/2 cup	4.0	Raisin bran	1 cup	7.5
Strawberries, raw	1 cup, sliced	3.8	Shredded wheat	2 biscuits	5.0
Apple, large with skin	1 apple	3.7	Wheat bran flakes	3/4 cup	4.6
Apple, medium	1 apple	3.3	Rice, brown, cooked	1 cup	3.5
Prunes, dried	5 prunes	3.0	Total cereal	3/4 cup	3.4
Orange	1 orange	3.1	Oatmeal, cooked	3/4 cup	3.0
Banana	1 banana	2.8	Wheatena, cooked	1 packet	3.0
Tangerine	1 medium	1.9	Oat bran muffin	One muffin	2.6
Peach	1 medium	1.8	Bread, whole wheat	1 slice	1.9
Peaches, canned	1/2 cup	1.3	Bread, whole grain	1 slice	1.7–2
Raisins	1 miniature box (14 g)	0.6	(check label)		
<b>Vegetables</b>			Rye crisp wafer	1 wafer	1.7
Peas, split, cooked	1/2 cup	8.1	Crackers, graham	2 squares	0.4
Lentils, cooked	1/2 cup	7.8	Bread, white wheat	1 slice	0.6
Beans, kidney, canned	1/2 cup	4.5	<b>Other</b>		
Lima beans, cooked	1/2 cup	4.5	Nuts, mixed, dry roast	1 oz	2.6
Black eyed peas	1/2 cup	4.0	Apple pie, sliced	1 slice	1.9
Peas, green, canned	1/2 cup	3.5	Chocolate cake, sliced	1 slice	1.8
Cauliflower	1 cup raw	2.5	Yellow cake, sliced	1 slice	0.2
Spinach, cooked	1/2 cup	2.2			
Cabbage, raw	1 cup	2.0			
Brussels sprouts	1/2 cup	2.0			
Squash, acorn	1 cup raw	2.1			
Carrots, raw	1/2 cup	1.8			
Potatoes, boiled	1/2 cup	1.6			
Zucchini, raw	1 cup	1.4			
Broccoli, raw	1/2 cup	1.3			
Celery, raw	1/2 cup	1.0			
Lettuce, iceberg	1 cup shredded	0.8

# HEMORRHOIDS

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: Thomas H. McConnell, *The Nature Of Disease Pathology for the Health Professions*, Philadelphia: Lippincott Williams & Wilkins, 2007.

### DEFINITIONS AND BACKGROUND

Chronic constipation is believed to be the main cause of hemorrhoids. The disorder is common in Americans (50% of Americans older than 50 years of age will have suffered at least once, especially if obese). Causes include increased abdominal pressure secondary to straining during bowel movements, heavy lifting, childbirth, and benign prostatic hypertrophy.

Internal hemorrhoids are normal anatomical structures and rarely are painful (they may only bleed). External hemorrhoids are usually from excessive diarrhea or from constipation; they are tender, painful, bluish, localized swellings of varicose veins at the anal margin. Bleeding, pain, soiling, and prolapse are the classic symptoms in hemorrhoid disease (Johannsson et al, 2005). Although some patients fear that rectal bleeding signifies colorectal cancer, most patients with the primary diagnosis of symptomatic hemorrhoids do not need further investigative procedures (Tang et al, 2005).

Techniques that fix the cushions back in position can be performed in outpatients with reasonable success rates. Sclerotherapy—Used to treat varicose veins, in this procedure a chemical solution is injected into the vein, which causes the hemorrhoid to collapse. Surgery should be aimed at symptomatic hemorrhoids. Stapled hemorrhoidectomy is safe and effective for acute thrombosed hemorrhoids (Wong et al, 2009). Patients have reduced pain, shorter length of

stay, and earlier return to work (Chung et al, 2005). Transanal hemorrhoidal dearterialization is also a potential treatment option for second-degree and third-degree hemorrhoids (Giordano et al, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Hemorrhoids are not likely to have a genetic origin.

Clinical/History	One or more	BUN
Height	hard tender	Transferrin,
Weight	lumps near	TIBC
BMI	the anus	Alb,
Diet history	Anoscope or sig-	transthyretin
I & O	moidoscopy	Stool (occult
Anal itching	History of diar-	blood)
Bright red	rhea	Na <sup>+</sup> , K <sup>+</sup>
blood on	Constipation	Ca <sup>++</sup> , Mg <sup>++</sup>
toilet		
tissue	<b>Lab Work</b>	
Pain during	H & H	
bowel move-	Serum Fe,	
ments	ferritin	

### INTERVENTION

### OBJECTIVES

- Provide comfort. Prevent prolapse and thrombosis.
- Avoid constipation, infection, and anemia.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Fiber Intake

**Assessment Data:** I & O and diet history revealing low fiber intake (<10 g daily).

**Nutrition Diagnoses (PES):** Inadequate fiber intake related to poor dietary intake as evidenced by recurrent hemorrhoids.

**Interventions:** Food and Nutrient Delivery—provide high fiber foods and extra fluids. Education—high fiber diet and how to assure adequate hydration; increasing physical activity such as walking.

**Monitoring and Evaluation:** Fewer complaints of hemorrhoids, straining during defecation at stool, dry stool consistency.

- Reduce possible irritation from excessive amounts of fiber. Avoid irritants, such as laxatives.
- After surgery, reduce irritation while patient heals. Promote rapid healing. Prevent future recurrence.

## FOOD AND NUTRITION

- Diet should be low in fiber only when the patient is in pain. Otherwise, a high-fiber diet (25–35 g) should be used.
- Fluids should be increased to 8–10 glasses daily.
- After surgery, a low-fiber/soft diet should be used until full recovery occurs. Eventually, adequate fiber (25–35 g) should be taken.
- Omit lactose and highly seasoned foods only if not tolerated by the individual.

## Common Drugs Used and Potential Side Effects

- Hemorrhoid creams with lidocaine, over-the-counter, can reduce pain.
- Laxatives and enemas may have caused faulty bowel function. Avoid use unless prescribed by the doctor.
- Troxerutin and carbazochrome are used as a combination therapy. Monitor for any untoward side effects.
- Lubrication with glycerin suppositories may help to reduce symptoms.
- Medicated suppositories such as Anusol HC (contains hydrocortisone) may help to decrease inflammation. Limit steroid-containing medications to less than 2 weeks of continuous use to avoid atrophy of anal tissues.
- Psyllium laxatives (Metamucil) can help with constipation; long-term use alters electrolytes. Flatulence or steatorrhea may occur.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Comfrey, plantain, butcher's broom, horse chestnut, and witch hazel have been recommended for this condition, but no clinical trials have proven efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Ensure that the patient adequately exercises, rests, and maintains regular bowel habits. Limit the time sitting on the toilet. Avoid straining.
- Teach the patient about the role of fiber in the diet.
- Persistent or recurrent bleeding requires medical attention, especially to monitor vitamin K, iron, and B-complex vitamin levels and to prevent additional losses.
- It is important to keep the anal skin area dry.
- Over-the-counter products may aggravate an allergic response.
- Warm sitz baths may help to reduce symptoms.

## Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual.
- If home TF or CPN is needed, teach appropriate sanitation and food-handling procedures.

# PROCTITIS

## NUTRITIONAL ACUITY RANKING: LEVEL 1

## DEFINITIONS AND BACKGROUND

Proctitis is inflammation of the lining of the rectal mucosa and may be acute or chronic. Proctitis may be a side effect of medical treatments such as radiation therapy or antibiotics. It may also be caused by UC, rectal injury, bacterial infection,

allergies, malfunction of the nerves in the rectum, Crohn's disease, or sexually transmitted diseases.

Proctitis is most common in UC patients at diagnosis, and younger patients are more likely than older patients to have extensive disease (Tarrant et al, 2008). For this form of proctitis, 5-aminosalicylic acid (5-ASA) or corticosteroids may

be applied directly to the area or taken in a pill form. Ileal pouch rectal anastomosis (IPRA) preserves bowel continuity and provides a good function (Kariv et al, 2009). There may also be a role for appendectomy in ulcerative proctitis (Bolin et al, 2009).

Antibiotics are used for proctitis caused by bacterial infection. Lymphogranuloma venereum (LGV) L2b proctitis may cause proctitis in HIV-positive men who have sex with men (MSM); doxycycline is the drug of choice (White, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

Clinical/History		
Height	Frequent or continuous	Gluc
Weight	urge to	BUN, Creat
BMI	defecate	Transferrin, TIBC
Diet history	Constipation	Alb,
I & O	Rectal fullness	transferrin
BP	Proctoscopy	CRP
Bowel habits	Sigmoidoscopy	Na <sup>+</sup> , K <sup>+</sup>
Abdominal pain		Ca <sup>++</sup> , Mg <sup>++</sup>
Rectal bleeding		Serum folate, vitamin B <sub>12</sub>
Mucus in stool	Stool (occult blood)	
Left-sided abdominal pain	HPV testing	
	H & H	
	Serum Fe, ferritin	

#### Lab Work

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Mineral (Iron) Intake

**Assessment Data:** I & O, abdominal pain, mucus and blood in stool, constipation, poor oral intake, medical diagnosis of anemia, labs indicative of anemia (low H & H, ferritin, Fe).

**Nutrition Diagnoses (PES):** Inadequate mineral (iron) intake related to blood loss and rectal bleeding in proctitis as evidenced by labs (low Fe, ferritin, H & H).

**Interventions:** Food and Nutrient Delivery—enhance food choices with iron-rich food choices. Educate about food choices that are rich in iron; discuss heme and nonheme sources. Counseling about use of medications and dietary changes that may be needed with abdominal pain.

**Monitoring and Evaluation:** Improvement in serum labs, less abdominal pain, fewer incidents of rectal bleeding.

## INTERVENTION

### OBJECTIVES

- Manage symptoms and alleviate pain. Prepare for surgery if needed.
- Reduce inflammation and promote healing.
- Correct anemia from blood loss where present.

### FOOD AND NUTRITION

- Diet therapy depends on the cause of proctitis. Identify appropriate etiology and review entries in this text for dietary management.
- Some patients find that avoidance of caffeine, red meat, dairy products, and artificial sweeteners can be beneficial.
- Use of omega-3 fatty acids may be helpful to reduce inflammation.

### Common Drugs Used and Potential Side Effects

- Ulcerative proctitis patients with frequent relapses may need a longer duration of topical therapy. Prolonged oral mesalazine treatment period protects against the proximal spread of rectal inflammation (Pica et al, 2004).
- 5-ASA or corticosteroids may be needed if IBD is the cause. Monitor for numerous side effects.
- Antibiotics are the best treatment for proctitis caused by a specific bacterial infection. When proctitis is caused by use of an antibiotic that destroys normal intestinal bacteria, a doctor may prescribe metronidazole (Flagyl) or vancomycin (Vancocin), which should destroy the harmful bacteria.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach the patient about the role of fiber in the diet.
- It is important to keep the anal skin area dry. Over-the-counter products may aggravate an allergic response.

#### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the individual.
- If home TF or CPN is needed, teach appropriate sanitation and food-handling procedures.

# Hepatic, Pancreatic, and Biliary Disorders

## CHIEF ASSESSMENT FACTORS

### Clinical Factors

- Abnormal Liver MRI, Ultrasound, or Biopsy
- Abdominal or Radiating Pain
- Anorexia, Malaise, Fatigue
- Ascites, Large Abdominal Girth, Pot Belly
- Brownish spots or blemishes on the skin
- Darkened urine
- Depression or mood swings
- Diabetes, Hyperglycemia, Hypoglycemia
- Diarrhea, Steatorrhea
- Edema in feet or ankles
- Encephalopathy?
- Flushed facial appearance
- Gastrointestinal (GI) Bleeding
- Hepatomegaly or Shrunken Liver (in cirrhosis)
- Itchy skin
- Hypoglycemia
- Jaundice
- Light colored stools
- Malnutrition, Subjective Global Assessment (SGA) Score
- Offensive body odor
- Red, swollen or itchy eyes
- Unusual Weight Loss or Gain
- Varices
- Vomiting, Nausea

### Laboratory Assessment

A “liver panel” usually includes tests for alanine aminotransferase (ALT), aspartate aminotransferase (AST), bilirubin, and alkaline phosphatase. Liver Function is best measured by the prothrombin time (PT), international normalized ratio (INR) and albumin (see below).

- Bilirubin (total or indirect) is released from destroyed red blood cells and passed on to the liver where it is excreted through bile.
- Bleeding/clotting times: PT, INR measure how long it takes blood to form a clot in seconds; a normal PT/INR indicates that a normal amount of blood-clotting protein is available.

- Blood product transfusions.
- Cholestasis tests: Serum alkaline phosphatase (Alk Phos), Gamma-glutamyltransferase (GGT). High alk phos level occurs when there is a blockage of flow in the biliary tract or a buildup of pressure in the liver, often from a gallstone.
- Family history of liver diseases.
- Glucose levels: poorly controlled diabetes can lead to fatty liver.
- Intake of medications, vitamins, herbs, drugs, and alcohol.
- Liver enzymes: ALT (SGPT), AST (SGOT). The AST level is not as helpful as the ALT level for checking the liver.
- Neutrophils: role in inflammation, formation of pus, and destruction of bacteria; check ANC regularly while on interferon treatment. Total white blood cell (WBC) count includes neutrophils plus the four other types (eosinophils, basophils, monocytes, and lymphocytes).
- Pancreatic enzyme levels.
- Serum proteins: PT, INR, albumin, globulin, mitochondrial antibodies, antinuclear and smooth muscle antibodies. A normal INR is 1.0. Low levels of total protein (TP) may indicate impaired liver function.
- Serum ammonia.
- Subjective global assessment (SGA:) evaluation of protein-energy malnutrition (PEM) based on evidence of edema, ascites, muscle wasting, subcutaneous fat loss, decreased functional capacity, and GI symptoms of diarrhea, nausea, and vomiting.

- Specific markers: serum ferritin, ceruloplasmin, alpha-fetoprotein (tumor marker), alpha-1 antitrypsin.
- Thyroid tests: thyroid stimulating hormone (TSH) is produced by the pituitary gland in the brain and causes the thyroid gland to produce thyroid (T4 and T3). TSH may be high if using interferon treatments.
- Viral hepatitis tests (hepatitis A, B, and C serologies).

## BACKGROUND: HEPATOBILIARY DISORDERS

Nutrition and the liver are interrelated since everything is refined and detoxified by the liver. The liver is the largest organ in the body, and it performs many complex and essential functions (see Table 8-1). As the body's internal chemical power plant, one cannot live without a liver. Mild elevations in liver chemistries such as ALT and AST can reveal serious underlying conditions, such as viral hepatitis, alcohol use, medication use, steatosis, fatty liver disease, nonalcoholic steatohepatitis (NASH), cirrhosis, or more chronic health conditions, such as diabetes, heart disease, or thyroid disease (Giboney, 2005). Serotonin is a mediator of several hepatic functions; in the diseased liver, it can promote hepatic fibrosis and steatohepatitis (Lesurtel et al, 2008).

Jaundice is a yellowish discoloration of the skin, mucous membranes, and some body fluids from accumulation of bile or bilirubin. Jaundice may be classified as *hemolytic* (from excessive red blood cell destruction), *hepatic* (from an immature liver or from damage), or *obstructive* (from obstructed biliary ducts or gallstones). In neonatal jaundice, there is a somewhat normal pattern of hyperbilirubinemia that is generally not detrimental. In obstructive jaundice, no bile pigment

**TABLE 8-1 Liver, Gallbladder, and Pancreatic Functions***Liver*

The largest single organ of the body; it is the central biochemical organ of the body. Functionally, it:

1. Converts galactose and fructose to glucose; makes glycogen; degrades glycogen upon demand.
2. Converts proteins into glucose; synthesizes albumin, globulin, fibrinogen, prothrombin, and transferrin; removes nitrogenous wastes (ammonia); provides transamination; synthesizes purines and pyrimidines; forms amines by decarboxylation.
3. Synthesizes triglycerides; forms very low-density lipoproteins (VLDLs); oxidizes fatty acids for energy and ketones.
4. Synthesizes cholesterol from acetate; makes high-density lipoproteins (HDLs).
5. Stores vitamins A, D, E, and K and some vitamin B<sub>12</sub> and C.
6. Hydroxylates vitamin D for renal activation; activates folic acid to tetrahydrofolic acid (THFA).
7. Stores minerals (e.g., iron, copper, zinc, magnesium).
8. Detoxifies drugs.
9. Produces bile.

*Gallbladder*

Stores bile, which helps counteract stomach acidity and aids in fat digestion through emulsification.

*Pancreas*

1. Produces pancreatic juice when stimulated by secretin. Pancreatic juice contains bicarbonate, which helps neutralize acid chyme.
2. Secretes insulin and glucagon hormones.
3. Secretes metabolic/digestive enzymes involved in protein, carbohydrate, and fat metabolism. Pancreatic secretion has gastric, cephalic, and intestinal phases. The islets secrete insulin (b) and glucagon (a). The acini secrete lipase, amylase, trypsin, chymotrypsin, ribonuclease, and carboxypolypeptidase. The pancreas secretes enzymes (trypsin, lipase, and amylase) into the collecting duct as stimulated by cholecystikinin (also called pancreozymin), which is produced by the duodenum.

is present; stools become pale and clay colored, indicating fat maldigestion or malabsorption. Obstructive jaundice leads to bacterial translocation by disruption of the gut barrier, intestinal microecology, and impaired host immune defense. Anorexia is common in obstructive jaundice; biliary drainage improves appetite. Oral administration of an arginine, omega-3 fatty acids, glutamine, and an RNA-supplemented enteral diet for immunonutrition may be useful.

Nonalcoholic fatty liver disease is accumulation of fat in the liver of people who drink little or no alcohol. It may have only symptoms of fatigue, or it may progress to hepatosteatosis (NASH) or liver failure. NASH may occur in obese individuals and may have an inflammatory origin.

Oxidative stress contributes to hepatic cell damage when there is an excess of reactive species derived from oxygen (ROS) and nitrogen (RNS), or a defect of antioxidant molecules (Leung and Chan, 2009). This cell damage aggravates alcoholic liver disease, chronic viral hepatitis, autoimmune liver diseases and nonalcoholic steatohepatitis. Antioxidants in S-adenosylmethionine (SAME), vitamin E, polyenylphosphatidylcholine, or silymarin have a protective effect on the liver and continue to be studied.

Malnutrition is often a problem in liver diseases. Oral nutritional supplements and tube feeding (TF) can be used to supplement intake when needed. TF improves nutritional status and liver function, reduces the rate of complications, and prolongs survival in cirrhosis and in acute liver

failure (ALF). Long-term PN still promotes hepatobiliary dysfunction and steatosis and is used less often.

Use herbs and alternative therapies with caution. Use of glycyrrhizin, phyllanthin, silibinin, milk thistle, and sho-saiko to show merit. However, some herbs are hepatotoxic and should be avoided; this includes comfrey, chaparral, german-der, and Chinese herbal mixtures.

## BACKGROUND: PANCREATIC AND GALLBLADDER DISORDERS

In the United States, acute pancreatitis, chronic pancreatitis, and pancreatic cancer are the most common pancreatic disease states. Pancreatic cancer is responsible for nearly 30,000 deaths annually. Excessive consumption of alcohol is the major risk factor for pancreatic disease, and smoking causes pancreatic cancer (Lowenfels et al, 2005). To reduce the burden of pancreatic disease, focus on the control of three lifestyle factors: smoking, drinking, and obesity.

Bile is the greenish-yellow fluid made of bile salts and waste products such as bile pigments. Bile flows through small bile ducts inside the liver, then into the common bile duct outside of the liver. Some flows directly to the duodenum, and the rest is stored in the gallbladder. After a meal, the gallbladder releases some bile into the small intestine to help digest fats. Gallbladder disease is also strongly associated with obesity.

## LIVER DISORDERS

# ALCOHOLIC LIVER DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

Alcohol is a hepatotoxin and is ulcerogenic, especially to the esophagus and other organs. Alcohol cannot be stored and is used preferentially over other energy fuels.

Alcoholic liver disease (ALD) is a major cause of illness and death. ALD affects about 2 million people in the United States. Signs and symptoms of alcoholism include restlessness, agitation, spider angiomas on the face or back or belly, insomnia, anorexia, weight loss, GI cramping, malnutrition, delirium tremens, and hand tremors. In men, altered hair distribution and gynecomastia may occur. Understanding alcohol addiction is key to treating ALD, since abstinence leads to improvement in all forms of alcoholic liver damage (Lucey, 2009). Section 4 addresses alcohol addiction. Table 8-2 lists stages and effects of alcoholism. Given the benefit of drug treatment, it is important to identify patients at risk of early mortality from alcoholic hepatitis using tools such as the Maddrey Discriminant Function, the Model of End-Stage Liver Disease score, and the Glasgow Alcoholic Hepatitis score (Maher, 2007).

Alcoholics may replace as much as one third of their daily energy requirements from alcohol. As a result, they are malnourished. Either they eat poorly or alcohol metabolism prevents them from properly absorbing, digesting, and using nutrients, particularly vitamin A (Plauth et al, 2006). Classic effects of malnutrition from alcoholism include Wernicke's

encephalopathy, Korsakoff's psychosis, muscle wasting, weight loss, and liver disease.

Most tissues of the body contain enzymes capable of ethanol metabolism, but significant activity occurs only in

**TABLE 8-2 Stages of Alcoholism-Related Effects**

Stage	Condition	Effects
I.	Fatty liver (steatosis)	Reversible. Acetaldehyde promotes hepatic fat accumulation. Hepatomegaly, hypertriglyceridemia, hypoalbuminemia, cytochrome P-450 2E1 induction, free radical generation, lipid peroxidation, and increased transcription of proinflammatory mediators, including TNF-alpha, occur.
II.	Alcoholic hepatitis	Fibrosis begins. Fever with tachycardia; liver enlargement is mild, and tenderness can occur.
III.	Cirrhosis	Not reversible. Diffuse necrosis and regeneration of fibrous tissue leading to loss of normal hepatic function.
IV.	Encephalopathy or Coma	May lead to death if not treated. Impaired mentation, altered neuromuscular function, and altered consciousness.

the liver and stomach (Lieber, 2005). Alcohol dehydrogenase is made with zinc. Alcohol decreases absorption of fats, fat-soluble vitamins, thiamin, folic acid, vitamin B<sub>12</sub>, and zinc. Nicotine adenine dinucleotide (NADH) is significant in alcohol metabolism by reduction of pyruvate and promotion of steatosis.

Adequate nutrition is critical and should be provided by TF if necessary (Maher, 2007). A prompt decline in serum bilirubin within 1 week indicates a favorable response to therapy; nonresponders have a 6-month mortality rate of 50% or higher (Maher, 2007).

Plasma homocysteine levels are altered in actively drinking patients, causing brain atrophy and withdrawal seizures (Bleich et al, 2005). Methionine needs to be activated to S-adenosylmethionine (SAM); this metabolism is impaired in liver disease. Folate deficiency accentuates abnormal methionine metabolism, lipid oxidation, and liver injury (Halsted et al, 2002; Schalinske and Nieman, 2005). SAM, betaine, and folate decrease oxidative stress by upregulation of glutathione and interleukin-10 and downregulation of tumor necrosis factor- $\alpha$ , TNF- $\alpha$  (Purohit et al, 2008). No benefit has been found in randomized, placebo-controlled clinical trials of colchicine, S-adenosylmethionine (S-AdMe), or phosphatidylcholine (Lucey, 2009). Betaine may attenuate ALD by increasing synthesis of SAM and glutathione, decreasing homocysteine (tHcy) levels (Song et al, 2008). More research is indicated.

Alcohol-induced liver injury is an immunological response of the liver; neutrophils damage liver cells through cytotoxicity (Leevy and Elbeshbeshy, 2005). Men and women metabolize alcohol differently. It takes less time and lower doses of alcohol exposure to cause liver damage in females than in males. Community-dwelling heavy drinkers who are not in alcoholism treatment have dose-related gray matter volume losses (Cardenas et al, 2005).

Treatment strategies for ALD include lifestyle changes for abstinence from alcohol consumption. Nutrition therapy and medications are also important. Serious alcoholic hepatitis has a mortality record of up to 50%. If necessary liver transplantation may be life-saving.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The dopamine (DR2) receptor promotes effects of alcohol. People with a genetic deficit of beta-endorphin peptide are susceptible (Manzardo et al, 2005; Zalewska-Kaszubska and Czarnecka, 2005). The dopaminergic mesolimbic system activates the endogenous mu and delta opioid receptors; mu receptor polymorphisms may be associated with ethanol dependence (Job et al, 2007). Polymorphisms in cytochrome P450 2E1 (CYP2E1), the major microsomal ethanol metabolizing enzyme, can alter detoxification of alcohol by glutathione-S-transferases M1 (GSTM1) and gamma-aminobutyric acid receptor gamma2 (Khan et al, 2009).

## INTERVENTION

### OBJECTIVES

- Remove alcohol to allow the disabled liver to function more effectively while protecting it from metabolic stress. Avoid alcohol in miscellaneous products, such as vinegar, sauces, and cough syrup.
- Improve health of liver so it can synthesize albumin and other serum proteins. Help liver tissue regenerate; replenish plasma proteins that are lost. Improve skeletal muscle synthesis.
- Prevent hypoglycemia from blocked gluconeogenesis. Correct metabolic syndrome, hyperglycemia, hypertension, or hypertriglyceridemia.
- Repair damage from fatty liver and diminished bile salt synthesis.
- Repair neural damage from malnutrition and malabsorption.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Excessive Alcohol Intake**

**Assessment Data:** Dietary intake records; low protein and energy intake for age/gender. Intake of one fifth of vodka per day to the exclusion of most meals.

**Nutrition Diagnosis (PES):** Excessive alcohol intake >25–30 g/d related to daily consumption above this level as evidenced by alcohol-induced liver injury, elevated LFTs and ascites.

**Intervention:**

**Food and Nutrient Delivery:** ND 1.1 General Healthful diet (avoid alcohol); ND 3.1.4 Modified food—increased calorie/protein intake.

**Education:** E 1.3 Survival Information. Educate about nutrient-dense foods and the role that alcohol plays in liver damage. E-1.1 Present concise and clear educational material with nutritional tips for patients with liver disease.

**Counseling:** C 2.5 Social support—avoid social outings with alcohol present.

**Coordination of Care:** RC 1.4 Referral to community agencies/programs. RC-1.3 Refer to social worker for alcohol rehabilitation. C-2.9 Relapse prevention by explaining the pros of following diet and medications as recommended, as the importance of maintain sober.

**Monitoring and Evaluation:** Track food intake through food diary or history. Coordinate care for rehabilitation program. Follow-up on intake of energy, protein and nutrients after omission of alcohol.

- Correct fluid and electrolyte imbalances, nutritional deficits such as iron deficiency anemia from chronic blood loss in varices, ulcers, and vomiting.
- Be honest and direct in approach. Gently confront conflicting information when stated by the patient.

## FOOD AND NUTRITION

- Avoid alcohol to allow the liver to begin heal (DiCecco and Francisco-Ziller, 2006).
- Malnourished alcoholics should consume a diet rich in carbohydrate and protein, preferentially via the oral or enteral route. Provide protein as 1.5 g/kg body weight if malnourished. Plan sufficient carbohydrates and fat to spare protein, but monitor for hyperglycemia or dyslipidemia.
- In hypertensive patients, a Dietary Approaches to Stop Hypertension (DASH) diet may be planned that provides a sufficient mixture of nutrients without excessive kilocalories. All fasting or very low-calorie diets should be avoided.
- Include a mix of fat from omega-3 (fish oils), omega-6 fatty acids, and medium-chain fatty acids.
- Micronutrient deficiencies require supplementation. Supplement the diet with B-complex vitamins, but supplemental vitamins A and D may not be well tolerated. Oral diet should provide adequate amounts of vitamins C, E, and K, phosphorus, potassium, selenium, magnesium, zinc, and calcium.

- Provide small frequent meals to prevent hypoglycemia, resulting from limited glycogen storage.
- Monitor iron intake to avoid excesses from diet or supplements, especially if there is the possibility of iron storage disease.
- Make meals appealing to stimulate the appetite.
- If TF is needed, avoid glutamine-enriched formulas which may increase ammonia levels.

## Common Drugs Used and Potential Side Effects

- Corticosteroids have become the standard of care in patients with severe alcoholic hepatitis (Lucey, 2009). Methylprednisolone improves the ability to produce albumin and to normalize PT and bilirubin levels. Side effects may include negative nitrogen balance, hypocalcemia, or hyperglycemia.
- Pharmacotherapy for alcoholism with naltrexone, acamprosate, topiramate, and baclofen is exciting (Lucey, 2009). Naltrexone is more effective in some individuals than in others (Rubio et al, 2005).
- Disulfiram (Antabuse) is given with patient's consent. It causes the patient to vomit after ingesting alcohol and can be dangerous.
- Beta-blockers (propranolol, nadolol) or octreotide (Sandostatin) may be used to reduce portal hypertension when varices occur.
- Insulin may be necessary; do not mix with alcohol. Alcohol intake may cause severe hypoglycemia in patients taking insulin (Pedersen-Bjergaard et al, 2005). Metformin should be avoided in patients with liver disease.

## Herbs, Botanicals, and Supplements

- Antioxidants are increasingly used. Agents involved in methionine metabolism such as SAM and betaine have shown efficacy in liver disease. Milk thistle (*Silybum marianum*) may have some therapeutic effect as well. *Curcuma longa* (turmeric) and *Glycyrrhiza glabra* (licorice) are being evaluated. Tea polyphenols, especially green tea, may alleviate liver damage (Zhang et al, 2005).
- Herbs and botanical supplements should not be used without discussing with the physician. Chaparral is especially toxic to the liver and should be avoided; severe hepatitis or liver failure may result. Aloe vera should be avoided orally.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Instruct patient on the sources of necessary nutrients in the diet and use of the prescribed multivitamins. Help patient in the planning and preparing of appetizing, nutrient-dense meals.
- Explain that alcohol is metabolized readily by the liver but cannot be used for muscular activity or energy production. Chemical addiction is a disease; self-help programs and follow-up can reduce dependency.
- General multivitamin–mineral supplementation may improve a poor appetite.

- Obesity, diabetes, and hyperinsulinemia play a role in the development of hepatic steatosis; weight loss remains a critical part of protecting the liver against damage.
- Identify sources of assistance for persons who need help with meal preparation or with access to meals.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## ASCITES AND CHYLOUS ASCITES

### NUTRITIONAL ACUITY RANKING: LEVEL 2

#### DEFINITIONS AND BACKGROUND

Ascites is defined as a distended abdomen due to pathological fluid in the peritoneal cavity. The development of ascites indicates a pathological imbalance between the production and resorption of intraperitoneal fluid; appearance and composition vary based on the underlying pathophysiology (Rochling and Zetterman, 2009). Ascites develops in decompensated cirrhosis, cardiac failure, or renal insufficiency. Portal hypertensive gastropathy (PHG) causes upper gastrointestinal bleeding in advanced cases. Liver transplantation may be the only way to improve survival in refractory ascites (Sandhu and Sanyal, 2005).

Although weight is not used for nutritional assessment here, it does help determine fluid balance. The goal of diuretic therapy in ascites is to promote weight loss of 1–3 kg/d. Nutrient depletion can occur if left untreated; fat, proteins, fat-soluble vitamins, and electrolytes may be lost. An oral diet devoid of long-chain triglycerides (LCTs) but that

includes medium-chain triglycerides (MCTs) may be used in mild cases.

Management of ascites from decompensated liver disease focus on low-sodium diets and diuretics, supplemented by paracentesis or transvenous intrahepatic portosystemic shunts (Rochling and Zetterman, 2009). While paracentesis improves patient comfort and reduces intra-abdominal pressure and secondary renal dysfunction, it also carries risk for spontaneous bacterial peritonitis (SBP) or renal failure (Sargent, 2006). Bacterial contamination of ascites fluid leading to SBP is caused by bacterial translocation with subsequent bacteremia; proton pump inhibitors (PPIs) suppress gastric acid secretion, and possibly should be avoided in this population (Bajaj et al, 2009).

**Chylous ascites** is a rare form of ascites, resulting from increased hydrostatic pressure and lymphatic blockade. Accumulation of LCT-dense chyle occurs in the peritoneum. Chyle leaks are a rare complication following abdominal surgery, trauma, cancer, or fistula. Although the incidence of chyle

leak post surgery is low (1–4%), this complication can present significant challenges (Smoke and Delegge, 2008). Any source of large fluid volume losses, lymph vessel obstruction, or leakage may cause chylous effusions in the peritoneal cavities. Most chylous effusions heal spontaneously. Early introduction of enteral feeding may encourage chyle leaks (Malik et al, 2007), whereas total parenteral nutrition along with somatostatin can relieve the symptoms rapidly (Huang et al, 2004).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** No specific genetic causes are clear in cases of ascites.

Clinical/History	Lab Work	
Height	Serum ascites-	ALT
Weight	albumin	AST
Dry weight or	gradient	H & H (high in
estimated dry	(>1.1 g/dL =	hemochro-
weight	portal hyper-	matosis)
BMI	tension)	Serum Fe,
Diet history	Alb (decreased)	ferritin
BP	Transthyretin	TIBC,%
I & O	CRP	saturation
Temperature	Na <sup>+</sup> , K <sup>+</sup>	Gluc
Ascites, mild to	Ca <sup>++</sup> , Mg <sup>++</sup>	Chol
severe	BUN, creatinine	Trig
Ultrasonography	(Creat)	

## INTERVENTION

### OBJECTIVES

- Reduce fluid retention, usually by diuretics. Mild ascites may present with fluid excess of 3–5 kg; moderate ascites may present with excess of 7–9 kg; and severe ascites may present with excess of 14–15 kg above usual weight.
- Prevent electrolyte imbalances.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Sodium Intake-Ascites

**Assessment Data:** Dietary intake records.

**Nutrition Diagnosis (PES):** Excessive sodium intake related to presence of ascites and portal hypertension as evidenced by paracentesis of 7–8 kg over 24 hours.

**Intervention:** Food and Nutrient Delivery—manage sodium intake. Educate about sodium sources and requirements. Counsel about preferred foods that are high in sodium and ways to alter intake that are acceptable; how to shop, dine out, travel.

**Monitoring and Evaluation:** Track food intake through food diary. Follow-up on intake of sodium and alleviation of ascites.

- Prevent further pain, fatigue, loss of lean body mass (LBM), and anorexia.
- If possible, prevent hepatorenal syndrome, which can occur in patients with severe liver disease. If severe, it may require transplantation. Prepare for surgery, especially nutritionally (Hasse, 2006).
- Individualize diet as needs change.
- For **chylous ascites**, treat the underlying cause to decrease production of the chylous fluid. Malnutrition is a common result if left untreated; essential fatty acid deficiency must be avoided. Fluid and electrolyte replacement may be needed.

## FOOD AND NUTRITION

- Energy needs are often as high as 1.5 times normal, and protein needs are often 1.5 g/kg of body weight (Hasse and Matarese, 2008). Smaller, more frequent meals are often better tolerated.
- If TF or central parenteral nutrition (CPN) is needed, use nutrient-dense formula but not glutamine-enriched formula; glutamine may increase ammonia production. While no high-quality data are available to prove that enteral nutrition is of benefit (Koretz, 2007), malnutrition should be addressed.
- Ensure that intake of vitamins and minerals is adequate. Water-soluble forms of vitamins may be needed; zinc and magnesium may be needed since levels are often low after diuretic therapy (Hasse and Matarese, 2008). Monitor for signs of malnutrition.
- Fluid restriction may be necessary (1–1.5 L/d), with two thirds with meals and one third for thirst/medicines.
- Restrict patient's intake of sodium to 2 g/d (Hasse and Matarese, 2008).
- Often, patients take spironolactone (Aldactone) or have renal insufficiency, which may increase potassium retention. Diet should be altered in potassium if serum levels so indicate. Other diuretics may cause potassium losses.
- For **chylous ascites**, a low-fat diet or enteral feeding is needed with MCTs as the preferred fat source; the addition of essential fatty acids (EFAs) will be needed. Adequate protein and calories are also needed since there may be significant losses. If oral diet fails, CPN may be needed (Assumpcao et al, 2008). Water-miscible forms of fat-soluble vitamins may be needed, along with extra fluid and electrolytes.

## Common Drugs Used and Potential Side Effects

- Diuretics are the most important treatment (Rosner et al, 2006). Furosemide (Lasix) is not very effective. Check whether the specific drug retains or spares potassium; spironolactone spares potassium.
- Albumin replacement, while costly, may help to maintain oncotic pressure.
- Somatostatin analogs have been demonstrated to be effective (Huang et al, 2004).
- With bacterial peritonitis, antibiotic therapy is needed. Monitor for specific side effects. PPIs increase enteric bacterial colonization, overgrowth, and translocation (Campbell et al, 2008).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Milk thistle may have some therapeutic effects in liver disease, but no controlled trials have shown efficacy for ascites at this time.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Instruct patient concerning good sources of key nutrients to include and which nutrients to limit. Instruct patient to follow high-energy, high-protein diet to prevent wasting.
- Ensure that the patient follows a 2-g, low-sodium diet. Explain which foods have hidden sources of sodium, and share recipes if needed.
- For chylous ascites, treatment is generally managed through a hospital stay.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# HEPATITIS

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### Nonviral hepatitis

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Hepatitis is defined as liver inflammation resulting from alcohol use, toxic materials (carbon tetrachloride), or viral

infection (transmitted in food, liquids, or blood transfusions). There is also an autoimmune hepatitis and a NASH.

Acute viral hepatitis is a widespread inflammation of the liver and is caused by hepatitis viruses A, B, C, D, or E. Hepatitis causes nausea, fever, liver tenderness and enlargement, jaundice, pale stools, and anorexia. The first stage of viral hepatitis is preicteric/prodromal (with flu-like symptoms); the second stage is icteric (with jaundice, dark urine, and light stools). The third stage is posticteric/convalescent.

With chronic active hepatitis, inflamed liver cells continue for years, which is usually an autoimmune response. Metabolic diseases, such as Wilson's disease, hemochromatosis, and alpha-1 antitrypsin deficiency, and use of some drugs, such as methyl dopa, nitrofurantoin, papaverine, dantrolene, clometazine, and ticrynafen, can cause chronic hepatitis (Hasse and Matarese, 2008). American Indian and Alaska Native (AI/AN) people suffer disproportionately from infectious diseases including **Hepatitis A virus (HAV)** and **Hepatitis B virus (HBV)**; childhood immunizations have reduced these disease disparities (Singleton et al, 2009).

**HAV**, which is transmitted by fecal-oral route, comprises approximately 50% of hepatitis cases. **HBV** is considered a sexually transmitted disease; 20% of those affected develop

**TABLE 8-3** Hepatitis Symptoms, Transmission, and Treatment

Type	Incubation	Symptoms	Transmission	Treatment
Hepatitis A Infectious HAV	30 days	Flu-like illness, jaundice, nausea, fatigue, abdominal pain, anorexia, diarrhea, fever	Ingestion of items contaminated with infected feces, drinking water or ice contaminated with raw sewage, eating fruits, vegetables, or uncooked food contaminated during handling. Risk factors: overseas travel, anal sex, IV drug use, living in poor sanitation.	Immunoglobulin 2–3 months before or 2 weeks after exposure. Vaccine is available.
Hepatitis B Serum HBV	Can survive 7 days outside of the body	Flu-like illness, jaundice, nausea, fatigue, vomiting, fever, often no symptoms	Contact with contaminated body fluids, exposure to sharp instruments that contain contaminated blood, human bites, blood transfusion before 1975. Risk factors: IV drug use, multiple sex partners, travel or work in developing countries, transfusion before 1975.	Interferon alfa and lamivudine. HBV immunoglobulin (HBIG) within 14 days of exposure. There are safe and effective vaccines. Ribavirin is under study.
Hepatitis C HCV	Average 7–9 weeks; can live 28 weeks	Often no symptoms until liver damage occurs, flu-like illness, fatigue, nausea headaches, abdominal pain	Blood-to-blood contact, especially IV drug use and shared needles. Exposure to items with contaminated blood, such as needles (tattoo, body piercing, acupuncture), razors, nail files, toothbrushes, scissors, tampons. Sexually transmitted disease with rashes or sores. Blood transfusions before July 1992. At risk: IV drug use, had a blood transfusion or organ transplantation before July 1992, snorts cocaine. Widespread—affects 4 million people. Silent. Leading cause of cirrhosis in the United States.	Interferon or combination drug treatments. Liver transplantation for end-stage. There are no vaccines. Treatment takes minimum of 1 year. Ribavirin is under study.
Hepatitis D HDV	Occurs only with HBV infection, cannot survive on own	Flu-like illness, jaundice, nausea, fatigue, vomiting, fever, often no symptoms	Sexual contact with HBV-infected person. Exposure to sharp instruments contaminated with HBV. At risk: IV drug use.	Interferon alpha for chronic cases. Vaccination against HBV provides protection against type D.
Hepatitis E HEV	2–9 weeks	Malaise, loss of appetite, abdominal pain, joint pain, fever	Fecal transmission, often through contaminated water. At risk: pregnant women, those who travel in developing countries.	No specific treatment.

some form of chronic liver disease. Table 8-3 provides symptoms and treatments for the many forms of hepatitis, including incomplete viral forms of **Hepatitis D and E**. Hepatitis E virus has been reported to result in chronic hepatitis in transplant patients.

**Hepatitis C virus (HCV)** is a complex and challenging medical condition. Nearly 20% of Americans test positive for HCV. Many persons with HCV develop chronic disease; 25% of cases lead to cirrhosis, liver cancer, or liver failure that requires transplantation. Recently, the gene marker that predicts response to HCV therapy has been identified; this is significant because about half of cases respond poorly to treatment. Regular coffee consumption is associated with lower rates of disease progression (Freedman et al, 2009) and may actually reduce onset of hepatocellular cancer (Inouye et al, 2005).

A deranged metabolic status and alcohol intake may trigger induction and progression of chronic HCV liver disease; variable intakes of carbohydrates, lipids, polyunsaturated fatty acids, iron, zinc, vitamin A, niacin, and alcohol are factors as are genotype, age, BMI, steatosis, and fibrosis (Loguercio et al, 2008). In the Hepatitis C Antiviral Long-Term Treatment Against Cirrhosis (HALT-C) trial, insulin resistance, histologic

features of fatty liver disease, and weight change promoted poor outcomes; improvement in weight may modify disease progression (Everhart et al, 2009). HCV-related cirrhosis can lead to decompensation, end-stage liver failure, and death (Bruno et al, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** How the hepatitis virus DNA evolves and changes is of great interest to researchers. Since the identification of the hepatitis viruses over the past decades, the understanding of host innate and adaptive immune responses has increased significantly (Rehermann, 2009). Drug-induced liver injury may stem from concomitant hepatic diseases, age, and poor health status; polymorphisms of CYP liver enzymes,

phenotyping and genotyping studies may also be needed (Tarantino et al, 2009).

<b>Clinical/History</b>	Hepatitis B e antigen (HBeAg)	Absolute neutrophil count (ANC)
Height	Hepatitis C Antibody (HCV Ab, anti-HCV)	BUN
Weight	Hepatitis C viral load test (or PCR test)	Serum ammonia
BMI	Bilirubin (increased)	Lipase
I & O	AST (increased)	Amylase (increased)
Diet history	ALT	PT or INR
Right upper abdominal pain	Alk phos (increased)	Gluc
Jaundice	Chol	Transferrin (increased in acute stage)
Temperature, fever	Lactate dehydrogenase (LDH) (increased)	H & H, ferritin
Severe nausea, vomiting	Alb, transthyretin	WBC
Dark urine	Globulin	GGT
Joint pain	CRP	Na <sup>+</sup> , K <sup>+</sup> , Ca <sup>++</sup> , Mg <sup>++</sup>
<b>Lab Work</b>		
IgM antibody for HAV		
Hepatitis B surface antibody (Anti-HBs or core antibody (Anti-HBc))		

## INTERVENTION

### OBJECTIVES

- Promote liver regeneration and rest. Prevent further injury.
- Prevent or correct weight loss, which often results from poor appetite, nausea, and vomiting.
- Spare protein by providing a diet high in carbohydrates.
- Force fluids to prevent dehydration, unless contraindicated.
- Encourage intake of coffee and antioxidant foods.
- Prevent the spread to others by hand washing and safe hygiene practices.

### FOOD AND NUTRITION

- For patients with all forms of hepatitis, provide a complete and balanced diet. If nutritional support is necessary, consider TF. Nocturnal feedings may be beneficial.
- Use CPN only if necessary because of ileus or obstruction, and avoid products containing glutamine.
- Progress to a diet of small, frequent feedings of regular or soft foods.
- Diet should provide 30–35 kcal/kg body weight. Provide sufficient carbohydrate to replenish liver stores of glycogen; include 50–55% total energy as carbohydrate.
- Intake of protein should be 1–1.2 g/kg body weight for acute hepatitis. Well-nourished or chronic active hepatitis patients may need levels that just meet dietary reference intake (DRI).

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Bioactive Substance Intake

**Assessment:** Weight and diet history; abnormal liver tests. Intake <25% for past 3–4 weeks. Diet history reveals low intake of fruits, vegetables, whole grains, and coffee.

**Nutrition Diagnosis (PES):** Inadequate bioactive substance intake related to loss of appetite as evidenced by low intake of nutrient-dense foods and coffee.

**Intervention:** Food-Nutrient Delivery: high-protein, high-calorie diet in frequent small meals. Educate about the role of bioactive substances in protecting the liver; encourage use of coffee as tolerated.

**Monitoring and Evaluation:** Evaluate diet history and weight. Assess for improvement in appetite and intake of foods rich in bioactive substances.

- Fat intake should be moderate to liberal, depending on tolerance. Cut back if diarrhea or other signs of malabsorption occur.
- Supplement diet a multivitamin supplement with B-complex vitamins (especially thiamin, folate, and vitamin B<sub>12</sub>), vitamin K (to normalize bleeding tendency), vitamin C, and zinc for anorexia and to improve encephalopathy. Monitor for excesses of iron and vitamin A, which may not be well tolerated in a supplemental form.
- Extra fluid should be encouraged, unless contraindicated. Encourage coffee intake (Freedman et al, 2009).

## Common Drugs Used and Potential Side Effects

- A combined HAV and HBV vaccine, Twinrix, is available in many parts of the world. Hepatitis B vaccine is found singly as Engerix-B, Recombivax, or Cornvax. Because of vaccinations, the incidence of HAV and HBV has declined, especially among children.
- Two formulations of interferon (standard interferon (IFN) and pegylated IFN) can be used for sustained response to HBV and five nucleoside analogues (lamivudine, adefovir, entecavir, telbivudine, and tenofovir) for treatment-maintained response (Buster et al, 2008). Interferon (Intron-A) can lead to dry mouth, stomatitis, nausea, vomiting, and calcium depletion. The oral antiviral entecavir (Baraclude) is more effective than lamivudine (Dienstag et al, 2007) or adefovir (Leung et al, 2009).
- The gold standard for new patients with chronic HCV is the combination of pegylated interferon (Pegasys or PEG-Intron) and ribavirin (Copegus, Rebetol); individualizing dose and duration improves the sustained virologic response (Camma et al, 2005; Degertekin and Lok, 2009; McHutchison et al, 2009). There may be hemolytic side effects, depression, and weight or lipid changes. Etanercept as adjuvant therapy to interferon and ribavirin improves response and has decreased adverse effects (Zein et al, 2005).
- Steroids may cause sodium retention, nitrogen depletion, or hyperglycemia.

- Monitor for idiosyncratic drug-induced liver injury (DILI); acute HCV may be present. DILI is caused by a single prescription medication in most cases and by multiple agents or dietary supplements in the remaining cases (Chalasani et al, 2008).

## Herbs, Botanicals, and Supplements

- Chaparral and kava kava are especially toxic to the liver and should be avoided.
- Avoid excessive fat-soluble vitamin intake (vitamins A and D). Vitamin A toxicity is possible in compromised liver function; monitor all supplements carefully. Beta-carotene is much less toxic and may offer reasonable antioxidant protection.
- *Silybum marianum* (milk thistle) has been shown to have clinical applications in the treatment of toxic hepatitis and viral hepatitis via its antioxidant properties.
- Oregano, sage, peppermint, garden thyme, lemon balm, clove, allspice, and cinnamon as well as the Chinese medicinal herbs *Cinnamomi cortex* and *Scutellariae radix* contain very high concentrations of antioxidants. In a normal diet, intake of herbs contributes significantly to the total intake of plant antioxidants and can be an even better source of dietary antioxidants than other foods.
- Herbs and botanical supplements should not be used without discussing with the physician. Carrot, schisandra, dandelion, Indian almond, and licorice have been recommended but need research.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help patient make attractive, appetizing meals. Encourage frequent, small meals.
- Educate patient about how to increase calorie, protein, and vitamin intakes. Discuss pros and cons of supplemental products.
- Encourage coffee intake as well as intake of other antioxidant-rich foods.
- Ensure patient abstains from alcohol and drugs that are hepatotoxic. DILI may occur with antibiotics, acetaminophen, CNS agents, herbal or dietary supplements.
- All children should receive Hepatitis B vaccinations.
- The NIH recommends that all immigrants be screened and treated for HBV when they move to the United States to prevent liver failure or hepatic carcinoma (NIH, 2008).
- In health care employment, follow standard precautions: handle needles and other sharps safely; report every needlestick on the job; get vaccinated against hepatitis B.
- Consider the risks of HCV before getting a tattoo or body piercing; infection is possible if the tools have someone else's blood on them, or if the artist or piercer does not follow practices such as washing hands and using disposable gloves.

## Patient Education—Food Safety

- HAV is usually spread by putting something in the mouth that is contaminated by the stool of another person with

hepatitis A. It is usually spread through household contact with an infected person, sharing utensils that are contaminated, eating or drinking contaminated food or water, touching a contaminated surface and then the mouth.

- Teach safe personal hygiene in regard to hand washing and use of disinfectants, especially when traveling overseas. Boil water or drink bottled water in areas where there is a risk for HAV contamination. Eat cooked foods and fruits that you can peel and avoid eating vegetables or fruits that could have been washed with contaminated water, such as lettuce. Avoid eating raw or steamed shellfish, such as oysters, that live in contaminated waters.
- Discuss other principles of food safety and personal hygiene. To protect against HCV, do not share items such as razors, toothbrushes, and other personal health items that might have had blood on them. Do not inject street drugs.

## HEPATIC CIRRHOSIS

### NUTRITIONAL ACUITY RANKING: LEVEL 2–3

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Cirrhosis is caused by chronic degeneration of the parenchymal liver cells and thickening of the surrounding tissue; the liver slowly deteriorates and malfunctions due to chronic injury. Alcoholism and hepatitis C are the most common causes; alcoholic cirrhosis is known as Laennec's cirrhosis. Cirrhosis may also result from biliary stenosis, hepatitis B-D, obesity with nonalcoholic fatty liver disease (NAFLD), autoimmune hepatitis, prolonged exposure to toxic chemicals, and inherited diseases such as glycogen storage disease, cystic fibrosis, alpha-1 antitrypsin deficiency, hemochromatosis, Wilson disease, or galactosemia.

Malnutrition plays a significant role in the pathogenesis of liver injury and should be carefully managed. Cirrhosis is a disease of accelerated use of alternative fuel (such as fat) since liver stores of glycogen tend to be depleted after an overnight fast. About 50% of energy kilocalories should be consumed from carbohydrate to minimize use of fat stores or protein for energy. Glucose intolerance, insulin resistance, and higher circulating glucagon may cause early satiety, hypophagia, and depleted nutrient stores. There is a high incidence of muscle

wasting, weight loss, and malnutrition with cirrhosis. Table 8-4 list the related forms of malnutrition.

Exercise and protein-rich nutrition at the early stage of liver cirrhosis can help to maintain or increase muscular volume (Kotoh et al, 2005). Nutritionally depleted patients need extra attention. Both enteral and parenteral nutritional support can improve the general nutrition condition; EN has fewer complications (Zhang et al, 2005). Cirrhosis related to CPN may be rapidly reversible after isolated intestinal transplantation (Fiel et al, 2009).

Plasma aromatic amino acid (AAA) concentrations (phenylalanine, tyrosine, and tryptophan) tend to increase from rapid muscle proteolysis and decreased synthesis of proteins. Branched-chain amino acids (BCAAs) leucine, isoleucine, and valine are then imbalanced; the low BCAA to AAA ratio contributes to hepatic encephalopathy. When AAAs are high, BCAAs are more limited in cerebral uptake. A higher BCAA intake helps to improve cognitive status (Bianchi et al, 2005; Charlton, 2006). Long-term BCAA supplementation is associated with decreased frequency of hepatic failure and overall complication frequency, along with improved nutritional status (Charlton, 2006).

Severe cirrhosis may lead to decreased serum lipids. Omega-3 fatty acids in enteral supplementation completely protect the liver; IV sources provide only partial protection (Alwayn et al, 2005).

Liver damage from cirrhosis cannot be reversed, but treatment can stop or delay further progression and reduce complications. Participants who consume a diet high in protein are at a higher risk of hospitalization or death due to cirrhosis; those who report a diet high in carbohydrates are at a lower risk after adjusting for daily consumption of protein, carbohydrate, fat, tea or coffee, and alcohol, gender, race, age, educational attainment, U.S. geographical region, diabetes, and BMI ratio (Ioannou et al, 2009).

Treatment will depend on the cause of cirrhosis and any related complications. Serum ammonia levels may be high. Fermentable fiber or lactulose may be used for management of cirrhosis. Antibiotic therapy works to prevent infections, including SBP in cirrhosis (Saab et al, 2009).

**Portal hypertension** causes increased collateral flow, often with varices in parts of the GI tract. These veins become distended, may bleed, and cause pain. Esophageal varices are the most serious complication of cirrhosis. **Splenorenal shunting** with a trans-jugular intrahepatic portosystemic shunt

**TABLE 8-4 Causes of Malnutrition in Cirrhosis***Decreased Oral Intake*

- Anorexia
- Ascites
- Altered mental status or encephalopathy
- Delayed gastric emptying
- Early satiety
- Inadequate diet or strict limits on protein, fluid and salt
- Medications causing GI distress or taste changes
- Nausea
- Restrictive diets or NPO for several days

*Maldigestion and Malabsorption*

- Accelerated intestinal transit
- Accelerated protein breakdown
- Anemia from impaired GI and liver function
- Bacterial overgrowth
- Biliary flow changes
- Choline depletion and betaine
- Decreased hepatic production and storage of nutrients
- Decreased fat absorption
- Diuresis, paracentesis, and micronutrient losses
- Increased rate of gluconeogenesis
- Increased urinary and fecal losses
- Lactulose use
- Pancreatic insufficiency
- Villi damaged by alcohol
- Vomiting

Adapted from Caly WR, et al. Different degrees of malnutrition and immunological alterations according to the aetiology of cirrhosis: a prospective and sequential study. *Nutr J*. 2:10, 2003.

Stocksager JL, et al. *Nutrition made incredibly easy*. Baltimore: Lippincott Williams & Wilkins, 2003, p. 242.

(TIPS) is performed when the portal vein is obstructed. Portacaval blood flow is diverted from the liver by anastomosing the portal vein to the inferior vena cava. The shunt procedure is positive in most cases. Liver transplantation is needed when encephalopathy, ascites, or bleeding varices are uncontrollable.

**ASSESSMENT, MONITORING, AND EVALUATION****CLINICAL INDICATORS**

**Genetic Markers:** Autoimmune hepatitis is caused by the body's immune system attacking liver cells and causing inflammation, damage, and cirrhosis; 70% of those with autoimmune hepatitis are female. A cirrhosis-risk score is being developed to assess host genetics and polymorphisms.

Clinical/History	Lab Work	Alb,
Height	MELD score for	transferrin
Weight	severity (INR	(not valid in
BMI	for clotting,	cirrhosis)
Weight loss?	bilirubin,	ALT
I & O	creatinine)	AST (increased)
Diet history	PT (prolonged);	Bilirubin
Bowel changes	INR	(increased)
Bleeding hemor-	BUN	Alk phos
rhoids	Globulin	(increased)
Confusion	Somatomedin C	WBC
Loss of libido	TP	Trig (increased)
Jaundice	UA	Chol (low?)
Ascites	Gluc (increased	LDH
Spider-like	or decreased)	(increased)
blood vessels	Na <sup>+</sup> , K <sup>+</sup>	Copper, cerulo-
on skin	Ca <sup>++</sup> , Mg <sup>++</sup>	plasmin
Itching	Transferrin	(increased)
Fatigue	H & H	Folate
BP (elevated?)	(decreased)	GGT
Easy bruising or	Serum ammonia	
bleeding	(elevated?)	
CT scan		
Liver biopsy		

**INTERVENTION****OBJECTIVES**

- Slow the progression of scar tissue and support residual liver function.
- Provide supportive treatment for ascites, edema, muscle wasting, weight loss, esophageal varices, and portal hypertension.
- Monitor steatorrhea; offer suggestions for managing.
- Correct nutritional deficiencies, which are common. Tube feed if needed.

**SAMPLE NUTRITION CARE PROCESS STEPS****Inadequate Oral Food and Beverage Intake**

**Assessment Data:** Dietary intake records indicating poor appetite and intake of <50% at most meals; diagnosis of NASH; mild weight loss 5% in past 3 months; mild jaundice.

**Nutrition Diagnosis (PES):** Inadequate oral food and beverage related to anorexia as evidenced by intake only about 50% and weight loss of × lb in past 3 months (5% UBW).

**Intervention:** Food and Nutrient Delivery—offer smaller meals and snacks every few hours while awake; increase nutrient density and quality of foods chosen. Educate about the role of good nutrition in liver health and recovery. Assure no intake of alcohol.

**Monitoring and Evaluation:** Improvement in appetite, reduced nausea or side effects of liver disease. Gradual return of usual weight.

- Monitor closely for signs of hepatic encephalopathy such as drowsiness or confusion.
- Provide adequate glucose for brain metabolism but beware of glucose intolerance, especially with alcoholic cirrhosis.
- Prevent long-term bone disease, hyperkalemia or hypokalemia, hyponatremia, renal failure, and anemia. If hepatorenal failure occurs, hemodialysis may be necessary.
- Avoid hepatic insults from alcohol, drugs, vitamins and herbal products. Consult the physician first.

## FOOD AND NUTRITION

- Increased energy is needed. Calculate energy at 50–75% above usual requirements if malabsorption is present or if repletion is needed. Use ideal or estimated dry weight.
- Diet should provide 1–1.5 g of high-quality protein/kg body weight with adequate carbohydrates to spare protein. Meat has a high level of AAAs; vegetable proteins or casein may be better tolerated.
- Fat is a preferred fuel in cirrhosis. Omega-3 fatty acids should be included (Alwayn et al, 2005). Malabsorption occurs from diminished lipase output; decrease LCTs in steatorrhea. Carefully monitor use of MCTs because they may cause diarrhea or acidosis.
- Supplement diet with B-complex vitamins, vitamins C and K, zinc, and magnesium through foods or supplements. Monitor need for vitamins A and D; do not use excesses in liver disease. Liquid form may be needed for patients with esophageal varices.
- TF can be used with cirrhosis or esophageal varices (Hasse and Matarese, 2008). PN is safe and improves mental state in patients with cirrhosis in whom enteral nutrition is insufficient or impossible (Plauth et al, 2009). Glutamine is not generally recommended in liver disease.
- Avoid alcoholic beverages.
- Control total carbohydrate intake with signs of hyperglycemia or with diabetes.
- Low sodium intake (2–4 g) is recommended with ascites.
- Decrease fluid if there is hyponatremia.
- Enhance nutrient density of food choices if malnourished.
- Antioxidants, such as vitamin E and selenium, might help in treating cirrhosis. Supplements of vitamins A, C, E, selenium, methionine, and co-enzyme Q10 provide no specific benefit; fresh fruits, vegetables, and whole grains should be consumed instead.
- Betaine (10 g twice daily) reduces elevated homocysteine levels and might be helpful in treating alcohol-induced cirrhosis.
- Bupleurum (*Bupleurum chinense*) is a Chinese herb with anti-inflammatory properties that may lower risk of liver cancer in people with cirrhosis.
- Licorice root (*Glycyrrhiza glabra*) contains glycyrrhizin. Stronger neominophagen C (SNMC) is a Japanese preparation that contains 0.2% glycyrrhizin, 0.1% cysteine, and 2% glycine that has anti-inflammatory or cytoprotective drug. Do not take licorice with high blood pressure, pregnancy, steroid use, digoxin (Lanoxin), diuretics, or anticoagulants (warfarin/Coumadin).
- Milk thistle (*S. marianum*) has been shown to have clinical applications in the treatment of cirrhosis through its antioxidative and anti-inflammatory effects. A total of 420 mg/d may protect the liver from damage caused by viruses, toxins, alcohol, and drugs such as acetaminophen, but milk thistle does not reduce mortality.
- SAM (Sadenosylmethionine 1200–1600 mg/d) may be effective in alcoholic cirrhosis. People with liver disease have low levels of SAME, and glutathione. Avoid use with prescription antidepressants.
- Zinc deficiency has been implicated in the pathogenesis of liver diseases. Supplementation with zinc may have therapeutic benefits.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Diet may be an important and potentially modifiable determinant of liver disease (Ioannou et al, 2009). Higher CHO and lower protein intake may be a reasonable goal.
- A better appetite at certain meals may be common; breakfast or another meal may be better tolerated. Some patients sleep late with a sleep reversal pattern.
- Discuss use of nutrient-dense foods and higher intakes of vegetable and dairy sources of protein.
- Dietary intake must be adjusted according to the changing status of the patient. Large meals increase portal pressure; recommend use of smaller meals throughout the day.
- Avoid skipping meals. Discuss proper menu planning.
- Avoid high doses of vitamins A and D, which may be toxic to the diseased liver. It is also not clear whether vitamin K supplementation is either safe or useful in cirrhosis. Vitamin E may be beneficial for its antioxidant properties; encourage dietary intake.

## Common Drugs Used and Potential Side Effects

- See Table 8-5.

## Herbs, Botanicals, and Supplements

- People with liver disease must be particularly careful because the liver processes almost everything consumed. Herbs and botanical supplements should not be used without discussing with the physician. Some herbal tea preparations may be harmful (such as Comfrey tea) and should be avoided. Chaparral is an herbal product that may contribute to severe hepatitis or liver failure (Stickel et al, 2005). Mistletoe, kava kava, European barberry, and germander should also be avoided.

## Patient Education—Foodborne Illness

- Avoid raw shellfish, which may contain *Vibrio vulnificus* which is dangerous to people with cirrhosis.

**TABLE 8-5 Medications Used in Cirrhosis**

Medication	Description
<b>Antibiotics:</b> tetracycline (Achromycin V), ampicillin (Polycillin), trimethoprim-sulfamethoxazole (Bactrim, Septra)	Antibiotics kill the bacteria that cause infections, a common complication of cirrhosis. Possible side effects include nausea and vomiting, poor appetite, diarrhea, sore mouth or tongue, and increased sensitivity to sunlight (tetracycline).
<b>Antiviral medications:</b> interferon-alpha (Alferon N, Roferon-A, Intron A), ribavirin (Virazole), lamivudine (Epivir, Epivir-HBV), baraclude (Entecavir)	These may be used if viral hepatitis B or C is the cause of cirrhosis. Treatment usually lasts for 4 months. Ribavirin is an oral antiviral agent that is given twice a day. Lamivudine is used to treat hepatitis B infection. Sometimes lamivudine is combined with interferon. Side effects may include severe GI pain, feeling of fullness, nausea, tingling, burning, numbness, or pain in the hands, arms, feet, or legs.
<b>Anti-inflammatory medications (corticosteroids):</b> prednisone, azathioprine (Imuran)	Corticosteroids reduce liver inflammation and prevent the progression of cirrhosis. High doses given long term are associated with an increase in serious side effects. Lower doses of prednisone may be used when combined with azathioprine. Possible side effects include: hypertension, glucose intolerance, and bone thinning.
<b>Antihypertensives (beta-blockers):</b> atenolol (Tenormin), metoprolol (Lopressor), nadolol (Corgard), propranolol (Inderal), timolol (Blocadren)	Beta-blockers are used to reduce venous blood pressure in the abdomen (portal hypertension) to reduce the risk of esophageal variceal bleeding and other complications. Possible side effects associated with beta-blocker use include: drowsiness, dizziness, cold sensitivity, and sleep disorders.
<b>Diuretics:</b> "Loop" diuretics: bumetanide (Bumex), furosemide (Lasix); thiazide diuretics: hydrochlorothiazide (HydroDIURIL, Esidrix), chlorothiazide (Diuril); potassium-sparing diuretics: amiloride (Midamor), triamterene (Dyrenium)	Diuretics are used to treat the buildup of excess fluid in the body that occurs with cirrhosis (as well as other diseases). These drugs act on the kidneys to increase urine output, which reduces the amount of fluid in the bloodstream. This can help to reduce portal vein hypertension and help alleviate some of the symptoms of cirrhosis, such as fluid accumulation in the abdomen and legs. Possible side effects associated with diuretic use include: loss of appetite, nausea and vomiting, dizziness, headache, lethargy, and altered blood potassium level.
<b>Insulin</b>	If insulin is needed, monitor carefully for hypoglycemic episodes.
<b>Laxatives:</b> beta-galactosidofructose (lactulose [Cephulac] and kristalose [Chronulac])	In cirrhosis, laxatives such as beta-galactosidofructose (lactulose) can help to absorb or bind toxins, such as ammonia, in the intestine and remove them from the body. Possible side effects associated with laxative use include: diarrhea, abdominal cramping, flatulence and bloating, dehydration, and weakness. Take with food or milk.
<b>Metal Chelating Agents:</b> penicillamine (Cuprimine, Depen), trientine (Syprine), deferoxamine (Desferal)	Metal chelating agents draw toxic metals from the bloodstream so that the body can excrete them. Chelating agents are used to rid the body of excess copper in Wilson's disease or excess iron in hemochromatosis. Both of these rare inherited diseases can produce liver damage resulting in cirrhosis. Possible side effects include: fever; joint pain; lesions on the face, neck, scalp, and/or trunk; rash, hives, or itching; swollen glands; sores or white spots on lips or in mouth; cyanosis; blurred vision; convulsions; wheezing or fast breathing; tachycardia; flushing of skin; nausea, vomiting or diarrhea; and blood in the urine.
<b>Vitamin K:</b> phytonadione (AquaMEPHYTON, Mephyton)	Bleeding abnormalities are common in cirrhosis. Vitamin K helps prevent excessive bleeding. Possible side effects include: flushing of the face and unusual taste.

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# HEPATIC FAILURE, ENCEPHALOPATHY, AND COMA

NUTRITIONAL ACUITY RANKING: LEVEL 3–4

## DEFINITIONS AND BACKGROUND

**Hepatic failure** is common in critical illnesses. Acetaminophen overdose is the leading cause of the acute form. Hallmarks include coagulopathy, usually an INR of 1.5 or more, and encephalopathy. Typical nutrition assessment measures may not reflect the severity of malnutrition because ascites can mask loss of LBM. Blood levels of lactate appear to be good markers for predicting which patients can be managed medically and which need a transplantation (MacQuillan et al, 2005). If hepatorenal syndrome occurs, hemodialysis may be needed; creatinine is not useful here but glomerular filtration rate (GFR) is an important measure.

**Hepatic encephalopathy (HE)** is a clinical complication caused by portosystemic venous shunting, with or without intrinsic liver disease (Munoz, 2008). HE can be precipitated by GI bleeding, abnormal electrolytes, renal failure, infection, diuretic therapy, use of sedatives or medications that affect the central nervous system, and constipation. HE is estimated to occur in 30–45% of patients with liver cirrhosis and in 10–50% of patients with portosystemic shunts (Eroglu and Byrne, 2009). Patients with HE present with the onset of mental status changes ranging from subtle psychologic abnormalities to profound coma (Munoz, 2008). See Table 8-6 for stages of HE. Acute forms may be reversible; chronic forms may worsen or lead to coma.

Brain glutamine, a byproduct of ammonia detoxification, is elevated in HE (Rama Rao et al, 2005). Causes of hyperammonemia include GI bleed, muscle catabolism, infection, dehydration, noncompliance with lactulose/neomycin, and constipation. The basis of neurotoxicity from ammonia, gamma-aminobutyric acid (GABA), or other agents is not clear. Astrocytes are the most abundant cell type in the brain; they buffer extracellular K(+), regulate neurotransmitter release, form the blood–brain barrier, release growth factors, and regulate the brain immune response (Gee and Keller, 2005). Acute exposure of the astrocytes to ammonia results in alkalization, with calcium-dependent glutamate release and dysfunction (Rose et al, 2005).

Encephalopathy is usually not caused by altered protein in the diet (Shawcross and Jalan, 2005).

Protein restriction is only necessary in rare, refractory encephalopathy. Patients who have been given a portacaval

shunt (TIPS) may benefit from mild protein restriction; nutritional status improves after the shunt.

Decreased dopamine and BCAAs occur in HE; increased AAAs and serotonin also occur. Nevertheless, the use of BCAA solutions is not fully supported by the literature.

Measuring nutritional status in HE can be a challenge. Subjective global assessment and other techniques are not very effective. Measuring handgrip strength may be useful in undernourished patients (Alvares da Silva and Reverbel da Silveira, 2005). Because oxidative stress is a possible trigger in the progression of chronic liver disease, antioxidants and omega-3 polyunsaturated fatty acids may be useful. In addition, because zinc improves taste and immune function, supplementation may improve neurological symptoms and nutrition (Grungrieff and Reinhold, 2005).

Minimal hepatic encephalopathy (MHE) is the mild cognitive impairment commonly seen in patients who have cirrhosis, but it often goes undiagnosed (Stewart and Smith, 2007). It is important to identify signs and symptoms that require medical attention. Commonly associated disorders include energy production deficiencies (hypoglycemia), coagulation abnormalities, immune system dysfunctions, cerebral edema, or **hepatic coma** (Cochran and Losek, 2009). Treatment of HE involves correction of sepsis, gastrointestinal bleeding, and electrolyte imbalance (Sundaram and Shaikh, 2009). Lactulose may be used.

Fischer's ratio between BCAAs and AAAs correlates with the degree of HE; the lower Fischer's ratio, the higher the grade of HE (Koivusalo et al, 2008). Some procedures, such as albumin dialysis, may be used; plasma levels of neuroactive amino acids, methionine, glutamine, glutamate, histidine, and taurine are lowered as a result (Koivusalo et al, 2008).

Signs of impending coma include irritability, change in mentation; disorientation to time and place; asterixis or involuntary jerky movements of the hands; constructional apraxia (inability to draw simple diagrams); difficulty with writing; ascites, edema; fetor hepaticus (sweet, musty odor of the breath); and GI or esophageal bleeding. Coma patients have increased intracranial pressure and brain edema with a poor prognosis without liver transplantation. Clearly, much more research is needed to resolve these life-threatening disorders.

**TABLE 8-6 Stages of Hepatic Encephalopathy—West Haven Classification**

Grade 0	Minimal hepatic encephalopathy. Lack of detectable changes in personality or behavior. Minimal changes in memory, concentration, intellectual function, and coordination. Asterixis is absent.
Grade 1	Trivial lack of awareness. Shortened attention span. Impaired addition or subtraction. Hypersomnia, insomnia, or inversion of sleep pattern. Euphoria, depression, or irritability. Mild confusion. Slowing of ability to perform mental tasks. Asterixis can be detected.
Grade 2	Lethargy or apathy. Disorientation. Inappropriate behavior. Slurred speech. Obvious asterixis. Drowsiness, lethargy, gross deficits in ability to perform mental tasks, obvious personality changes, inappropriate behavior, and intermittent disorientation, usually regarding time.
Grade 3	Somnolent but can be aroused, unable to perform mental tasks, disorientation about time and place, marked confusion, amnesia, occasional fits of rage, present but incomprehensible speech.
Grade 4	Coma with or without response to painful stimuli.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** HE is generally acquired.

Clinical/History	Electroen- cephalogram (EEG)	Serum iron, ferritin Na <sup>+</sup> , K <sup>+</sup>
Height		
Weight	Handgrip strength	Chol, Trig UA
Euvolemic (dry) weight	Acute Physiology and Chronic Health Evaluation (APACHE II) score	Ammonia Alb (decreased) Transferrin Nitrogen (N) balance CRP PT or INR Transferrin Gluc (decreased)
BMI		Actin-free Gc globulin (Af-Gc)
Diet history		Plasma isoleucine, leucine, valine
I & O		Plasma tryptophan, phenylala- nine, tyrosine
BP		Fischer's ratio
Muscle stiffness or rigidity		Serum insulin, epinephrine
Changes in men- tation or personality	<b>Lab Work</b>	Thyroxine
Daytime sleepi- ness	Serum lactate levels	
Decreased self-care	BUN (decreased)	
Dysfunctional movements, agitation	Creatinine (not valid?)	
Flapping tremor (positive Babinski reflex)	Bilirubin (increased)	
Jaundice	Alk phos (increased)	
Ascites	AST (increased)	
Early satiety?	Tumor necrosis factor (elevated)	
Musty odor of breath and urine	ALT, GGT Ca <sup>++</sup> , Mg <sup>++</sup> H & H (decreased)	

## INTERVENTION

### OBJECTIVES

- Treat specific causes and prevent multiple organ system failure. Stop any GI bleeding; offer life support if comatose.
- Provide nutrition support to promote regeneration of liver tissue. Support respiratory, neurological, GI, circulatory systems while the liver regenerates.
- Avoid skeletal muscle catabolism from inadequate oral intake, severely restricted diets or nothing by mouth (NPO) status.
- Decrease ammonia and toxin production. Normalize serum amino acid patterns.
- Avoid daytime or nocturnal fasting by using frequent meals and late evening snacks.
- Prevent hypokalemia, sepsis, starvation, and acute crises.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Underweight and Altered Nutritional Lab Values

**Assessment Data:** Dietary intake records; temporal wasting; low weight and BMI of 17; loss of LBM in arms and legs; ascites; confusion and signs of impending coma. Altered LFTs and albumin 2.1 g/dL.

#### Nutrition Diagnoses (PES):

NC 3.1 Underweight related to decreased appetite prior to admission as evidenced by 90% DBW, BMI 17.

NC 2.2 Altered nutrition related lab value related to liver dysfunction as evidenced by elevated ALT, ALP, AST, NH<sub>3</sub>, albumin 2.7 g/dL.

#### Interventions:

**Food and Nutrient Delivery:** ND 1.2 Modify, distribution type or amount of food and nutrients within meals or specified time (recommend diet change to 2 g sodium, 60 g protein, and six small meals per day; focus on lower animal proteins)

**Education:** E 1.1 Purpose of nutrition education

**Counseling:** C 2.2 Goal setting (improve lab values with change)

**Coordination of Care:** RC 1.1 Team meeting

**Monitoring and Evaluation:** Track food intake (food diary or history); improvement in albumin or other lab values. Improvement in weight and BMI.

- Reduce circulating amines and lessen shunting of blood around the liver. Control hemorrhage and blood loss into the gut.
- Correct anemia, zinc, and other deficiencies such as magnesium, thiamin, and folate (see Table 8-7).
- Prevent progression to hepatic cancer and improve quality of life.

## FOOD AND NUTRITION

Follow Practice Parameters of the American College of Gastroenterology (Blei and Cordoba, 2009):

- **Acute encephalopathy:** Withhold oral intake for 24–48 hours, and provide intravenous glucose until improvement is noted. Start TF if patient appears unable to eat after this period. Protein intake begins at a dose of 0.5 g/kg/d; progress to 1–1.5 g/kg/d.
- **Chronic encephalopathy:** Focus protein intake on dairy products and vegetable-based diets. Consider oral BCAAs for individuals intolerant of all protein.
- **Problematic encephalopathy:** Consider lactulose, neomycin, oral zinc, and surgical shunts.
- With coma, use TF with 0.5–0.6 g protein/kg body weight; advance to 1–1.5 g/kg euvolemic weight. Higher intake of BCAAs and glutamine-enriched products are not usually beneficial.
- Glucose is needed to reduce likelihood or presence of hypoglycemia. Start feeding slowly to prevent refeeding syndrome; then to progress to desired level of intake in the malnourished patient. It is prudent to start with

**TABLE 8-7 Nutrient Relationships in Hepatic Failure and Hepatic Encephalopathy**

Increased sodium and fluid	Edema; fluid retention
Decreased protein	Swollen belly (ascites) from decreased albumin production
Decreased protein and fat with malabsorption	Somnolence, euphoria, asterixis, coma
Decreased vitamin A	Increased respiratory infections
Decreased vitamins C and K	Hemorrhage; scurvy
Decreased magnesium, niacin, thiamin	Hallucinations, delirium, beri-beri, pellagra
Decreased B-complex vitamins, iron, and protein	Glossitis, anemias
Decreased thiamin	Amnesia, confabulation, Korsakoff's psychosis
Decreased niacin	Memory loss
Decreased folacin	Degeneration of spinal cord
Decreased vitamin K	Muscle weakness
Decreased magnesium	Marked anxiety, hyperirritability, confusion, seizures, tremor
Decreased zinc	Poor taste acuity, impaired wound healing

15–20 kcal/kg and progress as tolerated over several days.

- For the patient who is not comatose, diet should provide moderate-to-high levels of protein (Shawcross and Jalan, 2005). Protein restriction has been discontinued in most cases.
- Use enteral nutrition to correct protein–energy malnutrition. A calorie-dense product is desirable. A nasogastric tube placement may be better tolerated when there is ascites.
- To minimize muscle catabolism, diet should provide extra energy from carbohydrates and fats. Use 30 kcal/kg to maintain and 35 kcal/kg body weight to replete tissue; calculate needs using indirect calorimetry whenever possible. Fats should be 30–35% of kilocalories, using MCT if needed.
- When necessary, administer PN with 50% of energy as nonprotein kilocalories. Because PN does not use the gut, where bacteria may otherwise produce ammonia, parenteral protein is well tolerated and may be given as 1.0–1.5 g/kg. Parenteral solutions have risks of infection and metabolic complications.
- Ensure adequate intake of fluids and electrolytes as monitoring determines. Often, sodium is limited to aid diuresis. Restrict fluid only with dilutional hyponatremia (usually 1000–1500 mL).
- Vitamin–mineral supplements may be needed for niacin, thiamin, folate, phosphate, zinc, calcium, and magnesium.
- Monitor fat-soluble vitamin intake (vitamins A, D, E, and K) carefully and avoid excesses. Avoid copper and manganese at this time, and do not give iron supplements randomly.

- If oral diet is tolerated, use a bedtime snack to avoid hypoglycemia. Small meals and snacks throughout the day may increase intake; oral liquid supplements can be made readily available. Avoid severe restrictions of protein, sodium, fluid, fiber. Liquids are often better tolerated than bulky meals.

### Common Drugs Used and Potential Side Effects

- Drug-induced ALF accounts for approximately 20% of ALF in children and a higher percentage of ALF in adults; the most common cause of drug-induced ALF in children is acetaminophen (Murray et al, 2008). N-acetylcysteine is effective in ALF caused by acetaminophen overdose, with better results related to how soon it is given (Khashab et al, 2007).
- For other treatments of HE, see Table 8-8.

### Herbs, Botanicals, and Supplements

- Healthy enterocytes can degrade peptides and amino acids and use ammonia via glutamate, glutamine, citrulline, and urea synthesis (Bergen and Wu, 2009). Probiotic, CO<sub>2</sub>-producing lactobacilli are useful for enhancing gut microbial metabolism in HE (Bergen and Wu, 2009; Bongaerts et al, 2005). Other treatments using prebiotics and probiotics are under study; see Table 8-9.
- Avoid high doses of vitamins A and D, which may be toxic to the diseased liver.
- Herbs and botanical supplements should not be used without discussing with physician. For example, chaparral use can lead to liver failure. Kava kava and many other products should also be avoided in this population. *Silybum marianum* (milk thistle) is not proven to have a therapeutic role in liver failure.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Hospitalization is usually required; discuss symptoms that require immediate medical attention.
- Dietary intake must be adjusted according to the changing status of the patient. Large meals increase portal pressure; use smaller meals more frequently.
- Milk and eggs tend to produce less ammonia than meats or poultry.
- Discuss the importance of refraining from use of alcoholic beverages.
- A better appetite at certain meals may be common. Identify if breakfast or another meal is best tolerated. Some patients sleep late and have a sleep reversal pattern.
- Discuss proper menu planning. Avoid skipping meals.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

**TABLE 8-8 Medications Used for Hepatic Encephalopathy**

Medication	Description
<b>Antibiotics:</b> Neomycin	Orally administered antibiotics kill some of the bacteria present within the intestines that produce the dangerous toxins. Be careful not to miss doses. Adverse side effects are common.
Rifaximin	Rifaximin is a nonabsorbed antibiotic with a broad spectrum of activity against aerobic and anaerobic Gram-positive and Gram-negative organisms. It has a better safety and tolerability profile than that of lactulose and possibly neomycin.
<b>Cholestyramine or ursodeoxycholic acid</b>	For itching.
<b>Dietary supplements</b>	Vitamin D and calcium may be needed if osteopenia occurs. Fat-soluble excesses should be avoided since the liver is damaged.
<b>Laxatives:</b> Lactulose (Chronulac, Duphalac, Cholac Syrup, Constulose)	Lactulose is a synthetic sugar used to treat constipation. It is broken down in the colon into products that pull water out from the body and into the colon to soften stools. It also removes ammonia. One or two bowel movements a day are needed. Take lactulose with juice. It may cause abdominal bloating or gas. Be careful not to miss doses, but avoid excesses which can cause diarrhea.
<b>Zinc sulfate or acetate</b>	RNA oxidation and an increase of free intracellular zinc is a consequence of astrocyte swelling and ROS/RNOS production. RNA oxidation may impair postsynaptic protein synthesis, which is critically involved in learning and memory consolidation. Zinc supplementation is recommended.
<b>Medications to avoid</b>	Certain medications can increase the brain's sensitivity to ammonia and other toxins and should not be taken: sedative drugs (Valium, Ativan, Xanax), pain medications (Darvocet, codeine, Vicodin, Percocet, Demerol), antinausea agents (Phenergan, Compazine), antihistamines (Benadryl)

<sup>a</sup>Seventy percent of the body’s immunity is in the gut. There are 300–1000 species of bacteria, 100 trillion in the gut (about 3 lb). Alcohol, smoking, stress, poor bowel hygiene, aging, intestinal infections, antibiotics, and a poor diet can affect intestinal microbiota. The normal levels of lactobacilli, bifidobacteria, and other “good bacteria” may be decreased. Imbalanced flora may lead to abnormal GI function, such as constipation, diarrhea, flares of inflammatory bowel disease or irritable bowel syndrome, other pancreatic or abdominal inflammations, allergic responses, and an impaired immune system. Choosing foods wisely can improve gut health.

## LIVER TRANSPLANTATION

**NUTRITIONAL ACUITY RANKING: LEVEL 4****DEFINITIONS AND BACKGROUND**

Liver transplantation (LT) is now a viable alternative for patients with end-stage hepatic failure due to cirrhosis, viral hepatitis, chronic active liver disease, alpha-1 antitrypsin deficiency, primary sclerosing cirrhosis, cholangiocarcinoma, hemochromatosis, autoimmune hepatitis, Budd–Chiari syndrome, hepatoma, primary biliary cirrhosis, or cystic fibrosis.

Nutritional depletion occurs in this population before surgery. Muscle wasting, cachexia, and decreased fat stores are common. Supportive care for all patients with ALF includes adequate enteral nutrition, aggressive screening and treatment of infection, prophylactic broad-spectrum antibiotics, and antifungal agents (Hay, 2004).

Patients are screened carefully for other underlying conditions; many will not be suitable for transplantation. Alcohol is a major contributor to cirrhosis and the need for transplantation. NASH, obesity, diabetes, and hyperinsulinism play a role in cirrhosis and the need for transplantation. Older age, higher BMI, diabetes and HTN are associated with poor outcomes (Malik et al, 2009).

Symptoms and signs leading to the need for transplantation include ascites, jaundice, edema, CNS dysfunction, and cachexia. In living donor liver transplantation (LDLT), a

healthy, living person donates a portion of his or her liver to another person.

Preoperative and early postoperative nutrition may speed recovery, lessen time in the intensive care unit, and promote fewer infections. Subjective global assessment (SGA) is often useful because lab work varies so much in liver disease. SGA includes physical signs and symptoms, dietary changes and intolerances, medical/surgical history, GI symptoms and complaints, history of weight loss, and functional capacity. Transthyretin may be a reliable test when the inflammatory process resolves.

Patients with end-stage liver disease are prone to develop osteopenia and osteoporosis, and additional bone loss may occur with the use of immunosuppression agents after transplant. Bone loss occurs early after liver transplant and leads to postoperative fractures, especially with low bone mass. Calcium and vitamin D intake must be a priority.

In general, enteral nutrition is effective in maintaining nutritional status after transplantation. Nutritional supplementation after LT quickly restores protein synthesis. PN may be needed (Plauth et al, 2009). Patients with LT regain a normal life within months of surgery but have a lifetime of immunosuppressive treatment. Intravenous fish oil lipid emulsion may be useful.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Respiratory chain disorders may present with neonatal ALF, hepatic steatohepatitis, cholestasis, cirrhosis with chronic liver failure and the need for LT; molecular defects (mutations in nuclear genes such as SCO1, BCS1L, POLG, DGUOK, and MPV17 and the deletion or rearrangement of mitochondrial DNA) have been identified (Lee and Sokol, 2007). Methylmalonic acidemia with complete mutase deficiency (mut(0) type) is an inborn error of metabolism with high mortality and morbidity; LT may be a solution (Chen et al, 2009).

Clinical/History	Lab Work	Serum Fe, ferritin
Height	Serum lactate levels	Transferrin
Weight—usual	BUN, Creat	BUN, creatinine
Present weight	Alb,	Chol, Trig
BMI	Transthyretin	Carotenoids
SGA with diet history	N balance	AST, ALT
Cachexia?	Na <sup>+</sup> , K <sup>+</sup>	GGT
Edema	CRP (elevated?)	Gluc
Nausea and vomiting	Alk phos	PT or INR
I & O	Bilirubin	
BP	Amino acid profiles	
Ascites?	Serum ammonia	
Early satiety?	Cerebrospinal fluid (CSF)	
Jaundice	Ca <sup>++</sup> , Mg <sup>++</sup>	
CNS dysfunction?	H & H	
DEXA		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Intake From Enteral Nutrition

**Assessment Data:** I & O records showing long periods without enteral infusion for testing, lab work and nursing shift changes. Dry weight beginning to drop below desired range.

**Nutrition Diagnosis (PES):** Inadequate intake of enteral nutrition (NI-2.3) related to infusion being held for >3 hours daily as evidenced by intake at 70% of expected protein and kilocalories.

**Intervention:** Food and Nutrient Delivery—recalculation of TF formula to provide appropriate protein and kilocalories over 21 versus 24 hours daily. Education of nursing staff about necessary change in the TF order; coordination of care.

**Monitoring and Evaluation:** Track intake of enteral infusion; identify if weight is stable and labs are normal. Determine if current intake meets estimated needs; continue therapy. Evaluate every other day until discharge.

## INTERVENTION

### OBJECTIVES

#### Pretransplantation

- Correct malnutrition; lessen edema and ascites.
- Treat hyponatremia and electrolyte imbalances, depending on medications and renal function.
- Prevent or correct catabolic wasting of muscle mass from increased hormonal levels of insulin, glucagon, epinephrine, or cortisol.
- Provide nutritional support in an appropriate mode of feeding to provide a normalized nitrogen balance and other normalized laboratory values. Consider nausea, vomiting, anorexia, diarrhea.
- Correct fat malabsorption, with or without steatorrhea and diarrhea.
- Normalize blood glucose levels and prevent hypoglycemia; diabetes is common.
- Correct abnormal amino acid metabolism and neural accumulation of amino acids that are precursors for dopamine, serotonin, and norepinephrine. Normalize serum ammonia.

#### Posttransplantation

- Promote normalized protein synthesis in the liver for albumin, globulins, clotting factors. Monitoring nutritional parameters will not be a simple process; many usual measurements are not useful markers of nutritional decline (Shahid et al, 2005).
- Prevent or correct hyperglycemia, fasting hypoglycemia, and abnormal glucagon storage. Diabetes is a common complication from use of prednisone, cyclosporine, and tacrolimus.
- Prevent hypophosphatemia and refeeding syndrome.
- Support wound healing.
- Prevent infection and rejection, the most common complications. Portal venous complications have been well documented and can lead to graft failure (Woo et al, 2007).
- Manage long-term hypercholesterolemia, hypertension, obesity, osteopenia, or bone fractures.
- The role of probiotics in LT is unclear (Jenkins et al, 2005).

## FOOD AND NUTRITION

#### Pretransplantation

- Energy should be 35–45 kcal/kg dry weight for malnourished patients and 30–35 kcal/kg dry weight to maintain weight (Hasse, 2005). Use sufficient carbohydrate and fat to spare protein and meet energy needs. Monitor closely for hyperglycemia.
- Protein needs will vary: 0.8–1.0 g/kg dry weight in compensated liver disease. Calculate 1.5–2.0 g/kg dry weight in decompensated liver disease and 0.6–1.0 g/kg dry weight for HE.
- Modify for fluid, sodium, potassium, and other electrolytes depending on lab values and renal status. Restrict

**TABLE 8-10 Post-Liver or Pancreatic Transplant Nutrition Guidelines**

Nutrient	LIVER Short-Term	LIVER Long-Term	Pancreas Short-Term	Pancreas Long-Term
Calories	20–30% above normal or measure through indirect calorimetry; increase for weight gain	Maintenance: 30–35 kcal/kg depending on activity level	20–30% above normal or measure through indirect calorimetry; increase for weight gain	Maintenance: 30–35 kcal/kg depending on activity level
Protein	1.3–2 g/kg/d	1 g/kg/d	1.3–2 g/kg/d	1 g/kg/d
Carbohydrate	50–70% of calories	50–70% of calories; restrict simple sugars	45–55% of kcals; use CHO counting	45–55% of kcals; use CHO counting
Fat	30% of calories; up to 50% with severe hyperglycemia	<30% of total calories; <10% saturated fats	25–35% of kcals, depending on lipid levels Up to 50% of calories with severe hyperglycemia	25–35% of total calories; <10% saturated fats
Calcium	800–1200 mg/d	1–1.5 g/d (consider the need for vitamin D supplements)	800–1200 mg/d	1000–1500 mg/d (consider the need for vitamin D supplements)
Sodium	2–4 g/d	3–4 g/d	2–4 g/d	3–4 g/d
Magnesium and phosphorus	Encourage intake of foods high in these nutrients	Encourage intake of foods high in these nutrients; supplement as needed	Encourage intake of foods high in these nutrients; supplement as needed	Encourage intake of foods high in these nutrients; supplement as needed
Potassium	Supplement or restrict based on serum levels	Supplement or restrict based on serum levels	Supplement or restrict based on serum levels	Supplement or restrict based on serum levels
Other vitamins and minerals	Multivitamin–mineral: supplement to DRI or RDA levels	Adequate vitamin D will be needed to prevent deficiency; multivitamin–mineral: supplement to DRI or RDA levels	Multivitamin–mineral: supplement to RDA levels	Multivitamin–mineral: supplement to RDA levels

Source: Hasse J, Matarese L. Medical nutrition therapy for liver, biliary system, and exocrine pancreas disorders. In: Mahan L, Escott-Stump S, eds. *Krause's food nutrition and diet therapy*. 12th ed. St Louis: Elsevier, 2008.

sodium to 2- to 4-g and limit fluid to 1000- to 1500-mL with edema.

- Use a low-volume TF if needed, diluting the concentration. Avoid glutamine-enriched solutions with elevated serum ammonia levels. Consider use of BCAA-enriched formulas.
- Vitamins and minerals should be given at levels that meet but not exceed recommended daily allowances. Fat malabsorption is common; use water-miscible forms of vitamins A, D, E, and K with steatorrhea. B-complex vitamins may be depleted. Stores of calcium, magnesium, potassium, phosphorus, manganese, copper, and zinc are often low and should be repleted.

### Post-transplantation

- See Table 8-10.

### Common Drugs Used and Potential Side Effects

- See Table 8-11.

### Herbs, Botanicals, and Supplements

- Use of probiotics may be quite helpful in this population. A synbiotic composition in an enteral feeding, consisting of one lactic acid bacteria (LAB) and one fiber, greatly

reduces incidence of postoperative bacterial infections (Rayes et al, 2005).

- Chaparral should be avoided after transplantation. Herbs and botanical supplements should not be used without discussing with physician. St. John's wort interferes with the metabolism of cyclosporine and should not be used.
- In one study, 50% of LT patients admitted to using vitamins after surgery, and 19% used herbal remedies combined with vitamins, mostly silymarin (Neff et al, 2004).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of diet in wound healing, graft retention, and improvement in health status.
- Provide patient or family with recipes for no-added-salt and sugar-free foods as needed.
- Obesity can occur unless energy intake is controlled over the long term.
- Discuss sources of foods that contain calcium, magnesium, and other desirable nutrients. Individualize to patient preferences and needs.
- Discuss the need for alcohol rehabilitation, family counseling, or other available services. Ethanol (ETOH) abuse affects such key nutrients as niacin, folate, vitamin B<sub>12</sub>, zinc, phosphorus, and magnesium.

**TABLE 8-11 Medications Used after Liver Transplantation**

Medication	Description
Analgesics	Analgesics are used to reduce pain. Long-term use may affect such nutrients as vitamin C and folacin; monitor carefully for each specific medication.
Azathioprine (Imuran)	Azathioprine may cause anorexia, leukopenia, thrombocytopenia, oral and esophageal sores, macrocytic anemia, pancreatitis, vomiting, diarrhea, and altered taste acuity. Folate supplementation and other dietary modifications (liquid or soft diet, use of oral supplements, and flavor enhancements) may be needed. The drug works by lowering the number of T cells; it is often prescribed along with prednisone for conventional immunosuppression.
Corticosteroids (prednisone or Solu-Cortef)	Corticosteroids such as prednisone and Solu-Cortef are used for immunosuppression. Side effects include increased catabolism of proteins, negative nitrogen balance, hyperphagia, ulcers, decreased glucose tolerance, sodium retention, fluid retention, and impaired calcium absorption and osteoporosis. Cushing's syndrome, obesity, muscle wasting, and increased gastric secretion may result. A higher protein intake and lower intake of carbohydrate and sodium may be needed.
Cyclosporine	Cyclosporine does not retain sodium as much as corticosteroids do. Intravenous doses are more effective than oral doses. Nausea, vomiting, and diarrhea are common side effects. Hyperlipidemia, hyperglycemia, and hyperkalemia may also occur; decrease fat intake as well as sodium and potassium if necessary. Magnesium may need to be replaced. The drug is also nephrotoxic; a controlled renal diet may be beneficial. Taking omega-3 fatty acids during cyclosporine therapy may reduce toxic side effects (such as high blood pressure and kidney damage) associated with this medication in transplantation patients. Avoid use with St. John's wort.
Diuretics	Diuretics such as furosemide (Lasix) may cause hypokalemia. Aldactone actually spares potassium; monitor drug changes closely. In general, avoid use with fenugreek, yohimbe, and ginkgo.
Immunosuppressants	Immunosuppressants such as muromonab (Orthoclone OKT3) and antithymocyte globulin (ATG) are less nephrotoxic than cyclosporine but can cause nausea, anorexia, diarrhea, and vomiting. Monitor carefully. Fever and stomatitis also may occur; alter diet as needed.
Insulin	Insulin may be necessary during periods of hyperglycemia. Monitor for hypoglycemic symptoms during use.
Mycophenolate mofetil	Diarrhea is common. Extra fluids will be needed.
Muromonab (Orthoclone OKT3)	This drug can lead to nausea, vomiting, diarrhea, and anorexia, and meal adjustments may be needed.
Tacrolimus (Prograf, FK506)	Tacrolimus suppresses T-cell immunity; it is 100 times more potent than cyclosporine, thus requiring smaller doses. Side effects include GI distress, nausea, vomiting, hyperkalemia, and hyperglycemia; adjust diet accordingly by reducing carbohydrate or elevating potassium intake.

- Maintain a good diet and physical activity to support bone density.

### Patient Education—Foodborne Illness

- Careful food handling and hand washing are important to prevent introduction of foodborne pathogens to the transplantation individual who may be experiencing graft–host rejection.
- Prevent infections from foodborne illness; patients who have undergone transplantation may be prone to increased risk more than other individuals.

## PANCREATIC DISORDERS

## PANCREATITIS, ACUTE

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

## DEFINITIONS AND BACKGROUND

Acute pancreatitis is an inflammatory, clinical syndrome defined by a discrete episode of abdominal pain and elevations in serum enzyme levels (Gramlich and Taft, 2007). The exocrine pancreas secretes proteolytic, lipolytic, and amylolytic enzymes for nutrient digestion in the intestines. AP is initiated inside acinar cells by premature activation of digestive enzymes in the pancreas instead of the duodenum. Seventy-five percent to 85% of all pancreatic episodes are considered mild and self-limiting and do not require intervention with nutrition support (Gramlich and Taft, 2007). In the unfortunate 15–25% who need nutrition support, preventing multiple organ failure is important.

AP is common in men between the ages of 35 and 45 years, primarily from alcohol abuse or secondarily from gallstones (cholelithiasis). It is often difficult to differentiate between pancreatitis and acute cholecystitis; the correct diagnosis is important because treatments are very different. Other causes of AP include end-stage renal disease, lupus, biliary tract disease, abdominal trauma, certain dyslipidemias (especially triglycerides >1000 mg/dL), AIDS, and pancreatic cancer.

Symptoms of AP include sudden, severe abdominal pain, nausea, vomiting, and diarrhea. Complications include sepsis, acute renal failure, hypovolemia, circulatory shock, and pancreatic necrosis. Abdominal pain can be constant and disabling, causing some patients to become addicted to pain medications. About 25% of persons with AP go on to have chronic pancreatitis. Surgery for AP may include necrosectomy, pancreaticoduodenectomy, or sphincterotomy.

Oxygen free radical-mediated tissue damage is well established in the pathogenesis of AP. Cytokines involved in the systemic inflammatory response in AP include lipid mediators (prostanoids, thromboxanes, and leukotrienes) generated from arachidonic acid. Reactive oxygen species mediate inflammatory cytokine expression and apoptosis of pancreatic acinar cells (Parks et al, 2009). Omega-3 fatty acids DHA and alpha-linolenic acid (ALA), suppress the expression of inflammatory cytokines (IL-1beta, IL-6) and inhibit the activation of transcription factor activator protein-1 in cerulein-stimulated pancreatic acinar cells (Parks et al, 2009). Heat shock proteins (HSPs) that inhabit almost all subcellular locations and cellular membranes play a major role in the protection of cells against stressful and injury-inciting stimuli, including acinar cell injury in AP (Dudeja et al, 2009).

The role of the gut in maintaining immune system integrity is widely recognized. Therefore, nutrition support by the enteral route is preferred (Cao et al, 2008). Nasojejunal feeding tube and a low-molecular diet provide clear advantages compared to parenteral nutrition, such as fewer infectious complications, shorter length of hospital stay, lower cost, and less need for surgery (McClave et al, 2006; Meier and Beglinger, 2006; Petrov et al, 2008). Parenteral nutrition (PN) is used for short term when full nutritional requirements cannot be met enterally so that body composition is preserved (Chandrasegaram et al, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Evaluation for a susceptible genotype is important (Balog et al, 2005). This is true for pancreatic carcinoma more than pancreatitis per se.

Clinical/History	Lab Work	Mg <sup>++</sup> (decreased)
Height	CRP (used to	LDH (>700)
Weight	measure	ALT (elevated)
BMI (obese?)	severity in	AST (>250)
Diet history	AP)	WBC (>10,000
BP (low)	Procalcitonin	cells/mm <sup>3</sup> )
Rapid heart rate	(elevated?)	Alb (low)
Left upper quad-	Lipase	Partial pressure
rant abdomi-	(>110; more	of carbon
nal pain	sensitive than	dioxide
Nausea,	amylase)	(pCO <sub>2</sub> )
vomiting	Amylase (>250)	(increased)
Temperature	K <sup>+</sup> (decreased)	Partial pressure
Chvostek's sign	Na <sup>+</sup> (decreased)	of oxygen
Steatorrhea or	PT or INR	(pO <sub>2</sub> )
oily stools	Bilirubin	(decreased)
Multiple Organ	(elevated)	BUN
System Score	Ca <sup>++</sup>	H & H
(MOSS)	(decreased)	Serum folate
CT scan showing	Gluc (increased,	Alk phos
interstitial	>200)	(increased)
pancreatic	Chol (total	CT scan for
edema	decreased)	necrosis
Magnetic reso-	LDL cholesterol	Ultrasound
nance imag-	(elevated?)	Fecal fat study
ing (MRI)	Trig (increased)	

## SAMPLE NUTRITION CARE PROCESS STEPS

## Impaired Nutrient Utilization

**Assessment Data:** Patient statement of not taking enzyme medication, reports of abdominal pain, diarrhea after eating, vomiting.

**Nutrition Diagnosis (PES):** Impaired nutrient utilization related to pancreatic enzyme deficiency as evidenced by abdominal pain and steatorrhea and report of medication noncompliance.

**Intervention:** Interventions would address the appropriate dose and frequency of medication intake.

**Monitoring and Evaluation:** Plan would include asking patient time of next clinic visit. Evaluate change in steatorrhea and improvement in enzyme medication compliance.

## INTERVENTION

## OBJECTIVES

- Reduce pain. Achieve pancreatic rest simultaneously with gut use.
- Use enteral nutrition to reduce the systemic inflammatory response syndrome (Gramlich and Taft, 2007). Failure to use the GI tract in AP may exacerbate disease severity (McClave et al, 2006).
- Avoid pancreatic irritants, especially alcohol and caffeine. Monitor for increased need for pancreatic enzymes with the use of TF.
- Avoid overfeeding.
- Correct fluid and electrolyte imbalances and malnutrition. Acid-base imbalance is common with nasogastric suctioning, fistula losses, renal failure, nausea, and vomiting.
- Reduce fever; prevent shock and hypovolemia, hypermetabolism, sepsis, and compression of the stomach or colon. Avoid cardiovascular, pulmonary, hematological, renal, neurological, or metabolic complications with organ failure. Extensive necrosis and infection are associated with the development of organ failure (Garg et al, 2005).
- Use CPN if abdominal pain is refractory. CPN use can promote positive nitrogen balance (Chandrasegaram et al, 2005).

## FOOD AND NUTRITION

- Postpyloric TF is often well tolerated (Niv et al, 2009). Products containing MCT are useful for TF, especially when there is steatorrhea. Omega-3 fatty acids are also helpful (Lasztity et al, 2005). Transition to jejunostomy can be considered when pain is refractory, using a standard formula and needle catheter jejunostomy.
- Progress to a diet given in six daily feedings used with pancreatic enzymes for all meals and snacks.

- Alcoholic beverages and nicotine are prohibited. Limit gastric stimulants, such as peppermint and black pepper, if not tolerated.
- Diet should include adequate amounts of vitamin C, B-complex vitamins, and folic acid for water-soluble vitamin needs. Vitamin B<sub>12</sub> deficiency can occur because intrinsic factor is prevented from binding with vitamin B<sub>12</sub>. Use fat-soluble vitamins in water-miscible form.
- Antioxidants including selenium may be needed (Musil et al, 2005). Adequate calcium, magnesium, and zinc supplementation should also be provided.

## Common Drugs Used and Potential Side Effects

- Many drugs can trigger acute pancreatitis: furosemide (Lasix), azathioprine, dideoxyinosine, DDI (used for treating AIDS), 6-mercaptopurine, 6-MP (an immunosuppressant drug), angiotensin-converting enzyme (ACE) inhibitors, dapsone, acetaminophen, estrogens, methyl-dopa, nitrofurantoin, steroids, thiazides, cimetidine, erythromycin, salicylates, sulfonamides, and tetracyclines.
- The most common cause of death in AP patients is infection with enteric bacteria, but there is no convincing evidence for routine administration of prophylactic antibiotics (Wittau et al, 2008).
- See Table 8-12 for guidance on medications.

## Herbs, Botanicals, and Supplements

- Antioxidants have protective properties that can be beneficial. See Table 8-13.
- Other herbs and botanical supplements should not be used without discussing with physician as many have hepatotoxic properties.
- Probiotics have had mixed results; they may actually promote higher mortality in patients with AP (Besselink et al, 2008).

TABLE 8-12 Medications Used in Pancreatitis

Medication	Description	Acute	Chronic
Antibiotics	Antibiotics may be needed to manage necrosis and systemic complications.	X	X
Bile salts	Bile salts or water-miscible forms of fat-soluble vitamins may be needed.	X	X
Diuretics	Diuretics such as acetazolamide (Diamox) may be needed to control fluid retention. Nausea, vomiting, and diarrhea may result.	X	X
H <sub>2</sub> -receptor antagonists (cimetidine, ranitidine)	Cimetidine may deplete vitamin B <sub>12</sub> , especially among the elderly. Histamine H <sub>2</sub> -receptor antagonists or proton pump inhibitors can improve fat malabsorption and steatorrhea.	—	X
Insulin	Insulin may be necessary. Monitor for hypoglycemia during use.	X	X
Octreotide	Octreotide may have a beneficial role in the management of AP.	X	—
Opiates	Opiates may be prescribed for pain.	X	—
Painkillers	Pain control requires the use of morphine-like drugs (pethidine, morphine, and diamorphine), which have the risk of addiction, particularly if their use is not controlled.	—	X
Pancreatic enzymes	30,000 IU per meal may be needed to reduce steatorrhea to less than 20 g/d. Enteric coating is necessary to prevent destruction by enzymes. Take enteric-coated enzymes with cimetidine, food, or antacids. Capsules or tablets should be swallowed whole.	X	X

**TABLE 8-13 Antioxidants and Sources<sup>a</sup>**

Vitamins	Sources or Comments
<ul style="list-style-type: none"> <li>Vitamin A as beta carotene protects vegetables and fruits from solar radiation damage.</li> <li>Vitamin C (ascorbic acid) is a reducing agent.</li> <li>Vitamin E (alpha-tocopherol) protects lipid membranes. It also protects glutathione peroxidase (GPX-4). Some tocotrienol isomers also have antioxidant properties.</li> </ul>	<p>See beta-carotene (below). Supplements are not recommended for general use.</p> <p>Citrus fruits (oranges, sweet limes, grapefruit, tangerines), green peppers, broccoli, black currants, strawberries, blueberries, raw cabbage. Destroyed by long-term storage or cooking.</p> <p>Wheat germ, nuts, seeds, whole grains, green leafy vegetables, vegetable oil, fish oil. GPX4 is the only molecule that efficiently reduces lipid hydroperoxides within the cell membranes.</p>
<i>Vitamin Cofactors and Minerals</i>	
<ul style="list-style-type: none"> <li>Coenzyme Q10</li> <li>Manganese</li> <li>Copper</li> <li>Zinc</li> <li>Iodide</li> <li>Selenium and Glutathione</li> </ul>	<p>Ubiquinol is made in the body and is poorly absorbed from the gut</p> <p>Part of the superoxide dismutase (SOD) enzyme in mitochondria</p> <p>Part of the superoxide dismutase (SOD) enzyme in the cytosol and extracellular fluid</p> <p>Part of the superoxide dismutase (SOD) enzyme in the cytosol and extracellular fluid</p> <p>Iodized salt and seafood</p> <p>Liver contains a large amount as part of detoxification system. Glutathione is made from amino acids, but diet does not control its production. Acetylcysteine is a sulfur-containing amino acid that may increase glutathione levels.</p>

Vitamins	Sources or Comments
<ul style="list-style-type: none"> <li>Stilbenoids:               <ul style="list-style-type: none"> <li>Resveratrol</li> <li>Pterostilbene</li> </ul> </li> <li>Anthocyanidins               <ul style="list-style-type: none"> <li>Cyanidin</li> <li>Delphinidin</li> <li>Malvidin</li> <li>Pelargonidin</li> <li>Peonidin</li> <li>Petunidin</li> </ul> </li> </ul>	<p>Skins of dark-colored grapes, and concentrated in red wine</p> <p>Blueberries and grapes. Methoxylated analogue of resveratrol but not found in wine. May function like metformin to lower blood glucose; more research is needed.</p> <p>Grapes, bilberry, blackberry, blueberry, cherry, cranberry, elderberry, hawthorn, loganberry, acai berry and raspberry; apples, red cabbage, and plums.</p> <p>Blue-red grapes, pomegranate, cranberries.</p> <p>Red wine</p> <p>Ripe raspberries, blueberries, blackberries, plums, cranberries, pomegranates.</p> <p>Raw cranberries; blueberries, plums, grapes, cherries. Not found in frozen fruits; raw only.</p> <p>Chokeberries, muscadine grapes</p>
<i>Phenolic Acids and Their Esters</i>	
<ul style="list-style-type: none"> <li>Chlorogenic acid—a caffeic acid derivative</li> <li>Chlorogenic acid—produced from esterification of caffeic acid.</li> <li>Cinnamic acid and ferulic acid</li> <li>Ellagic acid</li> <li>Ellagitannins—hydrolyzable tannin polymer</li> <li>Gallic acid</li> <li>Gallotannins—hydrolyzable tannin polymer</li> <li>Rosmarinic acid</li> <li>Salicylic acid</li> </ul>	<p>Found only in <i>Echinacea purpurea</i>.</p> <p>High concentration in coffee (more concentrated in robusta than arabica beans), blueberries and tomatoes.</p> <p>Seeds of plants such as in brown rice, whole wheat and oats, as well as in coffee, apple, artichoke, peanut, orange and pineapple.</p> <p>Raspberry, strawberry. In ester form in red wine tannins.</p> <p>Formed when ellagic acid, a polyphenol monomer, esterifies and binds with the hydroxyl group of a polyol carbohydrate such as glucose</p> <p>Found in gallnuts, sumac, witch hazel, tea leaves, oak bark, and many other plants</p> <p>Formed when gallic acid, a polyphenol monomer, esterifies and binds with the hydroxyl group of a polyol carbohydrate such as glucose.</p> <p>High concentration in rosemary, oregano, lemon balm, sage, and marjoram.</p> <p>Found in most vegetables, fruits, and herbs; but most abundantly in the bark of willow trees (in aspirin).</p>
<i>Other Nonflavonoid Phenolics</i>	
<ul style="list-style-type: none"> <li>Curcumin</li> <li>Eugenol</li> <li>Flavoglycosides</li> <li>Flavonolignans—silymarin</li> <li>Xanthones—mangosteen and derivatives</li> </ul>	<p>Low bioavailability, because, much of it is excreted through glucuronidation. Chemopreventive.</p> <p>Oil of cloves. May be toxic if used in undiluted essential oils.</p> <p>Ginkgo</p> <p>Flavonolignans extracted from milk thistle.</p> <p>Mangostin may only be found in inedible shell</p>
<i>Other Organic Antioxidants</i>	
<ul style="list-style-type: none"> <li>Bilirubin, a breakdown product of blood</li> <li>Cannabidiol, THC and synthetic cannabinoids</li> <li>Citric acid</li> <li>Lignan—antioxidant and phytoestrogen</li> <li>N-Acetylcysteine—water soluble</li> <li>Oxalic acid</li> <li>Phytic acid (inositol, phytate)</li> <li>R-<math>\alpha</math>-Lipoic acid—fat and water soluble</li> <li>Uric acid</li> </ul>	<p>Possibly a significant antioxidant</p> <p>Cannabidiol is protective against glutamate neurotoxicity; a potent cerebral antioxidant.</p> <p>Lemons, limes, other citrus fruits. Part of citric acid cycle, so found in all living things.</p> <p>Oats, flax seeds, pumpkin seeds, sesame seeds, rye, soybeans, broccoli, beans, and some berries.</p> <p>Augments glutathione reserves in the body to protect hepatocytes in the liver from acetaminophen toxicity.</p> <p>Precursor in the formation of the antioxidant glutathione in the body with antioxidant effects to reduce free radicals.</p> <p>Rhubarb, buckwheat, star fruit, black pepper, parsley, poppy seed, spinach, chard, beets, cocoa, chocolate, most nuts, berries, beans.</p> <p>Storage form of phosphorus in bran and seeds. Sesame seeds, pinto beans, Brazil nuts, peanuts, soybeans, linseed.</p> <p>Lipoic acid is found in almost all foods; slightly more in kidney, heart, liver, spinach, broccoli, and yeast extract.</p> <p>In humans, uric acid accounts for roughly half the antioxidant ability of plasma</p>
<i>Other Substances</i>	
<ul style="list-style-type: none"> <li>Melatonin, a hormone</li> </ul>	<p>Easily crosses the blood-brain barrier. Once oxidized, it cannot be reduced to its former state.</p>

<sup>a</sup>Antioxidants prevent or slow down oxidation where free radicals damage cells; they are often reducing agents. While supplements are available from many health food stores and nutraceutical companies, clinical trials have not found them to be useful and some may be harmful in elderly or vulnerable populations. See also, Table 1-23 and Table 2-2.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Instruct patient to watch for signs and symptoms of diabetes, tetany, peritonitis, acute respiratory distress syndrome, and pleural effusion. These patients are best managed by a multidisciplinary team approach, especially in pediatrics (Stringer et al, 2005).
- Discuss omission of alcohol and gas-forming foods.
- Discuss tips for handling nausea and vomiting (e.g., dry meals, taking liquids a few hours before or after meals, use of ice chips, sipping beverages, asking physician about available antiemetics).
- If home enteral nutrition is needed, teach appropriate management methods.
- Teach use of a low-fat, high-protein, high-calorie oral diet when and if appropriate.
- Discuss the use of foods rich in antioxidants.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# PANCREATITIS, CHRONIC

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Asset provided by Anatomical Chart Co.

## DEFINITIONS AND BACKGROUND

Chronic pancreatitis (CP) is an inflammatory disorder that results in permanent impairment of the pancreas. CP involves edema, fat necrosis, cellular exudate, fibrosis, and decreased enzymatic processes with abdominal pain, nausea, vomiting, and diarrhea. CP typically develops in people between the ages of 30 and 40, and can be caused by hereditary disorders of the pancreas, cystic fibrosis, hypercalcemia, excessive use of alcohol, hyperparathyroidism, hyperlipidemia, or lipase deficiency. The autoimmune forms of CP have been identified through elevated IgG4 levels. Approximately 5% of persons with acute pancreatitis go on to have CP.

Very heavy alcohol consumption and smoking are independent risks for CP (Yaday et al, 2009). Chronic alcohol abuse is the cause in 70% of adult cases, proportional to the dose and duration of alcohol consumption. The factors determining which alcoholic will develop alcoholic CP involve genetic and dietary factors or pancreatic injury from trauma, gallstones, and viruses. There is a gradual decrease in antioxidant enzyme expression in the pancreatic cells in CP and many patients will progress to having diabetes or pancreatic cancer.

Analysis of pancreatograms and textural changes of the parenchyma help diagnose CP (Kwon and Brugge, 2005). To avoid nutritional deterioration, screen early for fat malabsorption from decreased lipase levels. Steatorrhea occurs when fecal fat >7 g/dL is noted and over 90% of pancreatic enzyme secretion is lost. Weight loss is common, as is pain after intake of foods containing fat and protein. Jaundice, hypoalbuminemia, pancreatic pseudocysts or calcification, and splenic vein thrombosis may also occur.

Abstinence from alcohol, dietary modifications, use of oral supplements, and pancreatic enzyme supplementation will suffice in most patients (Meier et al, 2006). Enteral nutrition may be necessary for those in whom weight loss continues. Long-term use of a jejunostomy feeding may be needed (Stanga et al, 2005). PN is very seldom needed and is not as beneficial.

Oxidative stress occurs when there is an imbalance between generation of reactive oxygen species and inadequate antioxidant defense systems, causing cell damage either directly or through altering signaling pathways. Antioxidant supplementation relieves pain and reduces levels of oxidative stress (Bhardwaj et al, 2009; Verlaan et al, 2006). Patients may benefit from supplementation of vitamins A, C, E, selenium, and carotenoids. Episodes of inflammation and duct obstruction cause disabling pain (Gabbrielli et al, 2005). Some patients become dependent on pain medications. Supportive treatments, inhibition of gastric acid secretion, nerve blocks, reduction of oxidative stress, and endoscopic and surgical treatments are used.

Surgery, such as distal pancreatectomy, achieves pain relief and better quality of life. The first successful autoislet cell transplants in patients who have severe CP were performed recently by surgeons at the University of Arizona Medical Center. This procedure avoids surgically caused diabetes.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Tropical calcific pancreatitis (TCP) is an idiopathic pancreatitis prevalent in Asia; trypsin inhibitor (SPINK1) N34S variant partially explains the genetic susceptibility (Sundaresan et al, 2009).

Clinical/History	Lab Work	
Height	Bicarbonate levels	K <sup>+</sup> , Na <sup>+</sup> , Ca <sup>++</sup> (decreased)
Weight		Gluc (often increased)
BMI	(decreased; sensitivity 95)	Lipase and Amylase (elevated?)
Diet history	Secretin stimulation test	Serum trypsinogen (low)
SGA evaluation	IgG4 level, ESR, rheumatoid factor, ANA	Chol (LDL up, or total decreased)
Alcohol intake	Thiobarbituric acid-reactive substances [TBARS] for oxidative stress	Trig (increased)
Smoking history	Ferric-reducing ability of plasma [FRAP] for antioxidant status	Mg <sup>++</sup> (decreased)
Left upper quadrant abdominal pain	Fecal elastase (<200 µg/g)	LDH (>700)
Vomiting	Sudan staining of feces	AST (>250)
Anorexia, nausea	Fecal fat test (24 hours on 100 g fat diet)	WBC (>200)
Steatorrhea	CRP and WBC (elevated)	Bilirubin and Alk phos (increased)
Temperature (fever?)		pCO <sub>2</sub> (increased) and pO <sub>2</sub> (decreased)
I & O		Alb, transthyretin
Chvostek's sign		BUN
CT scan or MRI		H & H
Endoscopic ultrasound		Serum folate
Exploratory laparotomy		
Endoscopic retrograde cholangiopancreatography (ERCP)		
See Table 8-3 also		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Bioactive Substance Intake

**Assessment Data:** Dietary intake records, Dx of CP with frequent abdominal pain.

**Nutrition Diagnosis (PES):** Inadequate bioactive substance intake related to low intake of antioxidant-rich foods and beverages as evidenced by frequent bouts of abdominal pain with CP.

**Intervention:** Food and Nutrient Delivery—encourage intake of foods rich in antioxidants (see Tables 8-13 and 8-14).

**Monitoring and Evaluation:** Track food intake (food diary or history) to assess increased intake of foods rich in antioxidants and fewer episodes of abdominal pain, hospitalization, and use of analgesics.

**TABLE 8-14 Oxygen Radical Absorbance Capacity (ORAC) Rating of Foods<sup>a</sup>**

Food	USDA Data on Foods with High ORAC Scores				
	100 g Serving	Household Equivalent	Antioxidant capacity (TE) per 100 g	Other Common Unit	TE per Unit
Cinnamon, ground	100 g	14 Tbsp	264,543	1 Tbsp	19,110

<sup>a</sup>Oxygen radical absorbance capacity (ORAC) is a method of measuring antioxidant capacities in biological samples. Values are expressed as the sum of the lipid soluble (e.g., carotenoid) and water-soluble (e.g., phenolic) antioxidant fractions (i.e., “total ORAC”) reported as in micromoles Trolox equivalents (TE) per 100 g sample. Foods rich in antioxidants have an ORAC rating of 1000 per 100 g.

For household measurements:

- 100 g = 3.5 oz dry ingredients
- 3 tsp = 1 Tbsp.
- 48 tsp = 16 Tbsp = 1 cup.
- 1 Tbsp fresh herbs = ½ teaspoon, dried, crushed
- 1 oz = 4½ Tablespoons allspice, cinnamon, curry, paprika or dry mustard
  - or 4 Tablespoons cloves or prepared mustard
  - or 3½ Tablespoons nutmeg or pepper
  - or 3 Tablespoons sage, cream of tartar or cornstarch
  - or 2 Tablespoons salt or any liquid
- 1 pound = 2 cups liquid
  - or 4 cups flour
  - or 10 eggs without shells
  - or 4 cups grated cabbage, cranberries, coffee or chopped celery
  - or 3 cups corn meal
  - or 2 cups uncooked rice
  - or 2¾ cups raisins or dried currants

## INTERVENTION

### OBJECTIVES

- Decrease pain from oxidative stress. Abstain from alcohol and smoking.
- Correct fluid and electrolyte imbalances and malnutrition; avoid overfeeding. Acid–base imbalance is common with nasogastric suctioning, fistula losses, renal failure, nausea, and vomiting.
- Provide optimal nutrition support for weight gain as weight loss is common in the late course of CP (Stanga et al, 2005).
- Alleviate steatorrhea; decrease number of stools per day if there is diarrhea.
- Avoid or control complications (cardiovascular, pulmonary, hematological, renal, neurological, or metabolic); prevent multiple organ dysfunction.
- With diabetes, it may be better to have glucose elevated slightly (200 mg/dL) than to allow prolonged hypoglycemia to occur.
- If tube fed, monitor for abdominal pain or discomfort, and offer pain medication as needed. Administer pancreatic enzymes with meals or TF (Dominguez-Munoz et al, 2005; Stanga et al, 2005). CPN may be needed for resistant cases where pain does not subside.

### FOOD AND NUTRITION

- If tolerated, use a diet with low-to-moderate fat (0.7–1 g/kg) and high carbohydrates; calculate needs accordingly. Diet should be low in fiber with six small meals a day. Include adequate amounts of antioxidants (Tables 8-13 and 8-14), minerals (calcium, magnesium, selenium, and zinc), fat-soluble vitamins (A, D, E, and K) in water-miscible form, and water-soluble vitamins.
- High-energy, standard feeding by enteral pump is desirable for those who need it. Estimate needs at 35 kcals/kg, 1–1.5 g protein per kilogram. Jejunal feeding is more beneficial than gastric placement. Needle catheter jejunostomy may be used safely (Stanga et al, 2005), but not with ascites.
- Treat steatorrhea to minimize symptoms of the underlying disease and to promote weight retention or gain. MCTs and pancreatic replacement therapy combat maldigestion and malabsorption (Stanga et al, 2005). Monitor for hyperglycemia with a high-carbohydrate diet.
- When CPN is needed (in about 1% of cases), estimate needs according to similar parameters as for oral diet. The benefits of BCAAs and glutamine are not clear. If intravenous lipids are used, do not use more than 1.5 g/kg for adults. Provide no more than 5 mg/kg/min of glucose.
- Alcoholic beverages are absolutely prohibited.

### Common Drugs Used and Potential Side Effects

- See Table 8-12 for guidance on medications.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Antioxidant therapy with green tea polyphenols and gene therapy with superoxide dismutase can markedly attenuate disease (Dryden et al, 2005).
- The combination of pre- and probiotics (synbiotics) have mixed results in this population. In the acute form of pancreatitis, probiotic use may actually increase mortality (Besselink et al, 2008).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Instruct patient to watch for signs and symptoms of diabetes, tetany, peritonitis, acute respiratory distress syndrome, and pleural effusion.
- Discuss omission of alcohol from the typical diet.
- Discuss tips for handling nausea and vomiting (e.g., dry meals, taking liquids a few hours before or after meals, use of ice chips, sipping beverages, asking physician about available antiemetics, etc.). Dietary counseling has been found to be as effective as dietary supplementation for managing CP (Singh et al, 2008). Gas-forming foods may need to be omitted. Teach high-calorie, high-protein, low-fat diet rich in antioxidant foods with a frequent small meal pattern.
- To prevent onset of pancreatic cancer, avoiding tobacco smoking.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## PANCREATIC INSUFFICIENCY

### NUTRITIONAL ACUITY RANKING: LEVEL 2–3

#### DEFINITIONS AND BACKGROUND

Pancreatic insufficiency is caused by the inability of the exocrine pancreas to secrete digestive enzymes such as lipase. Cystic fibrosis (CF), type 1 (autoimmune) diabetes, Shwachman-Diamond Syndrome (SDS), pancreatic cancer, or pancreatitis will often lead to pancreatic insufficiency. Other disorders of the gastrointestinal tract, such as celiac disease, inflammatory bowel disease, Zollinger–Ellison syndrome or gastric resection can either mimic or cause pancreatic exocrine Insufficiency (Keller et al, 2009).

Lipase is the key enzyme for breaking down triglycerides. Patients often have mild-to-moderate fat malabsorption. In CF, there may be recurrent problems with fatty acid abnormalities or pancreatitis (DeBoeck et al, 2005). Fecal elastase (FE) 1 levels indicate lipase activity; assessment should be used to verify pancreatic status (Cohen et al, 2005). A fecal fat or Steatocrit test may identify the problem.

Stool trypsin tests or low levels of trypsinogen are used to determine whether sufficient amounts of this pancreatic enzyme are reaching the intestines to metabolize proteins. Because the overt clinical symptoms of pancreatic exocrine insufficiency are steatorrhea and maldigestion (Keller et al, 2009), oral pancreatic enzyme supplements should be properly administered to ensure adequate gastric mixing with the food.

Nonendocrine pancreatic disease is a critical factor for development of diabetes; this “type 3c” affects over 8% of the general diabetic patient population (Hardt et al, 2008). There is a continuous interstitial matrix connection between the endocrine and exocrine pancreas; fibrosis and inflammation cause dysfunctional insulin-acinar-ductal-incretin gut hormone axis, resulting in pancreatic insufficiency and glucagon-like peptide deficiency and diabetes (Hayden et al, 2008).

The delivery of sufficient enzyme concentrations into the duodenal lumen simultaneously with meals can reduce nutrient malabsorption, improve the symptoms of steatorrhea, and in some cases alleviate pain (Ferrone et al, 2007). The best duodenal pH permits optimal efficacy of these extracts and the buffered, enteric-coated enzymes are most useful (Brady et al, 2006; Pezzilli, 2009).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Diagnosis of chronic pancreatic insufficiency is difficult in early stages; eventually, genetic testing may prove to be helpful. Hereditary pancreatitis involves a cationic trypsinogen gene (PRSS1) gene, where treatment involves attempting to inactivate that gene before it causes pancreatic insufficiency. CF patients will have the CFTR gene that is associated with pancreatic insufficiency.

<b>Clinical/History</b>	Abdominal bloating	CRP
Height	Stool weight	Serum carotene
Weight	CT scan or MRI	FE 1
BMI	ERCP	Ca <sup>++</sup> , Mg <sup>++</sup>
Weight loss?		Trig, Chol
Malabsorption		PT or INR
Steatorrhea	<b>Lab Work</b>	Bicarbonate
Diet history	Amylase	Gluc
I & O	(increased)	Na <sup>+</sup> , K <sup>+</sup>
Pale, bulky stools	Lipase	Alk phos
	Trypsinogen	H & H

#### INTERVENTION

#### OBJECTIVES

- Maintain or achieve BMI >19.
- Correct fatty acid abnormalities, maldigestion, diarrhea, and steatorrhea. Prevent EFA deficiency.
- Provide adequate energy intake while lowering intake of fats.
- Provide fat-soluble vitamins A-D-E-K and zinc with malabsorption. Prevent overload of iron.
- Attenuate intestinal inflammation (Pezzilli, 2009). Prevent or manage type 2 diabetes.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Malnutrition

**Assessment Data:** Dietary intake records; weight loss; steatorrhea; pale, bulky, foul stools.

**Nutrition Diagnosis (PES):** Malnutrition related to inability to digest nutrients as evidenced by steatorrhea and unintentional weight loss.

**Intervention:** Food and Nutrient Delivery—provide high kilocalories, high protein foods with low fat content. Include adequate pancreatic enzymes with every meal. Educate about the role of the pancreas in nutrient absorption. Counsel about ways to enjoy meals that are low fat while nutrient dense. Discuss the need for water-miscible forms of vitamins A, D E, and K if needed.

**Monitoring and Evaluation:** Track food intake (food diary or history). Evaluate for signs of malnutrition. Review lab test results. Monitor for improvement in weight, decrease in steatorrhea and pale, bulky stools.

## FOOD AND NUTRITION

- Encourage high-calorie, high-protein intake to maintain body weight. Dose pancreatic enzyme replacement adequately to minimize fat malabsorption.
- Use MCTs since they do not require lipase. They may be taken with simple sugars, jelly, jams and in mixed dishes.
- Increase use of omega-3 fatty acids from tuna, mackerel, salmon, and other fatty fish, as well as flaxseed. Probiotics may be considered.
- If diabetes is present, emphasize regular mealtimes and carbohydrate spacing to prevent hyperglycemia.
- Use tender meats and low-fiber fruits and vegetables.
- Alcoholic beverages are prohibited.
- Tube feed in severe cases of malnutrition. Night feeding may be a reasonable option.

## Common Drugs Used and Potential Side Effects

- Pancreatic extract preparations contain pancreatin and pancrelipase; both contain principally amylase, protease, and lipase. Pancreatic enzymes (Cotazym, Creon) should be taken with food. Take enteric-coated tablets with cimetidine or antacids. Administration of lipase 25,000–40,000 units/meal is given by using pH-sensitive pancrelipase microspheres, along with dosage increases and compliance checks (Ferrone et al, 2007).
- Fat-soluble vitamins should be taken in water-miscible form, with the pancreatic enzymes.

## Herbs, Botanicals, and Supplements

- New approaches may include the use of probiotics to reduce inflammation (Pezzilli, 2009).

- Lipase enzymes derived from microbial species show promise; plant-based enzymes, such as bromelain from pineapple, also serve as effective digestive aids in the breakdown of proteins (Roxas, 2008).
- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Instruct patient in the role of the pancreas in digestion.
- Discuss how pancreatic enzymes should be taken with meals or afterward for best results.
- Discuss appropriate measures for recovery and control.
- Share menu planning tips for a high protein, low fat diet and how to include desired nutrients.

## Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# PANCREATIC TRANSPLANTATION

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

Pancreatic islet cell transplantation is a treatment alternative for patients with type 1 diabetes who experience hypoglycemic unawareness despite maximal care (Onaca et al, 2007). Islet transplant can restore pancreatic endocrine function, endogenous insulin secretion, and insulin independence in more than 80% of patients, and recover the metabolism of glucose, protein, and lipids (Bertuzzi et al, 2006). It helps to decrease nephropathy, early or mild retinopathy, and neuropathy.

Pancreas transplantation alone (PTA) involves transplanting a pancreas from a cadaver to a patient whose kidneys have not been damaged by diabetes. Simultaneous pancreas and kidney (SPK) transplantation involves kidney and pancreas being transplanted at the same time from a cadaver, often leading to freedom from both dialysis and insulin dependency. Pancreas after kidney (PAK) surgery is another option, as is islet cell or isolated beta-cell transplantation. Pancreatic islet cells are highly sensitive to hypoxia, which contributes to poor islet yield, inflammatory events, and cellular death during the early posttransplantation period (Lau et al, 2009). Pancreatic transplantation is major surgery, with risk of bleeding, infection, and reactions to anesthesia. Antirejection medicines, which have many side effects, have to be taken for a long time.

Whole pancreas transplantation is associated with a significant risk of surgical and postoperative complications (Meloche, 2007). Islet cell transplantation has fewer side effects but does not yield an ideal level of glucose control. Persistent graft function results in improved glucose control and avoidance of hypoglycemic events (Onaca et al, 2007). Improved control of glycated HbA1c, reduced risk of recurrent hypoglycemia and of diabetic complications are benefits of islet cell transplantation, irrespective of the status of insulin independence (Bertuzzi et al, 2006).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Pancreatic transplantation is needed for type 1 diabetes, which has a genetic origin (American Diabetes Association, 2009).

Clinical/History	I & O	H & H
Height	BP	Serum Fe
Weight, dry	Temperature	Serum amylase
BMI		Urinary amylase
Diet history	<b>Lab Work</b>	(only if bladder drained)
Weight changes and goals	Gluc	Na <sup>+</sup> , K <sup>+</sup>
	BUN, Creat	Ca <sup>++</sup> , Mg <sup>++</sup>

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Oral Food and Beverage Intake

**Assessment Data:** Dietary intake records pretransplantation indicate poor oral intake of both food and beverages; status post-transplant, 21 days on enteral nutrition; wishes to try some liquids and soft foods.

**Nutrition Diagnosis (PES):** Inadequate oral food and beverage related to inability to be fed orally posttransplant as evidenced by 14 days on EN and now asking to attempt oral intake.

**Intervention:** Food and Nutrient Delivery—offer one to two small items at mealtimes or every few hours while awake; gradually increase food intake as tolerated. Educate about the role of nutrition in liver health and recovery; discuss ways to progress orally and wean from enteral nutrition.

**Monitoring and Evaluation:** Improved oral appetite. No nausea or unplanned side effects after surgery. Gradual return of usual weight and tolerance of oral intake closer to desired level.

### INTERVENTION

### OBJECTIVES

- **Preoperatively:** Meet nutritional needs; improve visceral protein stores; maintain lean tissue. Nutritional management of candidates requires management of renal function, and treatment of obesity in advance as a BMI >27 kg/m<sup>2</sup> may delay wound healing.
- **Postoperatively:** Support graft survival. Promote wound healing. Improve or maintain nutritional status.
- **Long Term:** Weaned off CPN within the first year to achieve optimal nutritional status. Prevent weight gain. Prevent complications such as gastroparesis, hypertension, hyperlipidemia, hyperglycemia, and osteoporosis. Attain near-normal blood glucose control and normal hemoglobin A1c levels without risks of severe hypoglycemia (Meloche, 2007).

### FOOD AND NUTRITION

- **Preoperatively:** Meet nutritional needs; improve visceral protein stores; maintain lean tissue.
- **Postoperatively:** Control carbohydrates if there is diabetes or hyperglycemia. Manage diet carefully to prevent hypoglycemia in patients who take insulin.

### Common Drugs Used and Potential Side Effects

- See Table 8-15.

**TABLE 8-15 Medications Used after Pancreatic Transplantation**

Medication	Description
Analgesics	Analgesics are used to reduce pain. Long-term use may affect such nutrients as vitamin C and folacin; monitor carefully for each specific medication.
Azathioprine (Imuran)	Azathioprine may cause leukopenia, thrombocytopenia, oral and esophageal sores, macrocytic anemia, pancreatitis, vomiting, diarrhea, and other complex side effects. Folate supplementation and other dietary modifications (liquid or soft diet, use of oral supplements) may be needed. The drug works by lowering the number of T cells; it is often prescribed along with prednisone for conventional immunosuppression.
Corticosteroids (prednisone or Solu-Cortef)	Corticosteroids such as prednisone and Solu-Cortef are used for immunosuppression. Side effects include increased catabolism of proteins, negative nitrogen balance, hyperphagia, ulcers, decreased glucose tolerance, sodium retention, fluid retention, and impaired calcium absorption and osteoporosis. Cushing's syndrome, obesity, muscle wasting, and increased gastric secretion may result. A higher protein intake and lower intake of carbohydrate and sodium may be needed.
Cyclosporine	Cyclosporine does not retain sodium as much as corticosteroids do. Intravenous doses are more effective than oral doses. Nausea, vomiting, and diarrhea are common side effects. Hyperlipidemia, hyperglycemia, and hyperkalemia may also occur; decrease fat intake as well as sodium and potassium if necessary. Magnesium may need to be replaced. The drug is also nephrotoxic; a controlled renal diet may be beneficial. Taking omega-3 fatty acids during cyclosporine therapy may reduce toxic side effects (such as high blood pressure and kidney damage) associated with this medication in transplantation patients (Tsipas and Morphake, 2003). Avoid use with St. John's wort.
Diuretics	Diuretics such as furosemide (Lasix) may cause hypokalemia. Aldactone actually spares potassium; monitor drug changes closely. In general, avoid use with fenugreek, yohimbe, and ginkgo.
Immunosuppressants	Immunosuppressants such as muromonab (Orthoclone OKT3) and antithymocyte globulin (ATG) are less nephrotoxic than cyclosporine but can cause nausea, anorexia, diarrhea, and vomiting. Monitor carefully. Fever and stomatitis also may occur; alter diet as needed.
Insulin	Insulin may be necessary during periods of hyperglycemia. Monitor for hypoglycemic symptoms during use; teach patient self-management tips.
Pancreatic Enzymes	Pancreatic enzymes may be needed if pancreatitis occurs again after transplantation.
Tacrolimus (Prograf, FK506)	Tacrolimus suppresses T-cell immunity; it is 100 times more potent than cyclosporine, thus requiring smaller doses. Side effects include GI distress, nausea, vomiting, hyperkalemia, and hyperglycemia; adjust diet accordingly by controlling carbohydrate and enhancing potassium intake.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- St. John's wort interferes with the metabolism of cyclosporine and should not be used after transplantation.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Encourage activity to prevent excessive weight gain; 14–30 lb may be a common gain.
- Discuss surgical stress. Encourage positive protein balance to promote anabolism and wound healing.
- Over the long term, follow a low-cholesterol and low-saturated fatty acid dietary plan.
- Sudden abdominal pain, fever, and increased amylase and glucose can occur and are signs of pancreatitis even after transplantation. Report these warning signs immediately to the physician.
- Problems after transplantation include diabetic complications, bone loss, and failure of the pancreas graft. A

multidisciplinary team is required to maximize long-term quality of life.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# ZOLLINGER–ELLISON SYNDROME

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Asset provided by Anatomical Chart Co.

## DEFINITIONS AND BACKGROUND

Zollinger–Ellison syndrome (ZES) is a severe disease with ulceratogenic tumor (gastrinoma) of the delta-cells of the pancreatic islets of Langerhans; the cells produce gastrin. Almost every patient with ZES has marked gastric acid hypersecretion and ulcerations in the esophagus, stomach, duodenum, and jejunum. It is more common among 30- to 50-year-old men. ZES occurs in less than 1% of all patients with duodenal ulcers.

Gastrinomas producing ZES are the most frequent symptomatic, malignant pancreatic endocrine tumors (Gibril and Jensen, 2005). They frequently are accompanied by secretory diarrhea. Interestingly, insulin production is often increased in the beta-cells. Of all cases, 60% occur in males; two thirds of cases are malignant. Widespread metastasis indicates a poor prognosis.

Gastric carcinoid tumors in patients with longstanding ZES may be symptomatic and aggressive and may metastasize to the liver; they require long-term medical treatment. Curing gastrinoma or appropriately inhibiting gastric acid

hypersecretion in ZES patients prevents death and favors long-term survival (Quatrini et al, 2005).

Resection of localized gastrinomas often does not require extended surgical resection and is associated with excellent long-term outcomes (Mortellaro et al, 2009). Total gastrectomy is reserved for patients with extensive tumor involvement of the gastric wall or for patients with emergency bleeding.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** The disease is more common in people who have an inherited condition called multiple endocrine neoplasia type 1 (MEN1). Evaluate for family history of hyperparathyroidism, nephrolithiasis, or gastrinoma.

### Clinical/History

Height  
Weight  
BMI  
Weight loss?  
Diet history  
I & O  
Burning abdominal pain  
Nausea, vomiting  
Severe esophageal reflux

### Heartburn

Diarrhea or malabsorption  
BP  
Negative *H. pylori* testing  
Upper GI endoscopy  
Somatostatin receptor scintigraphy (SRS)  
Gastrin radioimmunoassay  
CT Scan

### Lab Work

N balance  
 $\text{Na}^+$   
 $\text{Ca}^{++}$  (usually increased)  
Alb  
H & H  
 $\text{K}^+$  (decreased)  
 $\text{Mg}^{++}$   
BUN  
Serum insulin  
Serum gastrin  
Trig, Chol  
Gluc

## INTERVENTION

## OBJECTIVES

- Relieve stomach acid to lessen ulcer symptoms, usually with medications. Surgery may be needed to remove tumors.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Abnormal GI Function

**Assessment Data:** Dietary intake records, diarrhea, steatorrhea, weight loss, nausea and vomiting.

**Nutrition Diagnosis (PES):** Abnormal GI function related to excessive gastrin production as evidenced by gastrinoma with weight loss, nausea & vomiting, diarrhea and steatorrhea.

**Intervention:** Food and Nutrient Delivery—provide easily tolerated foods, low acid.

**Monitoring and Evaluation:** Track food intake (food diary or history).

- Overcome malabsorption and lessen diarrhea.
- Decrease problems with dysphagia and reflux.
- Prevent complications such as esophageal stricture or abdominal perforation.
- Manage or reduce cancer, which can occur in 25% of cases.

## FOOD AND NUTRITION

- Modify fiber, seasonings, and textures as necessary. Decrease intake of acidic foods if not tolerated (such as citrus juices, tomato products).
- Alter feeding modality to TF such as jejunostomy placement as needed.

## Common Drugs Used and Potential Side Effects

- PPIs are used for the treatment of acid-related disorders. Use of these medications can prevent the need for surgery (Hirschowitz et al, 2005). Take omeprazole (Prilosec), esomeprazole (Nexium), lansoprazole (Prevacid), or pantoprazole (Protonix) before meals. Iron and vitamin B<sub>12</sub> levels may become depleted. Rabeprazole (Acifex) has been tested and has fewer side effects than some other PPIs (Baldwin and Keam, 2009).
- Chemotherapy may be needed if surgery to remove the tumors is not feasible. Streptozotocin (Zanosar),

5-fluorouracil (Adrucil) or doxorubicin (Doxil) may be used. Monitor for side effects.

- Octreotide or interferon may also be used.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain which modifications of fiber in the diet are appropriate.
- Explain how malabsorption compromises nutritional status. Discuss limiting fat intake, as appropriate for the patient.
- Lower acid foods may be better tolerated; discuss ways to adjust recipes or good choices.

## Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## For More Information

- **NIDDK**  
<http://digestive.niddk.nih.gov/ddiseases/pubs/zollinger/>

## BILIARY DISORDERS

## BILIARY CIRRHOSIS

## NUTRITIONAL ACUITY RANKING: LEVEL 2

## DEFINITIONS AND BACKGROUND

**Biliary cirrhosis**, also called cholangiolitic hepatitis or obstructive jaundice, occurs in two to five cases per 100,000 worldwide. Symptoms include pruritus, jaundice, and portal

hypertension. Biliary atresia is the result of an inflammatory process that affects the intrahepatic and extrahepatic bile ducts, leading to fibrosis and obliteration of the biliary tract with development of biliary cirrhosis in infants (Tang et al, 2005).

**Primary biliary cirrhosis (PBC)** is characterized by progressive destruction of intrahepatic bile ducts; it primarily affects middle-aged women. Autoimmune factors may trigger the disease in genetically susceptible hosts; genetic susceptibility is a predisposing factor. Environmental factors (infection, chemicals, smoking) may also be relevant. Environmental xenobiotics may aggravate genetic weaknesses in mechanisms of immune regulation, and subsequent immunopathology (Gershwin and Mackay, 2008). PBC that is associated with other autoimmune diseases such as Sjögren's syndrome, scleroderma, Raynaud's phenomenon, or CREST syndrome is regarded as an organ-specific autoimmune disease. Osteoporosis is prevalent in this population (Guanabens et al, 2005) and celiac disease is also commonly found (Duggan and Duggan, 2005).

Homocysteine has been proposed to be involved (Ebrahimkhani et al, 2005). In symptomatic patients, advanced age, elevated serum bilirubin levels, and decreased serum albumin levels lead to shortened survival. PBC slowly progresses and may lead to liver failure where transplantation is the only effective therapy.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** There is a role for HLA to determine PBC susceptibility (Invernizzi et al, 2008). Vitamin D receptor polymorphisms are also being studied.

Clinical/History	Lab Work	
Height	Antimitochondrial antibodies (AMA)	Transferrin
Weight		Tissue transglutaminase (for celiac disease)
BMI	Bilirubin (increased)	Globulin
Diet history	Alk phos (increased)	Gluc
Jaundice	ALT/AST	Ca <sup>++</sup> , Mg <sup>++</sup>
Portal hypertension?	Alb, transthyretin	Na <sup>+</sup> , K <sup>+</sup>
Pruritus	PT (decreased)	Chol (increased)
Xanthomas	Serum homocysteine	Ceruloplasmin
Cholangiography		
Liver biopsy		

## INTERVENTION

### OBJECTIVES

- Correct diarrhea, steatorrhea, malnutrition, and osteomalacia. Prevention of bone density loss is important, as vitamin D deficiency is common.
- Limit or control symptoms. Prevent progression to end-stage liver disease when possible.
- Prevent or correct zinc and vitamin deficiencies.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Altered Nutrition-Related Labs

**Assessment Data:** Dx biliary cirrhosis with presence of AMA, elevated bilirubin and alk phos.

**Nutrition Diagnosis (PES):** Altered nutrition-related labs related to biliary cirrhosis with cholestasis as evidenced by AMA, elevated bilirubin and alk phos levels.

**Intervention:** Food and nutrient delivery—use antioxidant-rich foods, supplement with fat-soluble vitamins.

**Monitoring and Evaluation:** Track lab values.

- Manage related disorders (such as Sjögren's syndrome or celiac disease).

## FOOD AND NUTRITION

- Increase vitamin D and calcium intake to protect against osteopenia. Vitamin K may also play an important role in protection of bone health and may be supplemented (Plaza and Lamson, 2005). Use water-miscible sources of vitamins A, D, E, and K with steatorrhea.
- Reduce cholesterol and saturated fats in hypercholesterolemia.
- Ensure adequate intake of zinc from diet.
- To lower elevated homocysteine levels, which seem to aggravate hepatic fibrogenesis, be sure the diet contains adequate amounts of folic acid and vitamins B<sub>6</sub> and B<sub>12</sub> (Ebrahimkhani et al, 2005).
- If the patient also has celiac disease, omit gluten from the diet (e.g., wheat, rye, barley). Initiation of a gluten-free diet may help to resolve iron deficiency anemia, pruritus, and elevated serum liver biochemistries.
- Control carbohydrate intake with hyperglycemia.

## Common Drugs Used and Potential Side Effects

- Prolonged administration of ursodeoxycholic acid (UDCA) in patients with PBC is associated with survival benefit and delay of LT. Ursodeoxycholic acid (UDCA) is the only currently known medication that can slow the disease progression. When UDCA is ineffective, cholestyramine is the treatment of choice; it decreases bile acids but can cause belching or constipation.
- Budesonide is a glucocorticoid that may help when given with UDCA to improve liver status (Rautiainen et al, 2005). Weight gain and increased appetite often result.
- Bezafibrate, a hypolipidemic drug, has been shown to benefit patients with PBC in some studies (Akbar et al, 2005).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- High doses of vitamin E (tocopherol) will elevate transaminases.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of bile salts in fat and fat-soluble vitamin absorption. If supplements are used, water-miscible forms may be needed.
- Protection of bone mineral density will be important. Discuss the role of medications, calcium, and vitamin D on bone health (Plaza and Lamson, 2005).

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# CHOLESTASIS

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

### DEFINITIONS AND BACKGROUND

**Cholestasis** involves reduced bile flow in any liver disease with bilirubin over 2.0 mg/dL. Disturbance of the flow of bile leads to intracellular retention of biliary constituents. Hepatic causes of cholestasis include viral hepatitis, ALD, hemochromatosis, and autoimmune hepatitis. Biliary causes include primary sclerosing cholangitis (in which the intrahepatic and/or extrahepatic bile ducts undergo inflammation and fibrosis), choledocholithiasis, PBC, and biliary atresia. It can also occur with inflammatory bowel disease (Huang and Lichtenstein, 2005). Prolonged PN may be needed in the absence of GI tract stimulation.

Cholestasis interferes with excretion of the bile salts required for emulsification and absorption of dietary fat. Reduced bile secretion impairs micelle formation, which is needed for digestion of fat by pancreatic enzymes. Vitamin and mineral deficiencies and alterations are common, especially if cholestasis is significant. Zinc, magnesium, and calcium may be deficient because they are albumin-bound and the liver is not working properly. Deficiency of fat-soluble vitamins A, D, E, and K may occur. Of particular concern is vitamin E, which circulates in the blood almost exclusively attached to the lipoprotein fractions.

In chronic cholestasis with biliary obstruction, hyperlipidemia and accumulation of copper result, and manganese can accumulate in the brain; avoid overfeeding with copper

or manganese. Hepatic copper overload in CPN patients occurs through chronic cholestasis in CPN-associated liver disease regardless of duration (Blaszcyk et al, 2005).

Chronic CPN may induce fatty liver and inflammation, especially in patients with short bowel syndrome. Deficiency of choline in parenteral solutions has been proposed as the mechanism for liver disease. With CPN, cholestatic jaundice may occur from a lack of enteral nutrition and failure of biliary stimulation. In patients receiving home PN, prevalence of liver disease increases with duration.

Signs and symptoms of cholestasis can include glossitis from B-complex vitamin deficiency, protein and iron deficiency, hemorrhagic tendencies due to vitamin C or K inadequacy, and flatulence. Patients with steatorrhea may benefit from a low-fat diet or from use of MCTs. Intrahepatic cholestatic syndromes cause a decrease in bile flow with no overt bile duct obstruction; bile constituents accumulate in the liver and blood.

Ursodeoxycholic acid and adequate nutritional support are the usual treatments, with LT being performed in severe cases only (Huang and Lichtenstein, 2005). Depending on the cause (such as medication effects, postoperative jaundice, sepsis, CPN, or acalculous cholecystitis), treatment includes removal of offending drugs, supportive care, broad-spectrum antibiotic agents with drainage of infected fluids, CPN adjustment including cycling and limiting carbohydrates, and cholecystectomy.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Because ATP-binding cassette (ABC) transporters are important for normal bile secretion, hereditary and acquired ABC transporter defects play a central role in the pathogenesis of cholestasis (Trauner et al, 2007).

<b>Clinical/History</b>	Nausea	Serum carotene
Height	Flatulence	(increased or decreased)
Weight		
BMI	<b>Lab Work</b>	Bun, Creat
Diet history	Chol, Trig	H & H
Ascites	(increased)	Serum Fe
Edema	PT (prolonged)	Alb,
I & O	AST, ALT	transthyretin
Jaundice	(increased)	Globulin
Pale stools	Bilirubin	Amylase, lipase
Fatty yellow	(increased,	Serum
deposits in	>2 mg/dL)	manganese
skins	Somatomedin C	Serum zinc
Eas bleeding	Alk phos	Na <sup>+</sup> , K <sup>+</sup>
Small, spider-	(increased)	Ca <sup>++</sup> , Mg <sup>++</sup>
like blood	Gamma-	
vessels visible	glutamyl	
on skin	transpeptidase	
	(very high)	

## INTERVENTION

### OBJECTIVES

- Promote return of normal liver function and bile flow.
- Treat fat malabsorption and deficiency of any additional nutrients.
- Correct steatorrhea, GI bleeding, and copper overload when present.
- Prevent or correct for liver failure, osteomalacia, or osteoporosis.
- Correct nutrient excesses (e.g., manganese).
- Prepare for surgery when indicated.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive CPN Infusion

**Assessment Data:** Intake records indicating CPN solution exceeding estimated kilocalories requirements.

**Nutrition Diagnosis (PES):** Excessive CPN solution related to exceeding calculated needs as evidenced by cholestasis.

**Intervention:** Food and Nutrient Delivery—change CPN solution to meet and not exceed kilocalories needs.

**Monitoring and Evaluation:** Track CPN intake according to estimated needs; evaluate labs, weight, liver function.

## FOOD AND NUTRITION

- In chronic cases, 10–20% added kilocalories may be needed. Infants need more kilocalories, and adults tend to use CHO poorly. In acute stages, use IV glucose to prevent hypoglycemia and protein catabolism.
- In acute stages, infants will need 1.0–1.5 g/kg protein. Children, teens, and adults need 0.5–1.2 g protein/kg; highlight BCAAs sources. In chronic cases, use 3 g protein/d for infants and 1–1.5 g protein/kg in adults.
- Supplement with vitamins and minerals, especially fat-soluble vitamins. Vitamin D and calcium will be needed if osteopenia is present. Zinc and selenium may be needed.
- Small, frequent feedings and snacks may be better tolerated than large meals.
- Use enteral nutrition (where possible), if CPN has caused cholestasis. If CPN is required, early use of cyclic CPN may be useful. Avoid excesses of copper (Blaszcyk et al, 2005) in the solutions.

### Common Drugs Used and Potential Side Effects

- Ursodeoxycholic acid slows disease progression and should be used in relatively high doses as 20–30 mg/kg/d (Huang and Lichtenstein, 2005).
- Treat pruritus with bile acid-binding exchange resins such as cholestyramine or colestipol (Huang and Lichtenstein, 2005). Use with a low-fat diet and increase fluids and fiber. Constipation, nausea, or vomiting may be a side effect.
- Water-miscible forms of fat-soluble vitamins A, D, E, and K may be needed in cholestasis. Sample amounts of vitamin A may be given at 25,000–50,000 IU/d as Aquasol A; vitamin D may be given as 12,000–50,000 IU/d over a month; and vitamin E may be given as 10–25 IU/kg/d. Once nutrient stores are repleted and cholestasis is resolved, the supplementation can stop.
- Medications known to cause cholestasis include estrogens and anabolic steroids, chlorpromazine, erythromycin, and oxypenicillins.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician. Cholestatic liver injury may occur from some herbal remedies, such as greater celandine, glycyrrhizin, chaparral.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of fat in normal metabolic processes; simplify explanation in correlation to absorption of fat-soluble vitamins and other nutrients affected by the liver.
- Discuss ways to increase satiety from the diet with appetizing recipes.
- Discuss use of over-the-counter (OTC) vitamin and mineral supplements, especially regarding possible toxicity if taken in large doses with liver disease.

- LT works best in a well-nourished patient. Promote good tolerance and intake.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

## GALLBLADDER DISEASE

### NUTRITIONAL ACUITY RANKING: LEVEL 2

#### DEFINITIONS AND BACKGROUND

The **gallbladder**, located under the liver, collects and stores bile, which is made up of bile salts, electrolytes, bilirubin, cholesterol, and other fats. Bile helps the small intestine digest fats and remove waste products, especially through bilirubin. It passes from the liver's bile duct into the duodenum through the common bile duct. Bile contains 85–95% water; electrolytes (sodium, potassium, chloride, bicarbonate, calcium, magnesium); bile acids and bilirubin; lecithin, cholesterol and protein. Loss of bile can cause malabsorption and maldigestion of fat, electrolyte imbalances, and poor excretion of drugs or heavy metals.

**Cholelithiasis** is defined as the presence of gallstones. In developed countries, at least 10% of white adults harbor cholesterol gallstones, especially after age 65. Women have twice the risk (Shaffer, 2005). There is also prevalence among persons who have hepatitis C, diabetes, obesity, pregnancy, use of estrogens, insulin, oral contraceptives, cholestyramine (Bini and McGready, 2005; Ko et al, 2005). The western diet that is high in kilocalories, fat, and refined carbohydrate is also a factor. Being Hispanic or Native American predisposes to gallbladder disease, as does sickle cell anemia and some other genetic traits.

Gallstones are a hepatobiliary disorder due to biochemical imbalances in the gallbladder bile (Uppal et al, 2008). Some gallbladders can concentrate bile normally but cannot acidify it. The result is that calcium may be less soluble in bile and precipitates out. Increasing consumption of magnesium ( $Mg^{++}$ ) appears to decrease the risk of symptomatic gallstones in men (Ko, 2008). Magnesium deficiency can cause dyslipidemia and insulin hypersecretion, which may facilitate gallstone formation (Tsai et al, 2008).

Gallstones contain primarily cholesterol, bilirubin, and calcium salts, formed into either cholesterol or pigment stones. Symptoms include steady pain in the upper abdomen that increases rapidly and lasts from 30 minutes to several hours, pain in the back between the shoulder blades or under the right shoulder, nausea, vomiting, abdominal bloating, intolerance for fatty foods, belching, and indigestion.

Gallstones also form if the gallbladder does not contract completely or often enough to empty bile; this can also

occur after eating too little, after periods of starvation, or fasting. Rapid weight loss or crash dieting is to be avoided. Preventive measures include a controlled weight loss rate, reduction of the length of overnight fast, inclusion of a small amount of fat in the diet, and eating foods rich in magnesium (nuts, vegetable protein, beans, and soy).

**Cholecystitis** is inflammation of the gallbladder. Rather than a single clinical entity, cholecystitis is a class of related disease states with different causes, degrees of severity, clinical courses, and management strategies. Gallstones with low-grade inflammation, scarring, and thickening are common triggers. If the gallbladder is removed, fat absorption still occurs, but it is less efficient because bile is not as concentrated.

Endoscopic stent placement in the gallbladder is effective for patients with gallbladder disease who are poor surgical candidates (Conway et al, 2005). However, surgery is needed for most cases. There are over 700,000 cholecystectomies performed annually in the United States alone (Shaffer, 2005).

Laparoscopic cholecystectomy (LC) reduces the length of hospital stay and can be performed on patients who are morbidly obese (Simopoulos et al, 2005). Extracorporeal shock wave lithotripsy (ESWL) is also effective.

**Gallbladder cancer** is not common but is more prevalent in women who have had gallstones for many years. Jaundice, pain above the stomach, lumps in the abdomen, and fever should be addressed. Gallbladder cancer is usually associated with late diagnosis, unsatisfactory treatment, and poor prognosis.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Alagille syndrome is a genetic disorder with mutations in the JAG1 and NOTCH2 genes where there are too few bile ducts to function properly;

this occurs in one in 70,000 people. Activation of nuclear receptor liver X receptor (LXR) sensitizes mice to lithogenic diet-induced gallbladder cholesterol crystallization; studies are needed in humans (Uppal et al, 2008).

Clinical/History	Magnetic	Lab Work
Height	resonance	Mg <sup>++</sup> (low?)
Weight	cholangiography (MRC)	Alk phos (ALP),
BMI	Hepatobiliary	elevated?
Diet history	iminodiacetic	Bilirubin
Intolerance for fatty foods?	acid (HIDA) scan	(increased)
WBC	(cholescintigraphy)	AST, ALT
Jaundice	Endoscopic	(elevated?)
Nausea, vomiting	retrograde	Amylase, Lipase
I & O	cholangiopan	(increased?)
Temperature	creatography (ERCP)	Alb,
CT scan or endoscopic ultrasound	Cholecoscopy	transthyretin
		Chol
		Trig (elevated?)
		H & H
		Na <sup>+</sup> , K <sup>+</sup>
		Ca <sup>++</sup>

## INTERVENTION

### OBJECTIVES

- Lose excess weight, if needed but avoid fasting for rapid weight loss, which can lead to gallstones.
- Limit foods that cause pain or flatulence.
- For the patient with cholelithiasis, overcome fat malabsorption caused by obstruction and prevent stagnation in a sluggish gallbladder. Decreased bile secretion, bile stasis, bacteria, hormones, or fungi may be a problem;

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Fat Intake

**Assessment Data:** Dietary intake records indicating intake of fried foods at most every meal; dining at fast food restaurants six to seven times weekly; abdominal and back pain, nausea, vomiting for 3 days.

**Nutrition Diagnosis (PES):** Excessive fat intake related to extensive use of fried foods and fast food choices as evidenced by diet history and signs of cholecystitis.

**Intervention:** Food and Nutrient Delivery—offer lower fat meals; prep for surgery. Educate about the role of the gallbladder in fat metabolism. Counsel about postsurgical diet (low fat, frequent small meals perhaps better tolerated) and gradual return to a general diet that contains more nutrient-dense and lower fat options. Discuss the role of minerals such as magnesium in maintaining GB health.

**Monitoring and Evaluation:** Track food intake (food diary or history). Evaluate for resolution of abdominal pain, nausea and vomiting after surgery; tolerance for diet and use of foods that are more nutrient-dense and lower in fat.

bacterial overgrowth alters bile acids so that they can no longer emulsify fats.

- Prevent biliary obstruction, cancer, or pancreatitis.
- Provide fat-soluble vitamins (ADEK) with signs of steatorrhea.
- Include a high magnesium food source daily.
- Ascorbic acid affects the catabolism of cholesterol to bile acids and the development of gallbladder disease; supplement the diet if needed.

## FOOD AND NUTRITION

- In **acute cholecystitis**, NPO or a low-fat diet may be needed. Progress to a diet with fewer condiments and gas-forming vegetables, which cause distention, increased peristalsis, and irritation.
- In **chronic cholecystitis**, use a fat/calorie-controlled diet to promote drainage of the gallbladder without excessive pain. Patient should consume adequate amounts of CHO, especially pectin, which binds excess bile acids.
- In **cholelithiasis**, encourage a diet that is high fiber, low in calories (as needed).
- Assure an adequate dietary intake of magnesium from nuts, bran, halibut, pollack, spinach, black or lima or white beans.
- Fat-soluble vitamins A-D-E-K may need to in water-miscible form.
- Increase dietary intake of sources of vitamin C such as citrus fruits and juices. Use supplemental forms if needed.

## Common Drugs Used and Potential Side Effects

- Ursodiol (Actigall, Urso) is made from bile acid help dissolve small cholesterol gallstones over months or years. Take with food or milk. Ursodiol can lead to metallic taste, abdominal pain, mild diarrhea, or vomiting.
- The potent cholesterol absorption inhibitor ezetimibe reduces biliary cholesterol content and may be a promising strategy for preventing or treating cholesterol gallstones (Wang et al, 2008).
- Ursodeoxycholic acid decreases cholesterol saturation of bile and gallstone incidence during weight loss and may help to prevent gallstone formation. Orlistat is another option.
- Antibiotics may be used to counteract infection. Evaluate the need to take with food, milk or other liquids.
- If analgesics (Demerol, meperidine) are used to relieve pain, side effects such as nausea, vomiting, constipation, and GI distress can occur.
- Oral contraceptives and estrogens increase the risk of gallstones, especially after prolonged use. Orlistat has also been shown to cause gallstones for some patients. Thiazide diuretics have also been linked with gallstones (Leitzmann et al, 2005).

## Herbs, Botanicals, and Supplements

- Herbal medicine such as turmeric and oregon grape may reduce gallbladder inflammation and relieve liver congestion.

- Herbs and botanical supplements should not be used without discussing with physician. Celandine, peppermint, couch grass, and goldenrod have been recommended for gallbladder disease, but no clinical trials have proven efficacy at this time.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- After a cholecystectomy, fat intake should be limited for several months to allow the liver to compensate for the gallbladder's absence. Fats should be introduced gradually; excessive amounts at one meal should be avoided. Use more unrefined carbohydrates as well.
- If diarrhea persists after surgery, try using antidiarrheal medications, such as loperamide (Imodium) and a high-fiber diet for more bulk.
- Avoid fasting and rapid weight loss schemes.
- People who have had their gallbladders removed should have their cholesterol levels checked periodically. To prevent new gallstones from forming, maintain a healthy weight.

### Patient Education—Foodborne Illness

- If home TF is needed, teach appropriate sanitation and food-handling procedures.

# Endocrine Disorders

## CHIEF ASSESSMENT FACTORS

### Warning Signs of Type 1 Diabetes

- Drowsiness, Lethargy, Blurred Vision
- Extreme Thirst
- Frequent Urination
- Fruity, Sweet, Wine-Like Odor on Breath
- Glucose or Ketones in Urine
- Heavy, Labored Breathing
- Increased Appetite
- Sudden Weight Loss
- Stupor, Unconsciousness

### Risk Factors for Type 2 Diabetes

- Age  $\geq 45$  Years
- Ethnicity—African American, Hispanic American, Native American, Asian American, Pacific Islander
- Family History (Parents or Siblings with DM)
- Habitually Sedentary
- High-Density Lipoprotein Cholesterol Level  $\leq 35$  mg/dL and Triglyceride Level  $\geq 250$  mg/dL
- History of Gestational Diabetes Mellitus (GDM) or Women Delivering Babies Weighing  $> 9$  lb
- History of Impaired Fasting Glucose (IFG) or Impaired Glucose Tolerance (IGT)
- Hypertension (Blood Pressure  $\geq 140/90$  mm Hg)
- Obesity with Body Mass Index  $\geq 25$  kg/m<sup>2</sup>
- Polycystic ovarian syndrome, other conditions associated with insulin resistance
- Vascular disease

### Assessment in Diabetes

- Assessment for Mood Disorder
- Contraception; Reproductive and Sexual History
  - Current Treatment: Medications, Meal Plan, Results of Glucose Monitoring, Patients' Use of Data
  - Eating Patterns, Nutritional Status, and Weight History; Growth and Development in Children and Adolescents
    - Exercise History
    - Family History of Diabetes and Other Endocrine Disorders
    - Frequency, Severity, and Cause of Acute Complications Such as Ketoacidosis and Hypoglycemia

- History and Treatment of Other Conditions, Including Endocrine and Eating Disorders
- Infections: Skin, Foot, Dental, and Genitourinary Tract (Prior and Current)
- Laboratory Tests, Symptoms and Special Examination Results Related to the Diagnosis of Diabetes
- Lifestyle, Cultural, Psychosocial, Educational, and Economic Factors That Influence the Management of Diabetes
- Other Medications That May Affect Blood Glucose Levels
- Previous Treatment Programs (Nutrition and Diabetes Self-Management Education, Attitudes, and Health Beliefs)
- Prior HbA1c Records
- Risk Factors for Atherosclerosis: Smoking, Hypertension, Obesity, Dyslipidemia, and Family History
- Symptoms of Celiac Disease in Type 1 Diabetic Patients
- Symptoms and Treatment of Chronic Eye; Kidney; Nerve; Genitourinary (Including Sexual), Bladder, and Gastrointestinal Function; Heart; Peripheral Vascular; Foot; and Cerebrovascular Complications Associated with Diabetes
- Tobacco, Alcohol, and/or Controlled Substance Use

### Assessment in Other Endocrine Conditions

- Adult Changes in Size of Head, Hands, Feet
- Altered Consciousness; Numbness, Tingling, or Paresthesia
- Anorexia, Nausea, Abdominal Pain, Malabsorption, Gastroparesis
- Bone Pain
- Decreased Libido, Erectile Dysfunction
- Diagnosis of Thyroid Disease or Other Endocrine Disorder
- Dysuria
- Goiter; Exophthalmos; Intolerance to Heat or Cold
- Headache, Seizures, Syncope
- Hormone Imbalances (Excess or Deficiency)
- Hormone Therapy: Anabolic Hormones—Growth Hormones, Androgens, Sex Hormones; Catabolic Hormones—Stress Hormones (Causing Gluconeogenesis from Protein) Such as Catecholamines (Epinephrine, Norepinephrine), Glucocorticoids (Cortisone, Cortisol), or Glucagon
- Hyperglycemia, Hypoglycemia
- Postural Hypotension, Weakness
- Pruritus, Dryness of Skin or Hair
- Shortness of Breath, Hoarseness
- Weight Changes

## OVERVIEW OF DIABETES MELLITUS

LifeART image copyright © 2010. Lippincott Williams & Wilkins. All rights reserved.

Diabetes mellitus is a group of metabolic diseases characterized by hyperglycemia resulting from defects in insulin secretion, insulin action, or both. Hyperglycemia of diabetes is associated with long-term damage, dysfunction, and failure of various organs, especially the eyes, kidneys, nerves, heart, and blood vessels. Diabetes affects 24 million Americans; 54 million are estimated to have prediabetes, and over 200,000 individuals die each year of related complications (CDC, 2009; CMS, 2009).

Diabetes is divided into distinct types: type 1, type 2, gestational diabetes mellitus (GDM), and other types (see Table 9-1). Type 2 diabetes (T2DM), composing 90% of diabetes cases, is affected by both genetic and environmental factors. Types of diabetes affecting children and teens are listed in Table 9-2.

Adiposity-associated inflammation and insulin resistance are strongly implicated in the development of T2DM as well as the metabolic syndrome (Shah et al, 2008). Activation of nuclear transcription factor-B has been linked with a variety of inflammatory diseases, including diabetes. Antioxidant spices, herbs, and omega-3 fatty acids help to suppress inflammatory pathways.

Amino acids are also important; they support cell signaling, gene expression, and hormone synthesis. While physiological concentrations of amino acids and their metabolites (e.g., nitric oxide, polyamines, glutathione, taurine, thyroid hormones, and serotonin) are required, elevated levels of their products (e.g., ammonia, homocysteine, and asymmetric dimethylarginine) contribute to oxidative stress (Wu, 2009). Dietary supplementation with one or a mixture of arginine, cysteine, glutamine, leucine, proline, and tryptophan may be beneficial for ameliorating health problems including fetal growth restriction, neonatal morbidity and mortality, obesity, diabetes, cardiovascular disease (CVD), the metabolic syndrome, and infertility (Wu, 2009).

**Medical nutrition therapy (MNT)** replaced the term “diet therapy” years ago. There is no single “diabetic” or “ADA” diet. The recommended diet is an individualized nutrition prescription, based on assessment findings and treatment

**TABLE 9-1 Etiologic Classification of Diabetes Mellitus**

- I. Type 1 diabetes (results from auto-immune beta-cell destruction, usually leading to absolute insulin deficiency).
- II. Type 2 diabetes (results from a relative deficiency or insulin resistance).
- III. Other specific types of diabetes due to other causes, for example, genetic defects in beta-cell function, genetic defects in insulin action, diseases of the exocrine pancreas (such as cystic fibrosis), or drug- or chemical-induced diabetes (such as in the treatment of AIDS or after organ transplantation).
  - A. Genetic defects of beta-cell function: Maturity-onset diabetes of youth (MODY)
  - B. Genetic defects in insulin action: Leprechaunism, Rabson–Mendenhall syndrome, Lipodystrophic diabetes
  - C. Diseases of the exocrine pancreas: Pancreatitis, Trauma/pancreatectomy, Neoplasia, Cystic fibrosis, Hemochromatosis, Fibrocalculus pancreatopathy
  - D. Endocrinopathies: Acromegaly, Cushing's syndrome, Glucagonoma, Pheochromocytoma, Hyperthyroidism, Somatostatinoma, Aldosteronoma
  - E. Drug- or chemical-induced: Nicotinic acid, Glucocorticoids, Thyroid hormone, Beta-adrenergic agonists, Thiazides, Dilantin, Alpha-interferon
  - F. Infections: Congenital rubella, Cytomegalovirus
  - G. Other genetic syndromes sometimes associated with diabetes: Down's syndrome, Klinefelter's syndrome, Turner's syndrome, Friedreich's ataxia, Huntington's chorea, Myotonic dystrophy, Porphyria, Prader-Willi syndrome
- IV. Gestational diabetes mellitus (GDM) is diabetes first diagnosed during pregnancy.

Adapted from American Diabetes Association. Diagnosis and classification of diabetes mellitus. Web site accessed September 20, 2009, at [http://care.diabetesjournals.org/content/29/suppl\\_1/s43.full](http://care.diabetesjournals.org/content/29/suppl_1/s43.full); American Diabetes Association. Standards of Medical Care in Diabetes–2009.

goals. MNT considers usual eating habits and other lifestyle factors. Strategic patient counseling should identify benefits of the plan, self-efficacy, obstacles, and lifestyle changes the patient is willing to make; these interventions will help reach desired outcomes. Using open-ended discussion and counseling encourages the client to assess and determine a realistic self-management plan. MNT should be offered in phases, according to patient comprehension and readiness.

Screening for diabetes is outlined in Table 9-3. The nutrition care process include assessment, nutrition diagnosis, intervention, followed by monitoring and evaluation. Monitoring of blood glucose, medications, physical activity, education, behavior modification, and evaluation of cardiovascular and renal status are all relevant. In addition, prevention of complications is essential; see Table 9-4.

A diabetes educator is defined as a health professional who has mastered the core knowledge and skills, communication, counseling, and education. The credentials of certified diabetes educators (CDE) designate professionals who have at least 1000 hours of direct diabetes teaching and who have successfully completed an examination. An advanced credential has been developed for registered dietitians (RDs), nurses, and pharmacists who have advanced degrees and meet experiential requirements; this credential is known as BC-ADM.

**TABLE 9-2 Types of Diabetes in Children and Teens**

#### *Type 1 Diabetes (Immune-Mediated)*

- Usually not obese; often recent weight loss.
- Short duration of symptoms (thirst and frequent urination).
- Presence of ketones at diagnosis, with about 35% presenting with ketoacidosis.
- Often a honeymoon period after blood sugars are in control during which the need for insulin diminishes for awhile. Low dose of long-acting insulin, such as glargine (Lantus), may prolong the honeymoon phase.
- Ultimate complete destruction of the insulin-producing cells needing exogenous insulin for survival.
- Ongoing risk of ketoacidosis.
- Only about 5% with a family history (in first- or second-degree relatives) of diabetes.

#### *Type 2 Diabetes (Insulin-Resistant)*

- Usually overweight at diagnosis; little or no weight loss.
- Usually have sugar in the urine but no ketones.
- As many as 30% will have some ketones in the urine at diagnosis.
- About 5% will have ketoacidosis at diagnosis.
- Often little or no thirst and minimal increased urination.
- Strong family history of diabetes.
- 45–80% have at least one parent with diabetes.
- Diabetes may span many generations of family members.
- 74–100% have a first- or second-degree relative with diabetes.
- Typically from African, Hispanic, Asian, or American Indian origin.
- Disorders likely to cause insulin resistance are common.
- About 90% of children with type 2 diabetes have dark shiny patches on the skin (acanthosis nigricans), which are most often found between the fingers and between the toes, on the back of the neck (dirty neck), and in axillary creases.
- Polycystic ovarian syndrome (PCOS).

#### *Maturity-Onset Diabetes of the Young (MODY)*

- Rare form of diabetes; several varieties exist.
- Early age of onset (ages 9–25 years) with autosomal dominant inheritability.
- Results from defects to insulin-producing cells caused by a genetic defect in the pancreatic beta-cell function.
- Symptoms run the gamut from mild elevation in blood sugar to a severe disturbance.
- MODY can occur in all ethnic groups.
- Gene abnormalities are rare and can only be identified through testing that is currently available only in research laboratories.
- Not usually obese.
- Environmental stressors, such as illness or puberty, may unmask the genetically limited insulin secretory reserve of patients with undiagnosed MODY.
- Unlike type 1 diabetes, MODY does not cause polyuria, thirst, or extreme hunger. The primary goal is euglycemia.
- Fasting insulin and C-peptide levels are usually normal or elevated slightly.

Sources: American Diabetes Association, Web site accessed September 20, 2009, at <http://spectrum.diabetesjournals.org/content/18/4/249.full>; Children with Diabetes Web site accessed September 20, 2009, at <http://www.childrenwithdiabetes.com/clinic/mody.htm>

**TABLE 9-3 Evaluation for Diabetes**

Screen for prediabetes and diabetes in high-risk, asymptomatic, undiagnosed adults and children. An oral glucose tolerance test (OGTT) may be considered in patients with impaired fasting glucose (IFG) to better define the risk of diabetes. Testing for diabetes should be considered in all individuals at age 45 years and above, particularly in those with a BMI of 25 kg/m<sup>2</sup>, and if normal, testing should be repeated at 3-year intervals. The classic symptoms of diabetes include polyuria, polydipsia, and unexplained weight loss plus one of the following:

1. Symptoms of diabetes and a casual plasma glucose of 200 mg/dL. Casual is defined as any time of day without regard to time since last meal.
2. A fasting plasma glucose (FPG) test, a 2-hour OGTT (75-g glucose load), or both are appropriate. FPG  $\geq$ 126 mg/dL. Fasting is defined as no caloric intake for at least 8 hours.
3. Two-hour plasma glucose of 200 mg/dL during an OGTT. The test should be performed using a glucose load containing the equivalent of 75 g anhydrous glucose dissolved in water.

American Diabetes Association. Standards of Medical Care in Diabetes—2009. Web site accessed September 22, 2009, at [http://care.diabetesjournals.org/content/32/Supplement\\_1/S13.full](http://care.diabetesjournals.org/content/32/Supplement_1/S13.full)

**TABLE 9-4 Potential Complications of Diabetes****ACUTE**

<b>Hyperglycemia</b>	Symptoms include polyphagia, polydipsia, polyuria, dehydration, weight loss, weakness, muscle wasting, recurrent or persistent infections, hypovolemia, ketonemia, glycosuria, blurred or changed vision, fatigue, muscle cramps, and dry mouth. Blood glucose $>$ 250 mg/dL should be evaluated; monitor blood or urine ketones to check for diabetic ketoacidosis (DKA). Three forms of hyperglycemia may be noted in the hospitalized patient: (1) someone with a history of diagnosed diabetes; (2) previously unrecognized diabetes; (3) hospital-related fasting blood glucose of 126 mg/dL or random blood glucose of $>$ 200 mg/dL that reverts to normal after discharge.
<b>DKA or nonketotic hyperosmolar state</b>	The stress of illness, trauma, and/or surgery frequently aggravates glycemic control and may precipitate DKA or nonketotic hyperosmolar state. A vomiting illness accompanied by ketosis may indicate DKA, a life-threatening condition that requires immediate medical care to prevent complications and death (American Diabetes Association, 2009). Cerebral edema can occur. Early consultation with an endocrinologist is needed.
<b>Hypoglycemia</b>	<p>Symptoms include shakiness, confusion, diplopia, irritability, hunger, weakness, headache, rapid and shallow breathing, numbness of mouth/lips/tongue, pulse normal or abnormal, convulsions, lack of coordination, dizziness, staggering gait, pallor, slurred speech, tingling, diaphoresis, nausea, sweating, tremors, and nightmares.</p> <p>Treat when blood glucose level is <math>&lt;</math>70 mg/dL with 15 g of liquid or fat-free sources of glucose or carbohydrates (CHO); wait 15 minutes and retest, then treat with another 15 g of CHO if still <math>&lt;</math>70 mg/dL. Evaluate blood glucose after 1 hour. Continue to monitor until next meal. Adding protein to carbohydrate does not affect the glycemic response and does not prevent subsequent hypoglycemia, but adding fat may retard and then prolong the acute glycemic response (American Diabetes Association, 2009).</p> <p>In rare, severe hypoglycemia (when the individual requires the assistance of another person and cannot be treated with oral carbohydrate), emergency glucagon kits may be used; these require a prescription and they can expire over time (American Diabetes Association, 2009).</p>
<b>Dawn phenomenon</b>	The dawn phenomenon is the end result of a combination of natural body changes that occur during the sleep cycle. Between 3:00 a.m. and 8:00 a.m., the body naturally starts to increase the amounts of counter-regulatory hormones (growth hormone, cortisol, and catecholamines) which work against insulin's action to drop blood sugars. These cause a blood sugar levels to rise in the morning.
<b>Somogyi effect</b>	"Rebound hyperglycemia" leads to high blood sugar levels in the morning preceded by an episode of asymptomatic hypoglycemia. When blood sugar drops too low in the middle of the night, the body counters by releasing hormones to raise the sugar levels. Too much insulin earlier or not enough of a bedtime snack may be the problem.
<b>Acute illness or infection</b>	<p>Any condition leading to deterioration in glycemic control necessitates more frequent monitoring of blood glucose and urine or blood ketones (American Diabetes Association, 2009). Aggressive glycemic management with insulin is needed with severe acute illness (American Diabetes Association, 2009).</p> <p>The risk for DKA is higher during this time; test blood glucose, drink adequate amounts of fluid, ingest CHO (50 g CHO every 3–4 hours) if blood glucose levels are low, and adjust medications to keep glucose in desired range and to prevent starvation ketosis. Marked hyperglycemia requires temporary adjustment of the treatment program and, if accompanied by ketosis, frequent interaction with the diabetes care team (American Diabetes Association, 2009). Hospitalization may be needed. In a pediatric case, cerebral edema may occur; referral to a pediatric endocrinologist is important.</p>
<b>Vaccines</b>	Annually provide an influenza vaccine to all diabetic patients $\geq$ 6 months of age; provide at least one lifetime pneumococcal vaccine for adults with diabetes (American Diabetes Association, 2009). Persons who have diabetes tend to be at higher than normal risk for bacterial forms of pneumonia.
<b>Critical illness</b>	In critically ill patients, blood glucose levels should be kept as close to 110 mg/dL (6.1 $\mu$ mol/L) as possible and generally $<$ 180 mg/dL (10 $\mu$ mol/L); intravenous insulin is usually needed (American Diabetes Association, 2009). Scheduled prandial insulin doses should be given in relation to meals and should be adjusted according to point-of-care glucose levels; traditional sliding-scale insulin regimens may be ineffective and are not useful (American Diabetes Association, 2009).

(continued)

**TABLE 9-4 Potential Complications of Diabetes (continued)****INTERMEDIATE**

<b>Children with T1DM</b>	<p>Children's growth and development may be impaired with diabetes; adequate protein and energy must be provided. Children may be picky eaters.</p> <p>Blood glucose goals are less strict. Target range for normal blood glucose (90–130 mg/dL before eating for 13–19 year olds; 90–180 mg/dL for 6–12 year olds; and 100–180 mg/dL for 0–5 year olds) may be altered according to the health care provider's evaluation. Near-normalization of blood glucose levels is seldom attainable in children and adolescents after the honeymoon (remission) period (American Diabetes Association, 2009). The A1c goals also vary in children.</p> <p>Most children under 6 or 7 years of age have "hypoglycemic unawareness;" young children lack the cognitive capacity to recognize and respond to hypoglycemic symptoms (American Diabetes Association, 2009).</p> <p>Children with diabetes differ from adults in many ways, including insulin sensitivity related to sexual maturity, physical growth, ability to provide self-care, vulnerability to hypoglycemia, differing family dynamics, developmental stages, and physiological differences (American Diabetes Association, 2009). Work with the family and school to plan for emergencies such as low or high blood glucose levels.</p>
<b>Children with T2DM</b>	<p>Distinction between type 1 and type 2 diabetes in children can be difficult because autoantigens and ketosis may be present in a substantial number of patients (American Diabetes Association, 2009).</p> <p>Children with T2DM are usually overweight or obese and present with glycosuria with or without ketonuria, absent or mild polyuria and polydipsia, and little or no weight loss. Up to 33% have ketonuria at diagnosis; some may have ketoacidosis without any associated stress, illness, or infection.</p>
<b>Preconception</b>	All women with diabetes and childbearing potential should be educated about the need for good glucose control before pregnancy, the need for family planning, and need for early treatment for diabetic retinopathy, nephropathy, neuropathy, and cardiovascular disease (American Diabetes Association, 2009). A1c levels should be normal or as close to normal as possible (<1% above the upper limits of normal) in an individual before conception is attempted (American Diabetes Association, 2009).
<b>Pregnancy and diabetes</b>	<p>Infant mortality rates are approximately twice as high for babies born to women with uncontrolled diabetes compared with babies born to women without diabetes. To reduce the risk of fetal malformations and maternal or fetal complications, pregnant women and women planning to become pregnant require excellent blood glucose control. These women need to be seen frequently by a multidisciplinary team. Specialized laboratory and diagnostic tests may be needed. Women with diabetes must be trained in self-monitoring of blood glucose (SMBG).</p> <p>Nutrition recommendations for women with preexisting diabetes must be based on a thorough assessment. Monitoring blood glucose levels, blood or urine ketones, appetite, and weight gain is needed to develop an individualized nutrition prescription and to make adjustments to the meal plan.</p> <p>Plasma glucose should be maintained at 65–100 mg/dL before meals and in fasting; 110–135 mg/dL 1 hour after meals; and &lt;120 mg/dL 2 hours after meals.</p> <p>Use an extra 300 kcal daily during the second and third trimester; 1 g/kg/d or an additional 25 g/d of protein; 175 g/d of CHO; 600 µg folic acid. Added iron and calcium may also be required.</p>
<b>Gestational diabetes</b>	See the entry later in this chapter.
<b>Lactation</b>	Extra protein, calcium, and folic acid will be needed. Monitoring of blood glucose is recommended, but hypoglycemia should be avoided. Breastfeeding lowers blood glucose and may require women to eat a CHO-containing snack either before or during breastfeeding. Extra 330–400 kcal meets the needs of most lactating mothers.
<b>Older adults</b>	<p>Unexplained weight loss should be viewed as a symptom of a problem. Diabetes is an important health condition for the aging population; at least 20% of patients over the age of 65 years have diabetes. These patients tend to have higher rates of premature death, functional disability, and coexisting illnesses such as hypertension, heart disease, and stroke than those without diabetes (American Diabetes Association, 2009). New-onset diabetes in adults over the age of 50 may signal underlying pancreatic cancer, which should be investigated.</p> <p>Strict diets in long-term care are not warranted and may lead to dehydration and malnutrition; specialized diabetic diets are not required, and a balanced diet with consistent timing of CHO is to be recommended. Modify medications, rather than diet, as needed. Lower hypertension gradually; implement the DASH diet whenever possible. A multivitamin–mineral supplement may be beneficial for this population.</p>

**CHRONIC**

<b>A1c levels</b>	<p>Achieve and maintain normal blood glucose (BG) and lipids. Intensive therapy (IT) helps reduce onset or progression of vascular problems. Maintain hemoglobin A1c levels &lt;7% (A1c level of 7 = BG 170).</p> <p>For evaluation, note that A1c of 5% = BG 100; 6% = BG 135; 7% = BG 170; 8% = BG 205; 9% = BG 240; 10% = BG 275; 11% = BG 310.</p>
<b>Microvascular</b>	Retinopathy, ocular abnormalities, nephropathy, neuropathy (sensory or motor conditions, which may lead to ulceration or even limb amputation, orthostatic hypotension, intractable nausea and vomiting, and diabetic gastroenteropathy), diabetic cystopathy, and chronic diarrhea.

(continued)

**TABLE 9-4 Potential Complications of Diabetes (continued)****CHRONIC**

<b>Retinopathy</b>	<p>Retinopathy from diabetes accounts for 12,000–24,000 cases of blindness each year. Optimal glycemic and blood pressure control can substantially reduce the risk and progression of diabetic retinopathy (American Diabetes Association, 2009).</p> <p>In the presence of proliferative diabetic retinopathy (PDR) or severe nonproliferative diabetic retinopathy (NPDR), vigorous aerobic or resistance exercise may be contraindicated because of the risk of triggering vitreous hemorrhage or retinal detachment (American Diabetes Association, 2009).</p> <p>Pregnancy in T1DM may aggravate retinopathy; laser photocoagulation surgery can minimize this risk (American Diabetes Association, 2009).</p>
<b>Microalbuminuria and nephropathy</b>	<p>Early signs of nephropathy include hyperfiltration, renal hypertrophy, and microalbuminuria (loss of 30–300 µg/mg creatinine in the urine). Protein losses at a rate of &gt;300 µg/mg creatinine may indicate advancement toward chronic kidney disease (CKD). To reduce the risk and/or slow the progression of nephropathy, optimize glucose and blood pressure control (American Diabetes Association, 2009). Nephropathy is preceded by microalbuminuria for several years; onset of end-stage renal disease is about 5 years after onset of microalbuminuria. For diabetic nephropathy, liberalize CHO intake and control insulin levels accordingly.</p> <p>Controlled protein intake will slow down progression of nephropathy. Adults need &lt;0.8–1 g protein/kg daily (American Diabetes Association, 2009). Protein restriction is of benefit in slowing the progression of albuminuria, glomerular filtration rate (GFR) decline, and occurrence of end-stage renal disease (ESRD). Protein restriction should be considered in patients whose nephropathy seems to be progressing despite optimal glucose and blood pressure control and use of angiotensin-converting enzyme (ACE) inhibitors and/or angiotensin receptor blockers (ARBs) (American Diabetes Association, 2009).</p> <p>Intensive diabetes management with the goal of achieving near normoglycemia has been shown to delay the onset of microalbuminuria (American Diabetes Association, 2009). Refer to a physician experienced in the care of diabetic renal disease when the estimated GFR has fallen to &lt;60 mL/min or if difficulties occur in the management of hypertension or hyperkalemia (American Diabetes Association, 2009). ACE inhibitors are almost always prescribed to decrease progression.</p> <p>Phosphorus should be controlled at 8–12 mg/kg/d. Some people may need phosphate binders and calcium supplements.</p>
<b>End-stage renal disease</b>	<p>Diabetes is the leading cause of CKD, especially among blacks, Mexican Americans, and Native Americans. Diabetic nephropathy occurs in 20–40% of patients with diabetes and is the single leading cause of ESRD (American Diabetes Association, 2009). Creatinine and GFR should be assessed annually in this population. Microalbuminuria (30–299 mg/24 h) and macroalbuminuria (≥300 mg/24 h) should be carefully monitored (American Diabetes Association, 2009).</p> <p>While physical activity can acutely increase urinary protein excretion, there is no evidence that vigorous exercise increases the rate of progression of diabetic kidney disease (American Diabetes Association, 2009).</p>
<b>Autonomic neuropathy</b>	<p>About 70% of persons who have diabetes have some degree of neuropathy, including impaired sensation in the hands and feet, slowed digestion, or carpal tunnel syndrome. Autonomic neuropathy can decrease cardiac responsiveness to exercise, causing postural hypotension, impaired thermoregulation, impaired skin blood flow and sweating, impaired night vision, impaired thirst, risk of dehydration, and gastroparesis with unpredictable food delivery (American Diabetes Association, 2009). Neuropathy may be delayed with careful blood glucose management. Weight loss may be beneficial for obese persons.</p>
<b>Skin and joints</b>	<p>Decreased pain sensation in the extremities may increase risk of skin breakdown and infection and joint destruction; it may be best to encourage nonweight-bearing activities such as swimming, bicycling, or arm exercises (American Diabetes Association, 2009).</p>
<b>Genitourinary</b>	<p>Diabetic autonomic neuropathy is associated with recurrent genitourinary tract disturbances or bladder and/or sexual dysfunction.</p>
<b>Amputations</b>	<p>Lower extremity amputations are painful and disabling; prevention is desirable. Amputation and foot ulcers are the most common consequences of diabetic neuropathy and the major causes of morbidity and disability in people with diabetes (American Diabetes Association, 2009).</p>
<b>Cardiac neuropathy</b>	<p>Major clinical manifestations of cardiac neuropathy in diabetes include resting tachycardia, exercise intolerance, orthostatic hypotension, constipation, gastroparesis, erectile dysfunction, sudomotor dysfunction, impaired neurovascular function, “brittle diabetes,” and hypoglycemic autonomic failure (American Diabetes Association, 2009). Evaluate cardiac status before starting an exercise program.</p>
<b>Gastrointestinal (GI) neuropathy</b>	<p>GI disturbances (esophageal enteropathy, gastroparesis, constipation, diarrhea, and fecal incontinence) are common, and any section of the GI tract may be affected. Gastroparesis should be suspected in individuals with erratic glucose control (American Diabetes Association, 2009).</p>

(continued)

**TABLE 9-4 Potential Complications of Diabetes (continued)**

<b>Macrovascular</b>	CVD is a major cause of mortality and also a major contributor to morbidity in diabetics. T2DM is an independent risk factor for macrovascular disease (American Diabetes Association, 2009). Other risk factors include insulin resistance, hyperglycemia, hypertension, dyslipidemia, and smoking. Smoking is related to the premature development of microvascular complications of diabetes and may have a role in the development of T2DM (American Diabetes Association, 2009). Advise all patients not to smoke; include smoking cessation as a routine component of care (American Diabetes Association, 2009).
<b>Coronary artery disease and arterial vascular disease</b>	
<b>Dyslipidemia</b>	<p>Lifestyle modification focusing on the reduction of saturated fat and cholesterol intake, weight loss (if indicated), and increased physical activity has been shown to improve the lipid profile in patients with diabetes (American Diabetes Association, 2009).</p> <p>Guidelines promote low-density lipoprotein (LDL) cholesterol levels of &lt;100 mg/dL as optimal for all patients and lowering of triglyceride levels when &gt;150 mg/dL. Statins may be helpful. Elevate high-density lipoprotein (HDL) to levels &gt;50 mg/dL. If HDL is &lt;50 mg/dL and LDL is between 100 and 129 mg/dL, a fibric acid derivative or niacin might be used. Niacin raises HDL but can significantly increase blood glucose at high doses (American Diabetes Association, 2009). Use aspirin therapy (75–162 mg/d) as a secondary prevention strategy in those with diabetes with a history of CVD (American Diabetes Association, 2009).</p> <p>Tailor nutrition interventions according to each patient's age, type of diabetes, pharmacological treatment, lipid levels, and other medical conditions. Focus on the reduction of saturated fat, cholesterol, and trans fat intake (American Diabetes Association, 2009). Monitoring of homocysteine levels and related actions should be taken. Adequate insulin therapy often returns lipids to normal in T1DM. Elevated levels in T2DM require strict management; limit saturated fat to 7–10% of total calories.</p> <p>The rate of heart disease is about two to four times higher in adults who have diabetes; it is the leading cause of diabetes-related deaths. Since people with diabetes tend to have high triglyceride and low HDL levels, omega-3 fatty acids from DHA and EPA (fish and marine oils) can help.</p>
<b>Hypertension</b>	<p>Over 70% of adults with diabetes also have hypertension. Control of hypertension in diabetes has been linked to reduction in the progression of both microvascular and macrovascular disease. In T1DM, hypertension is often the result of underlying nephropathy, whereas in T2DM, it may be present as part of the metabolic syndrome (American Diabetes Association, 2009). Patients with systolic blood pressure <math>\geq 140</math> mm Hg or diastolic blood pressure <math>\geq 90</math> mm Hg should receive drug therapy in addition to lifestyle and behavioral therapy (American Diabetes Association, 2009).</p> <p>Blood pressure should be measured at every routine diabetes visit; patients with diabetes should be treated to reach a systolic blood pressure &lt;130 mm Hg and a diastolic blood pressure &lt;80 mm Hg (American Diabetes Association, 2009).</p> <p>In patients with T1DM with hypertension and any degree of albuminuria, ACE inhibitors have been shown to delay the progression of nephropathy. With T2DM, hypertension, and microalbuminuria, ACE inhibitors and ARBs have been shown to delay the progression to macroalbuminuria (American Diabetes Association, 2009).</p> <p>Modest weight loss is helpful. Prevent hypokalemia, which can blunt insulin release. Control glucose; limit alcohol and smoking; and add exercise. Use the DASH diet because it increases intake of calcium, magnesium, and potassium while lowering alcohol and excess weight.</p>
<b>Hypertension in pregnancy</b>	<p>Pregnancy-induced hypertension is two to four times more common in women with T1DM than in the general population. Screen for microalbuminemia as a strong predictor of pre-eclampsia.</p> <p>In pregnant patients with diabetes and chronic hypertension, blood pressure target goals are 110–129/65–79 mm Hg; avoid lower blood pressure because fetal growth may be impaired (American Diabetes Association, 2009). ACE inhibitors and ARBs are contraindicated during pregnancy (American Diabetes Association, 2009).</p>
<b>Stroke</b>	Stroke risk is two to four times higher among persons with diabetes, and high blood pressure should be carefully controlled.
<b>Catabolic illness</b>	<p>Catabolic illness (such as HIV infection, AIDS, or cancer) changes body compartments, with increased extracellular fluid and shrinkage of body fat and cell mass. Monitor unexplained weight losses carefully, especially 10% or more of usual weight.</p> <p>Standard tube feedings are usually well tolerated in persons with diabetes (50% CHO or lower); monitor fluid status, weight, plasma glucose and electrolytes, and acid–base balance. Overfeeding is to be avoided; start with 25–35 kcal/kg of body weight. Protein needs may be 1 g/kg up to 1.5 g/kg in stressed individuals, and pressure ulcers may require a higher level of protein and calories than normal for healing. Addition of insulin may be needed. Oral glucose-lowering medications need to be adjusted to achieve adequate control of glycemia.</p>

Additional data from: American Diabetes Association, 2009; Centers for Disease Control and Prevention, 2009.

**TABLE 9-5 Key Concepts in Diabetes Management***Glucose Control*

- Improved glycemic control benefits people with either type 1 or type 2 diabetes.
- For every 1% reduction in results of A1c blood tests (e.g., from 8.0% to 7.0%), the risk of developing microvascular diabetic complications (eye, kidney, and nerve disease) drops by 40%.
- A1c is the primary target for glycemic control. More stringent glycemic goals (i.e., a usual A1c, <6%) may further reduce complications at the cost of increased risk of hypoglycemia. Less-intensive glycemic goals may be indicated in patients with severe or frequent hypoglycemia.
- Postprandial glucose may be targeted if A1c goals are not met despite reaching preprandial glucose goals.
- Goals should be individualized, and lower goals may be reasonable based on benefit–risk assessment.
- Certain populations (children, pregnant women, and elderly) require special considerations. See guidelines:

Values by Age (years)	Plasma Blood Glucose Goal		A1c	Rationale
	Pre-prandial (mg/dL)	Bedtime/ Overnight		
Toddlers and preschoolers age (0–6)	100–180	110–200	<8.5% (but >7.5%)	High risk and vulnerability to hypoglycemia
School age (7–12)	90–180	100–180	<8%	Risks of hypoglycemia and relatively low risk of complications prior to puberty
Adolescents and young adults (13–19)	90–130	90–150	<7%	Risk of severe hypoglycemia; developmental and psychological issues; a lower goal <7% is reasonable if achieved without excessive hypoglycemia
Adults (20+)	90–130		<7%	Peak post-prandial <180 mg/dL 1–2 hours after beginning of meal

*Blood Pressure Control*

- Goal: blood pressure <130/80 mm Hg.
- Restriction of sodium to 2400 mg/d assists in the control of hypertension.
- Blood pressure control can reduce cardiovascular disease (heart disease and stroke) by approximately 33–50% and can reduce microvascular disease (eye, kidney, and nerve disease) by approximately 33%.
- In general, for every 10-mm Hg reduction in systolic blood pressure, the risk for any complication related to diabetes is reduced by 12%.

*Control of Blood Lipids*

- Improved control of cholesterol or blood lipids (e.g., high-density lipoprotein [HDL], low-density lipoprotein [LDL], and triglycerides) can reduce cardiovascular complications by 20–50%.
- Goals: Total cholesterol minus HDL should be  $\leq 130$  mg/dL; LDL <100 mg/dL; Triglycerides <150 mg/dL; HDL <40 mg/dL in men, >50 mg/dL in women.

*Preventive Care Practices for Eyes and Feet*

- Detecting and treating diabetic eye disease with laser therapy can reduce the development of severe vision loss by an estimated 50–60%.
- Comprehensive foot care programs can reduce amputation rates by 45–85%.

*Preventive Care for Kidneys (Prerenal Failure)*

- Detecting and treating early diabetic kidney disease by lowering blood pressure can reduce the decline in kidney function by 30–70%. Angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARBs) are most effective in reducing the decline in kidney function.
- With protein intakes greater than 20% of energy intake, there is an association with increased albumin excretion rate.
- Once albuminuria is present, reduce protein to 0.8–1.0 g/kg/d with microalbuminuria and to 0.8 g/kg/d with macroalbuminuria. There may be a benefit to lowering phosphorus intake to 500–1000 mg/d.
- There is evidence for a benefit on renal function, glucose, lipids, and blood pressure from weight-maintaining diets.

Collaborative, multidisciplinary teams are best suited to provide such care for people with chronic conditions such as diabetes and to empower patients' performance of appropriate self-management (American Diabetes Association, 2009). MNT provided by RDs to patients with type 1 and T2DM has been shown to improve glycemic outcomes. Community-based education that incorporates Social Cognitive Theory and Stages of Change Theory, with three group sessions focused on meal planning with cooking demonstrations, is effective; the education successfully promotes use of herbs in place of salt, use of olive or canola oils, use of artificial sweeteners in baking, knowledge of diabetes and nutrition, and self-efficacy (Chapman-Novakofski and Karduck, 2005). Table 9-5 offers more tips for diabetes management.

It is also important to address culturally specific eating habits. For example, a recent study in South Dakota found that a diet patterned after the historical hunter-gatherer type diet (with the 25% of energy supplied from protein), provided better blood glucose control and lower the circulating insulin levels in Northern Plains Indians with T2DM. The same may be true for other high-risk groups.

## DIABETES MELLITUS, COMPLICATIONS, AND RELATED CONDITIONS

## TYPE 1 DIABETES MELLITUS

## NUTRITIONAL ACUITY RANKING: LEVEL 4

Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinicopathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

## DEFINITIONS AND BACKGROUND

Type 1 diabetes mellitus (T1DM) is absolute insulin deficiency with total failure to produce insulin. Previously used terms include “type I,” “insulin-dependent diabetes mellitus (IDDM),” “juvenile,” “brittle,” or “ketosis-prone” diabetes. T1DM involves autoimmune destruction of the pancreatic beta-cells (the islets of Langerhans). Onset often follows viral infection such as mumps. It usually starts in children or young adults, affecting 10% of cases of diabetes; beta-cell damage is often more severe in patients diagnosed before puberty.

Signs and symptoms of diabetes include polyuria (frequent urination, including frequent bedwetting in otherwise

trained children), polydipsia (excessive thirst), polyphagia (extreme hunger), weakness, fatigue, irritability, and sudden weight loss. A fasting plasma glucose (FPG) test or an oral glucose tolerance test (OGTT) can be used. FPG is the preferred method; level of 126 mg/dL or higher is considered to be diabetes. With the OGTT, blood glucose is measured after fasting and 2 hours after drinking a glucose beverage; results between 140 and 199 mg/dL indicate pre-diabetes, and a level of 200 mg/dL represents diabetes. Hemoglobin A1c (HbA1c) test is not recommended for diagnosis; finger-prick tests are also not valid.

Serious complications begin earlier than previously thought. Glucose control really matters, as proven by the

results of the Diabetes Control and Complications Trial (DCCT) and other trials. More than 65% of people with diabetes die from heart disease or stroke (American Diabetes Association, 2009). Diabetes is the chief cause of blindness, renal failure, and amputations and is a leading cause of birth defects.

Intensive therapy to achieve near-normal glucose levels results in lower onset and progression of complications. Caution is needed to prevent hypoglycemia, especially in the very young (<6-year old) and those with vision loss or kidney disease. Fasting blood glucose should be measured three to eight times daily when on a new insulin regimen; this may be tapered down when stable (American Dietetic Association, 2009).

Protein and nutrient metabolism are affected by insulin availability. The long-term effects of diets high in protein and low in carbohydrate (CHO) are unknown at this time. Vitamin and mineral intakes are being studied for their various impacts on blood glucose levels. In addition, it is important to note that antioxidant foods and spices may be helpful in lowering blood glucose levels.

Individuals using insulin should eat at consistent times synchronized with the time-action of the insulin preparation used, monitor their blood glucose levels, and determine their required insulin doses for the amount of food usually eaten. Intensified insulin therapy, including multiple daily injections, continuous subcutaneous insulin infusion with an insulin pump, and rapid-acting insulin, allows for more flexibility in the timing of meals and snacks, as well as in the amount of food eaten.

Medical costs for patients with diabetes account for a significant percentage of all health care costs. National Standards for Diabetes Self-Management have been written to support a team approach to patient care; they include the RD as an essential team member. Ongoing nutrition self-management education includes assessment, care plans, treatment goals, desired outcomes, and monitoring metabolic parameters such as blood glucose, lipids, A1c, and related lab values.

The use of evidence-based MNT can lead to effective lifestyle changes. Use of technology to track quarterly weight and lab values is an effective way to help patients with their self-management goals (Chima et al, 2005). Multidisciplinary team interventions are suggested to help improve patients' A1c levels and to reduce complications, hospital readmissions, and hospital stays. The American Dietetic Association recommends a specific number of MNT visits to promote the desired outcome (see Table 9-6).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** The pathogenesis of most DM is multifactorial including both genetic and environmental factors. Interleukin, HLA-DR or HLA-DQ alleles, INS-23, and vitamin D receptor (VDR) gene polymorphisms may be associated with risk of developing T1DM. Much more research is needed to clarify how these present in various haplotypes or ethnic groups.

Hormonal imbalance controls key proteins that regulate the folate-SAM-homocysteine pathways. Poor folate status has been associated with endothelial dysfunction in adolescents with type 1 diabetes (Wiltshire et al, 2008). The methylene-tetrahydrofolate reductase (MTHFR) A>C genotype may confer protection against early nephropathy with lower homocysteine (tHcy) levels, whereas MTHFR 677 TT genotypes may have earlier onset of retinopathy (Wiltshire et al, 2008).

Clinical/History	Lab Work	
Height	HbA1c (goal	High-density lipoprotein (HDL)
Weight	<7%)	Low-density lipoprotein (LDL)
Weight:height percentiles	Fasting blood glucose (FBG)	Triglycerides (Trig)
Body mass index (BMI)	(goal 90–130 mg/dL)	Urinary ketones
Diet history	OGTT results	Na <sup>+</sup> , K <sup>+</sup>
Waist circumference	Urine glucose	Ca <sup>++</sup> , Mg <sup>++</sup>
Visual acuity	Blood urea nitrogen (BUN)	Serum phosphorous (PO <sub>4</sub> )
Blood pressure (BP)	Creatinine (Creat)	Thyroid-stimulating hormone (TSH)
Intake and output (I & O)	Microalbuminuria	Serum D <sub>3</sub> level
Absence of menstruation?	C-reactive protein (CRP)	
Increased hunger, thirst, urination	Total Cholesterol (Chol)	
Nausea, vomiting, abdominal pain		

## INTERVENTION

## OBJECTIVES

- Individualize MNT as needed to achieve treatment goals, preferably provided by an RD familiar with the components of diabetes MNT (American Diabetes Association, 2009).

**TABLE 9-6** Recommended Medical Nutrition Therapy Visits for Type 1 Diabetes

Encounter	Length of Contact	Time between Encounters
1	60–90 minutes	2–4 weeks
2, 3	30–45 minutes	2–4 weeks
4, 5	30–45 minutes	6–12 months
6, 7, 8	30–45 minutes	As indicated by clinical data and/or changes in medication

Adapted from: National Guideline Clearinghouse. Nutrition practice guidelines for type 1 and type 2 diabetes mellitus. Web site accessed September 20, 2009 at [http://guidelines.gov/summary/summary.aspx?doc\\_id=12816&nbr=006618](http://guidelines.gov/summary/summary.aspx?doc_id=12816&nbr=006618)

## SAMPLE NUTRITION CARE PROCESS STEPS

**Altered Nutrition Labs-Type 1 Diabetes**

**Assessment Data:** Blood glucose log and food history.

**Nutrition Diagnosis (PES):** Altered nutrition-related lab values related to wrong dose of insulin as evidenced by blood glucose readings consistently  $\geq 250$  mg/dL before lunch.

**Intervention:** Education and counseling to address appropriate timing of food and insulin dose; CHO counting.

**Monitoring and Evaluation:** Ask patient to fax blood glucose logs for next 3 days.

- Address the metabolic abnormalities of glucose, lipids, and BP (Kulkarni, 2006). Meet the specific needs of the patient; modify drug therapy to enhance outcomes and quality of life.
- Regularly evaluate food/nutrition history, physical exercise, activity patterns, excessive weight gain.
- Develop food/meal planning with client; share plan with medical team so an insulin regimen can be integrated into the client's usual lifestyle. In hospital settings, avoid use of restrictive diets.
- Promote lifestyle changes according to client readiness, educational, and skill level. Early referral for lifestyle changes and advice yields the most benefit (Kulkarni, 2006).
- Plan meal plan, exercise, and medication to achieve blood glucose and lipid goals. Minimize intake of trans fatty acids; saturated fat should be  $<7\%$  of total calories (American Diabetes Association, 2009).
- Prevent early onset of complications by controlling glucose, lipids, and BP. If there are complications, delay or prevent consequences. The DCCT intensive therapy group had substantially lower complication rates; fewer than 1% became blind, required kidney replacement, or had an amputation because of diabetes (DCCT Research Group, 2009).
- Both the amount (grams) of carbohydrate as well as the type of carbohydrate in a food influence blood glucose level. Monitoring total grams of carbohydrate remains a key strategy in achieving glycemic control (American Diabetes Association, 2009).
- Teach individuals how to use carbohydrate counting and how to adjust insulin doses based on planned carbohydrate intake.
- Promote self-monitoring of blood glucose (SMBG) multiple times per day, and more often during illness.

**FOOD AND NUTRITION**

- Determine appropriate energy intake for age. Pregnant and growing individuals should receive more: sedentary, 25 kcal/kg; normal, 30 kcal/kg; undernourished or active, 45–50 kcal/kg. Reassess as activity or life stage changes.
- Monounsaturated fatty acids and carbohydrates combined should provide about 60–70% of daily energy intake; limit saturated fats to  $<10\%$  of energy intake. Use a plan that includes CHO at 45–65% of total energy intake each day to prevent ketosis (American Diabetes Association, 2009).
- Apply carbohydrate counting, dietary guidelines, or MyPyramid food guidance principles. Focus on carbohydrates more than total energy or source of carbohydrate.
- Determine insulin to carbohydrate ratios for each individual. One CHO unit equals 15 g CHO (standard starch, fruit, sweet, or milk servings are based on 15 g CHO).
- Provide consistent carbohydrate with each meal and snack with set doses of insulin. Each of the following portions is one carbohydrate choice (15 g CHO):
  - Grains, breads, cereals: 1 oz bread (1 slice bread, 1/4 large bagel, 6'' tortilla); 1/2 cup cooked dried beans; 1/3 cup pasta or rice; 1 cup soup; 3/4 cup cold cereal; 1/2 cup cooked cereal.
  - Milk and yogurt: 1 cup milk; 2/3 cup unsweetened yogurt (6 oz) or sweetened with noncaloric sweetener.
  - Fruits: 1 small fresh fruit; 1/2 cup fruit; 1 cup melon or berries; 1/2 cup fruit juice; 1/4 cup dried fruit.
  - Sweets and snack foods: 3/4 oz snack food (pretzels, chips, 4–6 crackers); 1 oz sweet snack (two small sandwich cookies, five vanilla wafers); 1 tbsp sugar or honey; 1/2 cup ice cream.
  - Vegetables: 1/2 cup potato, peas, or corn; 3 cups raw vegetables; 1 1/2 cups cooked vegetables; small portions of nonstarchy vegetables.
- Most women need about 3–4 carbohydrate choices (45–60 g CHO) at each meal; men generally need about 4–5 carbohydrate choices (60–75 g CHO) per meal. Active young women may need 2500 kcal, or about 75–90 g CHO/meal; an active young man who needs 3000 kcal/d may need 90–100 g CHO/meal. Use 1–2 carbohydrate choices (15–30 g CHO) for snacks; body size and activity level will determine the number of choices needed.
- Include plenty of fiber from rice, beans, vegetables, barley, oat bran, fruits, and vegetables. Recommendations for fiber intake for people with diabetes are similar to the recommendations for the general public (DRI: 14 g/1000 kcal) and diets containing 44–50 g of fiber daily truly improve glycemia (American Dietetic Association, 2009). Whole grains are good sources of vitamin E, fiber, and magnesium.
- To reduce the risk of nephropathy, protein intake should be limited to the recommended dietary allowance (American Diabetes Association, 2009). If there is microalbuminuria, a more controlled protein intake may be required.
- Cut down or eliminate fried and creamed foods. Include omega-3 fatty acids (as from salmon, mackerel, tuna, walnuts, and canola oil) to control blood lipids and reduce inflammatory processes. A high-monounsaturated fat diet seems to have a favorable effect on lipoproteins in diabetes.
- For minerals, assure adequacy of intake; routine supplementation is not advised. Replenish potassium and magnesium, if needed. Adequate calcium is important: 500 mg in 1–3 year olds, 800 mg in 4–8 year olds, 1300 mg

- A meal plan based on the individual's usual food intake should be used as the basis for integrating insulin therapy into the usual eating and exercise patterns (American Diabetes Association, 2009).
- Choose a variety of heart-healthy foods, including an average of five servings of fruits and vegetables, six servings of grains (three whole grain), and two servings of low-fat dairy. Foods in the meat and fat groups do not directly affect blood glucose.
- Discourage meal skipping.

in 9–18 year olds, and 1000 mg in adults should be attained daily.

- Sodium intake should be limited to 2400 mg daily or less.
- Routine supplementation with antioxidant vitamins E and C and beta-carotene is not advised because of lack of evidence of efficacy (American Diabetes Association, 2009). Folate is important in women of childbearing ages; acquire 400 µg prepregnancy and 600 µg during pregnancy.
- Vitamin D has been found to play an important role in auto-immune disorders. Encourage intake of vitamin-D fortified foods, but also encourage adequate time in the sun.
- If foods containing sucrose are chosen, they should be substituted for other carbohydrate foods. Sucrose intakes of 10–35% of total energy intake do not affect on glycemic or lipid responses negatively when substituted for isocaloric amounts of starch (American Dietetic Association, 2009).
- If adults with diabetes choose to use alcohol, intake should be limited to 1 drink/d or less for adult women and 2 drinks/d or less for adult men. One drink is defined as 12 oz beer, 5 oz wine, or 1.5 oz distilled spirits (American Diabetes Association, 2009). To avoid hypoglycemia, alcohol should be consumed with a carbohydrate-containing food. Abstain in pregnancy, pancreatitis, advanced neuropathy, extremely elevated triglycerides, or a history of alcohol abuse.
- Nonnutritive sweeteners are safe when consumed within the acceptable daily intake levels established by the Food and Drug Administration (FDA) (American Diabetes Association, 2009). The FDA has approved use of several sweeteners; see Table 9-7.
- Adequate carbohydrate replacement during and after exercise is important to prevent hypoglycemia. Decrease rapid-acting insulin doses during the physical activity; 30–50% less is reasonable.
- In critical illness, blood glucose management is a challenge. Enteral feeding is generally preferred but specialty formulas are not usually required. Regular blood glucose monitoring and insulin replacement may be needed.
- If parenteral nutrition is needed, use strict blood glucose control. Hyperglycemia reflects illness severity and results in deleterious consequences. Plan 30% of nutrient intake as fat, 50% as CHO, and 15–20% as protein unless other disease states require alternative plans.

### Common Drugs Used and Potential Side Effects

- Anti-CD3 mAbs may prolong beta cell function up to 2 years in patients with new onset Type 1 diabetes (T1DM) but studies are still ongoing (Herold et al, 2009).
- Insulin/diet correlation is essential. Persons with T1DM are usually dependent on insulin for life. The primary potential effect is hypoglycemia. Sources of insulin must be noted because they affect the peak times and duration of effect, and some affect the speed of absorption. Human insulin is produced synthetically from *Escherichia coli* or yeast with identical amino acid sequence to the human insulin. See Table 9-8 for insulin onset, peak, and duration times.
- Insulin pumps (continuous subcutaneous insulin infusion [CSII]) may be good to maintain glucose levels. If a pump is used, meal schedules are not as strict but should not be abused. With multiple daily insulin injections (MDI), test blood glucose before meals to determine

insulin doses. Insulin pens available are convenient for insulin dosing. Insulin glargine (Lantus) is well tolerated in MDI regimens for pediatric patients with T1DM and may be more efficacious than NPH/Lente in those with elevated A1c (White et al, 2009; Chase et al, 2008).

- Insulin analogs match postprandial blood glucose excursions better than traditional insulin. Bolus analogs are used for more rapid onset to cover meal CHO and to correct hyperglycemia. Basal agents release at a more constant rate to cover between-meal glucose needs or the body's basal insulin needs. Premixed insulins are discouraged except when patients are not able to be compliant with MDI. Adverse effects include the potential for hypoglycemia, especially when HbA1c is less than 7%. Analog insulins are less likely to lead to hypoglycemia, especially overnight hypoglycemia. Weight gain with use of insulin can be counteracted with attention to food intake and physical activity.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. There is still insufficient evidence to draw definitive conclusions about the efficacy of beans, peanuts, onion, *Coccinia indica*, aloe vera, *Momordica charantia*, and bitter gourd.
- Adequate Vitamin D should be available, especially for bone health (Svoren et al, 2009).
- See Table 9-9 for guidance on specific herbs and supplements in diabetes. The American Diabetes Association also has a book on herbs and supplements for diabetes care, available from the Web site.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The RD should assess food intake (focusing on carbohydrate), medication, metabolic control (glycemia, lipids, and BP), anthropometric measurements, and physical activity to serve as the basis for implementation of the nutrition prescription, goals, and intervention that are tailored for the individual (American Dietetic Association, 2009).
- Diabetes self-management education (DSME) is an essential element of diabetes care, and national standards have been based on evidence. DSME helps patients optimize metabolic control, prevent and manage complications, and maximize quality of life in a cost-effective manner (American Diabetes Association, 2009). Learning can lead to behavioral changes (healthy eating, being active, taking medications, monitoring glucose, problem-solving) which may then lead to desired clinical and health outcomes. Overall, improved health status includes better quality of life, fewer days lost from school or work, fewer complications and health care costs. Weekly problem-based, self-management support interventions can yield health benefits (Tang et al, 2005), as can even a single session with a dietitian (Gaetke et al, 2006).
- Teach patient about the importance of self-care, optimal functioning, the roles of carbohydrate intake and physical activity in maintaining metabolic control. Blood glucose testing is essential. Insulin injections must be given at planned, regular intervals for persons with T1DM.

**TABLE 9-7 Sugar and Sweetener Summary**

The percentage of calories from carbohydrate (CHO) in the diet for diabetes will vary; it is individualized based on eating habits and glucose and lipid goals.

<b>Glycemic load (GL)</b>	GL = glycemic index $\times$ available CHO amount	Although various starches do have different glycemic responses, first priority should be given to the total amount of CHO consumed rather than the source of the CHO. If the use of glycemic index (GI) is proposed as a method of meal planning, the RD should advise on the conflicting evidence of effectiveness of this strategy. Studies comparing high versus low GI diets report mixed effects on A1C.
<b>Sweets</b>	Sugar equivalents (teapoons)	Soft drink, 12 oz (10 tsp) Chocolate bar, 1.5 oz (5.5 tsp) Froot-loop cereal, 1 cup (3.5 tsp) Sweet pickle, 1 oz (2.25 tsp) Catsup, 1 Tbsp (1 tsp) Barbequed chips, 1 oz. (1/2 tsp) Unsweetened cereal, 1 cup (1/3 tsp)
<i>Nutritive Sweeteners</i>		
<b>Sugar (sucrose)</b>	Sucrose = 16 kcal/tsp (4 g CHO)	Sucrose is saccharose ( $C_{12}H_{22}O_{11}$ ). Sucrose is a disaccharide; that is, it is made up of two monosaccharides—glucose and fructose. It is one of the sweetest of sugars. Sucrose-containing foods should be substituted for other carbohydrate foods. Sucrose intakes of 10–35% of total energy intake do not have a negative effect on glycemic or lipid responses when substituted for isocaloric amounts of starch.
<b>Corn syrup, molasses, dextrose, glucose, and maltose</b>	Corn sugar (called glucose, or dextrose), milk sugar (lactose), and malt sugar (maltose).	If sucrose is taken as a standard of 1, the sweetness of glucose is 0.5–0.6, that of lactose is 0.27, and that of maltose is 0.6. There is no evidence that foods sweetened with these sweeteners have any significant advantage or disadvantage over foods sweetened with sucrose in decreasing total calories or CHO content of the diet or in improving overall diabetes control.
<b>Fructose and honey</b>	Fructose: 11 kcal/tsp (3 g CHO); fruit sugar; 1.1–2 times as sweet as sucrose.	Fructose, found in fruits and honey, is the sweetest. Although dietary fructose produces a smaller rise in plasma glucose than equal amounts of sucrose and most starches, it is not to replace more than 20% of calories in adults because of its potential adverse effects on lipids, especially triglycerides. There is no reason to recommend that people with diabetes avoid consumption of fruits and vegetables, in which fructose occurs naturally. In children, fructose works well as a substitute in baked goods because their lipids are not yet a problem and fructose has little impact on blood glucose levels.
<b>Sugar alcohols</b>	Sugar alcohols: 2 kcal/g (50% of kilocalories of other nutritive sweeteners such as sucrose) Sorbitol: 50% as sweet as sucrose Xylitol: 16 kcal/tsp (4 g CHO)	Sugar alcohols produce a lower postprandial glucose response than sucrose or glucose and have lower available energy. With foods containing sugar alcohols, subtraction of one half of sugar alcohol grams from total CHO grams is appropriate, particularly when using the CHO counting method for meal planning. There is no evidence that the amounts of sugar alcohol likely to be consumed will result in significant reduction in energy intake or long-term improvement in glycemia. The use of sugar alcohols appears to be safe. Excessive amounts of polyols may have a laxative effect. The calories and CHO content from all nutritive sweeteners must be accounted for in the meal plan and have the potential to affect blood glucose levels.

(continued)

**TABLE 9-7 Sugar and Sweetener Summary (continued)***Non-Nutritive Sweeteners*

<b>Acesulfame potassium (Sunette®)</b>	Acesulfame: 200 times sweeter than sugar; heat stable	<p>The Food and Drug Administration has approved five non-nutritive sweeteners for use in the United States. All have undergone rigorous scrutiny and have been shown to be safe when consumed by the public, including people with diabetes and women who are pregnant.</p> <p>If persons with diabetes choose to consume products containing U.S. Food and Drug Administration (FDA)-approved non-nutritive sweeteners, at levels that do not exceed the acceptable daily intakes (ADIs), the RD should advise that some of these products may contain energy and carbohydrate from other sources that needs to be accounted for. Research on non-nutritive sweeteners reports no effect on changes in glycemic response.</p>
<b>Alitame</b>	Alitame is made from amino acids, 2000 times sweeter than sugar. Still awaiting FDA approval.	
<b>Aspartame (Equal®, NutraSweet®)</b>	Aspartame: 180 times sweeter than sugar; 4 kcal/tsp; contains phenylalanine and cannot be used in PKU. Equally contains aspartame, dextrose, and maltodextrin.	
<b>Neotame</b>	Neotame: 6000 times sweeter than sugar; heat stable	
<b>Saccharin (Sweet 'N Low®)</b>	Saccharin: 300–400 times sweeter than sugar; heat stable; leaves a slightly bitter aftertaste	
<b>Sucralose (Splenda®)</b>	Sucralose: 600 times sweeter than sugar; heat stable	

For more information: International Food Information Council, Web site accessed September 22, 2009, at <http://www.ific.org/publications/factsheets/lcsfs.cfm>; American Diabetes Association, 2009; National Diabetes Evidence-based guidelines, Web site accessed September 20, 2009, at [http://guidelines.gov/summary/summary.aspx?doc\\_id=12816&nbr=006618](http://guidelines.gov/summary/summary.aspx?doc_id=12816&nbr=006618)

- Identify potential or real obstacles; discuss options for resisting temptations, dining away from home, feeling deprived, time pressures, food offers from others, competing priorities, handling social events, family or social support, and food intolerances.
- Encourage regular mealtimes and snacks. Children and teens in particular may need planned snacks.
- A nondiet approach to diabetes management encourages regular eating according to actual hunger and making gradual changes for healthier eating.
- Discuss visual assessment of portions. Practice with measuring cups, spoons, and scales.
- Teach patient how to read labels and how to identify carbohydrates in processed foods.
- Empowerment is important; help patients to gain mastery over their affairs and to effect change (Funnell et al, 2005). Discuss emotional eating, such as from boredom, anger, frustration, loneliness, and depression; alternative choices should be designed from the client perspective. Research reports sustained improvements in A1c at 12 months and longer with long-term follow-up encounters with an RD (American Dietetic Association, 2009).
- Discuss the weight gain that occurs with intensive insulin therapy and improved glucose control.
- Low-carbohydrate diets are not recommended for the management of diabetes (American Diabetes Association, 2009).

**TABLE 9-8 Insulin Onset, Peaks, and Duration<sup>a</sup>**

Insulin Type	Begins Working	Peaks at	Ends Working in	Low Occurs at
<i>Rapid, Bolus</i>				
Humalog (Lispro)	15–20 minutes	30–90 minutes	3–4 hours	2–4 hours
Novolog (Aspart)	15–20 minutes	40–50 minutes	3–4 hours	2–4 hours
<i>Short-Acting</i>				
Regular (Novolin R, Humulin R)	30–60 minutes	80–120 minutes	4–6 hours	3–7 hours
<i>Intermediate-Acting</i>				
NPH	2–4 hours	6–10 hours	14–16 hours	6–12 hours
Lente	3–4 hours	6–12 hours	16–18 hours	7–14 hours
Ultralente	4–6 hours	10–16 hours	18–20 hours	12–24 hours
<i>Long-Acting</i>				
Lantus (Glargine)	2–3 hours	Almost no peak; flat action throughout duration	18–26 hours	4–24 hours

<sup>a</sup>Insulin can be used after 1 month if stored at cooler than 86°C and out of direct sunlight or heat. Unopened bottles of insulin should be stored in a refrigerator; do not freeze insulin. Syringes may be prefilled and stored in a refrigerator for up to 3 weeks. Roll the syringes before use to mix the insulin.

**TABLE 9-9 Herbs and Supplements in Diabetes Management**

Aloe vera	Studies in Japan found that the phytosterols in aloe vera might play a role in lowering blood glucose levels. Further research is needed.
Alpha lipoic acid (thioctic acid)	Alpha lipoic acid (thioctic acid) may have some potential benefits. It is found in the mitochondria and seems to have antioxidant properties that protect vitamin C, vitamin E, and glutathione. Natural sources include red meat, yeast, potatoes, and spinach. Supplementation may provide protection against cataracts, neuropathy in diabetes, cardiovascular disease; research is needed.
Antioxidants	Antioxidants from food should include good sources of beta carotene, vitamins C and E, selenium and zinc.
Bilberry	Bilberry contains anthocyanosides that counteract cellular damage to the retina. Mild drowsiness and skin rashes have been noted.
Biotin	Biotin shows preliminary evidence of being useful for controlling blood glucose.
Bitter melon ( <i>Momordica charantia</i> )	Bitter melon has traditionally been used as a remedy for lowering blood glucose.
Chromium	Chromium enhances use of insulin. Skin allergies, renal toxicity, and altered iron and zinc absorption can occur. There are no proven benefits if a patient is not deficient (American Diabetes Association, 2009).
Cinnamon	Doses of 1, 3, or 6 g capsules of cinnamon daily lowered blood glucose levels in individuals with diabetes.
Essential oils	Essential oils from cinnamon, cumin, and oregano may enhance insulin sensitivity. Studies are ongoing.
Evening primrose oil	Evening primrose oil may prevent or limit neuropathy due to gamma linoleic acid, an essential fatty acid. It may cause headache and gastrointestinal distress.
Fenugreek	Fenugreek may lower glucose, triglyceride and cholesterol levels due to its psyllium content. Note that it is part of the peanut family and may cause allergic reactions. Do not take with monoamine oxidase (MAO) inhibitors; it has the potential for drug interactions with other medications as well.
Gamma linolenic acid	Evening primrose oil may be useful for preventing neuropathy in diabetes.
Garlic	Garlic may lower blood glucose levels if used in large amounts; more studies are needed.
Ginkgo biloba	Ginkgo biloba may help control neuropathy by maintaining integrity of blood vessels and reducing stickiness of blood and clotting. It has some antioxidant properties. Avoid taking with warfarin, aspirin, and other anticoagulant drugs. Headache and interactions with other drugs can occur.
Ginseng, American	Ginseng (American) may lower blood glucose levels. Avoid with warfarin, aspirin, MAO inhibitors, caffeine, antipsychotics, insulin, and oral hypoglycemics because of fluctuations in blood glucose levels, bleeding, platelet functioning, blood pressure and heart rate. Avoid taking with steroids. Headache, insomnia, nausea, or menstrual difficulties can occur. Take with a meal.
Guar gum	Guar gum is a fiber that normalizes the moisture content of the stool, absorbs excess liquid in diarrhea, softens the stool in constipation, and decreases the amount of cholesterol and glucose absorbed from the stomach and intestines.
<i>Gymnema sylvestre</i>	<i>Gymnema sylvestre</i> is a hypoglycemic herb. It is highly potent and should be used only under doctor's supervision because it may change insulin requirements.
Magnesium	Magnesium is needed for hundreds of biochemical reactions; it helps regulate blood sugar levels and blood pressure. Some studies suggest that low magnesium levels may worsen blood glucose control in type 2 diabetes. Magnesium supplementation may help with insulin resistance, but avoid high doses.
Turmeric	Turmeric, the rhizome of <i>Curcuma</i> , may decrease blood glucose levels.
Vanadium	Vanadium may lower glucose levels. It has been associated with cancer cell growth and can be toxic at therapeutic levels.
Vitamin B <sub>6</sub>	Some studies suggest that an adequate intake of vitamin B <sub>6</sub> (pyridoxine) can help with both T1DM and T2DM.
Vitamin D	Supplementation of up to 2000 IU daily in infants were less likely to develop type 1 diabetes over the next 30 years in Finland. This vitamin has a strong, protective effect. Experts are now recommending supplementation at the upper end of the current recommendations (i.e., 1000 IU).
Zinc	Zinc is part of the production and storage of insulin in the body. Fresh oysters, ginger root, lamb, pecans, split peas, egg yolk, rye, beef liver, lima beans, almonds, walnuts, sardines, chicken, and buckwheat are sources from the diet. Zinc should not be used with immunosuppressants, tetracycline, ciprofloxacin, or levofloxacin because of potential antagonist effects.

- Discuss the risks for CVD and how to manage them (American Diabetes Association, 2009; American Dietetic Association, 2009).
- Eating disorders often occur in young women with diabetes; refer for psychotherapy if needed.
- A1c is often unacceptably high in adolescents; there is a need to more fully assess and understand factors such as race/ethnicity, education, and socioeconomic status on treatment recommendations (Paris et al, 2009).
- For sick days: Patients may require more insulin when ill. Liquid diets should provide 200 g CHO in equally divided amounts at mealtime and snacks; liquids should not be sugar free.
- For surgery: Blood glucose should be in good control; perioperative hyperglycemia can be managed with doses of short-acting insulin. Correct abnormalities before surgery when possible.
- Discuss reasonable use of the glycemic index (see Table 9-10).

**TABLE 9-10 Glycemic Index and Glycemic Load**

Glycemic index (GI) is a measure of serum glucose response to a food relative to a reference food that contains equal amounts of carbohydrate. It does not refer directly to quantified food exchanges. Glycemic load =  $GI \times \text{available carbohydrate amount}$ .

A mixed diet yields varying results on blood glucose levels. Choosing low-GI foods in place of conventional or high-GI foods has a small, clinically useful effect on medium-term glycemic control in patients with diabetes (Brand-Miller et al, 2003).

#### *Carbohydrate Choices*

Choose low-GI carbohydrates most often because they digest slower and will be less likely to elevate blood glucose. Each choice = 15 g of carbohydrate.

Choose desired number of carbohydrate choices per meal or as needed by the individual. Children and teens, as well as young adults and athletes, will need much more per meal than sedentary adults.

Glycemic Index	Grain or Bean Choices	Fruit Choices	Vegetable Choices
Low (best choice)	Barley, 1/3 cup Beans (kidney, pinto, etc.), 1/2 cup cooked Lima beans, 2/3 cup Muesli, 1/4 cup Oat bran, 1/3 cup	Apple, orange, or pear Cherries, 12 Grapes, 17 Grapefruit, 1/2 Cantaloupe or berries (blueberries, rasp- berries, strawberries, etc.) = 1 cup	Corn, 1/2 cup Squash, acorn, 1 cup cooked Peas, green or lentils, 1/2 cup cooked 1½ cups cooked or 3 cups raw vegeta- bles (asparagus, beets, broccoli, car- rots, cucumbers, mushrooms, onions, peppers, tomatoes, zucchini, and others)
Medium (choose less often)	Baked beans, 1/4 cup Bran flakes, 1/2 cup Bread, 100% whole wheat, 1 slice English muffin, whole wheat, 1/2 Granola, low sugar, 1/4 cup Hamburger or hot dog bun, 1/2 Oatmeal, old fashioned, 1/2 cup Pasta, 1/3 cup cooked Raisin bran, 1/3 cup Rice, converted or wild, 1/3 cup cooked Special K, 3/4 cup Tortilla, 6"	Banana, 1 small Canned fruit, drained, 1/2 cup Dried fruit, 1/4 cup Watermelon, 1¼ cups Raisins, 2 tbsp Orange juice, 1/2 cup Apple juice, 1/2 cup Grape juice, 1/3 cup	Potato, small, "new," 1/2 cup Sweet potato, 1/2 cup cooked
High (choose rarely)	Bagel, large, 1/4 bagel Bread, white, 1 slice Cream of wheat, 1/2 cup cooked Cheerios, 3/4 cup Corn flakes, 3/4 cup Instant oatmeal, 1/2 cup cooked Pancake, 4" Rice Krispies, 3/4 cup Rice, white, 1/3 cup cooked Shredded wheat, 1/3 cup Waffle, 4"		Potato, small russet, 3" diameter Potato, mashed, 1/2 cup

(continued)

**TABLE 9-10 Glycemic Index and Glycemic Load (continued)**

Glycemic Index	Combination Foods	Sweets/Snacks	Milk/Yogurt/Milk Substitutes
Low	Soup, cream, low fat, 1 cup	Ice cream, low fat, 1/2 cup	Milk, skim or low fat (1%), 1 cup
	Chili, low fat, 1/2 cup	Pudding, sugar free, 1/2 cup	Yogurt, low fat, artificially sweetened, 1 cup
Medium	Burrito, bean, flour tortilla, 7" long = 3 carb choices	Popcorn, microwave light, popped, 3 cups	Soy milk, low fat or nonfat, 1 cup
	Pasta dish, 1/2 cup	Cookie, 3" across, 1	Yogurt, low fat, sweetened, with fruit, 1/3 cup
High	Pizza, thin crust, medium, 1 slice (= 2 carb choices)	Muffin, small, 1/2	
	Pizza, thick crust, medium, 1 slice (= 3 carb choices)	Pretzel twists, mini, 15 pieces	
		Brownie or cake, no frosting, 2" square	
		Doughnut, 3", 1/2 doughnut	
		Granola bar, 1	
		Potato or tortilla chips, 15 chips	
		Syrup, 1 tbs	

Source: Brand-Miller et al, 2003.

- Aim for 30 min/d of physical activity to burn a minimum of 1500 kcal/wk (see Table 9-11).

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

### For More Information

# ISLET CELL TRANSPLANTATION

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

Some native pancreatic beta cell function persists even years after disease onset in most type 1 diabetic patients (Liu et al, 2009). However, the destruction of beta cells leads to permanent insulin dependence. Islet cell transplantation can lead to insulin independence with excellent metabolic control. Islet transplantation can require more than one donor pancreas to achieve insulin independence (Rickels et al, 2005). Transplants may be performed by a radiologist, who uses x rays and ultrasound to guide placement of a catheter through the upper abdomen and into the portal vein, where islets are slowly infused. If this is not feasible, a surgeon may perform the procedure under anesthesia.

The acute posttransplantation phase lasts up to 2 months; the chronic phase starts after 2 months. Drugs are needed to prevent rejection. Islet cell programs try to avoid using large doses of glucocorticoids. Most protocols are designed to use tacrolimus and sirolimus so that high-dose glucocorticoids would not have to be used.

During the acute period of care, there is the issue that patients are variably managed with insulin therapy to allow for recovery of the islets after they have been placed into their new and not totally adequate environment in the liver. Most centers treat patients for up to a month, and treating hypoglycemia during this time is a concern.

Long-term complications may include hyperlipidemia. In T1DM, the release of many hormones, not only from beta-cells, but also from adipocytes (adipokines) is altered (Stadler et al, 2009). After successful pancreas–kidney transplantation (PKTx), T1DM patients can revert to a nondiabetic metabolism, but altered adipokines are still present after PKTx; adipokines include visfatin, retinol-binding protein-4 (RBP-4), adiponectin, and high-molecular-weight (HMW) adiponectin (Stadler et al, 2009). More research in this area is needed.

Alkaline phosphatase (Alk phos)	Bilirubin Na <sup>+</sup> , K <sup>+</sup>	White blood cell (WBC) count
Aspartate aminotransferase (AST)	Hemoglobin and hematocrit (H & H)	Total lymphocyte (TLC) count
Alanine aminotransferase (ALT)	Serum Fe	Glucose (Gluc)
	Serum folacin	Chol, Trig
	BUN, Creat	CRP
	Ca <sup>++</sup> , Mg <sup>++</sup>	

### INTERVENTION

### OBJECTIVES

- Meet the specific needs of the patient; modify drug therapy to enhance outcomes and quality of life.
- Prevent infection and promote healing.
- Monitor for abnormal electrolyte levels.
- Monitor CHO intolerance but make sure that diet provides enough CHO to spare proteins. Treatment goals should reflect those of the American Diabetes Association; adjust as new evidence suggests.
- Alleviate rejection episodes.
- Control infections, especially during the acute phase. Support protein intake to prevent additional infections.
- Force fluids unless contraindicated, as in retention. Match fluid output.
- Help patient adjust to a lifelong medical regimen during chronic phase. Improve survival rate by supporting immune response.
- Correct or manage complications that occur.
- Control weight gain in the first year after transplantation.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Transplantation may occur for T1DM, where there is a genetic component.

<b>Clinical/History</b>	BP	Nitrogen (N) balance
Height	Temperature	Glomerular filtration rate (GFR)
Dry weight, present weight	<b>Lab Work</b>	
BMI	Albumin (Alb),	
Diet history	transferrin	
I & O	HbA1c	

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Poor Nutrition Quality of Life

**Assessment Data:** Weight, labs, nutritional history prior to transplantation, statement of “not liking to eat any more because of the pain.”

**Nutrition Diagnosis (PES):** Poor nutritional quality of life related to abdominal pain after meals as evidenced by weight changes, vacillating lab results and statements about not enjoying meals.

**Intervention:** Food and Nutrient Delivery—gradual weaning from nutritional support back to oral diet, using small portions of favorite foods. Education—how the transplant would eventually allow life without insulin shots and more normal meal experiences.

**Monitoring and Evaluation:** Tolerance after weaning from nutrition support to oral diet. Acceptance of several favorite foods, and trying new foods with assistance of family members.

**TABLE 9-12 Medications Used after Islet Cell Transplantation**

Medication	Description
Cyclosporine	Cyclosporine does not cause retention of sodium as much as corticosteroids do. Intravenous doses are more effective than oral doses. Nausea, vomiting, and diarrhea are common side effects. Hyperlipidemia, hyperglycemia, and hyperkalemia may also occur; decrease fat intake as well as sodium and potassium if necessary. Magnesium may need to be replaced. The drug is also nephrotoxic; a controlled renal diet may be beneficial. Take omega-3 fatty acids to reduce toxic side effects such as high blood pressure and kidney damage. Avoid St. John's wort.
Diuretics	Diuretics such as furosemide (Lasix) may cause hypokalemia. Aldactone actually spares potassium; monitor drug changes closely. In general, avoid use with fenugreek, yohimbe, and ginkgo.
Immunosuppressants	Immunosuppressants such as muromonab (Orthoclone OKT3) and antithymocyte globulin (ATG) are less nephrotoxic than cyclosporine but can cause nausea, anorexia, diarrhea, and vomiting. Monitor carefully. Fever and stomatitis also may occur; alter diet as needed.
Insulin	Insulin may be necessary during periods of hyperglycemia. Monitor for hypoglycemic symptoms during use; teach patient self-management tips.
Pancreatic enzymes	Pancreatic enzymes may be needed if pancreatitis occurs after transplantation.
Tacrolimus (Prograf, FK506)	Tacrolimus suppresses T-cell immunity; it is 100 times more potent than cyclosporine, thus requiring smaller doses. Side effects include gastrointestinal distress, nausea, vomiting, hyperkalemia, and hyperglycemia; adjust diet accordingly by controlling carbohydrate and enhancing potassium intake.
Tetranectin	Tetranectin binds plasminogen and may have a role in regulating pericellular proteolysis and in the survival of islets in the liver after islet transplantation.

## FOOD AND NUTRITION

- Progress solids as quickly as possibly postoperatively. Monitor fluid status, and adjust as needed.
- Daily intake of protein should be appropriate for age and sex; 1.5 g/kg while on steroids may be recommended. Energy needs should be calculated as 30–35 kcal/kg.
- Daily intake of sodium should be 2–4 g until the drug regimen is reduced. Adjust potassium levels as needed.
- Daily intake of calcium should be 1–1.5 times the daily requirements to offset poor absorption. Children especially need adequate calcium for growth. Daily intake of phosphorus should be equal to calcium intake.
- Supplement diet with vitamin D, magnesium, and thiamin as needed. Adequate vitamin intake will be essential to maintain immunity and to support wound healing.
- Control CHO intake with hyperglycemia (45–50% total kcal); encourage healthy food sources of carbohydrate. Transplantation patients are at risk of further glucose intolerance from multiple medications.
- Plan fats at 25–35% of total kilocalories (encourage monounsaturated fats and omega-3 fatty acids). Low saturated fats and cholesterol may be needed. A controlled fat intake is recommended for prevention and treatment of hyperlipidemia.
- Reduce gastric irritants as necessary if GI distress or reflux occurs.
- Monitor electrolytes carefully; hyperkalemia is common with cyclosporine or tacrolimus.
- Special diets may be discontinued when drug therapy is reduced to maintenance levels. Encourage exercise and a weight control plan thereafter.

## Common Drugs Used and Potential Side Effects

- Thymoglobulin is an antibody preparation to prevent organ transplant rejection. The START trial is underway

to determine whether Thymoglobulin treatment can halt the progression of newly diagnosed type 1 diabetes when given within 6 weeks of disease diagnosis.

- See Table 9-12 for other drugs used for the transplant.

## Herbs, Botanicals, and Supplements

- Herbals should be discouraged after transplantation. Those who self-medicate with herbals are taking a chance that their use of a herb may interact with their immunosuppressive drugs and either cause higher or lower than desired drug levels of these agents.
- Chaparral is an herbal product that may cause severe hepatitis or liver failure. St. John's wort interferes with the metabolism of immunosuppressants and should not be used after transplantation.
- See Table 9-9 for guidance on more specific herbs and supplements.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Indicate which foods are sources of key nutrients such as protein in the diet. If patient does not like milk, discuss how other sources of calcium may be used in the diet.
- Alcohol should be avoided unless permitted by the doctor.
- Patients should know when to seek medical attention.
- Discuss problems with long-term obesity and hypercholesterolemia.
- Encourage moderation in diet; promote adequate exercise.

**Patient Education—Foodborne Illness**

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# METABOLIC SYNDROME

**NUTRITIONAL ACUITY RANKING: LEVEL 3–4****DEFINITIONS AND BACKGROUND**

The metabolic syndrome (MetS; insulin resistance syndrome or syndrome X) has simultaneous clustering of low levels of HDL cholesterol, hyperglycemia, high waist circumference, hypertension, and elevated triglycerides. Any three of the following five criteria constitute diagnosis of MetS (Grundy et al, 2005):

- Elevated waist circumference: 40" or 102 cm in men; 35" or 88 cm in women.
- Elevated triglycerides (TG)  $\geq 150$  mg/dL or drug treatment for elevated TG.
- Reduced HDL cholesterol:  $< 40$  mg/dL in men and 50 mg/dL in women or drug treatment for low HDL cholesterol levels.
- Elevated BP:  $> 130$  mm Hg systolic BP or 85 mm Hg diastolic BP or drug treatment for hypertension.
- Elevated fasting glucose:  $> 100$  mg/dL or drug treatment for elevated glucose.

It is associated with CVD and often leads to T2DM. This condition affects some young people but usually affects persons aged 55 years and older. More than 64 million Americans have MetS, roughly one in four adults and 40% of adults aged 40 years and older.

Increased birthweight, excessive energy intake, physical inactivity, obesity, smoking, inflammation, and hypertension contribute to MetS. Individuals who are obese and insulin resistant are particularly prone to this syndrome. An "apple" shaped figure (high waist circumference) is riskier because fat cells located in the abdomen release fat into the blood more easily than fat cells found elsewhere.

Serum adiponectin levels are associated with insulin sensitivity; they are decreased in T2D and obesity. Genetic and environmental factors contribute to risk (Gable et al, 2006). The initial insult in adipose inflammation and insulin resistance is perpetuated through chemokine secretion, adipose retention of macrophages, and elaboration of pro-inflammatory

adipocytokines (Shah et al, 2008). In women, depressive symptoms are associated with MetS, especially with elevated afternoon and evening cortisol (Muhtz et al, 2009). Clearly, more research is needed.

Management of MetS should focus on lifestyle modifications, especially reduced caloric intake and increased physical activity (Deedwania and Volkova, 2005). Phytochemicals, MUFA, antioxidant foods, spices such as turmeric, cumin, and cinnamon have anti-inflammatory effects. Intake of whole milk, yogurt, calcium, and magnesium protect against MetS whereas intake of cheese, low-fat milk, and phosphorus do not (Beydoun et al, 2008; McKeown et al, 2009). Mild-to-moderate alcohol consumption is acceptable but binges and early onset of drinking are not acceptable.

**ASSESSMENT, MONITORING, AND EVALUATION****CLINICAL INDICATORS**

**Genetic Markers:** Candidate genes associated with CVD represent potential risk factors for the MetS (Goulart et al, 2009). Chronic inflammation and IL1beta genetic variants may be a concern; genetic influences are more evident among subjects with low (n-3) PUFA intake (Shen et al, 2007).

Clinical/History	BMI	Waist circumference (35" or 88 cm in women)
Height	Diet history	BP ( $\geq 130/85$ mm Hg)
Weight	Waist circumference (40" or 102 cm in men)	
Weight pattern history		
Central Obesity?		

Sleep apnea? Depression?	LDL Chol (high?) Trig (>150 mg/dL) Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup>	High fibrinogen or plasmino- gen activator inhibitor [−1] in the blood?
<b>Lab Work</b>		
Gluc (>100 mg/dL)	Serum insulin	Prothrombin time (PT)
HbA1c	Serum uric acid (elevated?)	International normalized ratio (INR)
HDL Chol (<40 mg/dL for men, <50 mg/dL for women)	CRP (elevated)	

## INTERVENTION

### OBJECTIVES

- Reduce the inflammatory state and insulin resistance caused by excessive adipose tissue. Improve body weight; lessen abdominal obesity in particular. A realistic goal for weight reduction should be 7–10% over 6–12 months (Bestermann et al, 2005).
- Promote physical activity. Recommendations should include practical, regular, and moderated regimens of exercise, with a daily minimum of 30–60 minutes and equal balance between aerobic and strength training (Bestermann et al, 2005).
- Achieve and maintain cholesterol, blood glucose, and BP at levels indicated by the American Heart Association, as follows (Grundy et al, 2005):

### For Atherogenic Dyslipidemia

- For elevated LDL cholesterol: Give priority to reduction of LDL cholesterol over other lipid parameters. Achieve LDL cholesterol goals based on patient's risk category. LDL cholesterol goals for different risk categories are:
  - High risk: seek 70–100 mg/dL
  - Moderately high risk: seek 100–130 mg/dL
  - Moderate risk: seek 130 mg/dL
  - Lower risk: 160 mg/dL is acceptable

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inappropriate Intake of Types of CHO—Metabolic Syndrome

**Assessment Data:** Food intake records: high refined CHO and soft drink intake; high juice but minimal fruit intake; low dietary fiber intake.

**Nutrition Diagnosis (PES):** Inappropriate intake of types of CHO related to knowledge deficit about MetS as evidenced by FBS of 140 mg/dL and triglycerides of 300 mg/dL.

**Intervention:** Education about desirable CHO, whole grains, and fiber; shopping tips; dining out.

**Monitoring and Evaluation:** Improved labs in 3–6 months; dietary records showing improvement in intake of whole grains, whole fruits, and vegetables.

- If TG is >200 mg/dL, then goal for non-HDL cholesterol for each risk category is 30 mg/dL higher than for LDL cholesterol. If TG is >200 mg/dL after achieving LDL cholesterol goal, consider additional therapies to attain non-HDL cholesterol goal.
- If HDL cholesterol is <40 mg/dL in men or <50 mg/dL in women, raise HDL cholesterol to extent possible with standard therapies for atherogenic dyslipidemia. Either lifestyle therapy can be intensified or drug therapy can be used for raising HDL cholesterol levels, depending on patient's risk category.

### For Elevated BP

- Reduce BP to at least achieve BP of >140/90 mm Hg (or <130/80 mm Hg if diabetes is present). Reduce BP further to extent possible through lifestyle changes.
- For BP >120/80 mm Hg: Initiate or maintain lifestyle modification via weight control, increased physical activity, alcohol moderation, sodium reduction, and emphasis on increased consumption of fresh fruits, vegetables, and low-fat dairy products in all patients with MetS.
- For BP >140/90 mm Hg (or >130/80 mm Hg if diabetes is present), add BP medication as needed to achieve goal BP.

### For Elevated Glucose

- For IFG, delay progression to T2DM. Encourage weight reduction and increased physical activity.
- In diabetes, for hemoglobin A1c at or above 7.0%, lifestyle therapy and pharmacotherapy, if necessary, should be used. Modify other risk factors and behaviors (e.g., abdominal obesity, physical inactivity, elevated BP, or lipid abnormalities).

### For Prothrombotic State

- Reduce thrombotic and fibrinolytic risk factors. Low-dose aspirin therapy or prophylaxis is recommended.

### For Proinflammatory State

- There are no specific therapies beyond lifestyle changes. The antioxidants and omega-3 fatty acids may be helpful.

## FOOD AND NUTRITION

- The general recommendations include low intake of saturated fats, trans fats, and cholesterol. Increase use of omega-3 PUFA intake (Shen et al, 2007) and MUFA (especially extra virgin olive oil).
- Plan a Mediterranean-type diet using more fiber and starches, especially whole grains, raw fruits, and vegetables. A plant-based diet may be useful (Barnard et al, 2005).
- The DASH diet contains 3–4 g sodium with good sources of potassium, calcium, and magnesium. Dairy products provide calcium, magnesium, and potassium.
- Monitor blood glucose levels. Carbohydrate restriction (CR) has been shown to improve dyslipidemias associated with MetS more than a low fat diet (Al-Sarraj et al, 2010).

- Encourage soy protein as a meat substitute several times a week; soy protein may help with weight reduction and dyslipidemia (Bestermann et al, 2005).
- Ensure adequate intake of folate, vitamins B<sub>6</sub>, B<sub>12</sub>, C, and E, preferably from food.
- Dark chocolate in small amounts regularly may help lower BP, improve cholesterol, and help with insulin sensitivity.
- Spread out the energy load by eating smaller meals.

### Common Drugs Used and Potential Side Effects

- To lower lipids, a statin should be used initially unless contraindicated (Bestermann et al, 2005). Statins decrease biomarkers of inflammation and oxidative stress in a dose-related manner; atorvastatin 80 mg compared with a 10-mg dose is superior for decreasing oxidized LDL, hs-CRP, matrix metalloproteinase-9, and NF- $\kappa$ B activity (Singh et al, 2008).
- Glucose-lowering medications must be carefully prescribed and monitored. Metformin may be indicated (Orchard et al, 2005).
- BP medications may be prescribed; monitor for necessary restrictions of sodium and/or higher need for potassium. An ACE inhibitor or an angiotensin receptor blocker is usually the first medicine (Bestermann et al, 2005).
- Medications that diminish insulin resistance and directly alter lipoproteins are necessary; combination therapy is often required (Bestermann et al, 2005).
- If patients with MetS have elevated fibrinogen and other coagulation factors leading to prothrombotic state, aspirin is used (Deedwania and Volkova, 2005). Low-dose aspirin is not generally a problem; taken with a meal or light snack to prevent potential for GI bleeding.

### Herbs, Botanicals, and Supplements

- Antioxidant supplements are not recommended, but intake of antioxidant-rich foods should be suggested (Czernichow et al, 2009). Thus far, trials with alpha tocopherol have been disappointing; further trials with gamma and alpha-tocopherols are warranted. Include phytochemicals, antioxidant foods, and spices such as turmeric, cumin, and cinnamon in the diet. See Tables 8-13 and 8-14.
- Chromium picolinate (CrPic) enhances insulin action by lowering plasma membrane (PM) cholesterol (Horvath et al, 2008). Coenzyme Q10 may have some merit, but further research is needed.
- High serum selenium concentrations have been associated with prevalence of higher FPG, LDL, TG, and glycosylated hemoglobin levels; further research is needed to determine its role in the development or the progression of MetS (Bleys et al, 2008).
- Other herbs and botanical supplements should not be used without discussing with physician. See Table 9-9 for guidance on more specific herbs and supplements.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Widespread screening is recommended to slow the growth of this syndrome. Prevention should start in childhood

with healthy nutrition, daily physical activity, and annual measurement of weight, height, and BP beginning at 3 years of age (Bestermann, 2005).

- Discuss the role of nutrition (DASH or Mediterranean diet principles) in managing this syndrome. Obesity is a major contributor to the problem, so weight loss (even 10 lb) can help improve health status. A diet rich in antioxidants and DHA is beneficial. Finally, the 2005 Dietary Guidelines are consistent with lowering risk for MetS (Fogli-Cawley et al, 2007).
- Regular physical activity can help to lower elevated blood cholesterol levels and BP. Walking, or an exercise that is pleasant for the individual, is the one to select. Aerobic and strength training exercises are beneficial. Reduce sedentary activities, including television and computer time (Ford et al, 2005).
- Smoking cessation measures may be needed. Offer guidance on how not to gain weight after quitting.
- Limit consumption of alcoholic beverages, which can elevate triglycerides in large doses.

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## PREDIABETES

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

#### DEFINITIONS AND BACKGROUND

Prediabetes (impaired glucose tolerance, IGT) distinguishes those people who are at increased risk of developing diabetes. People with prediabetes have IFG or IGT, or both. More than 54 million Americans are affected with this combination of genes, obesity, and physical inactivity. People who have prediabetes may have a family history of heart disease and apple-shaped (intra-abdominal) obesity. Elevated triglycerides and low HDL cholesterol are risks for T2DM (Zacharova et al, 2005); adiposity-associated inflammation and insulin resistance are also implicated (Shah et al, 2008). NIH has also reported that smoking increases insulin resistance and prediabetes.

Under recent criteria, a normal blood glucose level is <100 mg/dL. Table 9-13 shows the tests and classification for IGT and IFG.

Most people with prediabetes go on to develop T2DM within 10 years unless they make lifestyle changes. Studies have evaluated various interventions among people with IGT and risks for developing diabetes. The Diabetes Prevention Program (DPP) was a large prevention study of people at high risk for diabetes (American Diabetes Association, 2006). Half of the participants had MetS at the beginning of the study; lifestyle intervention and metformin therapy reduced development of the syndrome in the remaining participants (Orchard et al, 2005). Lifestyle interventions include modest weight loss from a low-calorie, low-fat diet,

and increased moderate-intensity physical activity (such as walking for 2½ hours each week).

People treated with an intensive lifestyle intervention reduce their risk of developing diabetes by half over 4 years, whereas people treated with metformin reduce their risk by only one third (American Diabetes Association, 2006). Metformin is most effective among younger, heavier people (those 25–40 years of age, 50–80 lb overweight) and less effective among older people and people with lower BMIs. In the STOP-NIDDM Trial, treatment of people with IGT with the drug acarbose reduced the risk of developing diabetes by 25% over 3 years.

The benefits of weight loss and physical activity strongly suggest that lifestyle modification should be the first choice to prevent or delay diabetes (American Diabetes Association, 2009). The dietitian plays an important role in nutrition education and counseling for these behavioral changes.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Researchers are learning how to predict a person's odds of getting diabetes; Caucasians with type 1 diabetes have genes called HLA-DR3 or HLA-DR4 (American Diabetes Association, 2009). The HLA-DR7 gene may put African Americans at risk, and the HLA-DR9 gene may put Japanese at risk.

The MTHFR C>T polymorphism has a significant association with diabetic neuropathy in Caucasians and in persons with T2DM (Zintzaras et al, 2007). More rigorous studies are needed to define the role of genotypes in diabetes complications and management.

Clinical/History	Waist circumference	I & O
Height	BMI	BP (>140/90?)
Weight	Diet history	Smoker?
		PCOS?

**TABLE 9-13 Prediabetes Classifications and Tests**

Condition/Classification	Test Used and Diagnostic Values
Impaired glucose tolerance (IGT)	<ul style="list-style-type: none"> <li>Oral Glucose Tolerance Test (OGTT), 75 g of glucose</li> <li>2-hour plasma glucose = 140–199 mg/dL</li> </ul>
Impaired fasting glucose (IFG)	<ul style="list-style-type: none"> <li>Fasting plasma glucose (FPG) after 8-hour fast</li> <li>Fasting plasma glucose = 100–125 mg/dL</li> </ul>

Heart disease?	Fasting glucose	Alb,
Hx gestational diabetes?	after 8 hours	transferrin
High risk ethnic background?	(100–120 mg/dL?)	Na <sup>+</sup> , K <sup>+</sup>
Sedentary lifestyle?	HbA1c	H & H
Family hx T2DM?	Chol, HDL and LDL profiles	Serum Fe
	Trig	Serum folacin
	CRP	BUN, Creat
		Ca <sup>++</sup> , Mg <sup>++</sup>
		GFR

**Lab Work**

Gluc  
OGTT with 2  
hours post-  
prandial  
(140–199  
mg/dL?)

**SAMPLE NUTRITION CARE PROCESS STEPS****Not Ready For Lifestyle Change**

**Assessment Data:** Blood glucose log and food history; BMI 29 at age 48; family Hx diabetes (T2DM); previous counseling on lifestyle changes to prevent diabetes. Recent random blood glucose >140 mg/dL.

**Nutrition Diagnosis (PES):** Not ready for lifestyle change related to potential for diabetes as evidenced by BMI 29, family history of diabetes, statement of “not being interested in many changes at this time.”

**Intervention:** Counseling about the importance of lifestyle changes to reduce likelihood of diabetes.

**Monitoring and Evaluation:** Follow-up clinic visit indicating that client did make some lifestyle changes after considering the last counseling session; random blood glucose 100 mg/dL; weight loss of 5 lb in two months; increase in physical activity noted.

**INTERVENTION****OBJECTIVES**

- Increase the probability of reverting from IGT to normal glucose tolerance. Prevent further insulin resistance, hyperglycemia, or progression to diabetes.
- Modest weight loss (5–10% of body weight) and modest physical activity (30 minutes daily) are the recommended goals (American Diabetes Association, 2006). Walking can be encouraged for most people.
- Prevent or delay heart and kidney diseases, stroke, eye disease, and other undesirable conditions.
- Design a program that includes elements from the successful DPP trial:

Clearly defined weight loss and physical activity goals	A flexible maintenance program
Individual case managers or “lifestyle coaches”	Culturally appropriate materials and strategies
Intensive, ongoing intervention	Local and national network of training, feedback and clinical support
A core curriculum	Supervised exercise sessions at least twice weekly

Source: CDC, Web site accessed September 25, 2009, at <http://www.cdc.gov/diabetes/faq/prediabetes.htm>.

**FOOD AND NUTRITION**

- Control CHO intake (about 45–50% of total kilocalories) and limit excess added sugars. Encourage less processed carbohydrate and fiber food sources. Individualize according to lab work, BMI, and other risk reduction requirements.
- Maintain protein at about 20% of total energy.
- Plan fats at about 30–35% of total kcal (encourage monounsaturated fats and omega-3 fatty acids). Low saturated fats and cholesterol may be needed to prevent or treat hyperlipidemia.

- A moderate reduction in total energy intake is important. Modest weight loss of 5–7% of body weight may be recommended.
- Sufficient intake of minerals such as magnesium may be protective against diabetes. Include more almonds, whole wheat, cooked spinach, baked potatoes, and other magnesium-rich foods.
- Excesses of iron and selenium should be avoided; studies suggest that high intakes cause deposits in the internal organs, including the pancreas.
- Include adequate intake of fiber. A low fat vegan diet has been found to improve glycemia and elevated lipids (Barnard et al, 2009).
- Essential oils such as fenugreek, cinnamon, cumin, and oregano enhance insulin sensitivity (Talpur et al, 2005). Cinnamon may improve blood sugar and lipid levels (1/2 teaspoon daily).
- When a tube feeding is needed, there is insufficient evidence to support the use of specialty products as compared with standard products at this time.

**Common Drugs Used and Potential Side Effects**

- Acarbose treatment in IGT subjects decreases the risk of progression to diabetes by 36% (Delorme and Chiasson, 2005).
- Metformin reduces risk of developing diabetes, especially among younger, heavier people such as those 25–40 years of age who are 50–80 lb overweight (Herman et al, 2005). It is less effective among older people and people who were not as overweight.

**Herbs, Botanicals, and Supplements**

- Herbs and botanical supplements should not be used without discussing with physician. See Table 9-9 for tips.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Community Health Workers (CHW) may be trained for peer counseling when administered through a Diabetes Care Center (Katula et al, 2010). Lifestyle weight (LW) loss intervention has a goal of  $\geq 7\%$  weight loss achieved through increases in physical activity (180 min/wk) and decreases in caloric intake (approximately 1500 kcal/d) with CHW-led group-mediated cognitive behavioral meetings that occur weekly for 6 months and monthly thereafter for 18 months (Katula et al, 2010). Monthly small-group education sessions for a year are recommended by the CDC.
- Weight loss is a key goal (Davis et al, 2009; Norris et al, 2005). Discuss foods and meal patterns that will help to reduce risk factors for the individual client.
- Look AHEAD (Action for Health in Diabetes) trial participants (overweight adults diagnosed with diabetes) exceed recommended intake of fat, saturated fats, and sodium, which may contribute to increasing their risk of CVD and other chronic diseases (Vitolins et al, 2009). Therefore, it is important to address total fat intake (type of fat) and to suggest increasing intake of antioxidant-rich, high fiber foods. A vegan or vegetarian diet can be safely recommended (Barnard et al, 2009).
- Promote 8 oz or more of low fat milk, an ounce a day of nuts, filtered coffee, 1/2 teaspoon of cinnamon, and plenty of nonstarchy vegetables.
- Exercise seems to promote more reliable glycemic control compared with specific dietary protocols (Nield et al, 2007). Promote physical activity that matches client interest and ability. Discuss how to handle medication changes accordingly.

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# TYPE 2 DIABETES IN ADULTS

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

T2DM arises because of insulin resistance, when there is failure to use insulin properly combined with relative insulin deficiency. Increased and unrestrained hepatic glucose production as well as diminished glucose uptake and utilization results from insulin resistance occurring in the cells of the liver and other peripheral tissue, especially skeletal muscle. Previous names for T2DM include “non–insulin-dependent diabetes (NIDDM),” “adult-onset,” “type II,” “maturity-onset,” and “ketosis-resistant” diabetes. T2DM accounts for 90% of all forms of diabetes. A significant per-

centage (about one third) of individuals who have T2DM are unaware of their diagnosis. Because T2DM is progressive, most patients will have already lost at least 50% of beta-cell function at the time of diagnosis.

The American Diabetes Association recommends diagnostic screening at 3-year intervals beginning at the age of 45, especially in individuals who have a BMI greater than 25 kg/m<sup>2</sup> (overweight). Risk factors include genetics, obesity, age, history of gestational diabetes, sedentary lifestyle, and smoking. Smoking cessation, decreasing BMI, and decreasing BP are major modifiable risk factors that are also major determinants of acquiring T2DM (Smith et al, 2005).

**TABLE 9-14 Number of Medical Nutrition Therapy Visits Recommended for Type 2 Diabetes**

Encounter Number	Length of Contact	Time between Encounters
1	60–90 minutes	2–4 weeks
2, 3	30–45 minutes	2–4 weeks
4, 5	30–45 minutes	6–12 months

From: National Guideline Clearinghouse. Nutrition practice guidelines for type 1 and type 2 diabetes mellitus. Accessed August 1, 2009, at [http://guidelines.gov/summary/summary.aspx?doc\\_id=12816&nbr=006618&string=nutrition+AND+visits+AND+diabetes](http://guidelines.gov/summary/summary.aspx?doc_id=12816&nbr=006618&string=nutrition+AND+visits+AND+diabetes)

For reducing BP, numerous clinical trials and experts support reduction of sodium intake; modest weight loss; increased physical activity; a low-fat diet that includes fruits, vegetables, and low-fat dairy products; and moderate alcohol intake. MNT from RDs in the treatment of T2DM improves glycemic outcomes with a decrease in A1c of approximately 1–2%, depending on the duration of diabetes. Early referral for lifestyle changes and advice will yield the most benefit (Kulkarni, 2006).

The body's first defense against invading pathogens or tissue injury is the innate immune system; the cholinergic anti-inflammatory pathway is a neural mechanism that suppresses the innate inflammatory response such as excessive cytokine release in T2DM (Oke and Tracey, 2009). The use of antioxidant foods, spices and the Mediterranean diet has shown positive results as compared with a low fat diet (Esposito et al, 2009).

Patients should be educated about the progressive nature of diabetes and the importance of glycemic control with appropriate food choices and physical activity in conjunction with antidiabetes medication (Kulkarni, 2006). Maintain focus on lifestyle strategies that will improve blood glucose, BP, and lipids. Diabetes self-management training (DSMT), consisting of a 4-hour class, followed by individual dietitian consults and monthly support meetings can lower A1c at a very low cost.

Weight management is especially helpful (Davis et al, 2009). Addition of a modest-cost, RD-led lifestyle case-management intervention to usual medical care does not increase health care costs and yields modest cost savings among obese patients with T2DM (Wolf et al, 2007). Weight loss significantly reduces diabetes costs; for every 1% weight lost, there is a 3.6% savings in total health costs and a 5.8% savings in diabetes care costs (Yu et al, 2007). The American Dietetic Association recommends four MNT visits initially, then one visit every 6–12 months (Table 9-14). Referral to a dietitian within the first month after diagnosis is important.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** T2DM has a stronger genetic basis than type 1, but depends more on environmental fac-

tors such as obesity and a western diet. From whole-genome studies, affected family members are studied; calpain 10 (CAPN10) and hepatocyte nuclear factor 4 alpha (HNF4A) have been identified.

Common genetic variation near melatonin receptor MTNR1B contributes to raised plasma glucose and increased risk of type-2 diabetes among Indian Asians and European whites (Chambers et al, 2009). Variants of the FTO (affectionately called the FATS0) gene are identified an obesity risk allele; this gene is associated with increased risk of TDM.

Clinical/History	Numbness or burning sensation in feet, ankles, legs	Trig (often increased)
Height		BUN, Creat
Weight		Na <sup>+</sup> , K <sup>+</sup>
BMI		ALT, AST
Obesity?	Signs of dehydration?	Lactate dehydrogenase (LDH)
Diet history	Smoking history	Alk phos
Waist circumference	Electrocardiogram (ECG)	Ca <sup>++</sup> , Mg <sup>++</sup>
BP (increased?)	before exercise program	Microalbuminuria
Blurred vision?		Plasminogen activator inhibitor type 1
Erectile dysfunction	<b>Lab Work</b>	Fasting insulin
Fatigue	CRP	Fasting C-peptide levels
Frequent, slow-healing infections	FPG	
Increased appetite, thirst, urination	HbA1c	
	Blood or urinary ketones	
	Total Chol, LDL, HDL	

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Self-Monitoring Deficit In T2DM

**Assessment Data:** Blood glucose self-monitoring records, food diary worksheets and meal records, blood glucose levels (fasting, 2-hour postprandial and/or HbA1c levels).

**Nutrition Diagnosis (PES):** Self-monitoring knowledge deficit related to lack of understanding how to record food and beverage intake as evidenced by incomplete food records at last two clinic visits and lab of HbA1c = 8.5 mg/dL.

**Intervention:** Teaching patient and family member(s) about use of simple blood glucose self-monitoring records (recording of timing, amount, blood glucose levels) and meal records.

**Monitoring and Evaluation:** HbA1c levels (goal <7 mg/dL); other glucose labs, food diary and records, discussion about complications of using the records.

## INTERVENTION

## OBJECTIVES

- Provide persons with diabetes initial basic nutrition messages and schedule time for MNT with an RD who has expertise in diabetes management.
- Maintain as near-normal blood glucose levels as possible by balancing food intake with insulin (either endogenous or exogenous) or oral glucose-lowering medications and activity levels. Improvement with MNT, if successful, is usually seen within 6 weeks and up to a maximum of 6 months. Medication may be needed if blood glucose levels are not under control.
- Maintain glycosylated A1c levels <7%, preprandial capillary plasma glucose levels between 90 and 130 mg/dL, and peak postprandial capillary plasma glucose levels <180 mg/dL. The target goal range for the patient may vary by age and underlying disorders.
- Protect beta-cell function by controlling hyperglycemia. A1c tests should be done at least two times a year in patients who are meeting treatment goals and quarterly in patients whose therapy has changed or who are not meeting glycemic goals.
- Achieve optimal serum lipid levels to reduce the risk for macrovascular disease. Dyslipidemia is a central component of insulin resistance in all ethnic groups.
- Emphasis of MNT is on lifestyle strategies to reduce glycemia, dyslipidemia, and BP. Strategies should lead to reduced energy intake and increased energy expenditure through physical activity. The A to Z (Atkins to Zone Diet) weight loss diet analysis found that premenopausal overweight and obese women who followed the Atkins diet (lowest carbohydrate intake), lost more weight at 12 months than women assigned to follow the Zone diet (Gardner et al, 2007). Therefore, for some patients, a low-carbohydrate, high-protein, high-fat diet may be a feasible alternative recommendation for weight loss.
- Maintain or improve overall health. The Dietary Guidelines for Americans and the MyPyramid food guide illustrate healthy nutritional guidelines and can be used by people with diabetes.
- Encourage regular mealtimes. Maintain lifestyle changes through behavior modification, education, and problem-solving strategies.
- Address individual needs according to culture, ethnicity, and lifestyle, while respecting willingness to change. For older adults, meet nutritional and psychosocial needs. For pregnant or lactating women, provide adequate energy and nutrients for optimal outcomes. Encourage therapeutic lifestyle changes (TLC), considering client's readiness, skills, resources, and current needs.
- Achieve BP levels that reduce risk for vascular disease and renal function decline.
- Manage problems related to compulsive or binge eating. Patients often report deliberate omission of insulin or oral hypoglycemic agents (OHA) to lose weight.
- Manage children with T2DM or maturity-onset diabetes of youth (MODY) differently than children who have T1DM; see appropriate entries.
- Prevent and treat the acute and long-term complications of diabetes listed in Table 9-2.

## FOOD AND NUTRITION

- The dietitian should calculate CHO and fat requirements individually according to lipid and glucose levels. Assess dietary history, physical exercise, and activity patterns.
- Include foods containing CHO from whole grains, fruits, vegetables, and low-fat milk. A vegan diet is also an effective consideration (Barnard et al, 2009; Turner-McGrievy et al, 2008).
- Moderate weight loss in an obese patient (5–10% of starting weight) may reduce hyperglycemia, dyslipidemia, and hypertension. A moderate caloric restriction (250–500 calories less than average daily intake as calculated from a food history) and a nutritionally adequate meal plan should be recommended. Extremely low-calorie diets for adults should be performed only in a hospital setting.
- In morbidly obese patients, bariatric surgery may be the only effective treatment. There are risks from surgery and anesthesia, but the benefits often outweigh the risks.
- Space meals and spread nutrient intake, particularly carbohydrate, throughout the day.
- Eating breakfast has beneficial effects on fasting lipid and postprandial insulin sensitivity. Avoid meal skipping. Individualize meal plan according to patient preferences.
- Carbohydrate should be calculated between 45% and 65% of energy intake. Consistency is important.
- Protein should be calculated at 15–20% of daily energy intake with normal renal function and control at 0.8–1.0 g/kg with renal disease. Where weight loss is needed, use of a diet slightly higher in protein may help to enhance insulin sensitivity.
- Fat should be 25–35% of energy intake (7–10% of kcal saturated fats, 10% polyunsaturated fats, and 10–15% monounsaturated fats). Limit intake of cholesterol to <200–300 mg/d.
- Foods that benefit both the carbohydrate and lipid abnormalities should be consumed often. Recommendations are the same as for the general population concerning fiber: use more brown rice, beans, green leafy vegetables, oat bran, legumes, barley, produce with skins, apples, oranges, and other whole fruit and produce.
- As part of a healthy lifestyle and to manage hypertension, teach the principles of the DASH diet; <2400 mg/d of sodium is recommended.
- For most vitamins and minerals, ensure adequate dietary intakes. Higher levels of magnesium (Rumawas et al, 2006), chromium, and zinc are recommended. A multivitamin–mineral supplement may be used. Because altered vitamin D and calcium homeostasis may play a role in the development of T2DM, dual supplementation may prevent T2DM in high-risk populations (Tremblay and Gilbert, 2009; Pittas et al, 2007). Vitamin K as phyloquinone may also have a role in glucose management (Yoshida et al, 2008).
- Discuss usefulness of artificial sweeteners and food diaries.
- Discuss use of alcohol. Avoid hypoglycemia by consuming alcohol with food. Limit to 1 drink daily for women and two for men. Light-to-moderate amounts of alcohol do not increase triglyceride or BP levels. Indeed, moderate alcohol consumption has been associated with a decreased incidence of diabetes and heart disease; alcohol has been

reported to increase insulin sensitivity and raise HDL cholesterol levels. Alcoholic beverages should be considered an addition to the regular food/meal plan. If consumed daily, calories from alcohol are calculated into the total energy intake. Abstain from alcohol in pregnancy, pancreatitis, advanced neuropathy, severe hypertriglyceridemia, and a history of alcohol abuse.

### Common Drugs Used and Potential Side Effects (see Table 9-15)

- T2DM is a progressive disease. Medications will need to be combined with lifestyle strategies. Insulin may be used in a combination with oral therapy or alone. If oral glucose-lowering medications do not achieve normoglycemia, combined oral therapies (drugs from two or more classes) can be initiated.
- If combination oral therapy does not work, insulin is needed. Insulin may also be needed for refractory hyperglycemia, diabetic ketoacidosis, stress, infection, or pregnancy.
- Multiple drug therapy is generally required to achieve BP targets. Angiotensin-converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), beta-blockers, diuretics, and calcium channel blockers may all be helpful.
- Aspirin therapy (75–162 mg/d) is recommended to protect against cardiovascular events.
- Overwhelming evidence suggests that the renin-angiotensin system (RAS) plays an important role in the pathogenesis of DM and its associated cardiovascular risks; RAS blockers may delay or prevent the onset (Braga and Leiter, 2009).
- In individuals with diabetes over the age of 40 years and without overt CVD, statin therapy to achieve an LDL <100 mg/dL is recommended. For people with diabetes and overt CVD, an LDL cholesterol goal of <70 mg/dL is recommended. Lifestyle modifications focusing on reducing saturated fat and increasing physical activity are also important.
- Antipsychotic agents contribute to the development of the metabolic syndrome and increase the risk for T2DM and heart disease. Monitor their use carefully.

**TABLE 9-15 Medications Used for Type 2 Diabetes**

Combination therapy rather than monotherapy is typically used to achieve glucose control in patients who are not at glycemic goals.

Classification	Medication	Route	The Way it Works	Time and Dose	Comments
Sulfonylureas	Glimepiride (Amaryl)	Oral	Increases insulin production.	One or two times a day	Never give to a patient who is fasting for any reason. Do not use with alcoholic beverages. May cause weight gain, nausea, diarrhea or heartburn. Check LFTs.
	Glipizide (Glucotrol)		Long-acting.		
	Glipizide ER (Glucotrol XL)				
	Glyburide (Diabeta, Micronase)				
Biguanides	Glucophage (Metformin) Glucophage XR	Oral	Lowers glucose from digestion; inhibits glucose release from the liver. Sensitizer.	Two to three times a day, XR once a day	Take with food. May cause diarrhea, flatulence, abdominal pain. Do not use with inflammatory bowel disease. Enhances weight loss.
Alpha-Glucosidase Inhibitors	Miglitol (Glyset) Acrobose (Precose)	Oral	Slows digestion, slows glucose production. Starch blocker that delays intestinal glucose absorption.	Take before each meal; swallow with first bite of food.	GI intolerance can occur. Exercise enhances effectiveness.
Thiazolidinediones	Rosiglitazone (Avandia) Pioglitazone (Actos)	Oral	Lowers glucose production; increases tissue glucose utilization, mostly in muscle.	Once daily with or without food	Liver damage is possible. Can lead to weight gain or heart failure.
Meglitinides	Repaglinide (Prandin) Senaglinide (Starlix)	Oral	Increases insulin production; short-acting.	5–30 minutes before meals	Offers better control of postprandial hyperglycemia and is associated with a lower risk of delayed hypoglycemic episodes.
DPP-4 Inhibitors	Sitagliptin (Januvia)	Oral	Lowers glucose by blocking an enzyme	100 mg. Once a day	
Incretin Mimetics	Exenatide (Byetta)	Injectable	Helps the pancreas make insulin, slows digestion	10 µg. Inject within an hour of AM and PM meals	Acid or sour stomach, belching, diarrhea, dizziness, nervousness.
Anti-hyperglycemic	Amylin (Symlin)	Injectable	Controls postprandial blood glucose	15 µg. Inject before major meals	

Source: Diabetes Medications, NIDDK. Web site accessed September 22, 2009, at [http://diabetes.niddk.nih.gov/dm/pubs/medicines\\_ez/](http://diabetes.niddk.nih.gov/dm/pubs/medicines_ez/)

- Medications such as steroids, beta-blockers, and diuretics may cause hyperglycemia in some patients. Supplements of Vitamin C may cause false-positive urinary glucose levels when given in large doses.
- Melatonin may have a role. Carriers of the risk genotype exhibit increased expression of MTNR1B in islet cells; these individuals may be more sensitive to the actions of melatonin, leading to impaired insulin secretion. Blocking the inhibition of insulin secretion by melatonin may be a novel therapeutic avenue for T2DM.
- Metformin improves insulin sensitivity in patients with IGT, but it does not reduce inflammatory biomarker levels (Pradhan et al, 2009).
- Xenical (fat blocker) may help cut heart risk in patients with T2DM. The obese diabetic patient who is poorly controlled may benefit from weight-reducing agents, such as sibutramine or orlistat.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician. See Table 9-9 for more details.
- Vitamin D and calcium in combined supplementation may be beneficial in optimizing glucose metabolism (Pittas et al, 2007).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Medical nutrition intervention in patients with diabetes should address the metabolic abnormalities of glucose, lipids, and BP (Kulkarni, 2006). To meet the specific needs of the patient, adapt drug therapy to enhance outcomes and quality of life.
- DSME is an essential element of diabetes care, and national standards have been based on evidence for its benefits. DSME helps patients optimize metabolic control, prevent and manage complications, and maximize quality of life in a cost-effective manner. Health care providers should refer newly diagnosed patients to a dietitian who should then regularly reassess patients over time for modification of medications and food intake patterns.
- Emphasize the importance of regular mealtimes, use of medications, self-care and optimal functioning with instructions on how to handle illness, stress, exercise, label reading, use of sucrose or fructose and sugar alcohols.
- Vegan diets increase intakes of carbohydrate, fiber, and several micronutrients even more than the American Diabetes Association recommended diet (Turner-McGrievy et al, 2008). It would be acceptable to promote a vegan lifestyle for diabetes management (Barnard et al, 2009).
- Some restaurants offer foods lower in cholesterol, fat, and sodium, and higher in fiber. All restaurants offer low calorie sweeteners in the blue, yellow, or pink packets, and diet drinks. Many offer reduced-calorie salad dressings, low-fat or fat-free milk, and salt substitutes. Choose salads, fish, vegetables, baked or broiled food, and whole-grain breads.
- Clinical trials using antihyperglycemic medications to improve glycemic control have not demonstrated the anticipated cardiovascular benefits in patients with T2DM (Jenkins et al, 2008).
- To improve glycemic control, assist with weight maintenance, and reduce risk of CVD, at least 150 min/wk of moderate-intensity aerobic physical activity (50–70% of maximum heart rate) is recommended or at least 90 min/wk of vigorous aerobic exercise (>70% of maximum heart rate). Activity should be distributed over at least 3 d/wk, with no more than 2 consecutive days without physical activity.
- While high-intensity exercise is beneficial, even in older adults, it should start gradually and increase to desired intensity and duration. Avoid high-intensity exercise and resistance training in persons with neuropathy, coronary heart disease, or retinopathy. In the absence of contraindications, people with T2DM should perform resistance exercise three times a week, targeting all major muscle groups and progressing to three sets of 8–10 repetitions.
- Decrease sedentary behaviors, especially prolonged TV or computer time.
- Identify potential or real obstacles. Discuss options for handling negative emotions, temptations, dining away from home, feeling deprived, time pressures, competing priorities, social events, family support, food refusal, and lack of support from friends.
- Regular consumption of breakfast, self-weighing, and infrequent intake of fast foods are strategies that work well (Raynor et al, 2008).
- Use culturally appropriate methods for teaching and guidance. For example, use of the Medicine Wheel in Plains Indians has shown more effective results than usual techniques (Kattelman et al, 2009).
- Encourage group support, behavior modification, and nutritional counseling for overweight.
- Small changes lead to greater self-esteem. Sequential rather than simultaneous dietary changes work well for most people and can improve the sense of self-efficacy.
- A comprehensive lifestyle self-management program using the Mediterranean low-saturated fat diet, stress management training, exercise, group support, and smoking cessation can reduce cardiovascular risk factors.
- Dietitians have a distinct role in MNT versus DSME; but both education and counseling are more medically effective than either one alone (Daly et al, 2009).
- A low-literacy tool can be useful in teaching key changes for those who need it. The goal is to achieve a sense of control over self-management of the diabetes.
- Before any type of surgery, blood glucose should be maintained between 100 and 200 mg/dL. Perioperative hyperglycemia may be managed with doses of rapid-acting insulin. Correct abnormalities before surgery, when possible.
- In noncritically ill hospitalized patients, premeal blood glucose should be kept as close to 90–130 mg/dL as possible, with a postprandial blood glucose <180 mg/dL; use insulin when necessary.
- In critically ill hospitalized patients, blood glucose levels should be kept as close to 110 mg/dL as possible and generally <180 mg/dL. These patients will usually require intravenous insulin.

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## TYPE 2 DIABETES IN CHILDREN AND TEENS

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

T2DM arises because of insulin resistance, when there is failure to use insulin properly combined with relative insulin deficiency. In children, obesity or puberty often unmasks T2DM in genetically susceptible individuals. For example, the emergence of T2DM presents a new challenge for pediatricians and other health care professionals; preventive efforts, early diagnosis, and collaborative care of the patient and family are essential.

Breastfeeding, reduced television and sedentary lifestyles, healthy eating principles, family-based approaches, and screening are all important in managing this epidemic. Screening should be available for children whose BMI is greater than the 85th percentile at puberty or at age 10 plus any two of the following risk factors: family history, increased risk by ethnicity, or signs of insulin resistance such as polycystic ovary syndrome

(PCOS), hypertension, dyslipidemia, or acanthosis. Weight greater than 120% of ideal for height also warrants screening.

In addition to obesity, family history of T2DM, and absence of GAD-65 antibodies, children with new-onset T2DM may be distinguished from those with T1DM by a combination of biochemical parameters of C-peptide, IGFBP-1, CO(2), and urine ketones (Katz et al, 2007). However, one third of the children with T2DM may have at least one detectable beta-cell autoantibody, classified as latent autoimmune diabetes in youth.

Fasting blood glucose levels should be checked at least every 2 years in high-risk children. T2DM in childhood can lead to end-stage renal disease and mortality in middle age; long duration is more detrimental (Pavkov et al, 2006). There is an ongoing effort for diabetes prevention in trials specifically designed to address the adolescent population (Karam and McFarlane, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The presence of multiple risk alleles amounts to a significant difference in children who have diabetes (Kelliny et al, 2009). Genetic variations for glucokinase (GCK), GCK regulatory protein (GCKR), islet-specific glucose 6 phosphatase catalytic subunit-related protein (G6PC2), and melatonin receptor type 1B (MTNR1B) are associated.

Clinical/History	C-peptide, IGFBP-1, CO(2) Beta-cell autoan- tibodies (anti-GAD, anti-IA-2, and anti-ICA)? Urine ketones CRP Urinary microal- buminuria Plasminogen activator inhibitor type 1	Total Chol, LDL (high?) HDL (usually low) Trig (often increased) BUN, Creat Na <sup>+</sup> , K <sup>+</sup> ALT, AST LDH Alk phos Ca <sup>++</sup> , Mg <sup>++</sup> Alb
Height		
Weight		
BMI		
Diet history		
Waist circumfer- ence		
BP (often increased)		
Sleep-disordered breathing?		
Lab Work		
FPG		
HbA1c		

## INTERVENTION

### OBJECTIVES

- Maintain as near-normal blood glucose levels as possible by balancing food intake with insulin (either endogenous

or exogenous) or oral glucose-lowering medications and activity levels.

- Try to maintain glycosylated A1c levels <7%. Target goal range for the patient may vary by age and underlying disorders: <6-year old, 7.5–8.5%; 6- to 12-year old, <8%; 13- to 9-year old, <7.5%. Preprandial capillary plasma glucose levels should be kept between 90 and 130 mg/dL.
- Protect beta-cell function by controlling hyperglycemia. A1c tests should be done at least twice a year in patients who are meeting treatment goals and quarterly in patients who are not meeting glycemic goals.
- Achieve optimal serum lipid levels to reduce the risk for macrovascular disease.
- Emphasis of MNT is on lifestyle strategies to reduce hyperglycemia, dyslipidemia, and hypertension.
- Prevent and treat acute complications, short-term illnesses, and exercise-related problems, the long-term complications of renal disease, autonomic neuropathy, hypertension, and CVD.
- Maintain BP levels that reduce risk for vascular disease. Elevated BP has a major impact on renal function.
- Improve overall health through optimal nutrition and physical activity. Dietary Guidelines for Americans and the MyPyramid food guidance system illustrate nutritional guidelines and can be used by young people with diabetes.
- Encourage regular mealtimes. Maintain lifestyle changes through behavior modification, education, and problem-solving strategies.
- Working with the whole family is important. Promote family and individualized psychosocial counseling to handle depression and emotions.
- Address individual needs according to culture, ethnicity, and lifestyle, while respecting willingness to change. Encourage TLC, considering the child's needs and family circumstances.
- Manage problems related to compulsive or binge eating. Patients often report deliberate omission of medication in order to lose weight.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Altered Nutritional Labs – T2DM In Teenager

**Assessment Data:** Blood glucose self-monitoring records, food diary worksheets and meal records, hour HbA1c levels 9 mg/dL, BMI >85% for age. Family Hx T2DM (both parents). BP normal but LDL cholesterol slightly elevated

**Nutrition Diagnosis (PES):** Altered nutritional labs related to overweight, knowledge deficit about diabetes and self-monitoring difficulty as evidenced by HbA1c = 8.5 mg/dL and LDL chol >130 mg/dL and statement that “I don’t really understand my diabetes very well.”

**Intervention:** Teaching patient and family member(s) about use of simple blood glucose self-monitoring records (timing, blood glucose testing, role of HbA1c in evaluating past 3 months, meal records).

**Monitoring and Evaluation:** HbA1c levels <7 mg/dL. Other labs WNL; food diary and glucose records showing improvement in outcomes of lab testing.

## FOOD AND NUTRITION

- Calculate CHO and fat requirements individually according to age, serum lipid, and glucose levels. Assess dietary history, physical exercise, and activity patterns. Studies support the importance of carbohydrate from whole grains, fruits, vegetables, and low-fat milk.
- Moderate weight loss (5–10% of starting weight) may reduce hyperglycemia, dyslipidemia, and hypertension. A moderate restriction of 250–500 calories less than average daily intake (as calculated from a food history) and a nutritionally adequate meal plan are recommended.
- For teen boys over age 15, it may be useful to calculate caloric needs as 18 kcal/lb for usual activity and 16 kcal/lb if sedentary. Teen girls over age 15 have needs that are estimated the same as those for an adult.
- Extremely low-calorie diets are not recommended for children or teens. In morbidly obese children, gastric bypass surgery should be the last option as malnutrition is a permanent side effect.

- Spacing of meals (spreading carbohydrate throughout the day) and eating breakfast have beneficial effects on fasting lipid and postprandial insulin sensitivity.
- Meal skipping should be discouraged. Individualize meal plan according to patient preferences.
- Carbohydrate should be calculated as 45–65% of energy intake. Daily consistency is important.
- Protein should be calculated at 15–20% of daily energy intake with normal renal function; control at 0.8–1.0 g/kg with presence of renal disease.
- Fat should be 25–35% of energy intake, with 7–10% of kilocalories saturated fats, 10% polyunsaturated fats, and 10–15% monounsaturated fats. Limit intake of cholesterol to 200–300 mg/d.
- Recommendations for fiber include rice, beans, vegetables, oat bran, legumes, barley, produce with skins, apples, oranges, other produce. Include 19–38 g/d, larger amounts for older children and teens.
- As part of a healthy lifestyle and to manage hypertension, teach the principles of the DASH diet; 2400 mg/d of sodium is recommended.
- For vitamins and minerals, ensure that patient has adequate dietary intakes. Higher levels of magnesium, chromium, and potassium are recommended when serum levels are low. There is no need for supplements of any singular nutrient; a pediatric multivitamin–mineral supplement may be used.
- Include phytochemicals and antioxidants in the diet (see Table 8-14 in the pancreatic chapter).
- Discuss use of artificial sweeteners, food diaries, menu options at school, fast food choices that are lower in total fat, benefits and goals for physical activity, and the need for adequate fluid intake.

### Common Drugs Used and Potential Side Effects (see Table 9-15 also)

- Oral agents may be used when blood glucose and other treatment goals are not met through diet and exercise alone. Glucophage should be the first oral agent used but not in children with known liver and kidney disease, low oxygen problems, or severe infections. Other oral agents such as a sulfonyleurea or meglitinide can be added if control does not improve after 3–6 months. Thiazolidinediones probably should not be used in children.
- Insulin therapy should be started in children with severely elevated blood sugar levels or children with intense thirst and frequent urination. There are a wide variety of insulin regimens that can be used, anywhere from bedtime alone to multiple daily injections. Once blood sugars are under control, glucophage can be added while decreasing insulin dosage.
- Pharmacologic options for weight loss, including metformin, orlistat, and sibutramine have been studied (Miller and Silverstein, 2006). They should be used only under close medical supervision.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used in children and teens. There is insufficient evidence to draw

definitive conclusions about the efficacy of individual herbs and supplements for diabetes, especially in children. However, inclusion of spices and seasonings in the diet would be acceptable.

- See Table 9-9 for guidance on more specific herbs and supplements that the client may be using.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Health care providers are encouraged to refer newly diagnosed patients to a dietitian. The dietitian should regularly reassess children and teens for overall growth and health status.
- Stress the importance of parental supervision and support.
- Children often benefit from attending diabetes camps for youth and support groups for family counseling. DSME is helpful for SMBG, medication use, physical activity goals, and meal planning.
- Emphasize the importance of regular mealtimes, proper use of medications, and balanced activity. Home blood glucose monitoring records and food/exercise records are important.
- Emphasize the importance of self-care and optimal functioning for illness, stress, dining out, exercise.
- Identify potential or real obstacles and discuss options for handling negative emotions, temptations, dining away from home, feeling deprived, time pressures, competing priorities, social events, family support, food refusal, and lack of support from friends.
- Explain food and nutrition labeling as well as how to manage sucrose, fructose, and sugar alcohols in the diet. Reduce sugar-sweetened beverage intake as much as possible.
- Encourage group support, behavior modification, and nutritional counseling for overweight. Small changes lead to greater self-esteem than continued failures. Sequential rather than simultaneous dietary changes work best and can improve self-efficacy.
- Reduce stress where possible. BMI and stress are independent determinants of TNF-alpha (an inflammatory cytokine) and adipocytokine among Latino children (Dixon et al, 2009).
- Suggest guidelines for physical activity: three to four times a week, exercise for 30–60 min/d. Aerobic exercise is protective against age-related increases in visceral adiposity (Kim and Lee, 2009).

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## GESTATIONAL DIABETES

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

GDM involves glucose intolerance with first onset or recognition during pregnancy. It affects 14–25% of all pregnancies, increasing over the past decade (March of Dimes, 2009).

Pregnancy itself is a metabolic stress test. During the first half of pregnancy, transfer of maternal glucose to the fetus occurs; during the second half of pregnancy, placental hormones outweigh glucose transfer and insulin requirements typically double.

The placenta functions as a nutrient sensor, altering placental transport according to the maternal supply of nutrients. Placental transporters are regulated by hormones such as insulin. Insulin resistance occurs when gestational hormones such as human placental lactogen (HPL) interfere with insulin action. The accelerated fetal growth in women with diabetes is characterized by increased activity of placental and glucose transporters (Jansson and Powell, 2006). Cell signaling for insulin changes in GDM; women with diabetes or GDM may need one to two times more insulin than other pregnant women.

All pregnant women should be assessed for risk of GDM at the first prenatal visit; most women are screened between 24 and 28 weeks of gestation. One or more of the following factors identifies women at risk for GDM:

- Ethnicity: Hispanic American, African American, Asian, Pacific Islander, American Indian.
- Family history of diabetes in a first-degree relative (parents or siblings).
- Gestational diabetes or presence of a birth defect in a previous pregnancy.
- History of pregnancy-induced hypertension, urinary tract infections, or hydramnios (extra amniotic fluid).
- History of abnormal glucose tolerance.
- Older maternal age ( $>25$ -year old).
- Prepregnancy overweight or obesity; BMI  $>29$ .
- Previous birth of a large baby ( $>9$  lb).
- Previous stillbirth or spontaneous miscarriage.

Hyperglycemia in pregnancy poses many complications and risks for the infant such as macrosomia, neural tube defects, hypocalcemia, hypomagnesemia, hyperbilirubinemia, birth trauma, prematurity, or neonatal hypoglycemia. Daily SMBG is important; fasting glucose levels should not

exceed 105 mg/dL. Excellent blood glucose control with diet and, when necessary, insulin will result in improved perinatal outcome. HbA1c testing is not useful in GDM.

Women with a prior history of GDM and obesity are at significant high risk of developing MetS (Vohr and Boney, 2009). There is a higher risk of hypertension, pre-eclampsia, urinary tract infections, cesarean section, and future diabetes. About half of women who have GDM will proceed to have T2DM later, especially women who are hypertensive.

Nutrition recommendations should be based on a thorough nutrition assessment. Monitoring blood glucose levels, urine ketones, appetite, and weight gain guides the individualized nutrition prescription and meal plan. Adjustments should be made to the meal plan throughout pregnancy to ensure desired outcomes. See Table 9-16.

In women who have had bariatric surgery, close nutritional evaluation will be needed. Deficiencies in iron, vitamin A, vitamin B12, vitamin K, folate, and calcium can result in both maternal anemia and fetal complications, such as congenital abnormalities, IUGR and failure to thrive (Guelinckx et al, 2009).

Offspring of women with GDM are at increased risk for respiratory distress, macrosomia, jaundice, hypoglycemia, hyperinsulinemia, birth trauma, and developmental problems. Development of MetS in late adolescence and young adulthood is related to maternal glycemia in the third trimester, maternal obesity, neonatal macrosomia, and childhood obesity (Vohr and Boney, 2009).

Although treatment of mild GDM does not significantly reduce the frequency of stillbirth, perinatal death, or several neonatal complications, it does reduce the risks of fetal overgrowth, shoulder dystocia, cesarean delivery, and hypertensive disorders (Landon et al, 2009). Family planning, early screening for fetal abnormalities, compliance, glycemic and BP control during pregnancy, and improved neonatal care can make a difference.

After birth, rapid adaptation is necessary for infants to be able to maintain independent glucose homeostasis; this is compromised in infants who are small for gestational age (SGA), premature, or large for gestational age (Beardsall et al, 2008). Obesity, insulin resistance, and abnormal lipid metabolism bear ominous consequences for future generations (Vohr and Boney, 2009). For women who are offered treatment for mild GDM in addition to routine obstetric care,

**TABLE 9-16 Glucose Testing for Gestational Diabetes Mellitus (GDM)**

GDM often presents with hyperglycemia and glycosuria. Selective screening at 24–28 weeks of pregnancy is generally recommended, with a glucose challenge test and 1-hour assessment using either a 100-g or 75-g oral glucose load. Two or more of the venous plasma glucose concentrations must be met or exceeded for a positive diagnosis. The test should be done in the morning after an overnight fast.

American Diabetes Association criteria for GDM are noted below:

#### One-Step Approach

Perform a diagnostic oral glucose tolerance test (OGTT) without prior plasma or serum glucose screening. The one-step approach may be cost effective in high-risk patients or populations.

#### Two-Step Approach

Perform an initial screening by measuring the plasma or serum glucose concentration 1 hour after a 50-g oral glucose load (glucose challenge test [GCT]), and perform a diagnostic OGTT on the subset of women exceeding the glucose threshold value on the GCT. When the two-step approach is used, a glucose threshold value  $>140$  mg/dL ( $>7.8$   $\mu\text{mol/L}$ ) identifies approximately 80% of women with GDM, and the yield is further increased to 90% by using a cutoff of  $>130$  mg/dL ( $>7.2$   $\mu\text{mol/L}$ ).

Glucose Load	Glucose (mg/dL)
Glucose load, 100 g	
Fasting	95
1 hour	180
2 hours	155
3 hours	140

Sources: American Diabetes Association. Standards of Medical Care in Diabetes—2009.

additional charges are incurred but fewer babies experience serious perinatal complication or death (Moss et al, 2007). Nutritional intervention for GDM saves thousands of dollars per case. All women with GDM should receive nutritional counseling by an RD. MNT, initiated within 1 week of diagnosis and with a minimum of three nutrition visits, results in decreased hospital admissions and insulin use, improves likelihood of normal fetal and placental growth, and reduces risk of perinatal complications, especially when diagnosed and treated early (American Dietetic Association, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** GDM is associated with increased anti-human leukocyte antigen (HLA) class II antibodies in the maternal circulation (Steinborn, 2006). There may be some link between both autoimmune and nonautoimmune forms of diabetes and GDM.

Clinical/History	Frequent	2-hour postprandial glucose (not above 120 mg/dL)
Height	urinary tract infections?	
Pregravid weight	Ultrasonography for fetal growth	$\text{Na}^+$ , $\text{K}^+$
Pregravid BMI		BUN
Pregravid waist circumference		Creat (often elevated)
Expected date of confinement (EDC)	<b>Lab Work</b>	Alb,
No. of risk factors for GDM	Ketones, fasting H & H	transferrin
Current weight	Serum Gluc on awakening (95 mg/dL or lower)	Microalbuminuria
Goal weight		Serum homocysteine levels
Weight gain pattern	1-hour postprandial glucose (not above 140 mg/dL)	$\text{Ca}^{++}$ , $\text{Mg}^{++}$
Diet history		TSH (altered?)
BP		OGTT
Edema?		CRP
Periodontal disease?		

## INTERVENTION

### OBJECTIVES

- Prevent complications, perinatal morbidity, and mortality by normalizing the levels of glycemia and other metabolites (i.e., lipids and amino acids) to the levels of nondiabetic pregnant individuals.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inconsistent CHO Intake and Knowledge Deficit

**Assessment Data:** Blood glucose self-monitoring records, food diary worksheets and meal records, blood glucose levels (fasting, 2-hour postprandial).

#### Nutrition Diagnoses (PES):

(1) Inconsistent CHO intake (NI 5.8.4) related to lack of knowledge and confusion concerning gestational diabetic meal plan and CHO portion sizes as evidenced by postprandial blood sugars above and below desired ranges.

(2) Food and nutrition-related knowledge deficit (NB 1.1) related to gestational diabetic meal plan as evidenced by patient reported confusion and lack of confidence in meal planning and reported diet recall indicating inconsistent carbohydrate intake.

**Interventions:** E 2.2—review purpose of meal plan, CHO containing foods, portion sizes, CHO limits at meals/snacks. E 2.3, 2.5—provide advanced training in CHO counting, food label reading, menu planning, shopping tips.

**Monitoring and Evaluation:** Improvements in blood glucose levels; food diary and meal records showing more consistent intake of CHO throughout the day and before bedtime. Monitor at routine clinic visits for HgbA1c and weight gain. Assess need for further education/counseling; patient verbalizes better understanding of a meal plan and agrees to continue following plan.

- Optimize growth and development of the fetus. Desirable maternal weight gain will vary according to prepregnancy and current weight. Optimal weight gain is generally as follows: first trimester 0.5–1 kg (1–2 lb); second and third trimesters 0.2–0.5 kg/wk (0.5–1 lb/wk). Prevent weight loss.
- Obese women should control weight gain carefully. Excessive weight gain may be a forerunner of the MetS in offspring (Pirkola et al, 2008).
- Prevent infections and unexpected outcomes. Fetal glucose exposure and consequent fetal insulin secretion is normally tightly regulated by glucose delivery from the mother during pregnancy (Beardsall et al, 2008). The risk of spontaneous preterm birth increases with increasing levels of pregnancy glycemia.
- Control BP.
- Avoid incidents of starvation ketosis (where glucose is needed) and diabetic acidosis (where insulin and potassium are needed) by regular preprandial and postprandial SMBG. Ketosis is harmful to the baby.
- Use insulin when necessary, based on measures of maternal glycemia with or without assessment of fetal growth. Insulin therapy is recommended when nutrition intervention fails to maintain fasting whole-blood glucose at desired levels.
- Prevent hypoglycemic episodes, urinary tract infections, and candidiasis.
- Promote healthy lifestyle changes for the mother that will last long after delivery.
- Women with GDM should be encouraged to breastfeed.
- Physical activity, especially after meals, can help to maintain blood glucose control. Contraindications to exercise may include pregnancy-induced hypertension, intrauterine growth retardation, preterm labor or history of preterm labor, incompetent cervix/cervical cerclage, and persistent second or third trimester bleeding (American Dietetic Association, 2009).

## FOOD AND NUTRITION

- Use a carbohydrate-controlled meal plan with adequate intake to keep weight gain appropriate while preventing glycemic shifts or ketonuria; manage for age and weight goals. Provide adequate energy and nutrients to meet the needs maternal blood glucose goals that have been established. The typical diet may include 30–35 kcal/kg; 20% protein, 40–45% CHO, and 35–40% fat.
- Select CHO from whole grains, one fruit portion, or one milk portion at a time. Limit juices, sweets, or desserts. Sufficient CHO intake is needed, 175 g at minimum. Many women with GDM undereat out of fear of needing insulin; interval weight loss may indicate presence of fasting ketones. Insulin may be needed.
- While a low glycemic index diet may be beneficial for some outcomes for both mother and child, results are inconclusive at this time (Tieu et al, 2008).
- For obese women (BMI >30), a calorie limit ~25 kcal/kg actual weight per day has been shown to reduce hyperglycemia and plasma triglycerides with no increase in ketonuria. For many women, this translates to an energy intake around 1700–1800 kcal. Artificial sweeteners may be used, but not saccharin.
- Maintain an adequate intake of polyunsaturated fats; keep saturated fats to 10% of total fat or less.
- Most women require three meals and four to five snacks; snacks are eaten at least 2–3 hours between feedings and should contain carbohydrate.
- Smaller, more frequent meals and snacks will be beneficial because of insulin resistance. Work closely with a dietitian to establish the best pattern according to typical blood glucose levels. A snack before bedtime may be needed.
- DASH diet principles may be helpful if BP is elevated. Include regular use of antioxidant foods and spices such as cinnamon.
- Ensure intake of a prenatal vitamin–mineral supplement (especially containing 600 µg folic acid, 30–60 mg iron, vitamin C, and adequate calcium). Include adequate chromium intake from diet (as in yeast breads).
- Tube feeding may be useful in patients who cannot be fed orally or with hyperemesis. CHO-controlled products are not necessarily required; monitor closely.
- After delivery, a review of glucose tolerance and postpartum nutrition is suggested at 6–12 weeks.

## Common Drugs Used and Potential Side Effects

- Investigators found no substantial maternal or neonatal outcome differences between use of glyburide or metformin compared with use of insulin in GDM (Nicholson et al, 2009). Insulin may be required to control blood glucose if diet and exercise do not help. Careful physician and self-monitoring is important. The insulin lispro is associated with fewer hypoglycemic events.
- Use prenatal vitamin–mineral supplements as prescribed. Avoid large doses of vitamin C, which may show false-positive urinary glucose levels; more than 200 mg/d is not needed.
- Low-dose estrogen–progesterone oral contraceptives may be used after GDM, if no medical contraindications exist. However, medications that worsen insulin resistance (e.g., glucocorticoids, nicotinic acid) should be avoided if possible.

## Herbs, Botanicals, and Supplements

- In general, pregnant women should not take any herbs and botanical products. They should discuss concurrent or previous use with their physician.
- Supplements of 1,25-dihydroxyvitamin D<sub>3</sub> may influence glucose metabolism in GDM by increasing insulin sensitivity. More research is needed on postpartum requirements.
- Only limited evidence exists to support prenatal omega-3 supplementation; use caution for an unbalanced high DHA intake during the first two trimesters of pregnancy, that is, DHA without additional amino acid (AA) supplementation (Hadders-Algra, 2008).

- Conflicting results have been found for specific nutrients. Zinc and selenium seem to be protective, whereas chromium does not; more research is needed for micronutrient recommendations to be made (American Dietetic Association, 2009).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The RD should monitor and evaluate blood glucose, weight, food intake, physical activity, and pharmacological therapy (if indicated) in women with GDM at each visit; MNT results in improved maternal and neonatal outcomes (American Dietetic Association, 2009).
- Communicate the importance of meal spacing, timing, adequacy, and consistency (i.e., patient should not skip meals). Instructions on what to eat and what to avoid will be important. Carrying a snack at all times is helpful (e.g., fruit, peanut butter, crackers). Follow current evidence-based guidelines.
- Regular aerobic exercise, such as walking, is beneficial. Exercise after meals may help to control blood sugar, but do not exercise until short of breath. Upper body exercises are also beneficial. Avoid exercises while lying on back as this decreases blood flow when the weight of the fetus presses on the main artery. Avoid exercises that increase the risk of falling.
- Encourage breastfeeding.
- Babies born to women who have GDM may have low levels of lipids such as arachidonic acid and docosahexaenoic acid (DHA); further studies are needed (Bitsanis, 2006).
- Encourage family planning to ensure optimal glucose regulation for all subsequent pregnancies. Women with a history of GDM are more likely to have recurrent diabetes if they are older, heavier and wait longer between pregnancies (e.g., 3 vs. 2 years) in many cases (Holmes et al, 2010). Recurrence of GDM is common, especially among non-Caucasian populations (Kim et al, 2007).
- Counsel regarding risk for T2DM. Any degree of abnormal glucose homeostasis during pregnancy independently predicts an increased risk of glucose intolerance and CVD postpartum (Retnakaran, 2009). Elevated FBG, OGTT 2-hour blood glucose, and OGTT glucose A1c are strong and consistent predictors of subsequent T2DM (Golden et al, 2009). Long-term lifestyle modifications, maintenance of normal body weight, and physical activity should be discussed.
- Discuss the potential impact of GDM on offspring, who are at increased risk of obesity, glucose intolerance, and diabetes in late adolescence or adulthood.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# PRE-ECLAMPSIA AND PREGNANCY-INDUCED HYPERTENSION

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Pre-eclampsia is defined as the association of pregnancy-induced hypertension (PIH) and proteinuria of 300 mg/24 h or more after 20-weeks gestation. It is more common in primigravidas and in patients with multiple gestation, T1DM, teenage mothers, family history of PIH, age over 40 years, or underlying vascular or renal disease. It affects 2–8% of pregnancies and is a severe complication, which may lead to fetal morbidity and mortality. Risks for the baby include poor growth and prematurity (Duley, 2009).

Pre-eclampsia can lead to problems in the liver, kidneys, brain, and the clotting system (Duley, 2009). Maternal morbidity includes placental abruption, HELLP syndrome (hemolysis, elevated liver enzymes, low platelets) or eclampsia; treatment consists of ending the pregnancy. Early sonogram is recommended; many women will have to have total bed rest. Severe pre-eclampsia that develops at <34 weeks of gestation is associated with high perinatal mortality and morbidity (Sibai and Barton, 2007). Women who are 37-week pregnant are induced immediately.

Criteria for **mild pre-eclampsia** include hypertension as defined at 140/90 to 159/109 mm Hg; proteinuria >300 mg/24 h; mild edema with weight gain >2 lb/wk or

>6 lb/month; and urine output >500 mL/24 h. Signs and symptoms include increased BP, proteinuria, facial edema, pretibial pitting edema, irritability, nausea and vomiting, nervousness, headache, altered states of consciousness, epigastric pain, and oliguria.

Criteria for **severe pre-eclampsia** include: BP >160/110 mm Hg on two occasions with patient on bed rest; systolic BP rise >60 mm Hg over baseline; diastolic BP increase of >30 mm Hg over baseline; proteinuria >5 g/24 h or 3+ or 4+ on a urine dipstick; massive edema; and oliguria <400 mL/24 h. Symptoms include pulmonary edema, severe headaches, visual changes, right upper quadrant pain, elevated liver enzymes, and thrombocytopenia in addition to the symptoms listed for mild pre-eclampsia.

In **eclampsia**, a seizure occurs. Eclamptic seizures and symptoms of the HELLP syndrome occur. In severe cases, there may also be hepatic rupture, pulmonary edema, acute renal failure, placental abruption, elevated creatinine, intrauterine growth restriction, cerebral hemorrhage, cortical blindness, and retinal detachment. Maternal mortality rate is 8–36%.

Because plasma homocysteine is often increased, sufficient intakes of folic acid, vitamins B<sub>12</sub> and B<sub>6</sub> are recommended (Mignini et al, 2005). Studies have also shown the effectiveness of magnesium in eclampsia and pre-eclampsia (Guerrera et al, 2009).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Disordered Eating Pattern

**Assessment Data:** Food records, weight records. Diet hx reveals intake of one large meal daily, mostly canned soup and sandwiches; no fruits and few vegetables. BP 170/90 average; abnormal lung function tests (LFTs).

**Nutrition Diagnosis (PES):** Disordered eating pattern (NB 1.5) related to lack of knowledge concerning nutrition during pregnancy as evidenced by excessive prenatal weight gain, frequent meal skipping, increased BP, and diet lacking in vitamins and minerals and statement that “I can’t eat more than once a day because it isn’t good for the baby.”

**Intervention:** ND 3.2.1—daily use of prenatal vitamin. Education and counseling about appropriate dietary intake and meal frequency during pregnancy; dangers of skipping meals; when to contact the doctor. E 1.2—priority modifications of diet include not skipping meals, ensure adequate calcium, folic acid, potassium and magnesium; control sodium intake. C 1.3—Health Belief Model of counseling used to motivate patient in making necessary dietary changes.

**Monitoring and Evaluation:** Weight and prenatal growth charts; improved intake. Lab reports and BP records showing improvement in all aspects. Check urine protein and presence of edema. Successful outcome for infant and mother, even if hospitalization is required.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Women with pre-eclampsia have higher levels of a peptide that increases BP in the pieces of tissue linking mother and fetus.

<b>Clinical/History</b>	BP (mild, ≥140/90 mm Hg; severe, >160/110 mm Hg)	Dizziness
Height		Visual changes (blurring, double vision)
Pregravid weight		Excessive nausea or vomiting
Pregravid BMI		Severe headaches
Pregravid waist circumference	Decreased urine output	Fever?
EDC	Confusion, apprehension	Blood in urine?
Current weight	Shortness of breath	
Weight gain pattern	Right upper quadrant abdominal pain	<b>Lab Work</b>
Diet history		GFR
Edema in lower extremities		Alb, transthyretin (often low)

Proteinuria (>300 mg/d is mild; >500 mg/d is severe)	BUN Creat (may be elevated) Homocysteine CRP	Liver function tests (AST, ALT, LDH) Microalbumin- uria
H & H Serum Fe Chol, Trig (elevated?)	PT, INR HELLP syndrome (decreased platelets, abnormal liver function tests)	
Gluc Ca <sup>++</sup> Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup> Uric acid (elevated)		

## INTERVENTION

### OBJECTIVES

- Reduce maternal and neonatal mortality and morbidity. In pregnant patients with diabetes and chronic hypertension, BP target goals of 110–129/65–79 mm Hg are suggested. Avoid lower BP because fetal growth may be impaired.
- Lessen edema when present. Correct any underlying malnutrition or micronutrient deficiencies.
- Monitor any sudden weight gains (1 kg/wk) that are unexplained by food intake.
- Prevent, if possible, chronic hypertension and MetS after delivery.

### FOOD AND NUTRITION

- Maintain diet as ordered for age and pregnancy stage (generally 300 kcal more than prepregnancy diet). Use extra fruits and vegetables and less sucrose.
- Sources of magnesium include green leafy vegetables, nuts, legumes, and whole grains.
- Supplement with prenatal vitamins. Include folic acid, calcium, other B-complex vitamins, protein, selenium, and potassium from diet. The role of vitamins C and E does not benefit women at risk for pre-eclampsia (Villar et al, 2009). Antioxidant supplements are also not recommended (Rumbold et al, 2008).
- Sodium intake may need to be controlled to 2 g/d if edema is severe. Diuretics generally are not used.
- There may be some merit for including a sufficient intake of omega-3 fatty acids from salmon, tuna, walnuts, and flaxseed oil.

## Common Drugs Used and Potential Side Effects

- The only interventions shown to prevent pre-eclampsia are antiplatelet agents, primarily low-dose aspirin, calcium

supplementation and magnesium sulfate for eclamptic seizures (Duley, 2009). Avoid excessive magnesium from supplements if this medication is being used.

- Corticosteroids for lung maturity may be necessary.
- During pregnancy, typical diuretics and cardiac drugs are not used. ACE inhibitors and ARBs are contraindicated. Calcium pump inhibitors are often a first line choice.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used in pregnancy.
- Evening primrose has been suggested for this condition. Coenzyme Q10 and alpha-tocopherol are potent antioxidants.
- See Table 9-9 for guidance on more specific herbs and supplements that the client may have used.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Rest is essential during this time. Biofeedback, yoga, meditation, and other forms of stress reduction are often beneficial.
- Meal skipping should be avoided at all costs.
- Discuss adequate sources of calcium from the diet, especially if dairy products are not tolerated or preferred.
- Good sources of potassium and magnesium include nuts, fruits and vegetables. The DASH diet is an excellent diet to continue, even after pregnancy.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# DIABETIC GASTROPARESIS

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### DEFINITIONS AND BACKGROUND

Gastroparesis occurs in approximately 50% of all cases of diabetes (Aring et al, 2005), with delayed gastric emptying (DGE) in the absence of mechanical obstruction. Diabetic gastroparesis is the result of ongoing damage to the nerves that are responsible for peristalsis and normal motility. Foods digest abnormally slowly or peristalsis is diminished so that it is difficult to match insulin action to digestion and absorption of the meals. If food stays in the stomach too long, infection is possible. Also, the food can harden into a solid lump; these bezoars may cause pain, nausea, and blockages in the digestive tract.

Hypoglycemia can occur if insulin is working and if food remains in the stomach too long. Later, insulin action is diminished and food finally digests, causing hyperglycemia. Problems occur more often in type 1 than in T2DM. Strict glycemic control is key.

A gastrostomy is rarely indicated, but a jejunostomy may be helpful in maintaining nutrition. Prokinetic agents are the best treatment option; see Section 7 for more details on management of gastroparesis. Gastric electrical stimulation may be used to send out brief, low-energy impulses to the stomach to decrease nausea and vomiting.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** T1DM has a genetic component, but gastroparesis would be individually acquired.

Clinical/History	Abdominal	Serum Fe
Height	bloating	Gastrin
Weight	or pain	Gluc (fasting
BMI	Upper	and 30 min-
I & O	endoscopy	utes after
Diet history	Barium x-ray	meals)
Early satiety	Gastric	Na <sup>+</sup> , K <sup>+</sup>
DGE	emptying	Alb,
Diarrhea or	scintigraphy	transferrin
constipation	(GES)	CRP
Vomiting	Gastric	Chol, Trig
undigested	manometry	
food		
Nausea	<b>Lab Work</b>	
Reflux or heart-	HbA1c	
burn	H & H	

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal GI Function

**Assessment Data:** Blood glucose self-monitoring records, nausea, gastroesophageal reflux (GERD) and reflux with meals, abdominal discomfort. Irregular FBG levels from day to day.

**Nutrition Diagnosis (PES):** Abnormal GI function related to gastroparesis as evidenced by nausea, GERD, and abdominal discomfort.

**Intervention:** Meal records and food diary listing symptoms and frequency of discomfort. Blood glucose self-monitoring records. Discussion about use of prokinetic agents.

**Monitoring and Evaluation:** Glucose records, food diary and records, discussion about GI symptoms.

### INTERVENTION

#### OBJECTIVES

- Correct the fluctuating blood glucose levels through careful food and insulin management, frequent blood glucose checks and monitoring records.
- For nausea and vomiting, restore volume and hydration and provide antiemetics generously.
- Relieve symptoms (pain, diarrhea, constipation) and maintain adequate nutritional status.
- Differentiate from ketoacidosis, which has similar symptoms of nausea and vomiting.
- Prevent infection or bezoar formation from accumulation of indigestible solids.

### FOOD AND NUTRITION

- Monitor intake carefully; blood glucose fluctuations are common. Include 200–240 g CHO daily, spread throughout the day. Use two to three CHO servings per meal. Be consistent from day to day.
- Soft-to-liquid diet may be useful to prevent delay in gastric emptying. Six small meals may be better tolerated than large meals.
- Use a low-fat diet to improve digestion and to improve stomach emptying. Stay sitting after meals.
- Decrease overall fiber intake from meals or supplements. Oranges, broccoli, green beans, berries, figs, and fresh apples may be difficult to digest.
- For dry mouth, add extra fluids and moisten foods with broth or allowed sauces or gravies.
- If nausea occurs, cold foods and low-odor choices may be better tolerated.

- In severe problems, a percutaneous jejunostomy (PEJ) tube feeding may be indicated. It can be used temporarily if needed to correct malnutrition.
- See Table 9-9 for guidance on more specific herbs and supplements.

### Common Drugs Used and Potential Side Effects

- Prokinetics such as metoclopramide (Reglan) may be given 30 minutes before meals to increase gastric contractions and to relax pyloric sphincter. Dry mouth, sleepiness, diarrhea or nausea can be side effects. Emetasol is a nasal spray form of this medication. Metoclopramide prophylaxis to reduce gastric volumes before elective surgery is unnecessary unless the patient has a prolonged history of poor blood glucose control (Jellish et al, 2005).
- Rapid-acting insulin should be injected with or after meals. Use SMBG to monitor delayed absorption and glucose changes. Insulin lispro (Humalog) is quite effective because it starts working shortly after injection. To control blood glucose, it may be necessary to take insulin more often, to take insulin after eating instead before, and to check blood glucose often after eating.
- If a liquid diet is used, more insulin may be needed. Insulin pumps may be beneficial because insulin delivery rates can be programmed to the patient's individual needs.
- Because there is a reciprocal relationship between gastric emptying and ambient glucose concentrations, newer diabetes therapies that decelerate the rate of gastric emptying may be a beneficial tool (Samsom et al, 2009).
- Antiemetics may be used for vomiting. Monitor for specific side effects. Zofran may cause constipation or headache.
- Erythromycin improves stomach emptying by increasing the contractions that move food through the stomach. Side effects are nausea, vomiting, diarrhea, and abdominal cramps.
- Dramamine (dimenhydrinate) is an antihistamine that helps prevent nausea and vomiting; slight-to-moderate drowsiness and thickening of bronchial secretions may occur.
- Motilium (domperidone) is used to manage the upper GI problems; side effects may include headache.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss delayed digestion and absorption of food.
- Discuss role of diet in maintaining weight and controlling discomfort. Emphasize nutrient-dense foods if intake has been poor. Blenderized foods or smoothies may be well tolerated.
- Bezoar formation may occur after eating oranges, coconuts, green beans, apples, figs, potato skins, Brussels sprouts, broccoli, sauerkraut, corn, sauerkraut, and other high-fiber foods.
- Discuss insulin management, as appropriate. Include information about SMBG and meal spacing. Advise the doctor if blood glucose levels are >200 mg/dL.

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# DIABETIC KETOACIDOSIS

NUTRITIONAL ACUITY RANKING: LEVEL 3–4

Adapted from: Thomas H. McConnell, *The Nature of Disease Pathology for the Health Professions*, Philadelphia: Lippincott Williams & Wilkins, 2007.

## DEFINITIONS AND BACKGROUND

Ketones in the urine mean that the body is burning fat to get energy because glucose is not available. The lack of insulin leads to gluconeogenesis in the liver; then glucose spills into the urine and causes an osmotic diuresis with dehydration. Free fatty acids are released from the adipose tissue and converted into acidic ketones (acetoacetate and  $\beta$ -Hydroxybutyrate) by the liver.

Large amounts of ketones in the serum and urine can be dangerous. Diabetic ketoacidosis (DKA) is classic metabolic acidosis, a medical emergency that accounts for more than 100,000 hospital admissions yearly in the United States. A patient with a low serum potassium level should be assumed to have a potentially life-threatening crisis.

Causes of DKA include not getting enough insulin from missed injections; alkaline reserves depleted by too little insulin, flu or colds, fever, pregnancy, stress, trauma, or myocardial infarction; infection (leading cause); urinary tract infections and pneumonia. The triad of uncontrolled hyperglycemia, metabolic acidosis, and increased total body ketone concentration characterizes DKA. These metabolic derangements result from the combination of absolute or relative insulin deficiency and increased levels of the counterregulatory hormones of glucagon, catecholamines, cortisol, and growth hormone. Table 9-17 provides defining characteristics for DKA and hyperosmolar hyperglycemic state (HHS).

DKA is seen primarily in patients with T1DM; a few type 1 diabetic patients presenting with DKA on initial diagnosis. In children, DKA is a leading cause of hospitalization and is a cause of cerebral edema, which may lead to death if untreated. DKA can also occur in T2DM, usually from urinary tract infections, trauma, stress, pregnancy, surgery, or myocardial infarction. Inflammatory processes may play a role. Both DKA and its treatment produce varying degrees of immunological stress (Jerath et al, 2005). All individuals with DKA should be tested for hyperthyroidism (Potenza et al, 2009). Use of standardized written guidelines have merit.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** There are no specific genes for DKA, but diabetes itself has a genetic component.

Clinical/History	Nausea and vomiting	Dim vision
Height	Hot or dry and flushed skin	Labored or rapid breathing (Kussmaul)
Weight	Diarrhea	Pruritus
BMI	Fruity breath	Polyuria
Diet history	Intense thirst	Cramping
Temperature	Profound dehydration	Seizures or drowsiness
I & O		
BP (often low)		

### Lab Work

<i>Mild:</i> blood pH 7.25–7.30; bicarbonate 15–18 $\mu\text{mol/L}$ ; alert	Beta-hydroxybutyrate levels $\text{K}^+$ (low?) Urinary glucose, ketones, osmolality T3, T4, TSH levels	$\text{pCO}_2$ (decreased) $\text{pO}_2$ Uric acid (increased) AST (decreased) ALT, LDH, creatine kinase (CK) (increased) Phosphate (often decreased) $\text{Mg}^{++}$ (often decreased) Chol (increased), Trig $\text{Ca}^{++}$
<i>Moderate:</i> pH 7.00–7.25, bicarbonate 10–15, mild drowsiness	CRP BUN (increased) Creat $\text{Na}^+$ (decreased) $\text{Cl}^-$ (decreased) HbA1c Amylase (increased) WBC (elevated with infections)	
<i>Severe:</i> pH < 7.00, bicarbonate < 10, stupor or coma		
Gluc (>250 mg/dL)		
HgbA1c		

## INTERVENTION

### OBJECTIVES

- Correct the high blood glucose level by giving more insulin. Frequent blood glucose and ketone monitoring is necessary. Note that urine ketones lag behind serum ketones because it takes time to empty the bladder, where they have accumulated and been stored.
- Replace fluids and electrolytes lost through excessive urination and vomiting.
- Promote return to wellness after poor health for several days.
- Evaluate precipitating factors such as surgery, trauma, urinary tract infection, pneumonia, or influenza.
- Monitor frequently to prevent recurrence of DKA.

**TABLE 9-17 Diagnostic Criteria for Diabetic Ketoacidosis (DKA) and Hyperosmolar Hyperglycemic State (HHS)**

Criteria	DKA			
	Mild	Moderate	Severe	HHS
Plasma glucose (mg/dL)	>250	>250	>250	>600
Arterial pH	7.25–7.30	7.00–7.24	<7.00	>7.30
Serum bicarbonate (mEq/L)	15–18	10–<15	<10	>15
Urine ketones	Positive	Positive	Positive	Small
Serum ketones	Positive	Positive	Positive	Small
Effective serum osmolality (mOsm/kg)	Variable	Variable	Variable	>320
Altered mental status	Alert	Alert/drowsy	Stupor/coma	Stupor/coma

Adapted with permission from Kitabchi AE, et al. Hyperglycemic crises in diabetes. *Diabetes Care*. 27:S95, 2004.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Self Monitoring Deficit

**Assessment Data:** Admission to unit with DKA, random blood glucose levels >600, semi-comatose state, unable to eat orally.

**Nutrition Diagnosis (PES):** Self monitoring deficit (NB-1.4) related to blood glucose monitoring and diabetes management as evidenced by DKA, BG > 600, lethargy, nausea and vomiting past 2 days, and report by family that “he doesn’t test his sugars as he should.”

**Intervention:** Food and nutrient delivery with IVs and tube feeding until semicomatose state resolves and glucose levels are below 200 consistently. Educate patient when possible about the dangers of not monitoring BG levels. Teach methods for simplifying records, tracking lab results, and self-monitoring of glucose and activity levels to match insulin therapy.

**Monitoring and Evaluation:** Improved cognition and ability to resume an oral diet. Able to describe how to track glucose, lab results, physical activity, and insulin; defined own goals for reporting signs and symptoms to doctor when hyperglycemia persists. Able to state the signs of impending DKA and measures to take immediately.

- Prevent complications such as shock, arterial thrombosis, renal failure, or cerebral edema (CEDKA). CEDKA remains a significant problem with a high mortality rate (Lawrence et al, 2005). Young children are especially vulnerable and may slip into a coma.
- For chronically high fasting glucose levels, adjust evening intermediate- or long-acting insulin doses or timing.

## FOOD AND NUTRITION

- If patient is comatose, intravenous insulin, electrolytes, and fluids are used. A nasogastric tube may be placed to prevent aspiration during feeding. If patient is alert and oriented, offer plenty of fluids orally.
- As treatment progresses, a 5% glucose solution is usually given as glucosuria and hyperglycemia subside. If glucosuria and hyperglycemia do not decrease, try tea and salty broth. Later, fruit juices and liquids high in potassium may be given.
- Resolution of DKA leads to the ability to tolerate oral nutrition and fluids, normalization of blood acidity ( $\text{pH} > 7.3$ ), and absence of ketones in blood ( $< 1 \mu\text{mol/l}$ ). Once this has been achieved, insulin may be switched to the usual regimen.

## Common Drugs Used and Potential Side Effects

- Insulin and fluid are usually given intravenously to decrease blood glucose by 50–75 mg/dL/h. Guidelines may recommend a bolus (initial large dose) of insulin of 0.1 unit of insulin/kg of body weight if potassium level is higher than 3.3. Regular and glulisine insulin are equally effective during the acute treatment of DKA; a basal bolus regimen with glargine and glulisine is safer than

NPH and regular insulin after the resolution of DKA (Umpierrez et al, 2009).

- Dextrose in saline is given once plasma glucose decreases to avoid accidental hypoglycemia.
- Potassium, phosphate and magnesium levels may be low. Bicarbonate therapy is needed only rarely (Trachtenberg, 2005).
- Intravenous antibiotic therapy will be needed where there is sepsis.
- Atypical antipsychotics, thiazide diuretics, and corticosteroids can lead to DKA if the patient is not carefully monitored.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- See Table 9-9 for guidance on more specific herbs and supplements.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain demand for more insulin during illness and infection. Use of a diabetes record may be useful if episodes of high blood glucose are frequent.
- Never exercise when there are ketones present.
- Because every episode of DKA implies breakdown in clinical communication, appropriate diabetes education should be reinforced. Education of patients and their social environment to promote frequent testing—especially during sick days—and to lower their glucose levels, as well as to recognize the early symptoms of hyperglycemia and DKA is of paramount importance in preventing the development of severe DKA (Weber et al, 2009).
- When strict control through insulin is administered, weight gain is common. Insulin omission and reduction, which are eating disorder symptoms unique to diabetes mellitus, are associated with an increased risk of DKA. Attention to this disorder is important in overall treatment planning and management.
- The biggest risk of insulin pump therapy is DKA since no long-acting insulin is used. Any interruption to insulin delivery or pump malfunctioning can cause DKA. To prevent this reaction, monitor blood glucose regularly. Insulin pump users also need to check often to see that insulin is still flowing through the tubing.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## HYPEROSMOLAR HYPERGLYCEMIC STATE

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

## DEFINITIONS AND BACKGROUND

Diabetic HHS is a life-threatening emergency with marked elevation of blood glucose, hyperosmolality, and minimal or no ketosis (Stoner, 2005). HHS is preventable if blood glucose is monitored regularly in order to correct elevating levels before problems occur. The condition occurs in patients older than age 70 years with T2DM and profound dehydration as precipitating factors. If recognized early, HHS can frequently be treated in the outpatient setting if the patient can take fluids. Table 9-18 provides diagnostic criteria. Sometimes DKA is the first time that diabetes is diagnosed.

Identification and treatment of the underlying and precipitating causes of HHS are absolutely essential. Predisposing factors for this syndrome include long-term uncontrolled hyperglycemia, pancreatic disease, infections or sepsis, stroke, surgery, extensive burns, renal or CVD, corticosteroid use, diuretics, excessive total parenteral nutrition (TPN), dialysis.

Underlying poor compliance with medications, infections, alcohol, or cocaine abuse are the most common causes. In children, corticosteroid use and gastroenteritis are common causes. The mortality rate is high at 10–20%. Areas of future research include prospective randomized studies to determine the pathophysiological mechanisms for the absence of ketosis in HHS and to investigate the reasons for elevated proinflammatory cytokines and cardiovascular risk factors (Kitabchi et al, 2008).

TABLE 9-18 Quick Sources of Glucose

4 oz grape, cranberry, or prune juice	19 g CHO
1 tbsp honey	17 g CHO
1/2 cup sweetened gelatin	17 g CHO
1 tbsp corn syrup, jam, jelly or glucose	15 g CHO
5 Lifesavers candies	15 g CHO
4 oz orange, apple, pineapple, grapefruit juice	12–15 g CHO
4 oz regular soft drink	13 g CHO
1 tbsp sugar, dissolved in water	13 g CHO
2 tablespoons raisins	10–15 g CHO
5–6 Lifesaver candies	10–15 g CHO
1 cup 2% or skim milk	12 g CHO
3–4 glucose tablets	4–5 g CHO each

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** HHS is acquired and not genetic, although T2DM has a genetic component. African Americans, Hispanics, and Native Americans have the highest rates.

Clinical/History	Weakness, lethargy Leg cramps Sleepiness or confusion Rapid pulse and abnormal respirations Convulsions, grand mal seizures, or coma Fever or hypothermia?	Serum osmolality (usually >320 mOsm) pH levels greater than 7.30 Mild or absent ketonemia Elevated serum urea nitrogen (BUN)-to-creatinine ratio
Height Weight BMI Diet history BP (hypotension?) I & O Profound dehydration (8–12 L) Excessive thirst and urination Dry, parched mouth Sunken eyes Dry skin with no sweating	<b>Lab Work</b> Gluc (>600 mg/dL) Na <sup>+</sup> , K <sup>+</sup> Bicarbonate >15 mEq/L	Alb H & H PO <sub>4</sub> Chol, Trig CRP

## INTERVENTION

## OBJECTIVES

- Correct dehydration, shock, and cardiac arrhythmias.
- Reduce elevated blood glucose levels with isotonic saline, then hypotonic saline along with insulin.
- Monitor fluid status and replace deficits, which may be 10–20% of total body weight. This may require up to 9 L in 48 hours (Stoner, 2005).

## SAMPLE NUTRITION CARE PROCESS STEPS

**Excessive Alcohol Intake**

**Assessment Data:** Blood glucose self-monitoring records with FBG >650; recent heavy intake of alcohol; fever; profound dehydration and signs of HHS; admitted to Emergency Room from a wedding reception; lives with son and daughter-in-law.

**Nutrition Diagnosis (PES):** Excessive alcohol intake related to lack of understanding about the impact of alcohol on diabetes as evidenced by confusion, profound dehydration, FBG >650, and fever after intake of four alcoholic beverages within 3 hours at a wedding reception.

**Intervention:** Teaching patient and family members about dangers of large doses of alcohol mixed with diabetes medication, especially with aging. Counseling about how to include an occasional alcoholic beverage and ways to participate in social events without excessive intake.

**Monitoring and Evaluation:** Improved glucose labs, resolution of HHS, fever and dehydration.

- Prevent future crises by appropriate DSME and regular monitoring of blood glucose.
- Prevent acute renal failure, which could result from prolonged hypovolemia.

## FOOD AND NUTRITION

- Offer fluid replacement, often 1 L/h until volume is restored; 9–12 L may be needed.
- Patient is likely to nothing by mouth (NPO) during a crisis or perhaps tube fed during a comatose state. As appropriate, intake may be progressed gradually to a balanced diet, controlling calories as needed.
- Correct electrolyte deficits. Potassium or magnesium may be needed.
- The reported sodium level should be corrected when the patient's glucose level is markedly elevated. In this circumstance, extracellular fluid (ECF) osmolality rises and exceeds that of intracellular fluid (ICF), since glucose penetrates cell membranes slowly in the absence of insulin, resulting in movement of water out of cells into the ECF (Merck Manual, 2009). Types of fluids administered will depend on the corrected serum sodium level, calculated using the following formula: measured sodium + [(serum glucose – 100)/100] × 1.6].
- A renal diet plan may be needed if renal failure is identified.

## Common Drugs Used and Potential Side Effects

- Insulin is needed to normalize blood glucose levels. Infusions will be needed until full rehydration is complete. DKA and HHS are associated with elevation of proinflammatory

cytokines; insulin therapy provides a strong anti-inflammatory effect (Stentz et al, 2004).

- Potassium replacements may be needed. Monitor carefully.
- Antibiotic therapy may be needed in cases of underlying infections.
- Drugs that may precipitate HHS include diuretics, beta blockers, clozapine, olanzapine, H2 blockers, cocaine, alcohol.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- See Table 9-9 for guidance on more specific herbs and supplements.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss, where possible, predisposing factors, how to avoid future incidents, and blood glucose monitoring.
- CHO-controlled diets may be beneficial if patient can comprehend. Family intervention may be required.
- Discuss possible neglect or abuse, if suspected.
- Continuous management of the fluid, electrolyte, and glucose disturbances is necessary until resolved.
- Provide diabetes teaching to prevent recurrence. Adjust insulin or oral hypoglycemic therapy on the basis of the insulin requirement once serum glucose level are stable.
- Coordinate home visits from nursing or dietitian if needed to evaluate the inadequate access to water.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# HYPOGLYCEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

Hypoglycemia occurs primarily in patients with T1DM. Except in diabetic patients receiving insulin or sulfonylureas, hypoglycemia is a rare disorder. True low blood sugar (70 mg/100 dL or lower) releases hormones such as catecholamines, which produce hunger, trembling, headache, dizziness, weakness, and palpitations.

Sources of bodily glucose are from dietary intake, glycogenolysis, and gluconeogenesis. The metabolism of glucose involves oxidation and storage as glycogen or fat. The body makes great effort to supply glucose for the CNS and red blood cells. Glycogenolysis is stimulated by secretion of glucagon from the alpha-cells of the pancreas; this is impaired in patients with T1DM.

As different causes can stimulate hypoglycemia, treatments will differ accordingly. Skipped or insufficient meals, errors in insulin dosing, taking too much insulin, alcohol consumption, or extra physical exertion can lead to hypoglycemic episodes. Oxidative stress and zinc release contribute to neuronal death after hypoglycemia (Suh et al, 2008). Recurrent episodes of iatrogenic hypoglycemia induce a state of hypoglycemia unawareness and defective counterregulation, which defines hypoglycemia-associated autonomic failure (HAAF).

It is essential to manage these episodes carefully. A pro-oxidant state is promoted in certain brain regions during hypoglycemia and after glucose reperfusion, which results from the activation of several oxidative stress pathways; subsequent cell death occurs in particular brain regions including the cerebral cortex, the striatum, and the hippocampus (Haces et al, 2010).

Approaches to the prevention of hypoglycemia include glucose monitoring, patient education, meal planning, and medication adjustment. Adequate carbohydrate replacement during and after exercise seems to be an important measure to prevent hypoglycemia. Insulin dosage adjustment with a decrease from 20% to 30% is needed only for exercise duration over an hour (Grimm et al, 2004).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** A genetic deficiency in the p47(phox) subunit of NADPH oxidase may be relevant (Suh et al, 2008).

## INTERVENTION

### OBJECTIVES

- Normalize blood glucose levels. If the problem is recurrent, stabilize blood glucose levels through consistent mealtimes, CHO consistency, insulin dose adjustments, and blood glucose self-monitoring. For those individuals on insulin, appropriate insulin timing with food or use of CHO to insulin ratio are important factors to consider.
- Minimize length of time between meals.
- Prevent seizures and coma, with precipitating symptoms such as neuroglycopenia with confusion, light headaches, and aberrant behavior.
- Determine frequency, symptoms of hypoglycemia, activity levels for the individual.
- Delayed hypoglycemia after strenuous or prolonged exercise may occur up to 24 hours after exercise and is related to increased insulin sensitivity from exercise as well as

## SAMPLE NUTRITION CARE PROCESS STEPS

### Excessive Physical Activity

**Assessment Data:** Blood glucose self-monitoring records, food diary worksheets and meal records, blood glucose levels (fasting, 2-hour postprandial and/or HbA1c levels). Recent exercise program including aerobic dancing for >1 hour thrice weekly. Low blood glucose levels and signs/symptoms of hypoglycemia twice weekly.

**Nutrition Diagnosis (PES):** Excessive physical activity related to a new exercise regimen as evidenced by two bouts of blood glucose levels below 70 in past week.

**Intervention:** Education of patient, exercise partner, and family member(s) about blood glucose self-monitoring records (timing, blood glucose levels before and after exercise), insulin dosing, and activity records. Counseling about timing of FBG testing, insulin reductions, and close monitoring before and after dance sessions.

**Monitoring and Evaluation:** Glucose lab results within desirable range; no symptoms of hypoglycemia. Food diary and activity records showing effective self-management.

repletion of glycogen stores. Plan appropriately by increasing carbohydrate, decreasing insulin for periods of activity, and increasing frequency of blood glucose monitoring.

- Always recheck blood glucose 15–20 minutes after treatment to make sure that problem is resolved. Very low blood glucose levels (<50 g/dL) may take 30 g CHO or more to resolve, especially after exercise.

## FOOD AND NUTRITION

- For insulin-induced hypoglycemia, use a normal diet with adequate CHO content. Consider a possible reduction of medication if the hypoglycemia is recurrent.
- Have patient ingest fruit juice when needed or use candy for an immediate corrective measure. If there are symptoms of hypoglycemia (blood glucose <70 g/dL), carry quick sources of glucose (see Table 9-18). Fat is not as effective as CHO in normalizing blood glucose.
- In most cases, mild hypoglycemia can be handled with use of readily available CHOs, including milk, fruit, and crackers. Balanced, regular mealtimes or frequent small snacks are also useful.
- For hypoglycemia at night that is caused by excessive insulin or insufficient dinner meal or evening snack, adjust evening and bedtime doses of insulin. A slightly larger dinner or snack containing CHO may be needed.

## Common Drugs Used and Potential Side Effects

- Insulin and other glucose-lowering medications must be carefully prescribed and monitored. Careful use of sliding scales of insulin is the goal (Smith et al, 2005). Glycemic control to a lower glucose target range can be achieved using a computerized insulin dosing protocol with particular attention to timely measurement and adjustment of doses (Juneja et al, 2009).
- Glucose tablets have 4–5 g CHO per tablet. Patients should receive instructions regarding quantity, when to use, and when not to use. Most people will need three to four tablets to treat low blood glucose levels.
- If the individual passes out from hypoglycemia and uses insulin on a daily basis, it may be necessary to give a glucagon shot and call for emergency assistance. Glucagon can cause vomiting. Intravenous dextrose is administered by medical professionals.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician. Clinical trials are lacking for this condition.
- See Table 9-9 for guidance on more specific herbs and supplements.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Teach benefits of frequent blood glucose monitoring. Explain signs, symptoms, and treatment of hypoglycemia.
- Review appropriate timing of meals, snacks, and medications. Promote regular mealtimes, meal spacing, and planned exercise.
- Teach routine blood glucose before and after exercise. Discuss carrying a quick source of glucose.
- Encourage patients to obtain and carry diabetes identification.
- Discuss observations that require medical attention. Teach when to contact physician for medication adjustment.
- Discuss use of alcoholic beverages and potential effects. Excess alcohol increases the risk of hypoglycemia. Alcohol is processed in the liver to acetaldehyde at a time when the liver cannot do gluconeogenesis because nicotinamide adenine dinucleotide (NAD) is depleted. The biggest risk occurs when a patient drinks alcohol without carbohydrates being available, such as 4 hours or longer after the last meal. One drink takes 1–1.5 hours to process in the liver. Women should stick to one alcoholic beverage a day; men should limit their intake to two per day; both should consume a CHO with their drinks.
- In the elderly who are monitoring blood glucose levels closely, the benefits of intensive therapy in an effort to lower A1c must be weighed against the greater risk of unpredictable hypoglycemia (Alam et al, 2005).

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# HYPERINSULINISM AND SPONTANEOUS HYPOGLYCEMIA

NUTRITIONAL ACUITY RANKING: LEVEL 3–4

## DEFINITIONS AND BACKGROUND

Hyperinsulinism consists of insulin levels above 3  $\mu\text{U/mL}$  when glucose levels are below 50 mg/dL. Treatment depends on the cause and the severity of the hyperinsulinism. **Congenital hyperinsulinism (CH)** is familial hyperinsulinism (FHI) with profound hypoglycemia because of excessive insulin secretion. CH can lead to developmental delay, mental retardation or death if untreated. CH occurs at an approximate frequency of 1/25,000 to 1/50,000 live births. New procedures spare healthy cells in the pancreas while allowing surgeons to remove abnormal tissue. **Spontaneous hypoglycemia** is an underlying symptom of some other diseases besides diabetes. Fasting and reactive hypoglycemia fall into the category of spontaneous forms. In **fasting hypoglycemia**, the body is not able to maintain adequate levels of sugar in the blood after a period without food in heavy drinkers who do not eat; people with islet cell tumors, viral hepatitis, cirrhosis, or liver cancer; and children with carbohydrate metabolic disorders. Hereditary

fructose intolerance, galactosemia, leucine sensitivity can cause this type of hypoglycemia. **Reactive hypoglycemia** describes recurrent episodes of hypoglycemia occurring 2–4 hours after a high CHO or glucose load. Etiologies include alimentary hypoglycemia (dumping syndrome following gastric surgery); hypothyroidism or other hormonal disorders; *h. pylori*-induced gastritis; or occult diabetes with an exaggerated hyperglycemia during a glucose tolerance test. Symptoms include weakness and agitation 2–4 hours after meals, perspiration, nervousness, and mental confusion. Diet remains the main treatment, although alpha-glucosidase inhibitors and some other drugs may be helpful. Brain glycogen supports energy metabolism when glucose supply from the blood is inadequate and its levels rebound to levels higher than normal after a single episode of moderate hypoglycemia (Oz et al, 2009). Glutamate serves important intracellular signaling functions; glutamate dehydrogenase (GDH) catalyzes the oxidative deamination of glutamate to alpha-ketoglutarate in brain, liver, kidney, and the pancreatic islets (Stanley, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Individuals with congenital hyperinsulinism (CH) should be tested for gene mutations. Mutations in *GLUD1*, *GCK*, or *HADHSC* are response to drug therapy, but CHI associated with mutations in *ABCC8* or *KCNJ11* often requires pancreatectomy.

Clinical/History		
Height	Dizziness	Growth
Weight	Lightheadness,	hormone
BMI	tremors	levels
Diet history	Headache	Chol
Recent weight	Flushing	Trig
losses	Irritability	Na <sup>+</sup> , K <sup>+</sup>
Craving for	Numb or cold	Trig
sweets	extremities	HgA1c
BP	<b>Lab Work</b>	Ca <sup>++</sup> , Mg <sup>++</sup>
Seizures,	Gluc	Acetone
confusion	Serum insulin	PO <sub>4</sub>
Heart palpitation	Serum glucagon	CRP
or fibrillation		

## INTERVENTION

### OBJECTIVES

- Reduce intake of concentrated CHO to a level that does not overstimulate the pancreas to secrete inappropriately large amounts of insulin, which may cause blood sugar to

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive CHO Intake

**Assessment Data:** Recent bouts of low blood glucose, (<50 mg/dL) without Hx of diabetes or insulinoma. Dumping syndrome 2–3 hours after meals with weakness, perspiration, heart palpitations, headache, and craving for sweets. Diet history reveals CHO intake averaging 250 g/d, especially between meals and before bedtime.

**Nutrition Diagnosis (PES):** Excessive CHO intake related to high intake of sweets as evidenced by diet history.

**Intervention:** Food and nutrient delivery—tracking of CHO intake at meals and snacks. Education—sources of CHO from each food group. Counseling—ways to decrease hunger; food diary for episodes of hypoglycemia; signs and symptoms and when to call the doctor; glycemic index and glycemic load of foods.

**Monitoring and Evaluation:** Improvement through decreased episodes of hypoglycemia following meals and snacks with limitation of intake to 130–150 g daily.

drop. Limit total intake of carbohydrate to 130 g/d to reduce the severity of symptoms.

- If required, ensure that patient loses weight gradually.
- Reduce counterregulatory hormone responses to excessive insulin.
- Exercise regularly and maintain consistency in meal times and daily routines.

## FOOD AND NUTRITION

- Diet should include frequent small meals, about every 3 hours. Eat a variety of foods, including meat, poultry, fish, or nonmeat sources of protein; whole grains; fruits and vegetables; dairy products.
- Choose high-fiber foods and food with a moderate-to-low glycemic load. Avoid white rice, potatoes, corn.
- Avoid or limit foods high in sugar, especially on an empty stomach; this includes sweetened beverages and dried fruits.
- Avoid alcohol, caffeine.
- Maintain protein intake at DRI levels; fat furnishes the remainder of calories. The traditional high protein, low CHO diet is not evidenced-based.
- For the *GLUD1* genetic form of HI, a low leucine diet and use of diazoxide may be needed. Most of the other genetic forms will require surgery or just drug use.

### Common Drugs Used and Potential Side Effects

- Diazoxide is needed for the GLUT1 form of HI. Diazoxide is believed to inhibit insulin secretion through opening KATP channels. Octreotide (a somatostatin analogue) or continuous dextrose is often used; but in KATP HI, drug therapy fails, and pancreatectomy is required.
- Chemotherapy (e.g., streptozocin, fluorouracil) may be used for insulinomas. Monitor GI side effects and nephrotoxicity.
- Alpha-glucosidase inhibitors may be where diabetes is identified.
- Monitor all medications for their potential hypoglycemic effects.

### Herbs, Botanicals, and Supplements

- Products such as hemicellulose and pectin may help in dumping syndrome.
- Herbs and botanical supplements should not be used without discussing with physician.
- See Table 9-9 for guidance on more specific herbs and supplements.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain that alcohol blocks gluconeogenesis and should be avoided.
- Ensure that patient keeps snacks available such as cheese and crackers. More frequent feedings are needed.

- Avoid skipping meals; eat meals on time. Avoid any one meal that is unbalanced or especially high in carbohydrates.
- Control caffeine intake and use of other stimulants, which may aggravate condition.

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

### For More Information

### Other Endocrine Disorders

Hormones can be separated into three categories: **amines**, these are simple molecules, **proteins and peptides**, which are made from chains of amino acids, and **steroids**, which are derived from cholesterol. **Glands** discharge hormones directly into the bloodstream, and they have feedback mechanisms that maintain a proper balance of hormones and prevent excess secretion. Endocrine disorders require varying levels of nutritional intervention. If medications are taken appropriately, many conditions can be readily managed. See Table 9-19.

**TABLE 9-19 Other Endocrine Conditions**

There are many other disorders of endocrine function besides those affecting the pancreas that require some level of nutritional intervention. Listed below are essential hormones and functions of the endocrine glands.

Gland	Hormones	Functions
Pancreas	Glucagon (from alpha-cells)	Alpha-cells in the pancreatic islets secrete the hormone glucagon in response to a low concentration of glucose in the blood.
	Insulin (from beta-cells)	Beta-cells in the pancreatic islets secrete insulin in response to high blood glucose concentrations. See diabetes section.
Gastric mucosa	Gastrin	Stimulates production of hydrochloric acid and the enzyme pepsin, used in digestive processes.
Small intestinal mucosa	Secretin	Stimulates the pancreas to produce bicarbonate-rich fluid to neutralize stomach acid.
	Cholecystokinin	Stimulates contraction of the gallbladder to release bile after a meal containing fat. Also stimulates the pancreas to secrete digestive enzymes.
Placenta	Human chorionic gonadotropin	Signals the mother's ovaries to secrete hormones to maintain the uterine lining during pregnancy.
Hypothalamus	Gonadotropin-releasing hormone (GnRH) and other releasing hormones	Hunger and thirst; emotional and sexual responses of the limbic system; heart rate and blood pressure; circadian cycles; body temperature; bladder function; moods. Hypothalamus links the nervous system by synthesizing and secreting neurohormones that stimulate release of hormones from the anterior pituitary gland.
Pituitary (anterior)	Adrenocorticotrophic hormone (ACTH)	Reacts with receptor sites in the cortex of the adrenal gland to stimulate the secretion of cortical hormones, particularly cortisol.
	Human growth hormone (hGH or somatotropin hormone)	Growth of bones, muscles, and other organs by promoting protein synthesis; influences height.
	Thyroid-stimulating hormone (TSH or thyrotropin)	Causes thyroid to secrete thyroid hormone.
	Gonadotropins (follicle-stimulating hormone [FSH]; luteinizing hormone [LH])	React with gonads to regulate growth and function of these organs. In females, FSH stimulates egg production; in males, it stimulates sperm production. In females, LH causes ovulation; in males, it causes the testes to secrete testosterone.
	Prolactin (PRL)	Promotes development of glandular tissue in the female breast during pregnancy and stimulates milk production after the birth of the infant.
Pituitary (posterior)	Oxytocin (OT)	Causes contraction of the smooth muscle in the wall of the uterus. It also stimulates the ejection of milk from the lactating breast.
	Vasopressin (antidiuretic hormone [ADH])	ADH promotes the reabsorption of water by the kidney tubules; less water is lost as urine to conserve water for the body. Insufficient amounts of ADH cause excessive water loss in the urine.

(continued)

**TABLE 9-19 Other Endocrine Conditions (continued)**

Gland	Hormones	Functions
Pineal gland	Melatonin (5-methoxy- <i>N</i> -acetyl-tryptamine)	Reproductive development and daily sleep–wake cycles; skin blanching. Derived from tryptophan. Production is stimulated by darkness and inhibited by light. Beta-blockers decrease release of melatonin.
Adrenal cortex	Mineralocorticoids (such as aldosterone)	Adrenal cortex has control of 28 hormones, all of which are steroids. Aldosterone conserves sodium ions and water.
	Glucocorticoids (such as cortisol)	Cortisol increases blood glucose levels.
	Gonadocorticoids (sex hormones: androgens and estrogens)	Normal reproductive functioning.
Adrenal medulla	Epinephrine (adrenalin) and nor-epinephrine (noradrenalin)	These two hormones are secreted in response to stimulation by the sympathetic nerve, particularly during stressful situations. They cause faster heartbeat and increased blood glucose levels.  A lack of hormones from the adrenal medulla produces no significant effects. Hypersecretion, usually from a tumor, causes prolonged or continual sympathetic responses.
Thyroid	Thyroid hormones: thyroxine (95%) and triiodothyronine (5%)	Growth and development, metabolism. Thyroid hormones need iodine.
	Calcitonin	Calcitonin is secreted by the parafollicular cells of the thyroid gland. This hormone opposes the action of the parathyroid glands by reducing the calcium level in the blood. If blood calcium becomes too high, calcitonin is secreted until calcium ion levels decrease to normal.
Thymus	Thymosin	Immunity; T cells; lymphocytes. Currently being studied for its possible role in AIDS and hepatitis.
Parathyroid glands	Parathyroid hormone (PTH)	Regulation of calcium and phosphorus; secreted in response to low blood calcium levels in order to increase those levels. PTH mobilizes calcium by increasing calcium resorption from bone and by raising calcium reabsorption in the proximal kidney tubule.
Gonads (testes and ovaries)	Androgens (testosterone)	Growth and development of the male reproductive structures; increased skeletal and muscular growth; enlargement of the larynx accompanied by voice changes; growth and distribution of body hair; increased male sexual drive.
	Estrogen and progesterone	Development of the breasts; distribution of fat evidenced in the hips, legs, and breasts; maturation of reproductive organs such as the uterus and vagina. Progesterone causes the uterine lining to thicken in preparation for pregnancy. Together, progesterone and estrogens are responsible for the changes that occur in the uterus during the female menstrual cycle.

## PITUITARY GLAND

## HYPOPITUITARISM

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Asset provided by Anatomical Chart Co.

## DEFINITIONS AND BACKGROUND

Hypopituitarism is an underactive pituitary gland. A deficiency in production of pituitary hormones may be caused by tumor, trauma, radiation to the brain, stroke or aneurysm, or surgery.

In hypopituitarism, there is a lack of one or more of these hormones and loss of function in the affected gland or organ. Table 9-20 lists symptoms of pituitary disorders. It may take years for an accurate diagnosis to be made. If all pituitary hormones are missing, this is panhypopituitarism; it is relatively rare.

Adrenocorticotrophic hormone (ACTH) stimulates the adrenal gland to release cortisol to maintain BP and blood glucose levels. If ACTH is missing, depression, fatigue, low BP, nausea and diarrhea, dizziness, pale skin, weakness, and weight loss are signs and symptoms. A shortage of cortisol can be life threatening.

Arginine vasopressin (AVP) was formerly known as antidiuretic hormone (ADH). AVP controls water loss by the kidneys. If AVP is deficient, severe thirst and excessive urination occur; diabetes insipidus may result. In rare instances, deficiency may occur after an event such as brain surgery.

**TABLE 9-20** Symptoms of a Pituitary Disorder

Headaches	Short stature if during growth period
Depression	Cold intolerance
Mood/emotion swings	Weight loss
Abdominal pain, anorexia	Infertility in women
Loss of memory	Impotence in men
Loss of sleep	Cessation of or irregular menses
Sexual dysfunction	Lethargy, fatigue
Failure in lactation	Weakness
Low blood pressure	Loss of armpit, body, pubic or facial hair

Source: Pituitary Network Association. Available at <http://www.pituitary.org/>

Growth hormone (GH) regulates somatic growth, carbohydrate and lipid metabolism, and adipocyte functions. There is a complex interplay between GH and insulin signaling (Perrini et al, 2008). If GH is deficient in children, short stature (below 5 feet) can result. This condition causes 10% of all dwarfism. In adults, there is abnormal body composition, osteopenia, impaired quality of life, cardiac dysfunction, and an adverse lipid profile. Follicle-stimulating hormone (FSH) and Luteinizing hormone (LH) control sexual function and fertility in males and females. When gonadotropin (FSH, LH) deficiency occurs, men and women will lose interest in sex and can experience fatigue, weakness, loss of body hair, impotence in men, and loss of menstruation in women. Oxytocin stimulates the uterus to contract during labor and the breasts to release milk. Oxytocin mechanisms are necessary for successful pregnancies (Kubler et al, 2009). Pregnancy is uncommon when oxytocin levels are low.

Prolactin stimulates female breast development and milk production. Prolactin deficiency is rare but can stop milk production in women.

TSH stimulates the thyroid gland to release hormones that affect the body's metabolism. When TSH is deficient, this can lead to an underactive thyroid (hypothyroidism). Cold intolerance, constipation, weight gain, and pale and waxy or dry skin can occur.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Transcription factors have an impact on target genes; different phenotypes result when the gene encoding the relevant transcription factor is mutated. Many genes are involved.

Clinical/History	Lab Work	Protein-bound iodine (PBI) uptake (decreased?)
Height	ACTH level	Glucose
Weight	Cortisol	Glucose tolerance test (GTT)
BMI	Serum estradiol	Chol, Trig
Diet history	Serum testosterone	Homocysteine
BP	Serum IGF-1	CRP
Brain scan	Thyroxine (T4) (decreased?)	Alb
Pituitary MRI	Triiodothyronine (T3)	Complete blood count (CBC)
Dual-energy x-ray absorptiometry (DEXA) scan	FSH, LH, TSH (decreased?)	

Osmolarity Na <sup>+</sup> , K <sup>+</sup> Ca <sup>++</sup> , Mg <sup>++</sup>	Serum Gluc Uric acid	H & H, serum ferritin Transferrin
---	-------------------------	---

## INTERVENTION

### OBJECTIVES

- Replenish missing hormones.
- Prevent dehydration, hypoglycemia, and related problems.
- Improve lean muscle mass stores.
- Monitor serum levels of cholesterol and triglycerides; prevent vascular complications.

### FOOD AND NUTRITION

- Dietary alterations may be needed, such as higher or lower energy intake, until hormone levels are normalized. A modified fat, cholesterol, and carbohydrate intake may be needed. Ensure sufficient intake of protein.
- Six small feedings may be better tolerated than larger meals.
- Increase fluids unless contraindicated.
- Ensure adequate intake of all vitamins and minerals. Calcium and vitamin D should be taken in sufficient amounts to prevent osteoporosis.

## Common Drugs Used and Potential Side Effects

Hormone replacement therapy may include any of all of the following:

1. Corticosteroids (hydrocortisone [Cortef], cortisol) are often used and can alter glucose, calcium, and phosphate tolerance. Potassium and folacin must be increased; sodium must be decreased. Monitor for signs of hyperglycemia.
2. Thyroid preparations (levothyroxine) may be needed.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Unsafe Food Handling

**Assessment Data:** On home tube feeding. Unsanitary habits noted during home visit.

**Nutrition Diagnosis (PES):** Unsafe food handling related to preparation and administration of tube feeding as evidenced by observations during home visit.

**Intervention:** Education on how to sanitize counters and maintain safe procedures while handling tubing and enteral product.

**Monitoring and Evaluation:** No signs of diarrhea or GI distress from contaminated TF.

3. GH (somatotropin) requires no specific dietary interventions. It may help alleviate elevated triglycerides. Long-term GH replacement therapy in adults is safe for lifelong therapy in order to maintain the benefits.
4. Estrogen, progesterone, or testosterone replacement should be monitored for side effects related to heart disease and elevated lipids.
5. Cortisone may be needed during periods of stress or illness if ACTH is deficient.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Have patient avoid fasting and stress.
- Discuss the need to use small, frequent meals instead of large meals.
- Discuss the possibility of hyperglycemia and how to manage.
- Hormone replacement is usually permanent, so doctor visits will be needed to check for diabetes and signs of osteoporosis.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## PITUITARY GLAND (ANTERIOR)

## ACROMEGALY

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: Weber J RN, EdD and Kelley J RN, PhD. *Health Assessment in Nursing*, 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

## DEFINITIONS AND BACKGROUND

Acromegaly is a hormonal disorder caused by overproduction of human GH by the pituitary gland. Incidence is rare, with 50–70 cases per million in the U.S. population. Diagnosis is made common about a decade after oversecretion of GH begins. If GH-producing tumors occur in puberty, the condition is called gigantism. Genetics and nutrition impact the height of most children; unusual, continuing growth in stature beyond the twenties should be evaluated.

GH (somatotropin) affects the growth of almost all cells and tissues and has direct and indirect effects. Direct effects of excessive GH include hyperinsulinism, lipolysis, insulin resistance in peripheral tissues, ketogenesis, hyperglycemia, and sodium and water retention. In over 98% of cases, overproduction of GH is related to a benign pituitary tumor. In a few patients, acromegaly is caused by tumors of the pancreas, lungs, or adrenal glands. Symptoms and signs of acromegaly include enlarged extremities with disproportionate growth of nose, lips, brow, lower jaw, tongue, hands, and feet. Serious side effects include heart failure, colon polyps that become cancerous, and diabetes.

Elevated insulin-like growth factor I (IGF-I) also occurs in acromegaly, resulting in greater protein synthesis, amino acid transportation, muscle and bone growth, DNA and RNA synthesis, and cell proliferation. High levels of GH and increased IGF-1 levels (three to ten times above normal) may be used to diagnose acromegaly. Hormone-secreting pituitary tumors account for about 30% of all pituitary tumors (Patil et al, 2009). Surgical removal of the pituitary gland provides a 50–70% chance of cure (Vance and Laws, 2005). Acromegaly is complicated by an increased incidence of diabetes mellitus caused by impaired insulin sensitivity and reduced beta-cell function (Higham et al, 2009). Bone and cartilage growth may lead to arthritis. Acromegalic patients present

with hypoadiponectinemia; studies suggest a link between adiponectin, visfatin, fat mass, and bone changes (Sucunza et al, 2009). Premature death may result if left untreated. Treatment may include surgical removal of the tumor, radiation therapy, or injection of a GH blocking drug. Somatostatin analogs have been key in medical therapy. Pegvisomant, a GH-receptor antagonist, competitively binds to the GH receptor, blocking IGF-I production and allowing for a better control of cardiac disorders and glucose metabolism (Vance and Lawes, 2005). Improved insulin sensitivity occurs after use from a reduction in overnight endogenous glucose production (Higham et al, 2009). Somatoline Depot (lanreotide) can be used for a long-term treatment in patients who have had an inadequate response to surgery and/or radiation.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Most pituitary tumors are from a genetic mutation that is acquired and not present from birth.

<b>Clinical/History</b>	Skin tags	BUN
	Impaired vision	Serum Creat (increased)
Height	Osteoarthritis,	Urine sugar
Weight	carpal tunnel	Gluc, HbA1c
BMI	syndrome	GTT
Weight changes	Deepening voice	Serum
Diet history	Headaches	insulin
BP (increased)	Fluid retention	Ca <sup>++</sup>
I & O		(decreased)
Increased coarse	<b>Lab Work</b>	Phosphorus
body hair	IGF-I levels (best	(increased?)
Coarse, leathery	marker)	Alb
skin	GH (>5× higher	Na <sup>+</sup> , K <sup>+</sup>
Excessive	than normal)	H & H
diaphoresis	N balance	
and oily skin		

## INTERVENTION

## OBJECTIVES

- Control weight.
- Prevent or control diabetes, hypertension, or heart disease when present.
- Prevent osteoporosis with calcium balance, which is often negative.
- Monitor for complications such as colon polyps, which may lead to cancer.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Involuntary Weight Gain**

**Assessment Data:** Diagnosis of acromegaly with recent weight gain of 10 lb over 6 weeks; FBG 130 mg/dL.

**Nutrition Diagnosis (PES):** Involuntary weight gain (NC-3.4) related to excessive GH and IGF-1 levels as evidenced by 10 lb weight gain in 6 weeks.

**Intervention:** Education—importance of controlling CHO and energy intake to manage weight and prevent diabetes. Counseling—tips for identifying hidden CHO sources and controlling energy intake.

**Monitoring and Evaluation:** Weight stabilized; HgbA1c, FBS and other available lab results. No additional signs of hyperglycemia and no further weight gain.

- Achieve the goal for GH levels as 1–2  $\mu\text{g/L}$  (Sheppard, 2005).

**FOOD AND NUTRITION**

- An CHO-controlled diet may be needed if diabetes is present.
- Extra fluid intake may be needed.
- Control sodium and fluid intake if there is heart failure.
- Offer sufficient intake of calcium and vitamin D; a multi-vitamin–mineral supplement may be useful.

**Common Drugs Used and Potential Side Effects**

- Bromocriptine (Parlodel) can be taken orally to reduce GH secretion. Side effects include gastrointestinal upset, nausea, vomiting, light-headedness when standing, and nasal congestion. Take with food.
- Octreotide (Sandostatin) injection is a synthetic form of somatostatin. Side effects include diarrhea, nausea, gallstones, and loose stools.
- Insulin may be needed if diabetes is also present. Be wary of excess doses; hypoglycemia is a dangerous side effect.
- Cardiac medications may be needed; monitor for specific side effects accordingly. Atorvastatin treatment is safe, well-tolerated, and effective (Mishra et al, 2005).
- Pegvisomant is used to normalize circulating levels of IGF-I, the principal mediator of GH action.
- Somatuline Depot delivers an injection subcutaneously instead of into the muscle; side effects include diarrhea, cholelithiasis, abdominal pain, nausea, injection site reactions, flatulence, arthralgia, and loose stools.

**Herbs, Botanicals, and Supplements**

- Herbs and botanical supplements should not be used without discussing with physician.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Discuss body changes and altered self-image. Exercise can help to improve physical functioning and quality of life (Woodhouse et al, 2006).
- Teach patient about control of diabetes or heart failure, where present.
- After surgery, potential complications include cerebrospinal fluid leaks, meningitis, and damage to the surrounding normal pituitary tissue, requiring lifelong pituitary hormone replacement.

**Patient Education—Foodborne Illness**

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## PITUITARY GLAND (ANTERIOR)

## CUSHING'S SYNDROME

NUTRITIONAL ACUITY RANKING: LEVEL 1–2

Adapted from: Rubin E. *Essential Pathology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 2000.

## DEFINITIONS AND BACKGROUND

Cushing's syndrome (CS) is a disease caused by an excess of cortisol. It can be caused by extrinsic and excessive hormonal stimulation of the adrenal cortex by tumor of the anterior pituitary gland, adrenal hyperplasia, or exogenous cortisol use. Differential diagnosis is not simple. No existing test is accurate when used alone; focused imaging, including computed tomography (CT), magnetic resonance imaging (MRI), and nuclear imaging modalities can provide the diagnosis (Lindsay and Nieman, 2005).

Pituitary CS occurs after puberty with equal frequency in boys and girls. In adults, it has a greater frequency in women than men, with most diagnosed between ages 20 and 50 years. The total incidence is about 10–15 million people per year. It is a disorder characterized by virilism, upper body obesity with thin arms and legs, hyperglycemia, glucosuria, hypertension, red moon face, vertigo, emotional lability, buffalo hump, purple striae over obese areas, acne, female balding or hirsutism, blurry vision, and pitting ankle edema. In some cases, osteoporosis and severe depression are present.

Chronic cortisol hypersecretion causes central obesity, hypertension, insulin resistance, dyslipidemia, and prothrombotic state, manifestations of a MetS. There is a complex interaction between CS and inflammation; raised levels of IL-8 and OPG in CS patients, despite glucocorticoid excess, may represent an inflammatory and pro-atherogenic phenotype (Kristo et al, 2008). If left untreated, CS can be fatal. Diagnosis is not simple. Late-night salivary cortisol may be a useful test (Carroll et al, 2009). Treatments differ according to the cause: ACTH dependent (pituitary or ectopic) or independent (an adrenal tumor), or iatrogenic (from excessive steroid hormone use). If iatrogenic, depletion of steroid hormones will be needed. If pituitary, the gland may need to be removed. CS caused by ACTH production from solid tumors can result in life-threatening hypercortisolemia (Uecker and Janzow, 2005). Radiation, chemotherapy, or surgery may be

needed. After surgical removal of the adrenal glands, most symptoms of CS disappear. Psychological impairment can persist despite successful treatment (Iacobone et al, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Rarely, CS results from an inherited tendency to develop tumors of one or more endocrine glands. With multiple endocrine neoplasia type 1 (MEN1), hormone-secreting tumors of the parathyroid glands, pancreas, and pituitary develop and may lead to CS.

<b>Clinical/History</b>	Decreased fertility in men	Urinary Gluc (increased)
Height	CT	Gluc (increased)
Weight	MRI for tumors	HbA1c
BMI	DEXA scan	Ca <sup>++</sup> , Mg <sup>++</sup>
Diet history		Urinary Ca <sup>+</sup>
BP (increased)	<b>Lab Work</b>	Lipid profile, Chol, Trig
Edema	24-hour urinary free cortisol level (>50–100 µg/d)	K <sup>+</sup> (decreased)
Buffalo hump		Na <sup>+</sup> (increased)
Moon face		Alb, N balance
Easy bruising, slow healing	Dexamethasone suppression test	CRP
Red or purple striae on skin		pCO <sub>2</sub> (increased), pO <sub>2</sub>
Weakened bones	Late-night salivary cortisol	WBC, TLC (decreased)
Sore, aching joints in hip, back, shoulders	Corticotropin-releasing hormone (CRH) stimulation test for ACTH levels (altered)	
Excess facial hair in women		

## INTERVENTION

## OBJECTIVES

- Control elevated blood glucose or lipids; manage diabetes and CVD.
- Promote weight loss if needed; decrease fat stores while increasing lean body mass.
- Control or lower BP.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Excessive Sodium Intake**

**Assessment Data:** Long-term corticosteroid use for lupus; dietary history reveals high intake of sodium from snack foods, canned soups and vegetables, luncheon meats; buffalo hump, slightly elevated glucose and lipids. BMI 27. BP averaging 190/80. Feet and hands edematous.

**Nutrition Diagnosis (PES):** Excessive sodium intake related to high intake of salted and processed foods as evidenced by diet history and requirement for corticosteroids.

**Intervention:** Education about a desirable lowering of sodium from dietary sources. Counseling about sources of well-flavored snack foods, use of more fruits and raw vegetables, use of varied spices and seasonings; choices in the supermarket, at restaurants, while traveling.

**Monitoring and Evaluation:** Evaluation of impact of lower sodium from diet on BP and edema. Improved intake of fruits, raw vegetables and nonprocessed meats. Improved quality of life.

- Prevent or control side effects of corticosteroid therapy: vertebral collapse, heart failure, bone demineralization, osteoporosis, and hypokalemia.

## FOOD AND NUTRITION

- Restrict sodium if steroids are used.
- Use an energy-controlled diet, if needed. Calculate diet according to patient's desirable body weight.
- Control glucose levels when elevated; carbohydrate counting can be useful.
- Ensure adequate intake of calcium and potassium.
- Ensure adequate intake of protein if losses are excessive (e.g., 1 g protein/kg or more).
- Use an anti-inflammatory diet rich in omega-3 fatty acids, herbs, spices and antioxidant foods; see Tables 8-13 and 8-14.

## Common Drugs Used and Potential Side Effects

- With glucocorticoid therapy, osteoporosis and hypercalciuria are common side effects. Withdrawal of these medications after autoimmune or cancer management may cause iatrogenic CS. Adrenal insufficiency or steroid

withdrawal symptoms may occur (Hopkins and Leinung, 2005).

- Large doses of vitamin D may be necessary; do not use for extended periods without monitoring for toxicity.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help patient control weight as needed.
- Explain which foods are good sources of calcium in the diet.
- Explain how to control elevated blood sugars and lipids through balanced dietary intake.
- Manage symptoms of MetS through dietary changes and exercise.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## PITUITARY GLAND (POSTERIOR)

## DIABETES INSIPIDUS

## NUTRITIONAL ACUITY RANKING: LEVEL 3

## DEFINITIONS AND BACKGROUND

Diabetes insipidus (DI) can be caused by defects in the posterior pituitary gland or from an insufficient renal response to AVP, formerly ADH. Distinction is essential for effective treatment (Makaryus and MacFarlane, 2006). DI may be primary (congenital) or secondary (acquired after trauma, surgery, tumor, or infection). Both forms of DI are marked by excessive thirst, copious urination, and dry skin. There is potential for dehydration and weakness. Urine output may be 5–10 L/24 h.

**Nephrogenic DI** is characterized by the kidney's inability to respond to AVP. The multiple and complex functions of the renal tubule in regulating water, electrolyte, and mineral homeostasis make it prone to numerous genetic abnormalities (Chadra and Alon, 2009). Nephrogenic DI requires careful monitoring of body chemistry and adequate hydration.

**Neurogenic (primary) DI** is more common in males. Children with DI may be irritable or listless and may have problems with bedwetting, fever, vomiting, or diarrhea (Linshaw, 2007). Neurogenic DI responds to nasal administration of 1-deamino-8-D-arginine vasopressin (desmopressin acetate) (DDAVP), a vasopressin analogue.

**Dipsogenic DI** is a very rare form of DI from a defect in the thirst mechanism in the hypothalamus.

**Gestational DI (GDI)** is also very rare. DI can complicate up to 1 in 30,000 pregnancies. If DI occurs with pre-eclampsia, the baby may have to be delivered early. DDAVP may be used (Ananthakrishnan, 2009).

Sometimes, the exact cause of DI is unknown. Patients undergoing surgery for pituitary tumors present with DI (Dumont et al, 2005). In acquired forms, the kidneys' ability to respond to AVP can be impaired by drugs such as lithium,

or by chronic disorders including polycystic kidney disease, sickle cell disease, kidney failure, partial blockage of the ureters, and inherited genetic disorders.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Abnormal posterior pituitary development is found in genetic forms of central DI. The exact genes are being studied.

Clinical/History	Lab Work	
Height	Arginine	Glucose
Weight	vasopressin	Bicarbonate
BMI	(AVP) in	Urinary specific
Diet history	serum, urine	gravity
BP	Urinary osmo-	(decreased)
Excessive thirst	lality (may	Uric acid
and urination	be <300	(increased in
I & O	mOsm/kg)	adults)
Fever?	Fluid deprivation	BUN
Vomiting,	test (neuro-	Creat
diarrhea in	genic vs.	Na <sup>+</sup> (increased)
children	nephrogenic	K <sup>+</sup> (altered?)
Brain MRI	forms)	Alb

## INTERVENTION

### OBJECTIVES

- Reduce urine osmolality and increase electrolyte-free water excretion.
- Raise serum sodium concentration.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Fluid Intake

**Assessment Data:** Polyuria, polydipsia; preference for cold beverages or ice. Signs of poor skin turgor and dehydration; pale urine. Diagnosis of nephrogenic DI.

**Nutrition Diagnosis (PES):** Inadequate fluid intake related to losses from frequent urination and diagnosis of DI as evidenced by pale urine, urination 10 times daily and during the night.

**Intervention:** Education about the importance of taking prescribed medication and increasing fluid intake because of Dx of DI. Counseling about sources of fluid from beverages and foods; discussion of signs of dehydration and when to contact the physician.

**Monitoring and Evaluation:** Reports of improved hydration status. Consistent use of medication. No emergency visits to the doctor or emergency room. Improved quality of life.

- Avoid fluid overload and rapid fluctuations in sodium concentration, especially in persons who cannot control their fluid intake themselves (Toumba and Stanhope, 2006).
- Check patient's weight three times weekly to determine fluid retention and effectiveness of drug therapy. At home, have weights recorded daily.
- Reduce excess workload for the kidney and prevent stone formation.

## FOOD AND NUTRITION

- Adjust fluid, sodium, and potassium intakes according to the cause.
- A low-sodium diet and diuretics may also be needed to minimize workload of the kidney.
- Sometimes a controlled-protein diet is needed to protect renal function.

### Common Drugs Used and Potential Side Effects

- DDAVP may cause abdominal pain, headaches, gastrointestinal distress, and weakness. It is administered parenterally, by pill, or by nasal spray. Patients should drink fluids or water only when thirsty, but be aware that a low urine volume is a risk factor for kidney stone formation (Mehandru and Goldfarb, 2005). Hyponatremic hypervolemia leading to seizures is a rare but potentially life-threatening side effect.
- If diuretics such as thiazides or amiloride are used, monitor for side effects. Potassium may be needed if a supplement is not used.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Fluid adjustments will be made according to the type of DI. Caution patients not to limit fluid intake in an effort to lessen urine output.
- Cold or ice water may be preferred.
- Select low-calorie beverages to prevent excessive weight gain.
- Avoid stimulant/diuretic-type beverages (e.g., coffee, tea, alcohol).

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## PITUITARY GLAND

## SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE (SIADH)

## NUTRITIONAL ACUITY RANKING: LEVEL 2

## DEFINITIONS AND BACKGROUND

Syndrome of inappropriate antidiuretic hormone (SIADH) involves hyponatremia and hyperosmolality of urine. Normal renal and adrenal functioning with abnormal elevation of plasma vasopressin occurs (inappropriate for serum osmolality). Hyponatremia and SIADH can occur among elderly long-term care patients with febrile illness (Arinzon et al, 2005). Other causes of SIADH are listed in Table 9-21.

Hyponatremia is usually the first symptom of SIADH. In severe hyponatremia, convulsions or coma can occur. Other signs and symptoms include irritability, lethargy, seizures, and confusion. SIADH or cerebral salt-wasting syndrome (CSWS) can occur after pituitary surgery; differential diagnosis can be difficult. SIADH syndrome often requires sodium replacement or use of loop diuretics.

BUN (low, <10 mg/dL)	Ca <sup>++</sup> , Mg <sup>++</sup> Bicarbonate (normal)	Uric acid (may be low) GFR (increased)
Creat K <sup>+</sup>		

## SAMPLE NUTRITION CARE PROCESS STEPS

## Inadequate Sodium Intake

**Assessment Data:** Serum Na<sup>+</sup> levels low at 110 mol/L; elevated urinary osmolality.

**Nutrition Diagnosis (PES):** Inadequate sodium intake related to salt wasting syndrome after pituitary surgery as evidenced by low serum Na<sup>+</sup> (110) and high urinary mOsm.

**Intervention:** Food-nutrient delivery – Add extra salt to meals; send extra salt packet with delivered meals.

**Monitoring and Evaluation:** Normal serum Na<sup>+</sup> and urinary osmolality at next lab visit.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** SIADH is usually acquired and not genetic.

<b>Clinical/History</b>	Irritability	Serum
Height	Lethargy,	osmolality
Current weight	confusion	<280
Edema-free	Low urine	mOsm/kg
weight	volume	Serum AVP
BMI		(elevated)
Diet history	<b>Lab Work</b>	Urine osmolality
I & O	Serum Na <sup>+</sup>	>500
Temperature	<135	μmol/kg
Edema	μmol/L	Urinary Na <sup>+</sup>
		(elevated)

**TABLE 9-21** Causes of Syndrome of Inappropriate Antidiuretic Hormone

Acute leukemia
Brain abscess, stroke or meningitis
Drugs: chlorpropamide, cyclophosphamide, carbamazepine
Gillain-Barre syndrome
Head injury
Lung cancer (especially small-cell lung cancer)
Lymphoma
Olfactory neuroblastoma
Pancreatic cancer
Pituitary surgery
Pneumonia
Prostate cancer
Rocky Mountain spotted fever
Sarcoidosis
Temporal arteritis, polyarteritis nodosa

## INTERVENTION

## OBJECTIVES

- Treat the cause.
- Restrict water intake.
- Replace electrolytes as appropriate; usually intravenous saline is provided.
- Normalize hormone secretion through drug therapy.

## FOOD AND NUTRITION

- Restrict fluid intake, usually 1000–1200 mL/d.
- Alter dietary sodium and potassium, as deemed appropriate for the condition. This will vary by patient condition and medications used.
- When enteral feeding is needed, select a formula that is fluid restricted, such as those that are 2 kcal/mL. Monitor carefully for signs of dehydration. Check content of formula for sodium and potassium; select according to patient status and needs.

## Common Drugs Used and Potential Side Effects

- Demeclocycline (Declomycin) may be used with side effects like those of tetracycline. Avoid taking with calcium or dairy products.
- Conivaptan is a new agent available for use to antagonize the effects of vasopressin, especially in heart failure patients (Schwarz and Sanghi, 2006).
- Hyponatremia as a result of SIADH is a relatively common serious side effect of the use of selective serotonin reuptake inhibitors (SSRIs) in (mostly elderly) adults (Vanhaesebrouk et al, 2005).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Provide counseling regarding water and fluid restrictions as ordered.
- Discuss any underlying conditions that may have caused the syndrome; highlight needed dietary alterations.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## OVARY

## POLYCYSTIC OVARIAN DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 2

## DEFINITIONS AND BACKGROUND

Polycystic ovarian disease (PCOD; or polycystic ovarian syndrome [PCOS]) is an endocrine disorder characterized by hyperandrogenism, bilaterally enlarged polycystic ovaries, and insulin resistance. This syndrome affects about 6–10% of women of childbearing age (Barbieri, 2000). There is a lack of consensus between endocrinologists and gynecologists in the definition, diagnosis, and treatment of PCOD (Cussons et al, 2005).

PCOD is currently considered as possibly the most frequent cause of female infertility; it is also closely associated with the MetS (Gleicher and Barad, 2006). Hyperandrogenism, insulin resistance, and acanthosis nigricans (HAIR-AN syndrome) cause presentation of the insulin-

resistant syndrome PCOD (Barbieri, 2000). Insulin resistance and hyperandrogenism are caused by both genetic and environmental factors. Acanthosis nigricans is a dark, velvety patch of skin that indicates insulin resistance (Scalzo and McKittrick, 2000). Women of Caribbean-Hispanic or African American descent seem to be more prone to this condition.

Women with PCOD may have had a history of GDM. Many adolescents present with hirsutism and irregular menses. In PCOD, elevated LH to FSH ratio, hirsutism, acne, oily skin, male pattern baldness, menstrual irregularity, oligomenorrhea, and obesity can occur. Abnormally elevated levels of testosterone and LH disrupt the normal maturation process for ovulation. Immature cysts remain on the ovaries, giving the appearance of a “string of pearls.”

Girls tested for anorexia nervosa (AN) may also have PCOD, with menstrual irregularities before weight loss and elevated LH and estrogen compared with individuals who have AN alone (Pinhas-Hamiel et al, 2006). In PCOD, biochemical abnormalities include hyperandrogenism, acyclic estrogen production, LH hypersecretion, decreased levels of steroid hormone-binding globulin (SHBG), and hyperinsulinemia (Mascitelli and Pezzetta, 2005). Infertility, hypertension, uterine cancer, diabetes, coronary heart disease, and endometrial carcinoma often follow (Legro, 2001).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Polymorphisms in the PPARGC1A, PPAR-delta and PPAR-gamma2 loci have been associated with PCOS.

Clinical/History	Lab Work	
Height	Vaginal ultrasound	Serum estrogen
Weight	with enlarged ovaries	Serum testosterone
BMI	Recurrent pregnancy loss?	LH
Diet history		LH:FSH ratio (elevated)
Weight gain pattern		Plasminogen activator inhibitor-1 (PAI-1) (shows abnormal clotting)
History (Hx) of GDM		H & H
Irregular menses	Glucose	Alb
Amenorrhea	CRP	BUN, Creat
Hirsutism	Chol, Trig (elevated?)	ALT
Infertility	Homocysteine	BP (elevated)
Acne	Fasting serum insulin (elevated)	
Male pattern baldness	C-peptide levels for insulin secretion	
Acanthosis nigricans (dark, velvety patches on skin)		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Food-Drug Interaction

**Assessment Data:** Recent Dx of PCOD; wt at 110% of normal for height. Currently taking metformin but complaining of GI distress.

**Nutrition Diagnosis (PES):** Food-drug interaction related to metformin use as evidenced by GI distress and use of the medication on an empty stomach.

**Intervention:** Education about the need to eat before taking the prescription to evaluate if GI distress resolves.

**Monitoring and Evaluation:** Follow-up about GI distress or other side effects while taking metformin. Evaluation of timing for food and medication use.

## INTERVENTION

### OBJECTIVES

- Lose weight or maintain a normal weight for height; obesity occurs in 50% of this population.
- Prevent heart problems, stroke, and heart attack. Improve lipid profile.
- Reduce serum androgens and improve menstrual regularity.
- Decrease risk for endometrial cancer.
- Alleviate glucose intolerance and insulin resistance.
- Improve anxiety, moods, and quality of life.

### FOOD AND NUTRITION

- Offer a weight-control and exercise plan to meet weight goals. Loss of 5–10 lb may reduce symptoms.
- Lower elevated blood glucose and lipids. Eat five to six small meals per day.
- The DASH diet may be helpful to lower BP. Include low-fat dairy products and more fruits and vegetables.
- Avoid low-fat, high-CHO diets, which promote extra insulin secretion (McKittrick, 2002). A diet of 30–40% fat, 45–50% complex CHOs, and 15–20% protein may be useful.
- Include sufficient fiber (20–35 g/d).
- Include sources of omega-3 fatty acids (fish, walnuts, and flaxseed).
- Dietary or supplemental chromium should be included.

### Common Drugs Used and Potential Side Effects

- Symptoms may be managed by antiandrogen medication (e.g., birth control pills, spironolactone, flutamide, or finasteride).
- Insulin-sensitizing drugs improve ovulation and hirsutism in PCOD (Azziz et al, 2001). Metformin (glucophage) allows for improved insulin sensitivity and reduced LH and testosterone. Metformin induces ovulation, has some marginal benefit in improving aspects of the MetS, improves objective measures of hirsutism, and seems to be effective in both obese and lean individuals (Lord and Wilkin, 2004). Do not use with heart failure, chronic obstructive pulmonary disease, or chronic kidney disease. Take with food; monitor for minor gastrointestinal side effects such as nausea, diarrhea, and flatulence. Hypoglycemia does not usually occur.
- Rosiglitazone (Avandia) and pioglitazone (Actos) pose minimal risk of hepatotoxicity compared with older medications.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Chromium picolinate (1000 µg) may be useful as an insulin sensitizer in the treatment of PCOD (Lydic et al, 2006).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Counsel about weight loss and nutrition. Regular meal-times and snacks may help control cravings and overeating.
- Encourage regular exercise and reduced sedentary lifestyle.
- Explain relationship of insulin resistance and increased risk for T2DM.
- Medical treatments may be needed to support reproduction. Some women will need in vitro fertilization (IVF) treatments.

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food handling procedures.

## ADRENAL GLAND (CORTEX)

# ADRENOCORTICAL INSUFFICIENCY AND ADDISON'S DISEASE

### NUTRITIONAL ACUITY RANKING: LEVEL 1-2

## DEFINITIONS AND BACKGROUND

In adrenocortical insufficiency, the adrenal cortex atrophies with loss of hormones (aldosterone, cortisol, and androgens). Primary adrenal insufficiency in the pediatric population (0–18 years) is most commonly attributed to congenital adrenal hyperplasia, which occurs in about 1 in 15,000 births, followed by Addison's disease, with a likely autoimmune etiology (Perry et al, 2005). Secondary forms often result from tuberculosis, cancer, or surgery in which the adrenal glands are destroyed or damaged. Of patients with adrenocortical insufficiency, 33% also have diabetes. With T1DM, the expression of organ-specific autoantibodies is very high (Barker et al, 2005), and this suggests a need for careful screening in both of these conditions.

Cortisol, a glucocorticoid, affects almost every organ and tissue in the body. Cortisol helps the body respond to stress. Among other tasks, cortisol helps to maintain BP and cardiac functioning, the immune system's inflammatory response, the effects of insulin in breaking down sugar for energy through metabolism of macronutrients, and proper arousal and well-being.

Aldosterone functions to conserve sodium and excrete potassium. When aldosterone is no longer secreted, the following events occur: excretion of sodium takes place, and the body's store of water decreases, which leads to dehydration, hypotension, and decreased cardiac output. The heart becomes slower due to reduced workload. Increased serum potassium can lead to arrhythmias, arrest, and even death.

Primary adrenal insufficiency causes abdominal pain, vomiting, weakness, fatigue, weight loss, dehydration, nausea, diarrhea, hyperpigmented (tan or bronze) skin, hypotension, low serum sodium, high serum potassium, and low corticosteroid levels. It may be temporary or may become a chronic insufficiency. Salt cravings can occur.

**Type I primary adrenal insufficiency (polyendocrine deficiency syndrome)** occurs in children and exhibits underactive parathyroid glands, pernicious anemia, chronic *Candida* infections, chronic active hepatitis, and slow sexual development. Autoimmune thyroid diseases are often associated with T1DM and Addison's disease, characterizing the autoimmune polyendocrine syndrome. **Type II primary adrenal insufficiency (Schmidt's syndrome)** affects young adults and presents with underactive thyroid gland, slow sexual development, diabetes, vitiligo and changing skin pigmentation.

In **secondary adrenal insufficiency**, which is much more common than the primary form, there is a lack of ACTH. Production of cortisol drops but not production of aldosterone. A temporary form of secondary adrenal insufficiency may occur when a person who has been receiving a glucocorticoid hormone such as prednisone for a long time abruptly stops or interrupts taking the medication. Glucocorticoid hormones, which are often used to treat inflammatory illnesses such as rheumatoid arthritis, asthma, or ulcerative colitis, block the release of both CRH and ACTH. Normally, CRH instructs the pituitary gland to release ACTH. If CRH levels drop, the pituitary is not stimulated to release ACTH, and the adrenals then fail to secrete sufficient levels of cortisol. In secondary adrenal insufficiency, darkening of the skin does not occur, and GI symptoms are less common. Hypoglycemia, anxiety, nausea, and palpitations can occur.

**Addison's disease** is a strict insufficiency state of adrenal hormones, including cortisol and aldosterone. It affects about one in 100,000 people. Autoimmune Addison's disease is caused by autoreactivity toward the adrenal cortex; T cells seem to be involved. An Addisonian crisis can be precipitated by acute infection, trauma, surgery, or excessive body salt loss. Patients with adrenal insufficiency, although on treatment, have a poor quality of life and an increased mortality (Debono et al, 2009). A normal lifespan is possible if daily medications are taken as prescribed. Delayed and sustained release oral formulations of hydrocortisone will match the more natural circadian rhythms of the body. Adrenalectomy may require steroid replacement therapy, a 2-g sodium diet, and control of carbohydrate to prevent hyperglycemia. Possibly, the addition of dehydroepiandrosterone (DHEA) to the treatment plan may lead to improved well-being and sexual function (Hahner and Allolio, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Cytotoxic T lymphocyte antigen 4 (CTLA-4), protein tyrosine phosphatase nonreceptor type 22 (PTPN22), major histocompatibility complex class II transactivator (CIITA), and C-lectin type genes (CLEC16A) play a role in the primary form (Michels and Eisenbarth, 2009).

Clinical/History	Lab Work	ACTH stimulation test
Height	Gluc	BUN (increased)
Weight	K <sup>+</sup> (increased)	Cortisol (decreased)
BMI	N balance	CRH stimulation test
Diet history	Na <sup>+</sup> (decreased)	Alb
BP (decreased)	Ca <sup>++</sup> (increased)	Mg <sup>++</sup> (increased)
I & O	Cl <sub>2</sub> (decreased)	HbA1c
Abdominal x-rays	WBC (decreased)	
Skin changes	ACTH (increased)	

## INTERVENTION

### OBJECTIVES

- Relieve symptoms of hormone deficiency by taking synthetic hormones (but not to excess).
- Prevent hypoglycemia; avoid fasting.
- Prevent weight loss. Improve appetite and strength.
- Modify sodium according to drug therapy. Prevent hyponatremia, especially in warm weather when sodium losses from perspiration are higher than usual.
- Prevent dehydration and shock.
- Correct diarrhea, hyperkalemia, nausea, and improper medication administration.
- If hyperglycemia or diabetes occurs, insulin may be needed.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Inadequate Sodium Intake**

**Assessment Data:** Adrenal insufficiency with inadequate intake of medication replacement; recent labs showing elevated potassium and low serum sodium levels.

**Nutrition Diagnosis (PES):** Inadequate sodium intake related to insufficient medication for Addison's disease as evidenced by high serum potassium and low serum sodium and diet history revealing low sodium intake for the past week.

**Intervention:** Educate about the importance of taking sufficient medication to maintain normal electrolyte levels and when to add salt to the diet.

**Monitoring and Evaluation:** Review of serum electrolytes, quality of life, fewer episodes of Addisonian crisis, diet hx revealing controlled sodium intake as per medical advice.

## FOOD AND NUTRITION

- During an Addisonian crisis, low BP, low blood glucose, and high levels of potassium can be life threatening. Intravenous injections of hydrocortisone, saline, and dextrose are given by the medical team.
- Use a high-protein, moderate-carbohydrate diet. Snacks may be needed. Control carbohydrate amount and frequency according to blood glucose and HgbA1c levels.
- Ensure intake of sodium is adequate according to medications given. Monitor potassium levels and adjust diet if needed.
- Force fluids (2–3 L) when allowed.

## Common Drugs Used and Potential Side Effects

- If aldosterone is missing, fludrocortisone (Florinef) is used as an oral, synthetic, sodium-retaining hormone. Be wary about overdosing, with potential side effects of hypertension and ankle edema. Postural hypotension can occur with a dose that is too low. Extra may be needed when exercising or in hot weather.
- Long-acting synthetic glucocorticoids, such as oral dexamethasone or prednisone, are given for replacement. Side effects can include loss of calcium, decreased bone density, or risk of osteoporosis. To decrease gastric irritation, take hormones with milk or an antacid.
- Signs of insufficient amounts of cortisol replacement include feeling weak and tired all the time, getting sick or vomiting, and anorexia. Weight loss can occur.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help patient individualize diet according to symptoms. During illness or injury, the body normally makes up to 10 times more cortisol than usual. Be prepared to avoid a crisis with a prompt treatment.
- Ensure patient does not skip meals. Instruct patient to carry cheese or cracker snack to prevent hypoglycemia.
- Discuss simple meal preparation to lessen fatigue.
- Discuss food sources of sodium and potassium according to the medical plan.
- Use of Medic-Alert identification is recommended. Patients with this condition may need to carry a syringe prefilled with dexamethasone.
- Pregnancy is possible, with carefully managed replacement medication. Evidence has accrued that fracture risk might be programmed during intrauterine life, mediated through pituitary-dependent endocrine systems such as insulin, growth hormone, and the HPA (hypothalamic-pituitary-adrenal) system (Cooper et al, 2009).

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## ADRENAL GLAND (CORTEX)

## HYPERALDOSTERONISM

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

## DEFINITIONS AND BACKGROUND

Hyperaldosteronism is an increased production of aldosterone by the adrenal cortex. Aldosterone controls water and electrolyte balance by acting on mineralocorticoid receptors in the kidney and in the vascular system (Oberliethner, 2005). Hyperaldosteronism causes endothelial dysfunction regardless of high BP. Patients may be quite vulnerable to cardiac events, including stroke (Milliez et al, 2005).

Primary aldosteronism (PA) is usually from an adenoma and involves hypertension, hypokalemia, and low plasma renin. Familial hyperaldosteronism type I (FH-I) represents about 1% of cases of primary hyperaldosteronism. It may be detected in asymptomatic individuals when screening the offspring of affected individuals, or patients may present in infancy with hypertension, weakness, and failure to thrive due to hypokalemia. It is inherited in an autosomal dominant manner.

**Conn's syndrome** is a benign tumor in one adrenal gland that can cause this condition. Urine 18-hydroxycortisol (18-OHF) measurements are used to detect Conn's syndrome with adrenal adenoma or glucocorticoid-suppressible hyperaldosteronism (Reynolds et al, 2005).

Secondary forms of aldosteronism may occur after cancer, heart failure, hyperplasia, malignant hypertension, pregnancy, estrogen use, or cirrhosis. Aldosteronism is a diagnosis that should be considered in refractory hypertension.

CT, MRI, and adrenal vein sampling (AVS) distinguish unilateral PA from the bilateral form; the unilateral form can be treated surgically, whereas bilateral PA is treated medically (Kempers et al, 2009).

## SAMPLE NUTRITION CARE PROCESS STEPS

## Excessive Sodium Intake

**Assessment Data:** Hypertension (190/95); diet hx indicating daily use of high sodium foods and salty snacks.

**Nutrition Diagnosis (PES):** Excessive sodium intake related to intake of high sodium foods and frequent salty snacks throughout the day as evidenced by dietary recall and food records estimated at about 8–9 g Na<sup>+</sup> daily.

**Intervention:** Food-nutrient delivery—limit dietary sources of sodium to 2–4 g sodium; monitor effects of medication. Educate about sources of sodium, potassium, and use of the DASH diet plan as appropriate. Counsel about ways to reduce sodium from foods and snacks; how to dine away from home; how to monitor for signs and symptoms requiring medical attention.

**Monitoring and Evaluation:** Lower BP; normal serum labs, especially potassium. Diet history indicating great improvement in sodium regulation. Able to verbalize use of the DASH diet principles.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Primary hyperaldosteronism may be the cause of essential hypertension in some people. Specific DNA mutations have emphasized the role of molecular genetics in this disorder (New et al, 2005).

Clinical/History	ECG with abnormalities from low K <sup>+</sup> levels	Aldosterone: renin ratio
Height		Urine sodium (altered)
Weight		Urine 18-hydroxycortisol (18-OHF)
BMI		Na <sup>+</sup> (altered)
Diet history		K <sup>+</sup> (low)
I & O		Urine potassium (altered)
BP (high)		Ca <sup>++</sup>
Fatigue		Mg <sup>++</sup> (altered)
Headache		pCO <sub>2</sub> (altered)
Weakness, intermittent paralysis		H & H
Numbness		Serum Fe
Abdominal CT scan for adrenal mass		
	<b>Lab Work</b>	
	Sodium load test (6 g common)	
	Plasma renin (low)	
	Plasma aldosterone (elevated)	
	Urinary aldosterone (elevated)	

## INTERVENTION

## OBJECTIVES

- Hydrate adequately.
- Alter diet as needed (sodium, potassium).
- Correct hypokalemia and hypertension.
- Prepare for surgery if a tumor is involved. Laparoscopic adrenalectomy (LA) is quite successful, after which BP returns to normal. If a tumor is not involved, medical treatment will be for life.

## FOOD AND NUTRITION

- Provide adequate fluid intake (unless contraindicated for other reasons).
- A sodium-restricted diet may be needed. A high potassium intake and the DASH diet may be required, depending on the medical or surgical treatment used.
- Small, frequent feedings may be needed.

## Common Drugs Used and Potential Side Effects

- Antihypertensives may be used; monitor side effects specifically for the medications prescribed. Aldosterone antagonists have been available for many decades; spironolactone may be used alone or with ACE inhibitors or ARBs.
- Eplerenone, a selective aldosterone antagonist, avoids the androgen and progesterone receptor–related adverse events that sometimes occur with spironolactone, such as breast tenderness, gynecomastia, sexual dysfunction, and menstrual irregularities (Pratt-Ubunama et al, 2005).
- Digitalis may be used. Avoid herbal teas, high-fiber intakes, and excessive amounts of vitamin D. Include adequate amounts of potassium. Take the drug 30 minutes before meals.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Products containing natural licorice should be avoided in this condition.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain altered sodium and potassium requirements. Teach principles of the DASH diet.

- Have patient avoid fasting, skipping meals, and fad dieting.
- Provide recipe suggestions.
- Avoid consuming large amounts of real licorice, which can aggravate the condition.

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## ADRENAL GLAND (MEDULLA)

# PHEOCHROMOCYTOMA

NUTRITIONAL ACUITY RANKING: LEVEL 1

## DEFINITIONS AND BACKGROUND

Pheochromocytoma (PHEO) is a rare tumor of the chromaffin cells most commonly arising from the adrenal medulla, resulting in increased secretion of epinephrine and norepinephrine. It is slightly more common in males. Hereditary PHEOs are typically intra-adrenal and bilateral, and patients typically present at a young age.

PHEO may occur as a single tumor or as multiple growths. Symptoms and signs include very high BP, headache, excessive diaphoresis, and palpitations. Less-common symptoms are anxiety, chest pain, fatigue, weight loss, abdominal pain, and nervousness. About 10% of these tumors are malignant and can spread. Persons who have difficult-to-treat hypertension, have onset before age 35 or after age 60, or are taking four or more BP medicines may need to be tested for PHEO.

BP often fluctuates up and down, daily testing is recommended. Diagnosis includes measurement of urinary catecholamines or their metabolites, vanillylmandelic acid and total metanephrines. The urinary metanephrines provide a highly sensitive clue to the presence of PHEO; see Table 9-22.

Treatment usually involves surgical removal of the tumor. Before surgery, alpha-adrenergic blockers may be used. After surgery, about one quarter of patients will still suffer from hypertension and require lifelong management.

endocrine neoplasia. Type IIB (MEN IIB) also leads to thyroid cancer and tumors of nerves in the lips, mouth, eyes and digestive tract. The NF1 neurofibromas may present with café-au-lait spots, an optic glioma, and PHEO.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** PHEO may be transmitted as an autosomal dominant trait. At least five different gene mutations can cause PHEO. One type causes multiple

## INTERVENTION

### OBJECTIVES

- Prepare for surgery to remove tumor. Patients with pre-operative endocrinopathies present a challenge because the “endocrine axis” is complex (Kohl and Schwartz, 2009). If the tumor cannot be removed, lifelong medication will be needed.

**TABLE 9-22 Catecholamines**

Catecholamine	Comments	Normal Urinary Value/24 h
Dopamine	A neurotransmitter (a chemical used to transmit impulses between nerve cells) found mainly in the brain. Metabolized by target tissues or by the liver to become inactive substances that appear in the urine—dopamine becomes homovanillic acid.	Dopamine 65–400 µg
Epinephrine	A brain neurotransmitter, but is also a major hormone secreted from the adrenal medulla in response to low blood glucose, exercise, and various forms of stress where the brain stimulates release of the hormone. Epinephrine causes a breakdown of glycogen to glucose in liver and muscle, the release of fatty acids from adipose tissue, vasodilation of small arteries within muscle tissue, and increases in the rate and strength of the heartbeat. In the urine: epinephrine becomes metanephrine and VMA.	Epinephrine 0.5–20 µg Metanephrine: 24–96 µg VMA: 2–7 mg*
Norepinephrine	The primary neurotransmitter in the sympathetic nervous system (controls the “fight or flight” reaction) and is also found in the brain. In the urine: norepinephrine becomes normetanephrine and vanillylmandelic acid (VMA).	Norepinephrine 15–80 µg Normetanephrine: 75–375 µg
Total		Total urine catecholamines: 14–110 µg

\*For testing, a VMA-restricted diet may be required for lab results; omit chocolate, vanilla extract, and citrus.

Source: Medline Plus. Catecholamines—urine. Accessed September 22, 2009, at <http://www.nlm.nih.gov/medlineplus/ency/article/003613.htm>

## SAMPLE NUTRITION CARE PROCESS STEPS

**Excessive Intake of Bioactive Substances**

**Assessment Data:** Hypertensive crisis following intake of caffeine and Chianti wine. Dx of PHEO; high levels of urinary epinephrine and norepinephrine, as well as vanillylmandelic acid and metanephrines. Diet history reveals recent intake of coffee, chocolate and Chianti wine at dinner meal, causing extreme heart palpitations and soaring BP.

**Nutrition Diagnosis (PES):** Excessive intake of bioactive substances (caffeine, tyramine) related to coffee, chocolate and Chianti wine as evidenced by very high BP and diet history.

**Intervention:** Education about foods to avoid, such as caffeine from food and beverages, tyramine-rich foods including beer, Chianti wine, processed meats, soy sauce, bananas, avocado.

**Monitoring and Evaluation:** No further hypertensive crises related to food and beverage intake.

- Stabilize BP before surgery. Avoid overstimulation from even slight exercise, cold stress, or emotional upsets.
- Correct nausea, vomiting, and anorexia.
- Manage long-term hypertension. A severe BP level is any reading above 180/110 mm Hg. Prevent hypertensive crises, which could cause sudden blindness, kidney failure, seizures, acute respiratory distress, arrhythmias or stroke.
- Manage any complications such as heart attack or cardiomyopathy (Kassim et al, 2008).

## FOOD AND NUTRITION

- For urine testing, some doctors order a VMA diet where patient avoids bananas, caffeine from coffee or Pepsi/Coke, chocolate, tea, vanilla in foods, pineapple, alcoholic beverages, eggplant, plums, walnuts. While this was a common practice in the past, there is no strong evidence to support its use.
- Increase fluids but avoid caffeinated beverages. Avoid tyramine-rich foods, especially if taking MAO inhibitors.
- Six small feedings may be better tolerated than large meals.
- Increase protein and calories if patient is having surgery. Postoperatively, provide adequate vitamins and minerals for wound healing.
- Re-expansion of plasma volume may be accomplished by liberal salt or fluid intake with use of alpha-1 adrenergic receptor antagonists.
- In recurrent cases, long-term drug therapy will be needed. Monitor for specific dietary changes and side effects.

## Common Drugs Used and Potential Side Effects

- Pharmacological treatment of catecholamine excess is mandatory.

- Phenoxybenzamine (or an alpha-1 adrenergic receptor antagonist such as prazosin) is needed to block alpha-adrenergic activity. Diuretics should not be used.
- Low doses of a beta-blocker such as propranolol are used to control BP and cardiac tachyarrhythmias but only after alpha blockade. Labetalol, an alpha- and beta-adrenergic blocker, has also been shown to be effective in the control of BP and symptoms of PHEO.
- Avoid decongestants, amphetamines, MAO inhibitors (Nardil, Parnate).
- High-dose MIBG may be used in the treatment of malignant PHEO but can have toxic side effects (Gonias et al, 2009).
- If diabetes occurs, insulin may be needed.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss avoidance of caffeinated foods and beverages (e.g., coffee, tea, and chocolate).
- Maintain a calm atmosphere for patient; prevent undue stress.
- Exercise should be limited until condition is under control.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## THYROID GLAND

## HYPERTHYROIDISM

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Asset provided by Anatomical Chart Co.

## DEFINITIONS AND BACKGROUND

Hyperthyroidism results from oversecretion of the thyroid hormones, triiodothyronine (T3) or thyroxone (T4). These hormones affect every cell through controlling body temperature, heart rate, metabolism, and production of calcitonin. Thyroid hormone affects glucose homeostasis through increased hepatic glucose output, increased futile cycling of glucose degradation products between the skeletal muscle and the liver, decreased glycogen stores in the liver and skeletal muscle, altered oxidative and nonoxidative glucose metabolism, decreased active insulin output from the pancreas, and increased renal insulin clearance (Potenza et al, 2009). When the hypothalamus signals the pituitary gland to produce TSH, normally this is regulated to be just enough. See Table 9-23 for interpretation of lab results for thyroid disorders.

The autoimmune thyroid diseases (AITD), Graves' disease, and chronic lymphocytic thyroiditis (CLT) are among the most common endocrine diseases in childhood and adolescence (Brown, 2009). Usually in hyperthyroidism, the

entire gland is overproducing thyroid hormone. Rarely, a single nodule is responsible for the excess hormone secretion. An elevated metabolic rate, tissue wasting, diaphoresis, tremor, tachycardia, goiter, heat intolerance, cold insensitivity, nervousness, increased appetite, exophthalmos, and loss of glycogen stores can occur. If left untreated, atrial fibrillation and osteoporosis can result.

**Autoimmune thyroiditis (AITD)** may start out temporary, then lead to hyperthyroidism. The most common causes include Hashimoto's thyroiditis, subacute granulomatous thyroiditis, or silent lymphocytic thyroiditis. The major environmental triggers of AITD include iodine, medications, infection, smoking, and possibly stress (Tomer and Huber, 2009). Specific digestive diseases (celiac disease or primary biliary cirrhosis) may be associated with autoimmune thyroid processes (Daher et al, 2009). Persons who have T1DM, mood disorders, psychosis, or Addison's disease also seem to be at higher risk.

**Graves' disease** (diffuse toxic goiter) is the most common form; **thyrotoxicosis** is more severe. Clinical thyrotoxicosis in Graves' disease patients is caused by thyrotropin receptor (TSHR)-stimulating autoantibodies (Schott et al, 2005). Most people who develop Graves' ophthalmopathy have one or more of the following symptoms: dry and itchy eyes, a staring or bug-eyed look (exophthalmos), sensitivity to light, excessive tearing, a feeling of pressure around the eyes, difficulty closing the eyes completely, and peripheral double vision. Thyrotoxicosis can alter carbohydrate metabolism in a type 2 diabetic patient to such an extent that DKA develops if untreated (Potenza et al, 2009).

**Thyroid storm (thyroid crisis)** is a potentially life-threatening condition that develops in a person with hyperthyroidism. The gland suddenly releases large amounts of thyroid hormone in a short period of time. Signs of thyroid storm include extreme irritability, high systolic BP, low diastolic BP, tachycardia, nausea, vomiting, diarrhea, high fever, confusion, and sleepiness. Shock, delirium, shortness of breath, fatigue, coma, heart failure, and death can result if not treated immediately. Emergency medical treatment is always needed.

If thyroidectomy is needed, antithyroid agents and iodine are often given 4–6 weeks before surgery to minimize the risk of thyroid crisis. With thyroidectomy, the patient may require a high-calorie, high-protein diet preoperatively. Evaluate needs postoperatively with the doctor's care plan.

TABLE 9-23 Thyroid Test Results

TSH	T4	T3	Interpretation
High	Normal	Normal	Mild (subclinical) hypothyroidism
High	Low	Low or normal	Hypothyroidism
Low	Normal	Normal	Mild (subclinical) hyperthyroidism
Low	High or normal	High or normal	Hyperthyroidism
Low	Low or normal	Low or normal	Nonthyroidal illness; rare pituitary (secondary) hypothyroidism

Source: Lab Tests On Line, web site accessed October 25, 2009, at <http://www.labtestsonline.org/understanding/analytes/t3/test.html>

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** In Graves' disease a specific combination of polymorphisms for thyroglobulin and HLA-DR markedly increases the odds ratio for developing disease

(Brown, 2009). Among the major AITD susceptibility genes that have been identified is the HLA-DR gene locus, as well as CTLA-4, CD40, PTPN22, thyroglobulin, and TSH receptor genes (Tomer and Huber, 2009).

<b>Clinical/History</b>	More frequent bowel movements	TSH (normal or low)
Height	Fatigue, muscle weakness	Protein-bound iodine (PBI)
Weight	Changes in menstrual habits	Gluc (increased)
BMI	Protruding eyeballs?	Alb, transthyretin
Rapid weight loss?	Excessive tearing from one or both eyes?	Ca <sup>++</sup>
Diet history	Thyroid scan	Mg <sup>++</sup>
Temperature	Goiter (enlarged thyroid gland)	(decreased)
BP		Na <sup>+</sup> , K <sup>+</sup>
I & O		H & H
Nervousness, anxiety		Serum ferritin
Tachycardia or palpitations		Chol, Trig (decreased)
Increased sensitivity to heat		BUN, Creat
Difficulty sleeping		N balance
Fine tremor of hands		Alk phos (increased)
	<b>Lab Work</b>	
	T3 (increased)	
	T4 (increased)	

## INTERVENTION

### OBJECTIVES

- Achieve a euthyroid state to avoid the effects of triiodothyronine (T3) on the heart and cardiovascular system: decreased systemic vascular resistance and increased resting heart rate, left ventricular contractility, blood volume, and cardiac output (Dahl et al, 2008).
- Prevent or treat complications accompanying high metabolic rate, including bone demineralization. This seems to be a greater problem in older women than in adolescents (Poomthavorn et al, 2005).
- Replenish glycogen stores. Replace lost weight (usually 10–20 lb).
- Correct negative nitrogen balance.
- Replace fluid losses from diarrhea, diaphoresis, and increased respirations. However, exophthalmos, caused by increased accumulation of extracellular fluid in the eyes, may require fluid and salt restriction.
- Monitor or treat fat intolerance and steatorrhea.

### FOOD AND NUTRITION

- Use a high-calorie diet (start with 40 kcal/kg). The patient's caloric needs may be increased by 50–60% in this condition (or 10–30% in mild cases). Ensure adequate intake of carbohydrates.
- Provide protein in the range of 1–1.75 g/kg body weight.
- Fluid intake should be 3–4 L/d, unless contraindicated by renal or cardiac problems.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Altered Nutrient Utilization

**Assessment Data:** Elevated T3 and T4, low TSH and serum calcium; BMI 18 with weight loss of 15 lb in 6 months. Dx hyperthyroidism.

**Nutrition Diagnosis (PES):** Altered nutrient utilization (NC-2.1) related to hyperthyroidism as evidenced by elevated T4 of 112 µg/100 mL; T3 of µg/100 mL; low TSH level at 0.10 µU/L; low serum calcium levels; weight loss of 15 lb in less than 6 months.

**Interventions:** Food and Nutrition Delivery: ND-1.3 provide information on high calorie diet to promote weight gain, ensure high carbohydrate intake, importance of 1 quart of milk daily or equivalent, caffeine to be avoided, be cautious of raw goitrogens ND-3.2.1 continue use of daily multivitamin. ND3.2.4 continue use of daily calcium supplement.

**Nutrition Education:** E-1.1 Discuss importance of high calorie diet (40 kcal/kg/d) to promote weight gain consisting of following healthy eating habits and to discuss interaction of raw natural goitrogens with antithyroid drugs.

**Counseling:** C-2.2 RD to work with patient to set goals of weight gain and taking antithyroid drug to be prescribed by MD.

**Coordination of Care:** RC-1.3 Collaboration with MD and referral to endocrinologist, to speak with MD about weight gain of 1–2 lb per week and drug–food interactions.

**Monitoring and Evaluation:** Prevent the thyroid from producing excess hormones with use of antithyroid drug, Tapazole. Follow a weight gain of 1–2 lb/wk till patient reaches normal body weight range of 125–130 lb. Daily use of multivitamin and calcium supplementation. Successful food recording in food diary. Patient can recite raw natural goitrogens to be avoid them in her diet. Patient eating frequent snacks. Patient successfully gained 1 lb in 2 weeks bringing her weigh to 116 lb, BMI now 19.3. Patient to visit endocrinologist in next week.

- Include 1 quart of milk or equivalent daily to supply adequate calcium, phosphorus, and vitamin D.
- Exclude caffeine and stimulants from diet because they aggravate excitability and nervousness.
- Supplement diet with vitamins A, C, and B-complex vitamins, especially thiamin, riboflavin, B<sub>6</sub>, and B<sub>12</sub>. A general multivitamin–mineral supplement may be beneficial; monitor for iodine content.
- Be aware of iodine in any supplements used. Chronic iodine intakes greater than 500 µg/L are associated with adverse effects (Zimmermann et al, 2005).
- Raw natural goitrogens (cabbage, Brussels sprouts, kale, cauliflower, soybeans, peanuts) should not be used with antithyroid medications because these substances increase side effects of the drugs. Cooking reduces this effect.

## Common Drugs Used and Potential Side Effects

- The goal of drug therapy is to prevent the thyroid from producing excess hormones. Antithyroid drugs, also called thionamides, such as methimazole (Tapazole) and propylthiouracil (PTU), can cause nausea, vomiting,

altered taste sensation, and gastrointestinal distress. They should be taken with food. Avoid use of natural goitrogens in raw form; cooked forms are not a problem.

- Thionamides represent the treatment of choice in pregnant women, during lactation, in children and adolescents, and in preparation for radioiodine therapy or thyroidectomy (Bartelena et al, 2005).
- Radioactive iodine may be used to damage or destroy some of the thyroid cells. It can cause a temporary burning sensation in the throat. Hydrochlorothiazide (HCTZ) may be used to improve radioiodine uptake in hyperthyroid patients; replace potassium.
- Some drugs can affect the thyroid glands. Amiodarone is a potent antiarrhythmic drug that also possesses beta-blocking properties; a 100-mg tablet contains an amount of iodine that is 250 times the recommended daily iodine requirement. Amiodarone-induced thyrotoxicosis is a difficult condition to diagnose and treat; monitor carefully (Basaria and Cooper, 2005).

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician. Bugleweed, verbena, lemon balm and kelp have been recommended; no clinical trials prove efficacy.
- Limit use of large quantities of iodine-rich seaweed such as kombu (*Laminaria japonica*).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Thyroid hormone affects adipokines and adipose tissue, predisposing the patient to ketosis (Potenza et al, 2009). Beware of hyperglycemia after carbohydrate-rich meals.
- Encourage quiet, pleasant mealtimes.

- Exclude use of alcohol, which may cause a hypoglycemic state.
- Frequent snacks may be needed. To avoid obesity, adjust patient's diet as condition corrects itself.

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## THYROID GLAND

# HYPOTHYROIDISM

### NUTRITIONAL ACUITY RANKING: LEVEL 1

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

Hypothyroidism is caused by the underfunctioning of the thyroid gland. It can be classified as primary (thyroid failure), secondary (from pituitary TSH deficit), or tertiary (from hypothalamic deficiency of thyrotropin-releasing hormone) or result from peripheral resistance to the action of thyroid hormones. Primary hypothyroidism causes about 95% of all cases.

The most common cause of thyroid gland failure is **Hashimoto's thyroiditis**, which is inflammation caused by the patient's own antibodies (as in pernicious anemia, lupus, rheumatoid arthritis, diabetes, or chronic hepatitis). The

second major cause of thyroid gland failure is from various medical treatments that affect the thyroid gland (e.g., surgery, chronic medication use).

Hypothyroidism affects up to 10% of adult women, usually middle-aged and older women. Women may experience menstrual irregularities or difficulty conceiving. Triiodothyronine (T3) and thyroxine (T4) are elevated during pregnancy and with oral contraceptive and estrogen use. Physicians must treat hypothyroidism to avoid long-term complications, such as depression, infertility, and CVD. Risk decreases if thyroid hormones are taken as directed.

**Congenital hypothyroidism (CH) or cretinism** is rare; incidence is one in 4000 births. Screening for this type of hypothyroidism is now common (Lanting et al, 2005). Treatment involves replacement of thyroid hormones and iodine. Cretinism can occur in areas where soil content of iodine is low.

**Myxedema** is a nonpitting edema that can occur in adults with hypothyroidism; hydrophilic mucopolysaccharide accumulates in the skin and muscles. In end-stage myxedema coma, untreated hypothyroidism leads to progressive weakness, stupor, hypothermia, hypoventilation, hypoglycemia, hyponatremia, water intoxication, shock, and even death. It occurs most often in older patients with underlying pulmonary and vascular disease. Signs and symptoms of hypothyroidism are listed in Table 9-24.

**Thyroid autoimmunity** is common and may contribute to miscarriages as well as to hypothyroidism. Infants are totally dependent on T4 from the mother during the first trimester for normal neurological development (Smallridge et al, 2005). Hypothyroidism from autoimmune disease or suboptimal iodine intake occurs in 2.5% of pregnant women; postpartum thyroid dysfunction (PPTD) occurs in 5–9% of women (Lazarus and Premawardhana, 2005). Because of the potential problems for mother and baby, screening, diagnosis, and treatment of thyroid problems among pregnant women is important.

**Endemic goiter** is an enlargement of the thyroid gland with swelling in front of the neck, resulting from iodine deficiency due to inadequate dietary intake or drug effects. Over 3 billion people in the world are on iodine supplementation programs. Optimal level of iodine intake to prevent thyroid disease is in a relatively narrow range around the recommended daily iodine intake of 150 µg.

**Subclinical hypothyroidism (SCH)** is mild thyroid failure and is diagnosed when peripheral thyroid hormone levels are within normal reference laboratory range but serum TSH levels are mildly elevated (Fatourehchi, 2009). Iodine, iron, selenium, and zinc deficiencies can impair thyroid function. Iron deficiency impairs thyroid hormone synthesis by reducing activity of heme-dependent thyroid Peroxidase; iron supplementation may improve the efficacy of iodine supplementation. Anemia is a major manifestation in hypothyroidism not only because of impaired hemoglobin synthesis, but also because of iron deficiency from increased iron loss with menorrhagia, impaired intestinal absorption of iron, folate deficiency due to impaired intestinal absorption of folic acid, and pernicious anemia with vitamin B<sub>12</sub> deficiency. Selenium deficiency and disturbed thyroid hormone status may develop in phenylketonuria, cystic fibrosis, as well as from poor nutrition in children, elderly people, or sick patients. In parts of the world where iodine and selenium are both deficient, dual supplementation may be advisable.

**TABLE 9-24 Symptoms of Hypothyroidism By Life Stage**

*Infants*

Constipation  
Cyanosis  
Developmental delay  
Hoarse cry  
Marked retardation of bone maturation  
Persistent jaundice  
Poor feeding  
Respiratory difficulty  
Somnolence  
Umbilical hernia

*Children*

Evidence of mental retardation  
Poor performance at school  
Retarded growth  
Stunting, short stature

*Adults*

Abnormal menstrual cycles  
Brittle nails  
Broad flat nose  
Coarse features with protruding tongue  
Coarse, dry hair  
Cold intolerance  
Dry, rough pale skin  
Decreased libido  
Delayed dentition  
Difficulty losing weight  
Easy fatigue  
Hair loss  
Hoarse, husky voice  
Impaired mental development  
Muscle cramps, frequent muscle aches  
Puffy hands and face  
Reduced conversion of carotene to vitamin A  
Short stature  
Weakness  
Weight gain  
Widely set eyes

Vitamin A deficiency (VAD) and the iodine deficiency disorders (IDD) affect >30% of the global population; these deficiencies often coexist in vulnerable groups (Zimmerman, 2007). Given alone, without iodine repletion, high-dose vitamin A supplementation in combined VAD and ID may reduce thyroid hyperstimulation and reduce risk for goiter (Zimmerman, 2007). More research on vitamin and mineral therapies will be beneficial.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutations in the DUOX2, PAX8, SLC5A5, TG, TPO, TSHB, and TSHR genes cause congenital hypothyroidism.

<b>Clinical/History</b> (see Table 9-24)	Ca <sup>++</sup> Mg <sup>++</sup> (increased)	Creatine phos- phokinase (CPK)
Height	H & H (decreased)	GFR (decreased?)
Weight		
BMI	Serum ferritin	Thyrotropin
Diet history	Chol, Trig (increased)	Somatomedin C (increased)
Temperature	Gluc	Uric acid
BP	Alk phos (decreased)	(increased)
Goiter?		Carotenoids (increased)
Thyroid scan	Serum copper (decreased)	Thyroglobulin (useful meas- ure after introducing iodized salt)
<b>Lab Work</b>	Na <sup>+</sup> and K <sup>+</sup> (decreased)	
T4 (decreased)	Serum folic acid and vitamin B <sub>12</sub> (low)	Serum vitamin D <sub>3</sub>
T3 (decreased)		
TSH (elevated)		
Urinary iodine concentration (UIC)		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Overweight (NC-3.3)

**Assessment Data:** Low serum levels of T4 and T3 with increased TSH. Unplanned weight gain of 30 lb in past 2 years. Recent Dx of hypothyroidism and initiation of Synthroid. BMI 30.

**Nutrition Diagnosis (PES):** Overweight (NC-3.3) as related to excess food and nutrition related knowledge deficit and hypothyroidism as evidenced by reports of overconsumption of high fat/calorie dense food and beverages, BMI 30, waist circumference >40 inches, and a fat mass of 51.7%.

**Interventions:** Nutrition prescription (ND-1) of a weight control/exercise plan with promotion of a diet including 30–40% fat, 45–50% complex carbohydrates, and 15–20% protein with a goal of cutting out 250–500 calories a day resulting in a 0.5–1 lb weight loss each week. Recommend adequate intake of fluid and foods high in fiber. Support use of Synthroid 25 µg once daily. Initial/Brief nutrition education (E-1) to begin instruction on following a weight control/exercise plan with a diet including 30–40% fat, 45–50% complex carbohydrates, and 15–20% protein with a goal of cutting out 250–500 calories a day and provide basic nutrition related educational information on natural goitrogens, fiber, fluids, use of iodized salt, and physical activity.

**Monitoring and Evaluation:** Follow up in 1 month to repeat a TSH and free T4 to reassess thyroid function status; repeat TSH and free T4 and adjust dose of Synthroid accordingly. Evaluate progress in weight loss and healthy eating habits. Schedule a counseling session for in-depth nutrition related knowledge regarding weight loss as well as hypothyroidism.

## INTERVENTION

### OBJECTIVES

- Control weight gain that results from a 15–40% slower metabolic rate, especially in the untreated patient. Measure weight frequently to detect fluid losses or retention.
- Correct underlying causes, such as inadequate intake of iodine or congenital deficiency. Hormone replacement will be given.
- Correct vitamin B<sub>12</sub>, folic acid, or iron deficiency anemias when present.
- Because vitamin D<sub>3</sub> has implications in autoimmune disorders, assure an adequate diet and supplementary source as needed.
- Improve energy levels; reduce fatigue.
- Improve cardiac, neurological, and renal functioning.
- Screen for thyroid problems in pregnant or postpartum women; assure hormone replacement as needed.
- Ensure an adequate supply of antioxidant and fiber-rich foods as well as fluids.
- For pregnant women or children, make sure that adequate amounts of iodine are consumed.
- Natural goitrogens in cabbage, turnips, rapeseeds, peanuts, cassava, cauliflower, broccoli, and soybeans may block uptake of iodine by body cells; they are inactivated by heating and cooking.
- Achieve optimal iodine intakes from iodized salt (in the range of 150–250 µg/d for adults) to minimize thyroid dysfunction (Zimmerman, 2009). Zinc, copper, and tyrosine are needed.
- Ensure adequate iodine status during parenteral nutrition, particularly in preterm infants (Zimmerman, 2009).

### FOOD AND NUTRITION

- Use an energy-controlled diet adjusted for age, sex, and height.
- A multivitamin–mineral supplement formula may be beneficial, especially to replace nutrients that have been
- Thyroid hormones (liotrix, sodium levothyroxine, or Synthroid) are used. Use caution with use of soy protein products since they can decrease effectiveness of the hormones. Thyroid hormones elevate glucose and decrease cholesterol; monitor persons who have diabetes carefully. Monitor

for weight changes and fluid shifts. If rapid weight loss, sweating, or other symptoms of hyperthyroidism occur, the doctor should be contacted for immediate follow-up.

- Lithium treatment for bipolar disorder has been associated with the development of goiter. Monitor patients closely.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Avoid kelp tablets and “thyroid support” supplements. Gentian, walnut, mustard, radish, and St. John’s wort have been recommended, but no clinical trials have proven efficacy.
- Curcumin and vitamins A, B<sub>12</sub>, D<sub>3</sub>, and E may be beneficial; longer human studies are needed.
- If large quantities of iodine-rich seaweed such as kombu (*Laminaria japonica*) are consumed, use should be monitored in patients who take thyroid replacement hormones.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss goitrogens in cabbage and *Brassica* vegetables, turnips, rapeseeds, peanuts, cassava, and soybeans; they are inactivated by heating and cooking.
- Encourage use of iodized salt, as permitted. Avoid self-medication with iodine supplements.
- Encourage adequate fluid intake.
- Women who are considering pregnancy may want to be screened to rule out thyroid problems. If their iodine intake is low, or if they live in an area without use of iodized salt, they may need an iodine supplement prescribed from their physician. A normal urinary iodine level would be 150–249 µg/L.
- In many developing countries, children are at high risk of iodine deficiency, VAD, and iron deficiency anemia. Select the proper supplements.

- Because subclinical hypothyroidism is common in individuals who have chronic kidney disease, close monitoring of GFR is recommended (Chonchol et al, 2008).
- Exposure to large doses of metals such as lead, molybdenum, or arsenic may reduce thyroid function, with adverse effects on development, behavior, metabolism and reproduction (Meeker et al, 2009).

### Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

## PARATHYROID GLANDS

The parathyroid glands have an overall regulatory role with action as a thermostat in the systemic calcium homeostasis to ensure tight regulation of serum calcium concentrations and appropriate skeletal mineralization. Parathyroid hormone (PTH) affects calcium, phosphorus, and vitamin D metabolism by removing calcium from bone to raise serum levels; it promotes hydroxylation of vitamin D to its active form. Calcitonin, in contrast to PTH, decreases serum calcium levels; it is secreted by the thyroid gland.

The body secretes PTH in response to hypocalcemia or hypomagnesemia; the hormone then stimulates osteoclasts to increase bone resorption. PTH also stimulates adenyl cyclase to increase renal tubular calcium resorption and phosphate excretion. PTH works with vitamin D to regulate

total body calcium by activating conversion of 25-hydroxyvitamin D to 1,25-dihydroxyvitamin D, the active form that stimulates calcium and phosphate absorption from the GI tract. Calcitonin, in contrast to PTH, decreases serum calcium levels and is secreted by the thyroid gland.

Fibroblast growth factor-23 (FGF23) is a hormone that regulates mineral and vitamin D metabolism (Juppner, 2009). Research on the effects of various genes and hormones in bone homeostasis is on-going.

# HYPOPARATHYROIDISM AND HYPOCALCEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

**Hypoparathyroidism** results from a deficiency of PTH from biologically ineffective hormones, damage or accidental removal of the glands, or impaired skeletal or renal response. In the hereditary form, parathyroid glands are either absent or not functioning properly; symptoms appear before age 10. Other causes include magnesium deficiency or neonatal immaturity. If untreated, hypoparathyroidism-retardation-dysmorphism (HRD) may result.

Cancellous bone in hypoparathyroidism is abnormal, suggesting that PTH is required to maintain normal trabecular structure (Rubin et al, 2010). Hypoparathyroidism with hypocalcemia is one of the most common results of damage to parathyroid glands during surgery; in fact, it may be diagnosed during a workup for hypocalcemia.

Vitamin D levels may also be deficient. Intraoperative PTH levels are used widely during parathyroidectomy as an indicator of parathyroid gland function; vitamin D supplementation after surgery may be given to anticipate decreased parathyroid gland function and to avoid symptomatic hypocalcemia (Quiros et al, 2005).

Hypoparathyroidism is a chronic condition that requires lifelong treatment with large doses of calcium and vitamin D supplements. Episodes of tetany are treated with calcium given intravenously to provide quick relief of symptoms. Controlled release of physiological concentrations of PTH can be achieved using a surgically implantable controlled-release delivery system (Anthony et al, 2005).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** There is a hypoparathyroidism-deafness-renal (HDR) dysplasia syndrome which is an autosomal dominant disorder caused by mutations of the GATA3 gene (Ali et al, 2007).

#### Clinical/History

Height  
Weight  
BMI  
Diet history  
Weakness, fatigue  
Hyperreflexia  
Chvostek's sign positive (with tapping of facial muscles)  
Irritability or psychosis

#### Seizures

Muscle cramps and tetany  
Tingling of the lips or fingers  
Hair loss, dry skin  
Dental hypoplasia  
Chronic cutaneous moniliasis  
Abnormal heart rhythms on ECG

#### Lab Work

PTH (low)  
Ca<sup>++</sup> (serum levels <2.5–3 mg/dL)  
Urinary Ca<sup>++</sup> (altered)  
Serum phosphorus (high)  
Mg<sup>++</sup> (may be low)  
Na<sup>+</sup>, K<sup>+</sup>

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Mineral Intake

**Assessment Data:** Abnormal labs with low PTH, serum calcium 2.4 mg/dL, high serum phosphorus; positive for Chvostek's sign and tetany with muscle cramps and abnormal ECG. Diet history indicates no dairy intake for past several years. Medical diagnosis of hypoparathyroidism after thyroid surgery.

**Nutrition Diagnosis (PES):** Inadequate mineral (calcium) intake related to nutritional intake low in calcium and hypoparathyroidism as evidenced by low PTH, low serum calcium (2.4), high serum phosphorus, and signs of tetany.

**Intervention:** Food and nutrient delivery—provide foods rich in calcium (nondairy if necessary) and provide a calcium supplement calculated for body size and age. Educate about the role of calcium in alleviating signs of tetany and abnormal labs. Counsel about nondairy sources of calcium and tips for increasing intake throughout the day.

**Monitoring and Evaluation:** Resolution of low serum calcium and PTH, high phosphorus. No signs of tetany, muscle cramps, irritability. Improvement in dry skin or hair loss. Normal ECG.

### INTERVENTION

#### OBJECTIVES

- Normalize serum and urinary levels of calcium, phosphorus, and vitamin D.
- Prevent long-term complications such as cataracts, pernicious anemia, Parkinson's disease, and bone disease.
- Prevent mental retardation or malformed teeth in affected children.
- Decrease symptoms of tetany and improve overall health status.

#### FOOD AND NUTRITION

- Use a high-calcium diet with dairy products, nuts, salmon, peanut butter, broccoli, and other green leafy vegetables. If tolerated, lactose should be included in the diet for better absorption of calcium.
- Oral supplements high in calcium should be used, such as calcium carbonate.
- Reduce excess use of meats, phytates (whole grains), and oxalic acid (spinach, chard, and rhubarb) if the diet contains large amounts.
- Intake of vitamin D and protein should be adequate, at least meeting recommended levels.

### Common Drugs Used and Potential Side Effects

- Calcium lactate (8–12 g) may be used. Ergocalciferol (Calciferol) is a vitamin D analog that is used with calcium

supplements in this condition. Calcitriol (Rocaltrol) also may be useful.

- Diuretics sometimes are given to prevent too much calcium from being lost through the urine, which is a problem that can lead to kidney stones. Taking diuretics also reduces the amount of calcium and vitamin D supplements needed.
- Overuse of steroids may cause hypocalcemia.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Indicate which foods are good sources of calcium, phosphorus, and vitamin D.
- Indicate which foods are sources of phytates and avoided, if dietary intake is a concern.
- Discuss role of sunlight exposure in vitamin D formation and how it relates to individual needs.

## Patient Education—Foodborne Illness

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# HYPERPARATHYROIDISM AND HYPERCALCEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinical-Pathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

### DEFINITIONS AND BACKGROUND

**Primary hyperparathyroidism (pHPT)** results from parathyroid adenoma in up to 80% of cases, hyperplasia of the

parathyroid glands in 10–20% of cases, or cancer. Double parathyroid adenomas occur in 2–15% of pHPT cases (Abboud et al, 2005). pHPT has been associated with premature death in CVDs and should, therefore, be quickly managed (Nilsson et al, 2005).

**Secondary hyperparathyroidism (sHPT)** occurs in renal failure or even after renal transplantation. Calcitriol deficiency and phosphorus retention are involved in the pathogenesis. Parathyroid gland hyperplasia develops in azotemic patients, producing hypercalcemia and hyperphosphatemia. Secondary hyperparathyroidism in chronic kidney disease is stimulated by dietary phosphate loading and ameliorated by dietary phosphate restriction (Martin et al, 2005). The disorder is complex in that not enough phosphate is cleared from the body; phosphate is released from bone and Vitamin D is not produced. Thereafter, absorption of calcium in the gut is low and serum levels of calcium are lowered.

In children with renal failure, growth can be impaired. Postmenopausal women after Roux-en-Y gastric bypass may show evidence of secondary hyperparathyroidism with elevated bone resorption. There is an effect of early breast tumors on calcium homeostasis; subclinical hyperparathyroidism may increase the risk for breast cancer (Martin et al, 2010). Age-induced increased PTH plasma levels have been associated with cognitive decline and dementia. Increased PTH levels may become a biological marker of both dementia and osteoporosis (Braverman et al, 2009).

Parathyroidectomy can induce long-lasting improvement in regulation of BP, left ventricular diastolic function, and other signs of myocardial ischemia, with improved life expectancy (Nilsson et al, 2005). A minimally invasive procedure is available. After surgery, mild cognitive changes seem to improve, especially for depression and anxiety (Walker et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Peroxisome proliferator-activated receptor gamma PPARgamma2 has a dominant role in controlling osteoblast differentiation and numerous gene-gene interactions suggests there is a “master” regulatory process (Shockley et al, 2009). Familial multiple endocrine neoplasia type 1 and familial tumoral calcinosis account for 2% of pHPT cases. In the second form, altered GALNT3 is usually present. More studies are needed on the effects of genes on calcium and bone homeostasis.

Clinical/History	Bone and joint	Urinary $\text{Ca}^{++}$
Height	pain	(elevated)
Weight	Bone x-rays	Serum phosphorus (high?)
BMI	showing	Calcium-phosphorus product ( $\text{Ca} \times \text{P}$ )*
Diet history	fractures or reabsorption	Albumin-corrected
BP	X-rays,	calcium level (Ca corr)
Weakness, fatigue	ultrasound, or Sestamibi scan of parathyroids	FGF23
Constipation		assessment, as available
Growth delay or rickets in children		$\text{Mg}^{++}$ , $\text{Na}^+$ , $\text{K}^+$
Anorexia, weight loss	<b>Lab Work</b>	Alb, BUN, Creatinine
Increased thirst	PTH (>60 pg/mL)	H & H, serum ferritin
Dehydration	Serum $\text{Ca}^{++}$ (>11 mg/dL)	Gluc
Itchy skin		
Back pain		

\*Calcium phosphate product ( $\text{Ca} \times \text{Pi}$ ) is a clinically relevant tool to estimate the cardiovascular risk of patients with renal failure.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Mineral Intake

**Assessment Data:** Abnormal nutritional labs with PTH 65 pg/mL; serum  $\text{Ca}^{++}$  12.5 mg/dL; urinary  $\text{Ca}^{++}$  levels elevated; elevated serum phosphorus; diagnosis of hyperparathyroidism related to early renal failure without dialysis. Signs of weakness and anorexia. Poor intake because of nausea. Unplanned weight loss of 2 lb recently.

**Nutrition Diagnosis (PES):** Excessive phosphorus intake related to inability of kidneys to metabolize vitamin  $\text{D}_3$  in renal failure as evidenced by abnormal labs (PTH 65 pg/mL; serum  $\text{Ca}^{++}$  12.5 mg/dL; urinary  $\text{Ca}^{++}$  levels elevated; serum phosphorus 6, anorexia and weight loss.

**Intervention:** Food-Nutrient Delivery—provide a low-phosphorus diet. Educate about foods to avoid and which to include (see Table 9-25). Counsel about dining away from home, packing a lunch, or other relevant guidelines, how to take Sevelamer and Sensipar according to doctor's orders.

**Monitoring and Evaluation:** Improvement in serum and urinary labs related to calcium, PTH and phosphorus. Resolution of symptoms including weight loss, nausea, anorexia. Able to state foods to avoid when PTH is elevated and when to contact the physician.

- Alleviate constipation, anorexia, weight loss, and weakness.
- Avoid clinical consequences such as renal osteodystrophy, hyperphosphatemia, cardiovascular calcification, extra-skeletal calcification, endocrine disturbances, neurobehavioral changes, compromised immune system, altered erythropoiesis, renal stones, and sleep disturbances.
- Prevent rickets and growth delay in children (Sabbagh et al, 2005).
- Prepare for surgery if parathyroidectomy is necessary.

### FOOD AND NUTRITION

- Use a low-calcium diet with fewer dairy products, nuts, salmon, peanut butter, and green leafy vegetables.
- Extra fluid is useful to correct or prevent dehydration, which can elevate serum calcium levels.
- Limit phosphorus-containing foods if hyperphosphatemia is present. See Table 9-25. Use alternatives such as nondairy creamer, sorbet, jams and jellies, white rice, noodles with margarine, cream cheese, whipped cream, popcorn, pretzels, gingerale or Kool-aid if extra calories are needed.
- Dietary protein 0.8 g/kg for a balanced intake of protein in adults.

## INTERVENTION

### OBJECTIVES

- Lower elevated serum calcium and urinary calcium levels. Maintain calcium levels between 8.4 and 9.5 mg/dL.
- Normalize serum phosphate; keep phosphorus between 3.5 and 5.5 mg/dL and calcium  $\times$  phosphorus product below 55 mg/dL.

### Common Drugs Used and Potential Side Effects

- Vitamin D therapy sends a signal to the parathyroid gland to slow down the making of PTH. This helps to prevent many of the unwanted complications of hyperparathyroidism.

**TABLE 9-25 Phosphorus Facts**

Normal PO<sub>4</sub> levels in plasma: 2.5–4.5 mg/dL

Total body PO<sub>4</sub> content: 500–700 g (85% in bone)

Dietary Reference Intake: 700 mg

Typical U.S. dietary intake: 1200 mg

GI absorption—Mainly passive, through Na/Pi transporter; enhanced by vitamin D

Kidney is major regulator—mediated by brush border Na/Pi transporter; PTH increases excretion and Vitamin D decreases excretion

#### *Phosphorus-Rich Foods*

##### Dairy Products

Milk

Cheese

Yogurt

Ice cream

Pudding and custard

##### Dried beans and lentils

Kidney, lima, pinto

Soy beans

Split peas

Black-eyed peas

##### Nuts and seeds

Almonds

Cashews

Sunflower seeds

Peanuts and Peanut Butter

##### Meats

Liver

Organ meats

Sweetbreads

Smelt, sardines, herring

##### Miscellaneous

Beer

Bran, bran flakes, wheat germ

Chocolate

Colas

- Treatment with active vitamin D from analogs can increase VDR expression, inhibit growth of parathyroid tumors, and reduce PTH levels (Akerstrom et al, 2005). Zemplar (paricalcitol) and Hectrol (doxercalciferol) are examples of vitamin D analogs. These products are especially useful for dialysis patients.
- Cinacalcet (Sensipar) has been approved to treat sHPT in renal patients and parathyroid cancer. It also appears to effectively treat pHPT. Cinacalcet normalizes serum calcium with only modest increases in PTH (Sajid-Crockett et al, 2008).
- Phosphate-binding agents that do not contain calcium offer therapeutic alternatives for managing renal osteodystrophy.

Sevelamer (Renagel) lowers serum phosphorus and PTH levels without inducing hypercalcemia. Sevelamer binds drugs such as furosemide, cyclosporine, and tacrolimus, making them less effective. The timing of administration should allow several hours between these medicines. Standard protocols are recommended for use of phosphate binders.

- Once-yearly intramuscular cholecalciferol injections (600,000 IU) have been used to correct vitamin D deficiency; controlled trials are needed to determine the effect on PTH levels over time.
- Some antacids may contain high levels of calcium; monitor carefully.
- Bisphosphonates may be needed to decrease risks for osteoporosis.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Conjugated linoleic acid (CLA) reduces prostaglandin E<sub>2</sub> synthesis, which is required for PTH release. More research is needed.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss foods that are sources of calcium, phosphorus, and vitamin D. Indicate food sources of phytates and oxalates, if intake is a concern.
- Discuss role of sunlight exposure in vitamin D formation and how it relates to individual needs.
- Drink plenty of liquids.
- In renal patients, focused counseling may help to clarify misunderstanding of simple dietary facts.
- The doctor should monitor Ca<sup>++</sup> and P monthly and PTH quarterly after stabilization.
- Exercise and smoking cessation may be needed.

### **Patient Education—Foodborne Illness**

- If home tube feeding is needed, teach appropriate sanitation and food-handling procedures.

# Malnutrition—Obesity and Undernutrition

## CHIEF ASSESSMENT FACTORS

- Anorexia, Nausea, Vomiting, Diarrhea—Frequency, Length of Time
- Blood Pressure, Either Elevated or Very Low Levels
- Body Mass Index (BMI) Using Height and Weight
- Frame Size—Small, Medium, Large
- Goal Weight and Current Percentage of Goal Weight
- Healthy Body Weight Range
- History of Usual Body Weight, Present Weight, Recent Weight Changes,% Usual Body Weight
- Laboratory Values—Glucose, Albumin/Transthyretin, Hemoglobin and Hematocrit (H & H), Lipids, C-Reactive Protein (CRP)
- Medical History—Disordered Eating; Cancer or Other Conditions or Disease States; Menstrual or Reproductive Problems in Women; Smoking and Alcohol Histories
- Physical Activity Level
- Sleep Apnea, Altered Lung Function; Sleep Disorder
- Triceps Skinfold (TSF) Measurements; Arm Muscle Circumference (AMC) Measurements—Comparing Individual Against Own Values Over Time
- Waist Circumference

## TYPES OF MALNUTRITION

The malnourished state arises from a combination of inflammation and a disturbed nutrient balance in either undernutrition or overnutrition (Soeters and Schols, 2009). Malnutrition is defined by the American Society of Parenteral and Enteral Nutrition (ASPEN) as any derangement in the normal nutrition status.

**Undernutrition** may be *primary*—from insufficient intake—or *secondary*—from impaired utilization; see Table 10-1. Malnutrition originates not only from an imbalance of calories but also from psychological, economic, physical, and social factors. Health problems, alcoholism, depression, restricted diets, and mobility problems may play a part. Undernutrition contributes to half of the world's mortality in children, particularly in India and sub-Saharan Africa.

Nutrition Day, which originated in Europe, is now recognized in the United States. The intent is to identify the type and percentages of malnourished patients in hospitals and nursing homes in order to clarify their impact on health outcomes.

**Overnutrition** is caused by excessive calorie intake and/or inadequate activity; see Table 10-2. The thrifty genotype

developed when food was scarce; now, an environment where food is plentiful contributes to the dilemma (Bouchard, 2007). The study of extreme human obesity caused by single gene defects has provided a glimpse into the long-term regulation of body weight through a disrupted hypothalamic leptin-melanocortin system and extremely heterogeneous factors (Ranadive and Vaisse, 2008).

In addition to the change in environment, thirst, hunger, and high calorie beverage intake have changed in the past few decades. The intake of energy-yielding beverages seems to be related to pleasure-oriented, hedonic factors rather than hunger or thirst (McKiernan et al, 2008). Pavlovian cues for rewards become endowed with incentive salience, guiding “wanting” to a learned reward (Tindell et al, 2009). Thus, the hedonic appetite has displaced genuine hunger in the current environment of plenty, perhaps in relation to conditioned stimuli. For example, salted food may be an addictive substance that stimulates the opiate and dopamine receptors in the brain's reward and pleasure center; both salted food and opiate withdrawal stimulate the appetite, increase calorie consumption, and augment the incidence of overeating, becoming overweight, and becoming obese (Cocores and Gold, 2009).

**TABLE 10-1** Concerns with Undernutrition

- The lack of adequate macronutrients or selected micronutrients (zinc, selenium, iron, and the antioxidant vitamins) can lead to clinically significant immune deficiency (Cunningham-Rundles et al, 2005). Iron deficiency alters myelination, monoamine neurotransmitter synthesis, and hippocampal energy metabolism in the neonatal period (Georgleff, 2007). Zinc deficiency alters autonomic nervous system regulation and hippocampal and cerebellar development (Georgleff, 2007).
- Inflammation and oxidative stress fuel each other. Cachexia includes distinct metabolic changes that are the result of an acute-phase response (APR) mounted by the host, including increased muscle proteolysis, increased fat lipolysis, and increased hepatic production of acute-phase proteins such as C-reactive protein and fibrinogen (Gullett et al, 2009).
- Children who are undernourished may not reach their potential in many aspects of development. Stunting represents growth failure resulting from poor nutrition and health during the pre- and postnatal periods (Milman et al, 2005). Intrauterine and early neonatal life is a period during which environmental and nutritional influences may produce chronic and frequent infections, long-term effects, and disease risk in adulthood (Buckley et al, 2005).
- The effect of any nutrient deficiency or overabundance on brain development will be governed by the principle of timing, dose, and duration (Georgleff, 2007).
- Bourre (2006) reported on nutritional requirements for the brain. The use of glucose by nervous tissue requires thiamin. Vitamins B<sub>6</sub> and B<sub>12</sub> are directly involved in the synthesis of some neurotransmitters. Supplementation with cobalamin improves cerebral and cognitive functions in the frontal lobe. Alpha-tocopherol is actively uptaken by the brain and is directly involved in the protection of nervous membranes. Vitamin K is also involved in nervous tissue biochemistry. Iron deficiency anemia is associated with apathy, depression, and fatigue. Iodine deficiency during pregnancy induces severe cerebral dysfunction, actually leading to cretinism.
- Long-chain polyunsaturated fatty acids are important for synaptogenesis, membrane function, and, potentially, myelination (Georgleff, 2007). The rise in autism, learning problems, cognitive decline with age, Alzheimer's, Parkinson's Disease, and the SIDS epidemic has a common link: dietary deficit in omega-3 brain-foods from fish and seafood (Saugstad, 2008).
- Undernutrition in adult women tends to be associated with high levels of undernutrition in children, reflecting overall food/nutrient insecurity (Nube, 2005). Prenatal exposure to famine can lead to low birth weight and cardiovascular disease in adulthood (Painter et al, 2005).
- A woman with a low body mass index (BMI) may have difficulty becoming pregnant; preconceptional undernutrition shortens gestation in those women who do become pregnant (Rayco-Solon et al, 2005).
- **Recent weight loss** appears to be the most important single indicator of nutritional status. Nutritional risk with muscle mass depletion increases lengths of stay in hospitals (Kyle et al, 2005). Undernutrition is associated with increased resting energy expenditure (REE; kcal/kg/d). Reduced respiratory quotient (RQ) and protein synthesis (g/kg/d) occur in patients with coexistent disease; refeeding normalizes this process (Winter et al, 2005).
- Involuntary weight loss can be categorized into one of three primary etiologies (Thomas, 2007): **Starvation** results in a loss of body fat and non-fat mass due to inadequate intake of protein and energy. **Sarcopenia** involves a reduction in muscle mass and strength occurring with normal aging, associated with a reduction in motor unit number and atrophy of muscle fibers; this leads to diminished strength and exercise capacity. **Cachexia** is severe wasting that accompanies disease states such as cancer or immunodeficiency disease.
- Malnutrition in pediatric hospitals ranges from 15–30% of patients, with an impact on growth, morbidity, and mortality; nutrition-support interventions can help (Agostoni et al, 2005).
- If a person has a BMI below 18, there is an increased risk for nutrition-related complications such as infections, poor wound healing, and pressure ulcer development.

(continued)

**TABLE 10-1** Concerns with Undernutrition (*continued*)

- Approximately 25–50% of hospital patients have been found to be malnourished. Only 50% of malnourished patients are identified by the medical and nursing staff (Kruizenga et al, 2005).
- Over half of older adults have protein–energy malnutrition at admission or acquire nutritional deficits while hospitalized (Peppersack, 2005). Malnutrition may come from the “11 Ds”: disease, drinking alcohol, drugs, deficits (sensory), desertion/isolation, dementia, delirium, depression, destitution, despair, and dysphagia. Cognitive function is particularly sensitive to glucose and insulin availability. Older individuals often have dementia, falls, mobility disorders, malnutrition, end-of-life issues, pressure ulcers, and urinary incontinence to consider.
- Nutritional screening and assessment must become routine. Subjective Global Assessment and the Mini Nutritional Assessment tools are used to detect patients who need preventive nutritional measures (Kyle et al, 2005). The short nutritional assessment questionnaire (SNAQ) is simple and may be used to screen for **appetite changes**—another important factor leading to undernutrition and its consequences (Wilson et al, 2005).
- Outcome monitoring and evaluation should include weight change, use of supplemental drinks and snacks between meals, use of tube feeding or parenteral nutrition, number of consultations by the hospital dietitian, and decreased length of hospital stay (Kruizenga et al, 2005).

**TABLE 10-2** Concerns with Overnutrition

- Obesity caused by excess nutrition or excess storage of fat relative to energy expenditure is a form of malnutrition that is increasingly seen in children (Cunningham-Rundles et al, 2005).
- Leptin is a cytokine-like immune regulator that has complex effects in both overnutrition and in the inflammatory response in malnutrition.
- BMI > 30 is the initial calculated measure used to determine obesity. If a person has too high a BMI, risks increase for high blood pressure, high blood cholesterol, diabetes, orthopedic problems, gallstones, gout, osteoarthritis, sleep apnea, and cancers of the breast, colon, gallbladder, and so on.
- Critical factors that may put a person at risk for obesity, as they accumulate and interact over an individual's life span, include rapid weight gain in infancy and childhood, early puberty, and excessive weight gain in pregnancy (Johnson et al, 2006).
- Obesity in women can lead to several health challenges. Epidemiological evidence shows that being overweight contributes to menstrual disorders, infertility, miscarriage, poor pregnancy outcome, impaired fetal well-being, and diabetes mellitus. Changes in sensitivity to insulin may occur. Pregnant women who are obese are more at risk for pregnancy-induced hypertension and preeclampsia.
- Weight management programs should include a strong component of nutrition education (Klohe-Lehman et al, 2006).
- Obesity in older adults is increasing in prevalence along with related macro- and micronutrient deficiencies (Flood and Carr, 2004).
- Individualized programs with the goal of achieving modest weight reduction in obese patients are likely to result in immediate (e.g., alleviation of arthritic pains and reduction of glucose intolerance) and possibly long-term (e.g., reduction in cardiovascular risk) healthcare benefits.
- Lifestyle modifications are best. Diets based on complex carbohydrates, fibers, red wine, fresh fruit and vegetables, and nonanimal fat may protect against age-related cognitive impairment and dementia (Flood and Carr, 2004).
- Permanent 100-kilocalorie reductions in daily intake among the overweight/obese would eliminate approximately 71.2 million cases of overweight/obesity; in the long term, this could increase national productivity by \$45.7 billion annually, and more aggressive diet changes of 500 kilocalories would yield benefits of \$133.3 billion (Dall et al, 2009).

Food variety is another factor with a major influence on energy intake (Epstein et al, 2009). Obese individuals prefer and consume more highly palatable foods more frequently than do persons of normal weight. There are 10 neurophysiologic pathways involved in the selection of food, which include reflexive and uncontrollable neurohormonal responses to food images, cues, and smells; mirror neurons that cause people to imitate the eating behavior of others without awareness; and limited cognitive capacity to make informed decisions about food (Cohen, 2008).

A transition in patterns and food intake occurs for immigrants. Any intervention aimed at reducing obesity must consider ethnicity, income, and degree of acculturation (Chen 2009). The intake of both sweetened drinks and meat increases among individuals emigrating to the United States (Novotny et al, 2009). The use of low-energy dense food (fruits and vegetables) and routine healthy breakfast consumption can help to maintain or lose weight (Greenwood and Stanford, 2008).

Restaurant and fast food consumption, large portion sizes, and consumption of sugar-sweetened beverages are closely associated with weight gain. Fructose from both sucrose and high fructose corn syrup is a concern (Bray, 2009). Fructose acutely increases thermogenesis, triglycerides, and lipogenesis as well as blood pressure; this leads to changes in body weight, fat storage, and triglycerides and increases inflammatory markers (Bray, 2009).

Many tools are available to assess food habits and weight status. Body mass index (BMI) standards are used to determine weight status. BMI correlates well with body fat for most individuals. Table 10-3 provides important weight and BMI calculations and guidelines. Whenever possible, use body mass index (BMI) to estimate a desirable weight range for height. Table 10-4 provides resources and calculations for estimating one's ideal body weight range; the Hamwi method (1974) is listed but is not evidence-based. Table 10-5 provides the standard BMI tables for adults. Table 10-6 provides several short methods for calculating energy needs.

**TABLE 10-3 Weight Calculations and Body Mass Index (BMI) Guidelines**

**Calculation of BMI:**  $(\text{Weight [lb]} \div \text{Height [in]}^2) \times 705$

BMI more often correctly predicts risks for chronic disease or malnutrition than life insurance tables.

**BMI Web sites:** There are many Web sites that make it easy to calculate BMI, which may be downloaded to a hand-held device, such as <http://www.cdc.gov/nccdphp/dnpa/bmi/calc-bmi.htm>.

For both English and metric calculations: <http://www.nhlbisupport.com/bmi/bminojs.htm>.

**Usual Body Weight and % Change:**

Calculation of % usual body weight =  $(\text{Actual Weight/Usual Weight}) \times 100$ .

Calculation of % weight change =  $(\text{Usual Weight} - \text{Actual Weight/Usual Weight}) \times 100$ .

**Waist measurements:** Waist circumference correlates with intra-abdominal adipose tissue. It is the most practical anthropometric measurement for assessing a patient's abdominal fat content before and during weight loss treatment. Computed tomography (CT) and magnetic resonance imaging (MRI) are both more accurate but impractical for routine use. Upper body obesity is defined as a waist circumference of >40 inches for men and >35 inches for women; this is the "apple shape." If more weight is around the hips, this "pear shape" has lower metabolic risks. Waist-hip ratio is often more useful in special populations such as HIV-AIDS and in older adults.

**Calculation of lean body mass:** Body composition is often measured using dual-energy X-ray absorptiometry (DEXA) or electrical impedance absorptiometry (BIA). BIA may underestimate body fat percentage more than DEXA.

**Ethnic-specific cut-off points:** Compared to Caucasians, African-Americans of the same age, gender, waist circumference, weight, and height may have lower total and abdominal fat mass when measured with DEXA bone density scanning or computed tomography (CT).

Because muscle mass may be higher in blacks, ethnic-specific cutoffs for what values represent overweight and obesity are needed. Dr. Dagogo-Jack summarized these findings at the Endocrine

Society's Annual Meeting in 2009. The determination of the health status of all individuals should be based on metabolic indicators of health rather than on BMI alone. Counselors should promote healthy lifestyles that include adequate amounts of physical activity and rest as well as a nutrient-dense diet.

*BMI Clinical Guidelines*

<18.5	Underweight
18.5–24.9	Normal
25–29.9	Overweight
≥30	Obese
≥40	Morbidly obese

[http://www.nhlbi.nih.gov/guidelines/obesity/ob\\_home.htm](http://www.nhlbi.nih.gov/guidelines/obesity/ob_home.htm).

*BMI for Pregnant Women*

The amount of weight a woman should gain during her pregnancy depends on her prepregnant BMI. To avoid complications and long-term health risks, the woman wants to gain enough weight to have a healthy baby but not too much weight. For twins, ideal weight gain is about 35–45 pounds (National Academy of Sciences, <http://books.nap.edu/books/0309041384/html/220.html#pagetop>).

Prepregnant BMI	Weight Gain During Pregnancy (lb)
≤19.5	28–40
19.6–26	25–35
27–29	15–25
≥30	~13–15

(continued)

**TABLE 10-3 Weight Calculations and Body Mass Index (BMI) Guidelines (continued)***BMI for Children*

Growth charts are used for children to watch the pattern of their growth. Charts cannot be used to diagnose obesity or malnutrition; if a child is over the 85th percentile or lower than the 5th percentile on the charts, the child should see a doctor. The curves on the growth chart show the pattern of growth. Growth charts for infants and children are calculated the same as for adults but interpreted differently based on BMI. Children are not just small adults; as they grow, their BMI will change. For example, it may be healthy for a 2-year-old child to have a BMI of 16.1 and for that same child to have a BMI of 15.5 at age 6 years and then a BMI of 20 at age 15 years. Children under the 5th percentile should be examined to see if they are normal but small children or if they have a problem that prevents normal growth rate. Growth charts can be found at <http://www.cdc.gov/growthcharts>. Tables adapted for use in WIC Clinics are at [http://www.nal.usda.gov/wicworks/Learning\\_Center/WIC\\_growthcharts.html](http://www.nal.usda.gov/wicworks/Learning_Center/WIC_growthcharts.html). A calculator for estimating requirements with physical activity levels can be found at <http://www.mydr.com.au/tools/child-energy-calculator>.

*BMI for Adolescents*

An expert consensus panel suggests that a BMI of 95% for age and gender should define obesity. BMI charts are used for the specific age and sex of the adolescent. Being over the 95th percentile on this chart is “overweight,” while 85th to 95th percentiles are “at risk of overweight.” Most guidance for teens is similar to that for adults. BMI calculators for teens include [http://kidshealth.org/teen/food\\_fitness/dieting/bmi.html](http://kidshealth.org/teen/food_fitness/dieting/bmi.html) or <http://apps.nccd.cdc.gov/dnpabmi/Calculator.aspx>.

*Template for Calculating Total Energy Expenditure*

An easy way to calculate daily EERs for adults includes a template based on physical activity level. The estimated energy requirement (EER) equations of the Institute of Medicine DRI Committee account for all factors and measurements to determine physical activity level and energy expended from daily physical activity.

$$\text{BEE} = 293 - 3.8 \times \text{age (years)} + 456.4 \times \text{height (meters)} + 10.12 \times \text{weight (kg)}$$

**For women:**

$$\text{BEE} = 247 - 2.67 \times \text{age (years)} + 401.5 \times \text{height (meters)} + 8.6 \times \text{weight (kg)}$$

$$\Delta \text{ PAL} = (\text{METs} - 1) \times [(1.15/0.9) \times \text{Duration (minutes)}]/1440$$

$$\text{BEE}/[0.0175 \times 1440 \times \text{weight (kg)}]$$

After the  $\Delta \text{ PAL}$  is calculated for each physical activity, the physical activity category (PAL: sedentary, low active, active, or very active) is determined based on the basal activity impact on energy expenditure (a factor of 1.1) and the sum of all activities (sum of  $\Delta \text{ PAL}$ ). This factor accounts for TEF and postexercise increase in energy expenditure. The PAL is automatically calculated as  $\text{PAL} = 1.1 + \text{sum of } \Delta \text{ PAL}_i$ , where  $\Delta \text{ PAL}_i$  is the list of each reported activity impact on energy expenditure. The template is available in an Excel spreadsheet at <http://www.ncbi.nlm.nih.gov/pmc/articles/PMC1784117/>; accessed 11/7/09.

*BMI and Mortality*

Both general adiposity and abdominal adiposity are associated with the risk of death and support the use of waist circumference or waist-to-hip ratio in addition to BMI in assessing the risk of death (Pischon et al, 2008). Lean men and women ( $\text{BMI} < 18 \text{ kg/m}^2$ ) experience increased all-cause mortality compared with those with a BMI between 20 and 22  $\text{kg/m}^2$ , particularly for cardiovascular and respiratory diseases.

It is important that public health messages regarding healthy eating are aimed at maintaining a healthy body weight rather than just “losing weight” (Thorogood, 2003). The following table indicates the lower ranges of BMI, below which mortality increases (Stevens, 2000).

Ages 20–29	BMI: Men 21.4; Women 19.5
Ages 30–39	BMI: Men 21.6; Women 23.4
Ages 40–49	BMI: Men 22.9; Women 23.2
Ages 50–59	BMI: Men 25.8; Women 25.2
Ages 60–69	BMI: Men 26.6; Women 27.3

*Using BMI for Older Adults*

TEE and physical activity level (PAL, defined as the ratio of total to resting energy expenditure) decline progressively throughout adult life in both normal weight and overweight men and women (Roberts and Dallal, 2005). In normal weight individuals (defined as BMI 18.5–25) TEE falls by approximately 150 kilocalories per decade, and PAL falls from an average of 1.75 in the second decade of life to 1.28 in the ninth decade (Roberts and Dallal, 2005). Thermic effect of food does not appear to change.

Waist-to-hip ratio (WHR) rather than BMI appears to be a more appropriate yardstick for health risk among older adults over age 70 (Srikanthan et al, 2009).

Himes JH. New equation to estimate body mass index in amputees. *J Am Diet Assoc*. 95:646, 1995.

*Adjustment for Obese Patients*

Indirect calorimetry is the “gold standard” for determining energy requirements in the obese patient, or equations can be used, such as 21 kcal/kg actual weight. Formulas for adjusted body weight for obesity [(actual body weight – ideal body weight)  $\times$  0.25 + ideal body weight] have not been validated, and predictive equations for resting metabolic rates (RMR) have many flaws. The Harris-Benedict Equation (Harris and Benedict, 1919) may lead to overfeeding, particularly in older adults. Estimated energy needs should be based on RMR using indirect calorimetry; if RMR cannot be measured, then the Mifflin-St. Jeor equation using **actual** weight is the most accurate for estimating RMR for overweight and obese individuals.

Mifflin-St. Jeor Equation:

Men:  $RMR = 9.99 \times \text{weight} + 6.25 \times \text{height} - 4.92 \times \text{age} + 5$

Women:  $RMR = 9.99 \times \text{weight} + 6.25 \times \text{height} - 4.92 \times \text{age} - 161$

For the obese elderly (Frankenfield et al, 2009):  $Mifflin (0.71) + T_{max} (85) + Ve(64) - 3085$  (ADA, Weight Management, 2009; Dobratz et al, 2007).

*Adjustment for Critically Ill Patients*

In critical illness, energy needs often fluctuate substantially. Nutrition delivery may be influenced by the risk of refeeding syndrome, hypocaloric feeding regimens, inadequate access, feeding intolerance, and feeding-delay for procedures (Walker and Heuberger, 2009). No equation accurately predicts REE in hospitalized patients. Only indirect calorimetry (IC) will provide accurate assessment of energy needs (Boullata et al, 2007).

When comparing popular equations (Harris-Benedict, Ireton-Jones, Penn State 1998 and 2003; Swinamer, 1990), prediction accuracy is rarely within 10% of the measured energy expenditure (Walker and Heuberger, 2009). Thirteen studies comparing RMR and the Harris-Benedict equation without adjustments report an underestimation of energy needs in the critically ill population, by as much as 1000 kilocalories or more (ADA, 2009).

Use of hand-held indirect calorimeters have significant advantages when metabolic carts are not available (Spears et al, 2009). Prediction of metabolic rate is imperfect and requires clinical judgment. The ADA evidence analysis library has described comparisons of these estimated calculations (ADA, 2009). The Penn State equation provides the most accurate assessment of metabolic rate in critically ill patients (79%) if indirect calorimetry is unavailable (Frankenfield et al, 2009). This equation follows:  $RMR = BMR (0.85) + V_E (33) + T_{max} (175) - 6433$

**TABLE 10-6 Short Methods for Calculating Energy Needs***Weight and Height Conversion Factors*

1 kg = 2.2 lb
1 lb = 0.453 kg
1 ft = 30.48 cm
1 in = 2.54 cm
1 cm = 0.39 in
1 m = 39.37 in

Goal	Level of Activity or Illness		
	Low	Moderate	High
Lose weight	15 kcal/kg	20 kcal/kg	25 kcal/kg
Maintain weight	20 kcal/kg	25 kcal/kg	30 kcal/kg
Gain weight	25 kcal/kg	30 kcal/kg	35 kcal/kg

*Energy Needs Based on Gender for Adults*

Men, active women	15 kcal/lb body weight
Most women, sedentary men, and adults over 55 years	13 kcal/lb body weight
Sedentary women, obese adults	10 kcal/lb body weight
Pregnant women	
1st trimester	13–15 kcal/lb body weight
2nd and 3rd trimester	16–17 kcal/lb body weight
Lactating women	15–17 kcal/lb body weight

*Energy Needs Based on Age for Children*

There is a general decline in the calories needed per pound as a child gets older. These figures are not accurate for obese children.

0–12 months	55 kcal/lb body weight
1–10 years	45–36 kcal/lb body weight
11–15 years–young women	17 kcal/lb body weight
11–15 years–young men	30 kcal/lb body weight
16–20 years–young women	15 kcal/lb body weight
<b>16–20 years–young men</b>	<b>18 kcal/lb body weight</b>

## OVERNUTRITION

## OVERWEIGHT AND OBESITY

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinical-pathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

## DEFINITIONS AND BACKGROUND

Overweight is defined as a BMI of 25–29; obesity is defined as a BMI of 30 or more. Obesity is a problem because the percentage of body fat is much greater than lean body mass. Micronutrients are often consumed at lower than desirable levels, while macronutrients are eaten in large amounts. Obesity has reached epidemic proportions in the United States, with 35.1% of adults being classified as obese (Catenacci et al, 2009). The World Health Organization (WHO) labels the increase in obesity and related syndromes as an epidemic in both industrialized countries and in developing countries (Misra and Khurana, 2008).

Obesity is a complex multifactorial chronic disease that develops from an interaction of genetic, social, behavioral, cultural, physiological, and metabolic factors (NHLBI, 2009; Thorleifsson et al, 2009). Genetics account for 30–40% of the variations in weight between individuals (Pi-Sunyer and Kris-Etherton, 2005). Indeed, weight and BMI are highly heritable (Thorleifsson et al, 2009). Environmental factors include low physical activity, energy intake, smoking cessation, overconsumption of high-fat foods.

The prevalence of overweight (BMI >25) and obesity (BMI >30) has steadily increased over the past decade. Approximately 34% of American adults are obese, and 14.6% of low-income, preschool-aged children are obese (CDC, 2009). Blacks have a 51% higher prevalence of obesity than whites, and Hispanics have a 21% higher obesity prevalence

compared with whites (CDC, 2009). However, abdominal visceral adipose tissue (VAT) is significantly greater in white men and women; African American men and women have higher subcutaneous adipose tissue (SAT) than whites (Katzmarzyk et al, 2009). An increased understanding of race-based differences in adiposity in specific body depots helps to explain the differential health risks associated with obesity.

The current generation in the United States may have a shorter life expectancy than that of their parents if the obesity epidemic is not controlled (Catenacci et al, 2009). In Project EAT, researchers found that the use of low-calorie soft drinks was a marker for more general dietary behaviors and weight concerns; there was no association between sugar-sweetened beverage consumption, juice consumption, and adolescent weight gain over a 5-y period; and adolescents who consumed little or no white milk gained significantly more weight than their peers who consumed white milk (Vaneslow et al, 2009).

Recent evidence also shows a link between obesity and viral infections, particularly with human adenoviruses (Atkinson, 2007; Mitra and Clarke, 2009). The human distal gut harbors microbiota that provide important metabolic capabilities including the ability to extract energy from otherwise indigestible dietary polysaccharides (Turnbaugh et al, 2009). Metagenomic studies demonstrated that certain mixes of gut microbiota may protect or predispose the host to obesity by increasing dietary energy harvest, promoting fat deposition, and triggering systemic inflammation (Tsai and Coyle, 2009). Each person's gut microbial community varies in the specific bacterial lineages present, which may lead to differences in leanness or obesity (Turnbaugh et al, 2009).

Both overweight and obesity increase the risks of contracting chronic diseases, secondary symptoms, and impaired quality of life. Waist circumference, waist-hip ratio, and BMI may predict chronic disease and mortality. Hypertension is common in persons with central-type obesity, and women who have a BMI over 30 may have problems with fertility. Morbid obesity (BMI >40) is a strong predictor of premature death. When a patient reaches the overweight stage, he or she should be given guidance on how to avoid obesity (see Table 10-7 and figure).

Reimbursement for obesity counseling and management is a complicated issue. Not everyone loses weight easily or steadily, and there are indirect costs such as pain and suffering to consider. BMI can help predict those who may benefit from weight loss counseling, but there are no guarantees of success.

There are varied options for the management of overweight and obese patients including dietary approaches, altered physical activity patterns, behavior therapy techniques, pharmacotherapy, surgery, and combinations of these techniques. Studies have shown that small changes in weight and increases in physical activity can make significant improvements in health.

Starvation diets are not the solution. Orthostatic hypotension may complicate very low-calorie diets (VLCD) because of sodium depletion and depressed sympathetic nervous system activity. It is more desirable to calculate basal energy

**TABLE 10-7** Suggested Weights for Initiation of Weight Management Counseling

Height (in)	Overweight in lb (BMI >25)	Obese in lb (BMI >30)

requirements for the individual and to determine a reasonable energy intake accordingly. Evidence suggests that weight loss diets should include moderate carbohydrate (35–50% of energy), moderate fat (25–35% of energy), and protein as

Consequences of Obesity. Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinicopathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

25–35% of energy (Schoeller and Buchholz, 2005). Specifically, avoid consuming large portions of energy-dense foods or snacks, high-calorie beverages, and foods with empty calories (Pi-Sunyer and Kris-Etherton, 2005).

Energy-reduced, isocaloric very-low-carbohydrate, high-fat (VLCHF) diets and high-carbohydrate, low-fat (HCLF) diets produce similar weight loss results (Tay et al, 2008). However, the use of appropriate types of fat is important to protect the heart. Comparisons of the biological effect of popular diets such as Atkins, South Beach, and Ornish during weight maintenance periods show that the Atkins diet leads to the least favorable results in flow-mediated vasodilation (Miller et al, 2009). The HCLF diet has favorable effects on the blood lipid profile (Tay et al, 2008). To estimate the percentage of fat calories for a nutritional plan, review Table 10-8.

Hormones, genes, nutrients and the central nervous system converge to manage energy intake. Dysregulation in the system of fuel-sensing signals may underlie problems such as obesity and diabetes (Sandoval et al, 2008). Leptin is a mediator of long-term regulation of energy balance, suppressing food intake, and inducing weight loss. Leptin is produced within white adipose tissue, brown fat, the placenta, and in a fetal heart, bone, and cartilage. As the amount of fat stored in adipocytes rises, leptin is released into the blood and signals to the brain that the body has had enough to eat. Altered leptin receptor genes (LEPR) can lead to changes in BMI over time. Obesity markedly influences serum insulin, leptin, growth hormone (GH) secretion, and free fatty acid (FFA) levels. Most overweight people have altered levels of serum leptin.

**TABLE 10-8 Calculation of Fat Grams**

Divide desired body weight by 2. Examples:

120 lb/2 = 60 g	130 lb/2 = 65 g
140 lb/2 = 70 g	150 lb/2 = 75 g
160 lb/2 = 80 g	170 lb/2 = 85 g
180 lb/2 = 90 g	190 lb/2 = 95 g
200 lb/2 = 100 g	210 lb/2 = 105 g

Hormones and peptides such as melatonin, ghrelin, obestatin, and leptin perform dual functions in the pancreas by maintaining metabolic homeostasis; appetite-controlling neuropeptides such as ghrelin, orexin A, and neuropeptide Y regulate pancreatic secretions (Chandra and Liddle, 2009). Ghrelin acts quickly for meal initiation and is produced in the stomach.

Satiety signals from the pancreas and intestine include cholecystokinin, peptide YY, pancreatic polypeptide (PP), glucagon-like peptide 1 (GLP-1), oxyntomodulin (OXM), and amylin (Wren and Bloom, 2007). Cholecystokinin induces satiety by interacting through CCK-1 receptors located in the hindbrain; it also inhibits the expression of orexigenic peptides in the hypothalamus and prevents stim-

ulation of specialized neurons by ghrelin (Chandra and Liddle, 2007). Ghrelin, peptide YY, and cholecystokinin are all influenced by macronutrient intake (Orr and Davy, 2005).

Elevated cholecystokinin levels decrease appetite and also reduce intestinal inflammation caused by parasites and bacterial toxins (Chandra and Liddle, 2007). Elevated inflammatory markers—such as tumor necrosis factor (TNF) alpha, soluble TNF receptor II (sTNF-RII), interleukin-6 (IL-6), and C-reactive protein (CRP)—are characteristically found in the serum in obese patients. Night eating syndrome (NES) is also affected by disordered neuroendocrine functioning; see Table 10-9.

It is important to discuss psychological well-being, particularly feelings about food and body image. The Power of Food Scale (PFS) assesses individual differences in appetitive responsiveness to rewarding properties of the food environment; it is a reliable and valid tool for assessing food cravings and binge eating (Lowe and Butryn, 2007). The PFS evaluates the appetite for palatable foods at three different levels of food proximity: food available, food present, and food tasted (Lowe et al, 2009). See Table 10-10 for the questions asked in the Power of Food Scale. Setting achievable goals will require individualized approaches (Nonas and Foster, 2009).

Self-esteem, body image, self-efficacy, locus of control, motivation, stress management, problem-solving and

**TABLE 10-9 Night Eating Syndrome Description and Questionnaire**

Night eating syndrome (NES) is a special condition that affects 1–1.5% of the general population, 6%–16% of patients in weight reduction programs, and 8%–42% of candidates for bariatric surgery (Stunkard et al, 2008). Viewed as a delay in the circadian rhythm of food intake, NES is defined by two core criteria: evening hyperphagia (ingestion of at least 25% of daily calories after supper) with awakenings and ingestions at least three times a week (Stunkard et al, 2008). Single PET scans have shown significant elevation of serotonin transporters in the midbrain of night eaters; this is from a genetic vulnerability transmitted as part of the established heritability triggered by stress (Lundgren et al, 2006). Because of elevations in serotonin transporter levels, sertraline (an SSRI) helps to alleviate impaired circadian rhythm and resulting NES (O'Reardon et al, 2006).

#### Night Eating Questionnaire

1. How hungry are you usually in the morning?
2. When do you usually eat for the first time?
3. Do you have cravings or urges to eat snacks after supper but before bedtime?
4. How much control do you have over your eating between supper and bedtime?
5. How much of your daily food intake do you consume after suppertime?
6. Are you currently feeling blue or down in the dumps?
7. When you are feeling blue, when is your mood lower?
8. How often do you have trouble getting to sleep?
9. Other than using the bathroom, how often do you get up in the middle of the night?
10. Do you have cravings or urges to eat snacks when you wake up at night?
11. Do you eat in order to get back to sleep when you awake at night?
12. When you get up in the middle of the night, how often do you snack?
13. If you snack in the middle of the night, how aware are you of your eating?
14. How much control do you have over your nighttime eating?

**TABLE 10-10 Power of Food Scale**

Please indicate the extent to which you agree that the following items describe you. Use the following 1–5 scale for your responses:

- 1 don't agree at all  
 2 agree a little  
 3 agree somewhat  
 4 agree  
 5 strongly agree

1. I find myself thinking about food even when I'm not physically hungry.
2. When I'm in a situation where delicious foods are present, but I have to wait to eat them, it is very difficult for me to wait.
3. I get more pleasure from eating than I do from almost anything else.
4. I feel that food is to me like liquor is to an alcoholic.
5. If I see or smell a food I like, I get a powerful urge to have some.
6. When I'm around a fattening food I love, it's hard to stop myself from at least tasting it.
7. I often think about what foods I might eat later in the day.
8. It's scary to think of the power that food has over me.
9. When I taste a favorite food, I feel intense pleasure.
10. When I know a delicious food is available, I can't stop myself from thinking about having some.
11. I love the taste of certain foods so much that I can't avoid eating them even if they're bad for me.
12. When I see delicious foods in advertisements or commercials, it makes me want to eat.
13. I feel like food controls me rather than the other way around.
14. Just before I taste a favorite food, I feel intense anticipation.
15. When I eat delicious food, I focus a lot on how good it tastes.
16. Sometimes, when I'm doing everyday activities, I get an urge to eat "out of the blue" (for no apparent reason).
17. I think I enjoy eating a lot more than most other people.
18. Hearing someone describe a great meal makes me really want to have something to eat.
19. It seems like I have food on my mind a lot.
20. It's very important to me that the foods I eat are as delicious as possible.
21. Before I eat a favorite food, my mouth tends to flood with saliva.

Didie ER. The Power of Food Scale (PFS): development and theoretical evaluation of a self-report measure of the perceived influence of food. A thesis submitted to the faculty of Drexel University, June 2003. Accessed November 2, 2009 at [http://dspace.library.drexel.edu/bitstream/1860/205/7/didie\\_thesis.pdf](http://dspace.library.drexel.edu/bitstream/1860/205/7/didie_thesis.pdf).

decision-making, and assertiveness are important considerations. Stress may cause those who are overweight to add more pounds (Block et al, 2009). Elevated cortisol or other hormone levels may be the trigger from stress.

Traditional weight management programs can be helpful. Sustained modest weight loss by obese adults can result in substantial health and economic benefits. Successful weight management to improve overall health for adults requires a lifelong commitment to healthy lifestyle behaviors emphasizing sustainable and enjoyable eating practices and daily physical activity (Seagle et al, 2007). The American Dietetic Association has recommended eight medical nutrition therapy visits for adult weight management. (See Figure on page 613)

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Research into the genetics of obesity is extensive (Farooqi and O'Rahilly, 2007). The human Ob gene has been mapped to chromosome 7. The FTO (fat mass and obesity-associated) gene is found on chromosome 16. A genome-wide association (GWA) study has linked thousands of SNPs close to or in the FTO, melanocortin-4 receptor (MC4R), brain-derived neurotrophic factor (BDNF), and SH2B adapter protein (SH2B1) genes (Thorleifsson et al, 2009). Other genes may play a role. The fatty-acid binding protein (FABP2) gene is associated with fat absorption and metabolism. The peroxisome proliferator-activated receptor gamma (PPARG) gene has a key role in the formation of fat cells. The adrenergic beta-2-receptor (ADRB2) gene mobilizes fat cells for energy, whereas the adrenergic beta-3-receptor (ADRB3) gene regulates the breakdown of fat from tissues in response to exercise. The glutamate decarboxylase 2 (GAD2) gene is released from pancreatic and brain cells. GAD2 codes for the GABA neurotransmitter, which regulates food intake. Clearly, these multiple hormones and genes suggest that future obesity treatment will require a genetic profile and individualized plan.

## INTERVENTION

### OBJECTIVES

The Clinical Guidelines on the Identification, Evaluation, and Treatment of Overweight and Obesity in Adults (NHLBI, 2009) suggest the following objectives:

1. Reduce body weight, maintain a lower body weight over the long term, and prevent further weight gain. It is better to maintain a moderate weight loss over a prolonged period than to regain from a marked weight loss. See Figure 10-6 for tips.

# MAINTAINING A HEALTHY WEIGHT

## Healthy Diet Plan

If you are concerned about your diet, no particular food plan is magical and no particular food must be either included or avoided. Your diet should consist of foods that you like or can learn to like, that are available to you, and that are within your means. The most effective diet programs for weight loss and maintenance are based on physical activity and reasonable serving sizes, with less frequent consumption of foods high in fat and refined sugars.

## Physiological Hazards That Accompany Low-Carbohydrate Diets

### Heart Failure

Carbohydrates maintain sodium and fluid balance. A carbohydrate deficiency promotes loss of sodium and water, which can adversely affect blood pressure and cardiac function if not corrected.

### High Blood Cholesterol

Low-carbohydrate diets can raise blood cholesterol because in these diets, fruits, vegetables, breads, and cereals are replaced by meat and dairy products, which are rich in fat and protein. High fat and protein intakes, especially from meat and dairy products, raise LDL and total cholesterol.

### Metabolic Abnormalities

When carbohydrate intake is low, ketones are produced from fat to replace carbohydrates as a source of energy for the brain. Since ketones are acids, high levels can make the blood acidic, altering respiration and other metabolic processes that are sensitive to an increase or decrease in acidity.

## The Risk in Low-Carbohydrate Diets

Low-carbohydrate diets, especially if undertaken without medical supervision, can be dangerous. Low-carbohydrate diets are designed to cause rapid weight loss by promoting an undeniably high concentration of ketone bodies (a byproduct of fat metabolism). The sales pitch is that you'll never feel hungry and that you'll lose weight faster than you would on any "ordinary diet". Both claims are true but the low-carb diets are true but misleading. Fast weight loss means loss of water and lean tissue, which are rapidly regained when people begin eating their usual diets again. The amount of body fat lost will be the same as with a conventional low-calorie diet. Fat loss is always equal to the difference between energy consumed in food and energy expended in activity.

## Overweight Problems

As the amount of body fat increases, especially around the abdomen, so does the risk of:

- Respiratory disease
- Obstructive sleep apnea
- Complications during surgery
- Gallbladder disease
- Stroke
- Non-insulin-dependent (type 2) diabetes
- Some forms of cancer, especially breast and colon
- Coronary heart disease
- Hypertension

## Strategies for Diet Planning:

- Adopt a realistic long-term plan.
- Individualize your diet, include foods that you like, and indulge yourself once in a while.
- Include foods from all five food groups.
- Eat foods that contain a lot of nutrients.
- Stress the Dos and not the Don'ts in your diet and your way of living.
- Eat on a regular schedule at least three times a day. Don't skip meals.

## Suggestions and Tips for Physical Activity:

- Walk at least 10–20 minutes daily.
- Take the stairs instead of the elevator.
- Sports (basketball, baseball, tennis...)
- Dance classes
- Aerobics classes
- Incorporate exercise into your normal routine.
- Concentrate on strengthening your muscles as well as your heart and lungs.

## Excess Fat Distribution

**Apple Shaped** Excess fat is distributed around the abdomen. Common in men, postmenopausal women, and with aging. Associated with increased risk of Type 2 diabetes.

**Pear Shaped** Excess fat is distributed around the hips and buttocks. Common in women. Associated with increased risk of osteoarthritis.

## Understanding Calories

Calories are a standard measurement of heat energy. Technically, 1 calorie is 1 kilocalorie, which is the amount of heat required to raise the temperature of 1 kg. of water by 1°C.

A person's energy needs are determined by the amount of lean tissue or muscle and by the level of activity. A small, elderly, sedentary woman may need only about 1200 calories to meet her energy needs each day, whereas a tall, young, physically active man may need as many as 4000 calories daily.

## How to Calculate Your Total Daily Energy (Calorie) Needs

- 1 Convert your weight from pounds (lb) to kilograms (kg) by dividing your weight in pounds by 2.2 lb/kg.
- 2 Multiply your weight in kilograms by 30 kcal/kg if you are a man and 25 kcal/kg if you are a woman.

### Example

- 1 150 lb ÷ 2.2 lb/kg = 68.18 kg
- 2 68.18 kg × 30 kcal/kg = 2045 kcal

Result: A 150 lb man needs approximately 2045 kcal (calories) a day to maintain her weight.

## Energy Demands of Activities

Activity	Body Weight (lb)				
	110	125	150	175	200
CALORIES PER MINUTE					
Aerobics	6.8	7.8	9.3	10.9	12.4
Basketball (vigorous)	10.7	12.1	14.6	17.0	19.4
Bicycling					
13 miles per hour	5.0	5.6	6.8	7.9	9.0
Cross-country skiing					
8 miles per hour	11.4	13.0	15.6	18.2	20.8
Golf (carrying clubs)	5.0	5.6	6.8	7.9	9.0
Rowing (vigorous)	10.7	12.1	14.6	17.0	19.4
Running					
5 miles per hour	6.7	7.6	9.2	10.7	12.2
Soccer	10.7	12.1	14.6	17.0	19.4
Studying	1.2	1.4	1.7	1.9	2.2
Swimming					
20 yards per minute	3.5	4.0	4.8	5.6	6.4
Walking (brisk pace)					
3.5 miles per hour	3.9	4.4	5.2	6.1	7.0

## Underweight Problems

When body weight decreases to 15–20% below desirable weight (BMI < 18.5), the amount of energy being consumed is not sufficient to support the function of vital organs. Lean tissue is being broken down and utilized for energy to make up the deficit. The results are:

- Low body temperature
- Abnormal electrical activity in the brain
- Altered blood lipids
- Dry skin
- Impaired immune response
- Loss of digestive function
- Abnormal hormone levels
- Malnutrition
- Anemia

## What Is Your Body Mass Index?

Your body mass index (BMI) is your weight in kilograms divided by the square of your height in meters. It is used to indicate whether or not you are overweight or underweight.

### How to Calculate Your Body Mass Index:

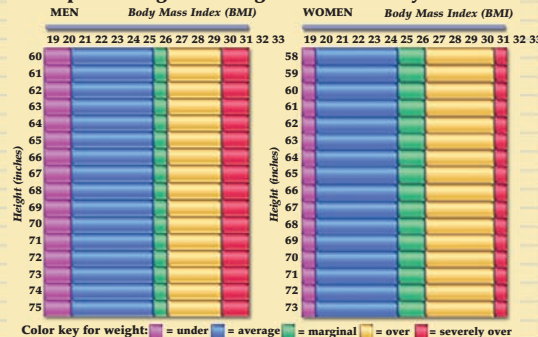

- 1 Convert your weight in pounds (lb) to kilograms (kg) by dividing your weight in pounds by 2.2 kg.
- 2 Convert your height in inches (in) to meters (m) by multiplying your height in inches by .0254 m.
- 3 Take your height in meters and square it by multiplying it by itself.
- 4 Divide your weight in kilograms by your height in meters squared (your calculated height from step 3).

**Example:** Mark weighs 150 lb and is 5 ft, 10 in tall (70 in).

- 1 150 lb ÷ 2.2 kg = 68.18 kg
- 2 70 in × .0254 m = 1.778 m
- 3 1.778 m × 1.778 m = 3.161 m<sup>2</sup>
- 4 68.18 kg ÷ 3.161 m<sup>2</sup> = 21.56

Mark's BMI is 21.56

### Acceptable Weight for Height Based on Body Mass Index

Source: Compiled from Body Mass Index Table from Hamilton, Whitney, and Sizer, 1991. *Nutrition concepts and controversies*. New York: West. and Body Mass Index from 1998 Centers for Disease Control and Prevention.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Not Ready for Lifestyle Change**

**Assessment:** Diet, weight, and physical activity histories and psychosocial issues.

**Nutrition Diagnoses (PES):** Not ready for diet/lifestyle change (NB 1.3) related to excessive oral food/beverage intake as evidenced by increased weight gain in spite of previous counseling sessions and statements such as, "I just don't want to lose weight; I can't see the point."

Overweight (NC-3.3) related to excess energy intake as evidenced by BMI >25, waist circumference >40 inches, and reports of overconsumption of high-fat/calorie-dense food and beverages.

**Interventions:** Nutrition prescription (ND-1) of 2200 kilocalories per day with approximately 25–30% of calories from fat and less than 10% of intake from saturated fat.

Initial/brief nutrition education (E-1) to address motivation to get to the next stage of change; reinforce instructions on following the diet plan; provide basic nutrition-related information; discuss the importance of physical activity and the benefits of weight loss.

Transtheoretical Model/Stages of Change (C-1.5): to help patient move from the precontemplation stage to the contemplation stage of change.

Collaboration (RC-1.3): MD and RD to collaborate on helping patient choose to lose weight.

**Monitoring and Evaluation:** Assess changes in motivation in one month. Evaluate for changes in weight, other lab values.

2. The initial goal of weight loss therapy should be to reduce body weight by approximately 10% from baseline. With success, further weight loss can be attempted if indicated through further assessment.
3. Weight loss should be about 1–2 lb/wk for a period of 6 months, with the subsequent strategy based on the amount of weight lost.
4. Promote use of low-calorie diets (LCDs). A diet that is individually planned to help create a deficit of 500–1000 kcal/d should be an integral part, aimed at achieving a weight loss of 1–2 lb/wk.
5. Increased physical activity is recommended since it produces some weight loss, decreases abdominal fat, and increases cardiorespiratory fitness. Physical activity is an integral part of weight maintenance. All adults should set a long-term goal to accumulate at least 30 minutes or more of moderate-intensity physical activity on most, and preferably all, days of the week.
6. Behavior therapy is a useful adjunct. Practitioners need to assess the patient's motivation and readiness to implement the plan; they must provide ongoing support for positive outcomes.
7. Weight-loss drugs that are approved by the Food and Drug Administration (FDA) may be used as part of a comprehensive weight-loss program but never without additional lifestyle modifications. Continual assessment of drug therapy for efficacy and safety is necessary.

8. Weight-loss surgery is an option for patients with morbid obesity (BMI  $\geq 40$  or  $\geq 35$  with comorbid conditions) when less invasive methods of weight loss have failed.
9. Weight-loss maintenance is enhanced by an ongoing program of dietary therapy, physical activity, and behavior therapy. Drug safety and efficacy beyond 1 year of total treatment has not been established. A weight maintenance program should be a priority after the initial 6 months of weight loss therapy; a high frequency of contacts between the patient and the practitioner should be provided over the long term.
10. All smokers, regardless of their weight status, should quit smoking.
11. In seniors, restrictions on overall food intake due to dieting could result in inadequate intake of protein or essential vitamins or minerals. Involuntary weight loss could be indicative of occult disease. Proper nutritional counseling and regular body weight monitoring in older persons is desirable. Weight reduction may improve cardiovascular risk factors in older and younger adults.
12. Tailor approaches to the needs of various patients or cultural/religious preferences.

**Other Advice**

- Reduce exposure and heighten awareness of the "obesogenic" environment, including calorie abundance, decreasing physical activity, and increasing automation.
- Maintain a normal or slightly higher protein intake to maintain nitrogen balance and to decrease perceived hunger with energy-restricted diets (Nickols-Richardson et al, 2005).
- Have the patient set his or her own goals. Self-monitoring is important for maintaining calorie, fat gram, and physical activity goals.
- Weigh weekly on the same scale with the same clothing at about the same time of day. After reaching a desired weight, daily weighing often helps maintain motivation for continuing effective lifestyle changes.
- Intake of foods with high water content reduces subsequent energy intake (Rolls et al, 2005). The DASH diet works well because it encourages intake of more fruits and vegetables.
- Avoid or correct disordered eating (e.g., abnormal eating, diet cheating, compulsive eating, addictive or manipulative habits, eating disorders, night eating syndrome). Healthy eating patterns, not constant evaluation of body fat, are the desired end behaviors.
- Use nutrient-dense, antimicrobial spices and antioxidant foods to enhance immunity.

**FOOD AND NUTRITION**

- Plan a diet with moderate carbohydrate (35–50%), moderate fat (25–35%), and protein as 25–35% of energy (Schoeller and Buchholz, 2005). Total energy reduction is the goal.
- A lower glycemic load is helpful for some people. Foods that have a low glycemic index include salads with an oil and vinegar dressing, high-fat granola cereal, and most

fresh fruits and vegetables (Pittas et al, 2005). **Glycemic load = glycemic index × available carbohydrate amount.**

- Schedule 6–8 small meals at frequent intervals to prevent cheating and overeating.
- Breakfast should be emphasized (Song et al, 2005). Cereal consumption may play a role in helping to maintain a healthful BMI (Barton et al, 2005) and a high-fiber choice may curb appetite at lunch.
- Fiber-rich foods take longer to chew, are low in calories, and increase satiety. Encourage the consumption of 25–35 grams of fiber per day. For example, eating 4–6 walnuts before meals may curb appetite and intake. Oats and barley with their soluble fiber, beta-glucan, may also be particularly useful grains.
- The American Dietetic Association supports a “total diet approach,” where the overall food pattern is more important than one food or meal (American Dietetic Association, 2007). If food is consumed in moderation with appropriate portion size and regular activity, a positive approach to food makes the client feel less anxious and guilty.
- Diet should provide adequate fluid intake to excrete metabolic wastes; use 30 cc/kg of body weight for an estimate.
- Decrease the overall salt intake if fluid retention is a concern. Use other spices and herbs.
- NHLBI guidelines recommend 35% kilocalories from fat, more from monounsaturated sources and less from saturated fats. Fat substitutes, when used in moderation, can be safely used to lower total energy intake. With elevated triglycerides, cut down on sugars and alcoholic beverages.
- For a modified fast, a meal replacement product for 1–2 meals per day can get the patient started. This method is not recommended for the long term unless sufficient fiber is also available.
- For obese patient in hospitals or critical care, estimating needs may be inaccurate. Indirect calorimetry is the gold standard. Most medical intensive care unit (ICU) patients require only 25 kcal/kg, with greater energy requirements needed in burn or trauma units.

### Common Drugs Used and Potential Side Effects

- Some medications cause weight gain, particularly those affecting the neurological system. See Table 10-11.
- Phenylpropanolamine (PPA) produces dose-related, life-threatening cardiovascular and central nervous toxicity from adrenergic overstimulation. Because of these effects and the risk of hemorrhagic stroke, the FDA stopped the use of PPA in cold medicines and prescription diet aids.
- Pharmacotherapy alone is not sufficient for permanent weight loss. Behavior modification must be taught for long-term success. See Table 10-12 for approved weight management medications. Many products on the market are either not safe or not efficacious.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing it with a physician.
- Because supplements are often taken for stimulating weight loss, dietitians should check for information on

efficacy and safety (Dwyer et al, 2005). Health providers must also disclose a real or perceived conflict of interest if they promote or sell supplements to their clients (American Dietetic Association, 2009).

- Bitter orange, chitosan, conjugated linolenic acid (CLA), calcium, and hydroxycitric acid have not shown efficacy (Dwyer et al, 2005).
- Chromium picolinate may improve glucose and lipid metabolism. There is little evidence for benefit in weight loss, but there are few adverse effects (Dwyer et al, 2005).
- Ephedra (ma huang) contains ephedrine and works as an anorexiant. The FDA removed it from the market because it elevates blood pressure and can cause significant problems.
- Garcinia is not effective; it has cytotoxic effects and is toxic in animals.
- Green tea contains polyphenols and catechins, which help to promote weight loss (Nagao et al, 2005).
- Melatonin may improve glucose control by restoring the vascular action of insulin; more studies are needed.
- Modulation of gut microbiota using probiotics or prebiotics will be possible in the future for obesity management (Tsai and Coyle, 2009). Antimicrobial spices such as oregano, thyme, cinnamon, bay leaf, palmarosa, clove bud, lemongrass, and allspice may be safely used.
- Stanols (Take Control) and sterols (Benecol) do not affect weight; they are safe when used as directed to lower elevated cholesterol levels.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- A multidimensional program is best for weight management; it should include the formulation of reasonable goals, the prevention of unnecessary weight loss or gain, weight loss when necessary, prevention of relapse, and the acceptance of physique for “health at every size.”
- Individualize according to psychosocial, behavioral, and biological factors. Obesity is a chronic condition that requires chronic care with varying levels of intensity (Nonas and Foster, 2009). Emphasize a balance of foods rather than any one food or meal (American Dietetic Association, 2007).
- Identify the mind–body connection. Teach the patient about physical hunger and how to identify true hunger from emotional “hunger.” Practical advice and hunger rating scales are available.
- Low-energy diets tend to be higher in nutritional value if carefully planned using water-rich fruits, vegetables, cooked grains, and soups (Rolls et al, 2005). Noncalorie sweeteners and chewing sugarless gum are useful; chewing gum may help fight cravings for sweets and suppress the appetite.
- Develop reduced-calorie eating plans that meet personal food preferences and provide satisfying food portions (Rolls et al, 2005).
- Instruct the patient on how to plan menus and use recipes. Recipe modifications are useful for replacing fat in recipes (e.g., use applesauce or pear puree in muffins or sponge cake; prune or black bean puree in brownies or spice cake or chocolate cake; or white bean puree in cookies).

**TABLE 10-11 Medications That Cause Weight Gain**

Medications that affect the central nervous system can cause clinically relevant resting metabolic rate (RMR) effects (from 262–680 kcal/d) in all age groups (Dickerson and Roth-Yousey, 2005a). Sedation or analgesia may produce temporary reductions in RMR (Dickerson and Roth-Yousey, 2005a). Medications that may cause weight gain are listed here.

Medication	Description	Alternatives to Consider
<b>Antianxiety Agents:</b> benzodiazepine (alprazolam [Xanax], chlordiazepoxide [Librium])	Psychotropic drugs can cause weight gain.	
<b>Antidepressants:</b> Selective Serotonin Reuptake Inhibitors (SSRIs)— fluoxetine (Prozac), sertraline (Zoloft), paroxetine (Paxil), fluvoxamine (Luvox), Celexa	SSRIs cause weight loss at first and then weight gain within 6 months. Paxil causes the most weight change. Prozac is often used for patients with bulimia nervosa; it may cause hyperglycemia.	bupropion (Wellbutrin, Zyban)
<b>Antidepressants:</b> Tricyclics (TCAs)—amitriptyline (Elavil, Vanatrip), doxepin (Sinequan), imipramine (Tofranil), nefazodone (Serzone), nortriptyline (Aventyl; Pamelor), trimipramine (Surmontil), mirtazapine (Remeron)	General gains of 0.4–4.12 kg/month; minority of patients gain 15–20 kilograms in 2–6 months from slowed metabolism and increased carbohydrate cravings.	bupropion (Wellbutrin, Zyban)
<b>Antidepressants:</b> Monoamine Oxidase Inhibitors (MAOIs)— isocarboxazid [Marplan], phenelzine [Nardil], tranylcypromine [Parnate]	MAOIs cause more weight gain. Less profound than tricyclics; some gain with phenylzine.	MAOI selective reversible drugs (RIMAs), such as moclobemide (Aurorix, <i>Manerix</i> ) or toloxatone ( <i>Humoryl</i> ) are not as weight-enhancing as other antidepressants.
<b>Mood Stabilizers:</b> lithium (Eskalith, Lithobid); Mogan, Clozaril, Serlect, and Zeldox	Mood stabilizers made with lithium can cause weight gain in 11% to 65% of treated patients; up to 10 kilograms or more in 6 to 10 years.	
<b>Antipsychotics:</b> haloperidol [Haldol], perphenazine [Trilafon], thiothixene [Navane], thioridazine HCl (Mellaril), olanzapine [Zyprexa], risperidone [Risperdal]	Antipsychotics often cause weight gain.	ziprasidone (Geodon); quetiapine (Seroquel)
<b>Anticonvulsants:</b> valproic acid (Depakote/Depakene), gabapentin (Neurontin), carbamazepine (Tegretol)	These medications can increase appetite and insulin levels, and variable gains of up to 15 to 20 kilograms.	topiramate (Topamax), lamotrigine (Lamictal), zonisamide (Zonegran)
<b>Antihistamines:</b> diphenhydramine (Benadryl, Nytol)	Used for allergy management. If used to induce sleep, may mask sleep apnea.	Decongestants or inhalers
<b>Cardiovascular Agents:</b> beta-adrenergic blockers—Propranolol (Inderal), atenolol (Tenormin), carvedilol, bisoprolol, metoprolol (Lopressor) alpha-adrenergic blockers—prazosin (Minipress), doxazosin (Cardura), terazosin (Hytrin)	These medications can reduce RMR by 4–12% over time (Dickerson and Roth-Yousey, 2005a).	ACE inhibitors such as enalapril (Vasotec) Angiotensin II Inhibitors such as candesartan (Atacand) Ca <sup>++</sup> channel blockers such as amlodipine (Norvasc), verapamil (Calan, Isoptin), diltiazem (Cardizem)
<b>Chemotherapy</b>	Chemotherapy can decrease metabolic rate by 6–11% in patients with leukemia, breast cancer, and some solid tumors (Dickerson and Roth-Yousey, 2005b).	Treatment is short term.
<b>Diabetes Agents:</b> insulin (Humalog)	Weight gain of up to 8 kg with intensive treatment.	metformin (Glucophage; glucophage XR)
<b>Diabetes Agents:</b> thiazolidinediones	rosiglitazone (Avandia) pioglitazone Actos	acarbose (Precose) miglitol (Glyset)
<b>Diabetes Agents:</b> sulfonylureas	Glipizide (Glucotrol) may reduce RMR by 3.5% (Dickerson and Roth-Yousey, 2005b). Weight gain <u>≤5 kilograms</u> over 3–12 months.	metformin (Glucophage; Glucophage XR); acarbose (Precose); miglitol (Glyset)
<b>Steroid Hormones:</b> corticosteroids	Hormones can cause weight gain if taken over a long time. cortisone, prednisolone, human growth hormone, somatotropin [Serostim]	NSAIDs if appropriate
<b>Steroid Hormones:</b> progestational agents; androgens	medroxyprogesterone acetate [Provera, Depo-Provera], oxymetholone [Anadrol-50], testosterone [Andro- derm, Testoderm])	—

DIABETES TREATMENTS (Up to 8 kilograms gained in an intensive 3-month treatment course)

**TABLE 10-12 Medications Used for Weight Reduction in the United States**

Diethylpropion (Tenuate)	Appetite suppressant. Dry mouth and GI upset can occur; short-term use is recommended. Average weight 4–6%, drug alone.
Orlistat (Xenical)	Decreases pancreatic lipase and decreases fat absorption. Soft stools and anal leakage may occur, particularly if a diet high in fat (>90 g) is consumed. Orlistat helps minimize weight regain after weight loss and appears to be well-tolerated for the long term. Fat-soluble vitamins may be required during chronic therapy because absorption may be decreased. Patients on orlistat should have a BMI over 27 with risk factors or a BMI over 30 without risk factors; the drug is not for everyone. Weight loss of 8% with behavioral approaches. Alli is an over-the-counter version, which contains a lower dose of orlistat; weight loss is slower.
Phentermine (Adipex, Ionamin)	Appetite suppressant; may cause excitability, gastrointestinal (GI) distress, and insomnia, as well as dry mouth. Average weight 4–6%, drug alone.
Sibutramine (Meridia)	Increases energy expenditure and satiety; it acts via the central nervous system (CNS) as a serotonergic and noradrenergic reuptake inhibitor. It can be used long term. Elevates plasma epinephrine, plasma glucose, and blood pressure. Weight loss of about 16% with behavioral approaches.

Adapted from: Nonas CA, Foster GD. *Managing obesity: a clinical guide*. 2nd ed. Chicago: American Dietetic Association, 2009.

- Steps to normalize eating include awareness training, changing thoughts and beliefs about food, handling issues of deprivation and guilt, and refocusing on areas other than food and weight. Self-efficacy is particularly important (Wamsteker et al, 2005). Correcting unrealistic weight goals is also an issue; it is better to correct them before treatment begins (Wamsteker et al, 2009).
- Provide guidance on how to eat at parties, events, and restaurants. Low-calorie snacking and the selection of low calorie food preparation methods are needed. Avoid buffets when possible.
- Teach portion control. Sometimes measuring and weighing foods can be useful. Table 10-13 provides a handy portion adjustment guide using everyday objects.
- Behavior therapy may be helpful in self-monitoring (food diaries, weights, activity). Teach stimulus control of cues, family intervention, slowing down while eating, and monitoring of intake while at parties and during work breaks.
- To delay automatic eating, drink a glass of water and wait 20 minutes. If the sensation persists, it is probably hunger. Make meals last 20 minutes or longer. Eat slowly; chew well.
- The best diet is “don’t buy it” to reduce temptations later.
- The use of meal replacements for one meal a day can be beneficial for improving cholesterol levels, plasma glucose, and diastolic blood pressure.
- Avoid an energy level that is too low, which causes hypophagia and could lead to sudden death syndrome. Low energy intake (<1200 kilocalories for women or <1500 kilocalories for men) requires the use of a multi-vitamin supplement.
- Physical activity is integral to weight loss maintenance; see Table 10-14. Encourage moderate levels of physical activity for 30–60 minutes daily whenever possible. It is reasonable to encourage the expenditure of 1000 kcal/wk in some type of physical activity. Resistance training increases muscle mass; aerobic exercise should be directed at 70% of maximal oxygen consumption.
- Cultural emphasis on thinness may lead to unhealthy weight loss efforts. Instead, focus on enhancement of self-esteem.
- The real challenge involves keeping weight off after it has been lost. Teach the patient to splurge by plan and not by impulse. Special considerations are important in specific age groups.
- Pregnant mothers should follow established recommendations for diet, exercise, and weight gain during pregnancy. A weight gain of 15–25 pounds in an overweight or <15 pounds in an obese mother leads to better outcomes (Crane et al, 2009).
- New mothers should breastfeed, and then provide wholesome, nourishing foods with low energy density for their children (Melanson, 2009).
- Between pregnancies, women with a history of GDM who gain more than 10 pounds are at higher risk for C-section and adverse outcomes (Paramsothy et al, 2009).
- Parents of young children must help them to develop good eating habits early in life.
- In puberty, it is common for young women to begin gaining weight. Women should not assume that premenstrual fluid weight gain is permanent; this may vary from 2–5 pounds per month.
- Encourage adequate sleep; deprivation increases a hunger hormone that can trigger overeating. Table 10-15 discusses sleep apnea and Pickwickian syndrome; a sleep study may be needed.
- Smoking cessation can lead to weight gain; see Table 10-16.
- Multiple and relentless forms of marketing, poor foods promoted in schools, and a variety of other conditions undermine personal resources, individual responsibility, and parental authority for preventing obesity among children and teens (Brownell et al, 2009). The current environment tends to promote overeating and minimal activity, yet there are social stigmas against being overweight.
- Obesity is increasing across all socioeconomic groups and educational levels (Cohen, 2008). Overall, fat intake tends to be higher in poorer neighborhoods (Keita et al, 2009). Children who live with overweight or obese individuals are often unaware of their desirable body weight range.
- Reduced activity and metabolism are factors that should be addressed to manage weight changes among older adults.
- Permanent lifestyle changes are better than popular diets or trends. Avoid bizarre fad dieting, skipping meals, or

**TABLE 10-13 Portion Adjustments Using Everyday Objects***Bread, Cereal, Rice, Pasta*

- 1 cup potatoes, rice, or pasta = 1 tennis ball or 1 ice cream scoop or a fist
- 1 pancake = 1 compact disc (CD)
- 1/2 cup cooked rice = a cupcake wrapper full
- 1 piece cornbread = bar of soap
- 1 slice bread = audiocassette tape
- 2 oz of pretzels = 2 handfuls

*Vegetables*

- 1 cup green salad = 1 baseball or a fist
- 1 baked potato = a fist
- 1 cup of vegetables = a fist
- 1/2 cup tomato juice = small Styrofoam cup
- 1/2 cup broccoli = 1 scoop ice cream or one light bulb
- 1/2 cup serving = 6 asparagus spears, 7–8 baby carrots, or 1 ear of corn on the cob

*Fruit*

- 1/2 cup grapes (15) = a light bulb
- 1/2 cup fresh fruit = 7 cotton balls
- 1 medium size fruit = a tennis ball or a fist
- 1 cup cut-up fruit = a fist
- 1/2 cup raisins = 1 large egg

*Milk, Yogurt, Cheese*

- 1 1/2 oz cheese = one 9-volt battery or 3 dominos
- 1 oz cheese = pair of dice or your thumb
- 1 cup ice cream = 1 large scoop the size of a baseball

*Meat, Poultry, Fish, Dry Beans, Eggs, Nuts*

- 2 tbsp peanut butter = ping pong ball
- 1 tsp peanut butter = fingertip
- 1 tbsp peanut butter = thumb tip
- 3 oz cooked meat, poultry, fish = your palm; a deck of cards
- 3 oz grilled or baked fish = a checkbook
- 3 oz cooked chicken = one chicken leg, thigh, or breast
- 1 oz of nuts = 1 handful
- 1 oz of cheese = your index finger

*Fats, Oils*

- 1 tsp butter or margarine = size of a stamp, the thickness of your finger or thumb tip
- 2 tbsp salad dressing = 1 ping pong ball

**TABLE 10-14 Physical Activity Equivalents**

According to the National Weight Control Registry, people who have lost weight and kept it off for 2 years or longer, limit their intake to about **1800 kilocalories daily** and **walk about 4 miles a day**. MET is a practical means of expressing the intensity and energy expenditure of physical activities.

Physical Activity	MET
<b>Light Intensity Activities</b>	
Sleeping	<3
watching television	0.9
writing, desk work, typing	1.0
walking, less than 2.0 mph (3.2 km/h), level ground, strolling, very slow	1.8
<b>Moderate Intensity Activities</b>	
bicycling, stationary, 50 watts, very light effort	2.0
sexual activity (position dependent)	3 to 6
calisthenics, home exercise, light or moderate effort, general	3.0
bicycling, <10 mph (16 km/h), leisure, to work or for pleasure	3.3
bicycling, stationary, 100 watts, light effort	3.5
<b>Vigorous Intensity Activities</b>	
jogging, general	4.0
calisthenics (e.g. pushups, sit-ups, pull-ups, jumping jacks), heavy, vigorous effort	5.5
running jogging, in place	>6
	7.0
	8.0
	8.0

Other beneficial activities that burn kilocalories include the following:

Warm Weather	Calories/hour	Cold Weather
Jogging 6 mph	450	Jumping rope
Hiking on steep hills	400	Indoor rappelling
Aerobics (low impact)	400	Snow shoveling, light
Rowing	400	Rowing machine
Swimming	400	Skiing cross-country
Tennis, singles	390	Racquetball
Cycling 10 mph	300	Stationary bike 10 mph
Golf with walking	300	Splitting logs
Gardening	280	Window cleaning
Mowing lawn	275	Mopping floors
Tennis, doubles	235	Indoor basketball
Badminton	250	Indoor volleyball
<b>Walking 3 mph</b>	<b>250</b>	<b>Mall walking</b>

**TABLE 10-15 Weight Management for Sleep Apnea and Pickwickian Syndrome**

Obstructive sleep apnea (OSA)	Short-duration (<1 minute), repetitive episodes of impaired breathing during sleep. It mostly occurs in obese individuals, which contributes to pharyngeal obstruction. OSA acutely impacts the cardiovascular system and can increase morbidity or mortality. Morbid obesity can be associated with excessive daytime sleepiness even in the absence of sleep apnea. See Section 5 for more details.
Pickwickian syndrome	The individual is obese and hypersomnolent with cor pulmonale, polycythemia, nocturnal enuresis, and personality changes. Even mild obesity can affect lung function, particularly in men. Weight loss is desirable.

emphasis on any one nutrient. A “no fad diet” approach encourages healthy eating patterns. Table 10-17 describes some weight loss programs, several popular diets, and available Web sites.

- Large permanent changes are required to keep weight off. Promote small changes in diet and physical activity to initially prevent further weight gain (Hill, 2009). America On the Move (AOM) is a national initiative that promotes an increase in walking by 2000 steps/d and reductions in energy intake by about 100 kcal/d; people seem to be able to make positive changes in response to these

messages (Stroebele et al, 2009). Greater self-reported physical activity was the strongest correlate of weight loss in the Look-Ahead Trial, followed by treatment attendance and consumption of meal replacements (Wadden et al, 2009).

- Discourage weight cycling. Cyclers tends to have a larger body fat percentage, lower metabolic rates, and higher BMI than non-cyclers (Strychar et al, 2009).
- Group counseling or corporate wellness programs may be effective.
- Electronic feedback, one-on-one advice from a nutrition counselor, phone or mail follow-ups can also help to maintain positive momentum in weight loss or maintenance.
- Given that people have a limited ability to shape the food environment individually and have no ability to control automatic responses to unconscious food-related cues, society as a whole may need to regulate the environment through the number and types of food-related cues, portion sizes, food availability, and food advertising (Cohen, 2008).
- Overweight adults diagnosed with type 2 diabetes experience significant improvement in health-related quality of life (HRQOL) by enrolling in a weight management program that yields significant weight loss, improved physical fitness, and reduced physical symptoms (Williamson et al, 2009).

### **Patient Education—Food Safety**

There are no specific food handling techniques that are unique to overweight or obesity.

**TABLE 10-16 Smoking Cessation and Weight Gain**

Nicotine addiction is a chronic, relapsing condition.

Smoking cessation lowers cardiovascular and cancer risks even when compensating for possible weight gain; cessation lengthens life by several years and is worth the effort.

Weight gain is common after cessation because of increased caloric consumption, changes in activity levels, and a decrease in the basal metabolic rate. Past smokers are more likely to be obese than current smokers.

Contemplation of and experimentation with smoking is often related to weight concerns among boys and girls. Women fear weight gain more than men.

Women who quit smoking typically gain 6–12 pounds in the first year after quitting.

Interventions that address weight control are recommended. Moderate to heavy smokers who attempt to quit may need to reduce intake by 100–200 kcal/d just to maintain weight.

Behavioral weight control counseling helps to slow the rate of weight gain. Fruit often helps relieve the craving for sweets.

Exercise often helps relieve the desire to smoke. Walking is a great stress reliever.

Sustained-release bupropion (bupropion SR) was the first non-nicotine pharmacological treatment approved for smoking cessation. Others are now available.

Teach good principles of weight management:

- Weight gain is a problem requiring lifelong, multidisciplinary management.
- Weight is regulated by a complex set of biologic/environmental factors, not by a lack of willpower.
- Modest weight loss has benefits.
- Work to alter fundamental thoughts and assumptions versus unrealistic expectations.
- Emphasize slow, steady loss, followed by maintenance.
- Focus on long-term outcomes/sustained changes.

**TABLE 10-17 Diet Program Comparisons**

Programs	Description	Web Address	Pro	Con
Diet Center	Personal counseling	<a href="http://www.dietcenter.com">http://www.dietcenter.com</a>	Consider “Exclusively You” option	
eDiets.com	Online dieting	<a href="http://www.ediets.com">http://www.ediets.com</a>	Bargain	Must be self-motivated
Jenny Craig	Personal counseling; at home	<a href="http://www.jennycraig.com">http://www.jennycraig.com</a>	Well-structured	Expensive
LA Weight Loss	Personal counseling	<a href="http://www.laweightloss.com">http://www.laweightloss.com</a>	Good exercise centers	Costly foods
NutriSystem	Online dieting	<a href="http://www.nutrisystem.com">http://www.nutrisystem.com</a>	Healthy choices; good structure	
Overeaters Anon	Group support	<a href="http://www.oa.org">http://www.oa.org</a>	Physical, emotional, spiritual support	
Registered Dietitian	Expert personal counseling	<a href="http://www.eatright.org">http://www.eatright.org</a>	Most flexible; personalized concerns	
Take Off Pounds Sensibly	Group or online support	<a href="http://www.tops.org">http://www.tops.org</a>	Inexpensive	Not personalized
Weight Watchers	Group or online support	<a href="http://www.weightwatchers.com">http://www.weightwatchers.com</a>	Comprehensive and sound principles	

Popular diets such as Weight Watchers, Atkins, the Zone, and Ornish achieve weight loss and reductions in LDL cholesterol, CRP, and insulin as long as calories are reduced and adherence continues for up to a year (Dansinger et al, 2005). In another study of the popular diets, Gardner et al (2007) found that premenopausal overweight and obese women assigned to follow the low CHO Atkins diet lost more weight at 12 months than women assigned to follow the Zone diet and experienced comparable or more favorable metabolic effects than those assigned to the Zone, Ornish, or LEARN diets. In general, any diet or program that achieves macronutrient reduction should yield acceptable results.

Type of Diet	Total Calories	Fat grams (% calories)	Carb grams (% calories)	Protein grams (% calories)	Nutrition Adequacy
Typical American diet	2200	85 (35%)	275 (50%)	82.5 (15%)	Varies by food choice and nutrient density.
High fat	1414	96 (60%)	35 (10%)	105 (30%)	Low in several nutrients: Vitamins A, B <sub>6</sub> , D, E, thiamin, folate, calcium, magnesium, iron, zinc, potassium, and dietary fiber. This type of diet also contains excess amounts of total fat, saturated fat, and dietary cholesterol. Nutritional supplementation is highly recommended.
Low-carbohydrate diet		Fat level range: 35–65%			
• Dr. Atkins Diet					
• Zone Diet					
• Sugar Busters					
• Protein Power					
Moderate fat diet	1450	40 (25%)	218 (60%)	54 (15%)	Usually a nutritionally balanced eating plan assuming the dieter eats a variety of foods from all food categories. Limiting any food categories can lead to deficiencies in certain nutrients particularly calcium, iron, and zinc. Weight watchers scores are the highest here for long-term adherence.
• USDA Food Guide Pyramid		Fat level range: 21–34%			
• DASH Diet					
• American Diabetes Association					
• Weight Watchers					
• Jenny Craig					
Low- and very low-fat diet	1450	20 (13%)	235–271 (70%)	54–72 (17%)	Deficient in zinc and vitamin B12 due to infrequent meat consumption. This type of diet can be inadequate in vitamin E—a nutrient found in oils, nuts, and other foods rich in fat. Volumetrics rates the highest in this group for helping people lose weight effectively.
• Volumetrics		Fat level varies: 10–20%			
• Dean Ornish’s Eat More, Weigh Less					
• New Pritikin Program

## UNDERWEIGHT AND MALNUTRITION

## UNDERWEIGHT AND UNINTENTIONAL WEIGHT LOSS

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

## Underweight Problems

When body weight decreases to 15–20% below desirable weight (BMI < 18.5), the amount of energy being consumed is not sufficient to support the function of vital organs. Lean tissue is being broken down and utilized for energy to make up the deficit. The results are:

- Low body temperature
- Abnormal electrical activity in the brain
- Altered blood lipids
- Dry skin
- Impaired immune response
- Loss of digestive function
- Abnormal hormone levels
- Malnutrition
- Anemia

## DEFINITIONS AND BACKGROUND

**Underweight** is defined as having a BMI below 18.5; approximately 8–9% of the population is underweight. Weight gain may be difficult for some healthy individuals because of a genetic tendency toward leanness, excessive activity, or routine eating patterns. Being underweight may or may not be associated with pathology. There are serious health risks associated with very low weight and with efforts to maintain

an unrealistically lean body mass. Identification and treatment of disordered eating can be important for improving the health status of underweight individuals at any age. See Section 4 for eating disorder guidelines.

Body storage of glycogen is approximately 1100 kilocalories or about a 12- to 16-hour supply. Body storage of protein equals approximately 40,000 kilocalories of muscle tissue; the loss of 30–50% of lean body mass is incompatible with survival. Body fat is the remainder of calories in fuel storage; it varies depending on the weight of the individual compared with BMI tables for height and sex and by level of physical fitness.

Low BMI is a significant predictor of mortality among young as well as older hospitalized patients (Flegal et al, 2005; Sergi et al, 2005). A BMI value of 20 kg/m<sup>2</sup> seems to be a reliable threshold for defining underweight in older adults at high risk for short-term mortality (Sergi et al, 2005). The Women's Health Initiative Observational Study evaluated 40,657 women aged 65–79 years at baseline and measured frailty including muscle weakness, impaired walking, exhaustion, low physical activity, and unintended weight loss; hip fractures, activities of daily living disability, hospitalizations, and deaths were also tracked (Fugate Woods et al, 2005).

Underweight is often correlated with frailty and poor outcomes. Underweight is associated with significantly increased mortality from non-cancer, non-CVD causes (Flegal et al, 2007). Indeed, a low BMI tends to have the most risk for mortality (Heather et al, 2009).

The Ancel Keys studies (Keys et al, 1950) demonstrated that starvation results in food preoccupation, unusual eating habits, increased use of caffeine and tea, binge eating, depression, anxiety, social withdrawal, poor judgment, apathy, egocentrism, edema, sleep disturbances, hypothermia, gastrointestinal disturbances, and lowered basal metabolism. Death related to starvation is often from decreased respiratory muscle function and terminal pneumonia. In addition, patients who have chronic obstructive pulmonary disease (COPD) are more likely to have additional exacerbations when weight loss and poor intake occur (Hallin et al, 2006).

The most common cause of a person being underweight is inadequate access to food. While this problem is most significant in sub-Saharan Africa and south Asia, many Americans go to bed hungry every night. Financial resources, politics, geography, and economics play a role; food inadequacy may also relate to high prices and limited healthy choices at the local grocery store.

**Unintentional weight loss** with debility, cachexia, and loss of lean body mass suggests some undesirable condition or pathology, particularly among chronically ill or institutionalized individuals. Malnutrition in older adults is generally characterized by faulty or inadequate nutritional status, insufficient dietary intake, poor appetite, muscle wasting, and weight loss. Blunted responsiveness to neuropeptide Y (NPY)—a feeding stimulant—often occurs concurrently with age-related anorexia and hypophagia.

**TABLE 10-18 Strengthening Tips**

In healthy young people, 30% of body weight is muscle, 20% is adipose tissue, and 10% is bone; muscle accounts for 50% of lean body mass and 50% of total body nitrogen. By age 75, about half the body's muscle mass has disappeared: 15% of body weight is muscle, 40% is adipose tissue, and 8% is bone (Merck, 2009). Hospitalized or bedridden elderly people require early physical therapy and individualized exercise regimens (Merck, 2009). With restricted mobility, loss of muscle mass and strength (deconditioning) occurs, mostly in the antigravity muscles—those used to sit up, stand up, and pull up (Merck, 2009).

Up to 1.5%/d of muscle mass can be lost; for 1 day of absolute bed rest, up to 2 wks of reconditioning may be necessary to return to baseline function (Merck, 2009). Patients who can and will comply with a proper exercise program gain muscle protein mass, strength, and endurance and are often more capable of performing activities of daily living (NIA, 2009).

1. Start with a weight that can be lifted 5 times without too much effort.
2. When that is easy, rest a few minutes, and do it again (2 sets).
3. Increase to 3 sets.
4. Lift weight 10 times in each set.
5. Lift weight 15 times in each set.
6. Slowly increase weight and sets.

Merck Manual of Geriatrics. Accessed November 7, 2009 at <http://www.merck.com/mkgr/mmg/sec7/ch48/ch48d.jsp>.

NIA. Exercise: a guide from the National Institute on Aging. Accessed November 7, 2009 at <http://www.nia.nih.gov/HealthInformation/Publications/ExerciseGuide/chapter04a.htm>.

Nutritional frailty includes sarcopenia with the loss of lean body mass, which leads to a failure to thrive and functional disability. Cytokines contribute to lipolysis, anorexia, muscle protein breakdown, and nitrogen loss. Patients with cardiac cachexia or chronic obstructive pulmonary disease (COPD) are often debilitated if they have lost weight rapidly. In older adults, micronutrient deficiency is a common result and should be addressed. Table 10-18 provides tips for helping debilitated persons to strengthen their muscles.

Carefully monitor for unintentional weight loss in adults following their admission into residential health care facilities. Red flags include early satiety, bloating, anorexia, dyspnea, fatigue, constipation, and dental problems.

Protocols must emphasize thorough assessment, interventions, frequent weighing and effective communications between all involved parties. Other populations who are at risk for weight loss and poor intake should be monitored (e.g., persons with chronic renal insufficiency, tuberculosis, HIV-AIDS, and cancer).

The American Dietetic Association Unintended Weight Loss (UWL) in Older Adults Evidence-Based Nutrition Practice Guideline was published in 2009. Qualified dietitians help to identify nutritional risk factors and recommend interventions based on the medical condition, needs, goals and desires of the individual. Studies support an association between increased mortality and underweight (BMI <20 kg/m<sup>2</sup> or current weight compared with usual or desired body weight) and/or unintended weight loss, such as 5% in 30 days (American Dietetic Association, 2009).

In long-term care, usual body weight is often more meaningful than comparison with an ideal body weight chart. Quality of life and resident-directed care plans ("I Care" plans) must be considered when designing interventions. The move from institutional to person-centered dining is a positive step in the right direction. The American Dietetic Association has recommended at least three MNT visits for adults who have had unintentional weight loss; it also has a Long-Term Care Toolkit for use during the nutrition care process with standardized language for that setting.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Underweight may be part of a genetic disorder or inherited naturally.

Clinical/History		
Height	Loss of teeth or dental pain?	Serum ferritin, if anemia is suspected
Weight	Nausea or frequent emesis?	CRP (elevated?)
Usual weight	Amenorrhea, anemia, hair loss?	T3, T4, TSH
Recent weight changes	Osteoporosis or fractures?	Albumin (Alb) below 3.5 g/dL
BMI	Stress, medication overuse?	Transthyretin below 17 g/dL
Diet history	Cognitive decline or depression?	Chol (may be low)
BP	Eating dependency?	Trig
Intake and output (I & O)	Skinfold measurements (over time)	Fasting glucose
Dehydration?		Blood urea nitrogen (BUN)
DETERMINE checklist, MNA or other screening tool		Creatinine (Creat)
Exercise tolerance		Nitrogen (N) balance
Parasitic infections?		Na <sup>+</sup> , K <sup>+</sup>
Sarcopenia?		Alkaline phosphatase (Alk phos)
Xerostomia, mucositis?	<b>Lab Work</b>	Ca <sup>++</sup> , Mg <sup>++</sup>
Inflammatory bowel disease?	Hemoglobin and hematocrit (H & H)	
Cancer or HIV infection?		

## SAMPLE NUTRITION CARE PROCESS STEPS

**Underweight**

**Assessment Data:** Diet, weight, and physical activity histories. Medical history, frequent infections.

**Nutrition Diagnosis (PES):** Underweight related to a mismatch of energy intake and expenditure as evidenced by a 6-lb loss in 1 month without change in the usual oral intake.

**Intervention:** Address appropriate matching of energy intake and physical activity. Weight training may be beneficial. Counsel on food choices and ways to increase intake of energy-dense foods.

**Monitoring and Evaluation:** Ask patient to return in 2–4 weeks to assess weight. Review diet and activity logs, changes in BMI over time, fewer infections.

## INTERVENTION

## OBJECTIVES

- Increase body weight gradually if indicated. Encourage weight gain of approximately 1 lb weekly.
- Keep a food diary or log to determine changes that have been made and whether they are successful.
- Provide a 3-meal, 3-snack regimen as a baseline. Encourage increased consumption of calorie and nutrient-dense foods and beverages.
- In the case of recent acute illness or general chronic disease, provide diet as tolerated to improve nutritional status. Progress slowly; it may take several days to stimulate the patient's appetite.
- If confusion is present, dehydration may be a factor; evaluate carefully and rehydrate if appropriate.
- Try anabolic agents, exercise/physical activity, and cytokine inhibition.

## FOOD AND NUTRITION

- Calculate patient's goal weight: basal energy requirements plus kilocalories according to activity or stress factors. Each pound of fat requires 3500 kilocalories; therefore, diet should be increased by 500 kcal/d to promote a weight gain of 1 lb/wk.
- Use 15–20% protein, 60–70% CHO diet with frequent feedings, adequate micronutrients, and supplements as needed. Include healthy fats from avocado, nuts, fatty fish, olive, and canola oils.
- Plan meals and snacks according to appetite and preferences; encourage a small snack approximately every 2–3 hours. Patients who have cancer or other chronic illnesses may not want to eat large meals.
- Try serving the high calorie foods first if satiety is a problem; consume beverages between rather than with meals. Smaller, more frequent meals are recommended; avoid rushing mealtimes. Prepare items with fats, oils, extra sweets if feasible. Choose beverages with added calories such as a milkshake with chocolate syrup and peanut butter.

- Offer something to eat or drink every few hours, or keep snacks close at hand. If necessary, set an alarm to remember to eat something.
- With dyspnea, rest before meals and use bronchodilators in advance. Eat slowly and use pursed lip breathing between bites. Keep food and snacks within easy reach.
- For easy fatigue, rest before meals. Serve pre-prepared meals that are readily available. Use oral supplements between meals if intake is poor at mealtime.
- For constipation, a stool softener and adding extra fiber and fluid may be useful.
- For dental problems, change the food textures as needed (grind, chop, mash). Fix the problem with a dental appointment, or repair dentures if needed.
- For swallowing difficulty, work with the Speech and Language Pathologist (SLP) to identify appropriate solid and liquid consistencies.
- Provide enteral feeding if needed and appropriate. In some cases, feeding at night is well tolerated.

## Common Drugs Used and Potential Side Effects

- Appetite may be stimulated through use of medications such as megestrol acetate, dronabinol, prednisone, or oxandrolone. Not everyone responds positively with an increased appetite and weight gain. Side effects vary and are most concerning with prednisone.
- Antidepressants may be warranted when a qualified professional has documented depression. Monitor for dry mouth and other side effects specific to ordered medication.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- When a registered dietitian, as part of the healthcare team, provides medical nutrition therapy (MNT) for older adults with unintentional weight loss, improved outcomes are seen for increased energy, protein and nutrient intakes, improved nutritional status, improved quality of life, and weight gain (American Dietetic Association, 2009).
- Help patient make meals in a simple manner, using attractive foods.
- Identify spices, seasonings, and other flavor enhancements that will stimulate the senses.
- The use of high-caloric density foods may be useful in programs where the patient refuses to eat or to take supplements. Adding them by “hiding” calories and extra protein in food may also be feasible (extra dry milk powder in soups, shakes, or mashed potatoes).
- Offer tips on weight gain such as eating a small snack every 2–3 hours. A high-calorie bedtime snack is often beneficial (for example, a milkshake or sandwich). If homemade items are not available, high calorie commercial supplements can be used.

- Dietary restraint and inadequate weight gain in pregnancy is not desirable. There are tools to assess restraint that may identify women at risk so that they can be counseled early in pregnancy (Mumford et al, 2008).
- Malnutrition often presents with loss, loneliness, dependency, and chronic illness, and it impacts morbidity, nutrition quality of life, and morbidity. Coordinate referrals such as home-delivered meals.
- Promote lean body mass development through strength training where appropriate. Increased physical activity appropriate for the clinical condition can help to improve appetite and intake in many cases. Exercise training has been successful for the treatment of wasting associated with sarcopenia, cancer, and some other conditions.
- Coordinate care with other health team members, as shown in this flow chart:

<b>INTERDISCIPLINARY NUTRITION CARE PLAN</b> <b>Involuntary Weight Loss</b>

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

## UNDERNUTRITION AND PROTEIN-ENERGY MALNUTRITION

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

#### DEFINITIONS AND BACKGROUND

The undernourished category of malnutrition leads to the loss of body cell mass, which, together with inflammation, diminishes host response and quality of life (Soeters and Schols, 2009). Protein–energy malnutrition (PEM) decreases cardiac output, blood pressure, oxygen consumption, total lymphocyte count (TLC), number of T cells, and glomerular filtration rate (GFR). Undernutrition is associated with increased infection rates, emphysema and pneumonia, GI tract atrophy, intestinal bacterial overgrowth, hepatic mass losses, and anemia. In PEM, anemia is a result of ineffective erythropoiesis (Borelli et al, 2007).

Physical assessment and thorough clinical history are essential in determining the etiology of the PEM and appropriate interventions; see Table 10-19. Malnutrition may be assessed by estimating nutrient balance but, subsequently, to measure body composition (muscle mass), inflammatory activity (plasma albumin and C-reactive protein), and muscle endurance and force (Soeters and Schols, 2009).

Malnutrition is the leading cause of death among children in developing countries. Clinically, in children, PEM has three forms: dry (thin, desiccated), wet (edematous, swollen), or a combination; grading is mild, moderate, or severe. Grade is determined by calculating weight as a percentage of expected weight for length using international standards (normal 90–110%; mild 85–90%; moderate 75–85%; severe <75%). The dry form, **marasmus**, results from near starvation with a deficiency in protein and non-protein nutrients. The wet form is called **kwashiorkor**—an African word meaning “first child–second child”—because the first child often develops malnutrition after the second child arrives and nutrient-poor foods replace breast milk.

The combined form of malnutrition is called **marasmic kwashiorkor**; these children have some edema and more body fat than those with marasmus.

Nutrients and growth factors regulate brain development during fetal and early postnatal life. The rapidly developing brain is more vulnerable to nutrient insufficiency yet also demonstrates its greatest degree of plasticity (Georgieff, 2007). Chronic protein energy malnutrition (stunting) affects the ongoing development of higher cognitive processes during childhood and may also result in long lasting cognitive impairments (Kar et al, 2008). The nutrients that have greater effects on brain development than do others include protein, energy, certain fats, iron, zinc, copper, iodine, selenium, vitamin A, choline, and folate (Georgieff, 2007).

Adult malnutrition syndromes differ from those in underdeveloped countries; an understanding of the systemic inflammatory response should help guide assessment, diagnosis, and treatment (Jensen et al, 2009). In adult patients with acute illnesses, the prevalence of malnutrition is high, particularly related to age and metabolic stress (Martinez Olmos et al, 2005; Pirlich et al, 2006). Of patients admitted to hospitals, 35–55% are malnourished on admission and 25–30% more become malnourished during stay. Problems are common in gastrointestinal (GI) patients, particularly patients with inflammatory bowel disease (IBD); ventilator, radiation, or chemotherapy patients; burn and surgical patients; and patients with renal failure. Even with dialysis, renal patients are at high risk (Kopple, 2005), mostly from cardiovascular disease with markers of a malnutrition–inflammation complex syndrome (Colman et al, 2005).

Tissue catabolism usually begins with lowered plasma proteins, red blood cells, and leukocytes; later, wasting of organs, skeletal muscle, bone, skin, and subcutaneous tissue

**TABLE 10-19 Complicating Effects of Chronic Malnutrition on Body Systems**

<b>Cardiac and Hematological System</b> —Anemia; altered clotting time; decreased heart size; decreased amount of blood pumped; slow heart rate; decreased blood pressure; heart failure; decreased number of blood cells.
<b>Digestive Tract</b> —Frequent, chronic, or even fatal diarrhea; bacterial translocation in gut; low HCl production in stomach; progressive weight loss; gastrointestinal mucosal or villous atrophy with loss of immune function.
<b>Endocrine System</b> —Decreased body temperature (hypothermia); fluid accumulation in skin from lower subcutaneous fat and decreased albumin levels; vitamin and mineral deficiencies.
<b>Immune System</b> —Depressed cell-mediated immunity; increased infection, particularly gram-negative sepsis; impaired wound healing; more wound infections or disruption; impaired ability to fight infections; delayed response to cancer chemotherapy or radiation therapy.
<b>Muscular System</b> —Decreased activity; delayed physical rehabilitation; decreased muscle size and strength; delayed hospital discharge and ability to perform work.
<b>Nervous System</b> —Irritability, weakness, and apathy even if intellect remains intact.
<b>Pulmonary System</b> —Depressed ventilatory response to hypoxia; decreased lung capacity; slow breathing; pneumonia and eventually respiratory failure.
<b>Quality of Life</b> —Increased and prolonged use of hospitals, critical care units, and expensive drugs; excessive requirements of hospital support.
<b>Renal System</b> —Fluid, electrolyte, and acid–base malfunctioning; increased frequency of urinary tract infections; elevated blood urea nitrogen from muscle and tissue breakdown; decreased glomerular filtration rate.
<b>Reproductive System</b> —Decreased size of ovaries or testes; decreased libido; cessation of menstruation.
<b>Skin and Skeleton</b> —Pale, thin, dry inelastic skin; pressure ulcers; decreased subcutaneous fat; loss of bone density.

will occur. Chronic undernutrition of protein, calories, and micronutrients (particularly zinc) will compromise cytokine response and affect immune cell functioning. Nutrients act as antioxidants and as cofactors in cytokine regulation (Cunningham-Rundles et al, 2005). The central nervous system is the last system to be catabolized, and magnetic resonance imaging (MRI) scans taken of children who have moderate to severe malnutrition show cerebral atrophy (Odabas et al, 2005). Total starvation is fatal in 8–12 weeks.

Certain types of stress and surgery can lead to malnutrition; pancreatic surgery is one specific example (Schnelldorfer and Adams, 2005). Because malnutrition and involuntary weight loss are common problems in seniors, there is a significant increase in infection rate, a decrease in the rate of healing, and an increase in length of stay in older, malnourished burn patients when compared with those who are well nourished (Demling, 2005).

Common causes of malnutrition in the elderly involve decreased appetite, dependency on help for eating, impaired cognition and/or communication, poor positioning, frequent acute illnesses with GI losses, medications that decrease appetite or increase nutrient losses, polypharmacy, decreased thirst response, decreased ability to concentrate urine, intentional fluid restriction because of fear of incontinence or choking if dysphagic, psychosocial factors such as isolation and depression, monotony of diet, and higher nutrient density requirements, along with the demands of age, illness, and disease on the body (Harris and Fraser, 2004).

Poor nutritional state may be associated with an increase in postoperative complication rate; low serum albumin levels can be reflected by a higher rate of infectious complications as well as increased intensive care unit stays (Schnelldorfer and Adams, 2005). The Subjective Global Assessment (SGA) is a tool for nutritional screening that can be used on hospital admission. The SGA score, disease category, presence of malignancy, serum albumin level, percent triceps skinfold thickness, and percent arm muscle circumference are significant predictive parameters for hospital stay in patients with

digestive diseases (Wakahara et al, 2007). SGA has also been found to be useful in chronic kidney disease, hemodialysis, and cardiac disorders as well as liver diseases and cancer.

It is important to use designated descriptions or codes for malnutrition in the medical record so that proper attention is given. Table 10-20 describes several types of undernutrition that are common in hospitals. Table 10-21 describes a malnutrition universal screening tool (MUST). The MUST tool has been developed to screen all adults, even if weight and/or height cannot be measured. This tool provides more complete information on malnutrition prevalence; MUST screening predicts clinical outcome in the hospitalized elderly where malnutrition is common in over half of the population (Stratton et al, 2006). Other tools are available in Appendix B.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** While genetics are typically not responsible for malnutrition, some conditions make an individual prone to poor nutriture. Examples include inherited disorders such as cystic fibrosis, inflammatory bowel disease, and celiac disease. Recent studies have shown that vitamin D<sub>3</sub> and calcitriol impact over 1000 genes, and deficiency contributes to rickets, cancers, hypertension, stroke, heart attack, diabetes, bone fractures, multiple sclerosis, and periodontal disease (Edlich et al, 2010). Vitamin D up-regulates cathelicidin—a naturally occurring broad-spectrum antibiotic—and may even play a role in protecting against viral respiratory infections including the common cold and influenza (Cannell and Hollis, 2009).

<b>Clinical/History</b>	Cachexia? TSF MAMC, MAC	Total iron-binding capacity ( $<250$ mg/dL)
Height, arm length, or knee length		
Stunting in a child	<b>Lab Work</b> CRP	Urine acetone T3, T4
Weight	Alb,	$\text{Ca}^{++}$ , $\text{Mg}^{++}$
BMI	transferrin	BUN
Recent weight; weight changes	(may be altered)	(decreased)
Usual weight	Chol, Trig	Creat
Desirable BMI	(decreased)	White blood cell count
Diet history—poor appetite	Serum Fe, ferritin	(decreased)
I & O	Alk phos	$\text{Na}^+$ , $\text{K}^+$ , $\text{Cl}^-$
BP	(decreased)	Serum $\text{B}_{12}$ , folate, $\text{B}_6$
Edema	Gluc	Serum $\text{D}_3$ [25(OH)D]*
Muscle wasting	H & H	
Sarcopenia?	Oxygen saturation levels	

\*Natural vitamin D levels in humans living in a sun-rich environment are between 40 and 70 ng/mL (Cannell and Hollis, 2009).

## INTERVENTION

## OBJECTIVES

- Provide adequate macronutrients and micronutrients. Work up to 100% of estimated needs over several days.
- Correct weight loss, weakness, infections, and poor wound healing. Improve signs of apathy and irritability.
- Reduce the costs of care. International studies suggest that disease-related malnutrition increases hospital costs by 30–70%; with this large cost of disease-related malnutrition, intervention can result in substantial absolute cost savings (Elia, 2009).
- Avoid hazards of refeeding (hypophosphatemia, low magnesium, and potassium). Fluid administration must be monitored carefully. Prevent sepsis, overfeeding, hyperglycemia, heart failure, or other organ failure by refeeding slowly.
- Allow normal growth of brain and prevent permanent IQ deficits in children.
- Correct malnutrition in patients who have dysphagia as it may contribute to further declines in the capacity for rehabilitation.
- Provide sufficient nutrients for gene expression.
- Prevent complications, which can include dehydration, electrolyte imbalances, infections, vitamin-mineral deficiencies, and other biochemical changes (Table 10-22).

TABLE 10-20 Indicators of Malnutrition

Category	Criteria for Nutrition Diagnosis of Malnutrition
Severe malnutrition	At least one of the following criteria must be met:
Protein-energy malnutrition	– BMI $\leq 16.0$ – Weight loss of $\geq 26\%$ of UBW within $\leq 6$ months
Moderate malnutrition	At least one of the following criteria must be met:
Protein-energy malnutrition	– BMI 16.0–16.9 – Weight loss of 16–25% of UBW within $\leq 6$ months
Mild malnutrition	At least one of the following criteria must be met:
Protein-energy malnutrition	– BMI 17–18.4 – Weight loss of 5–15% of UBW within $\leq 6$ months – Weight loss of $\geq 5\%$ of UBW within $\leq 1$ month
Malnutrition, unspecified	Albumin must be below 3.4 and at least one of the following criteria must be met:
Disease/injury related malnutrition	– One indicator of malnutrition as described above – Peripheral edema or anasarca – Delayed wound healing – History of acute or chronic disease or trauma

Albumin should not be used as the sole indicator of visceral protein status in fluid imbalance, liver disease, post-operative states, infection, and nephrotic syndrome. Serum albumin levels drop when there is inflammation; when inflammation is corrected, levels may rise again regardless of nutritional intake. Albumin is a marker of severity of illness, not as a marker of protein nutriture.

Adapted from the Nutrition Support Committee, Emory Hospitals, Atlanta GA; 2008.

Accessed November 1, 2009 at [http://www.eatright.org/cps/rde/xchg/ada/hs.xsl/nutrition\\_10448\\_ENU\\_HTML.htm](http://www.eatright.org/cps/rde/xchg/ada/hs.xsl/nutrition_10448_ENU_HTML.htm).

**TABLE 10-21 Malnutrition Universal Screening Tool (MUST)**

MUST is a 5-step screening tool to identify adults who are malnourished, at risk of malnutrition (undernutrition), or obese. It includes management guidelines for care planning. It is used in hospitals, community care settings and other care settings and can be used by all care workers. It was established by the British Association for Enteral and Parenteral Nutrition (BASPEN). The guide contains the following:

- A flow chart showing 5 steps to use for screening and management
- BMI chart
- Weight loss tables
- Alternative measurements when BMI cannot be obtained by measuring weight and height

A more detailed MUST explanatory booklet should be used for procedures when weight and height cannot be measured and when screening with more interpretation is needed (e.g., those with fluid disturbances, plaster casts, amputations, or critical illness, or pregnant or lactating women).

The 5 MUST steps are as follows.

*Step 1: Measure height and weight to get a BMI score using the chart provided.*

**If height cannot be measured:** use recently documented or self-reported height (if reliable and realistic). If the subject does not know or is unable to report their height, use one of the alternative measurements to estimate height (ulna, knee height, or arm span).

**If height and weight cannot be obtained:** use mid upper arm circumference (MUAC) measurement to estimate BMI category.

**If BMI cannot be determined:** use subjective clinical impression—thin, acceptable weight, overweight. Obvious wasting (very thin) and obesity (very overweight) can also be noted.

BMI	Score
>20	<input type="checkbox"/> 0
18.5–20	<input type="checkbox"/> 1
<18.5	<input type="checkbox"/> 2
BMI score = _____	

Alternative procedures are available from the guide <http://www.baspen.org.uk/the-must.htm>.

*Step 2: Note percentage of unplanned weight loss, and score using tables in the screening tool.*

**If recent weight loss cannot be calculated:** use self-reported weight loss (if reliable and realistic).

**Unplanned weight loss:** clothes and/or jewelry have become loose fitting (weight loss); history of decreased food intake, reduced appetite or swallowing problems over 3–6 months; underlying disease or psychosocial/physical disabilities likely to cause weight loss.

**Record presence of obesity.** Control underlying conditions before treating obesity.

% of Unplanned weight loss in past 3–6 months	Score
<5%	= 0
5–10%	= 1
>10%	= 2
Weight loss score = _____	

*Step 3: Establish the acute disease effect and score.*

No nutritional intake or likelihood of no intake for more than 5 days = score 2.

Acute disease effect score = \_\_\_\_\_

*Step 4: Add scores from steps 1, 2, and 3 to obtain the overall risk of malnutrition.*

0 = Low Risk  
1 = Medium Risk  
≥2 = High Risk

(continued)

**TABLE 10-21 Malnutrition Universal Screening Tool (MUST) (continued)**

*Step 5: Develop care plan and treat.*

Observe and document dietary intake for 3 days if patient is in hospital or long-term care (LTC) facility.

If improved or adequate intake—little clinical concern. If no improvement—clinical concern; follow local policy. Repeat screening: Hospital, weekly; LTC facility, at least monthly; community, at least every 2–3 months.

*Treat unless detrimental, no benefit is expected from nutritional support, or death is imminent:*

Record need for special diets and follow local policy.

Record malnutrition risk category; as needed, refer to dietitian or nutritional support team or implement local policy.

Treat underlying condition and provide help and advice on food choices, eating, and drinking when necessary.

Improve and increase overall nutritional intake.

Monitor and review care plan: hospital, weekly; LTC facility, monthly; community, monthly.

©BAPEN 2003. This document may be photocopied for dissemination and training purposes.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Malnutrition

**Assessment Data:** Diet, intake records, weight, medical history, frequency of infections, serum levels of vitamins such as vitamin A, lipids such as total cholesterol.

#### Nutrition Diagnoses (PES):

Malnutrition (NI-5.2) related to lack of appetite and poor food selection as evidenced by diet recall showing consumption of only 1200 kcal/d and 25 grams PRO, percent wt change of > 10% over the past 6 months, BMI of 18, serum cholesterol of 130, and albumin of 2.5 g/dL.

Involuntary weight loss (NC 3.2) related to inadequate dietary intake as evidenced by reported dietary recall and daily intake of 500–700 kilocalories was less than estimated needs.

#### Interventions:

Food and Nutrient Delivery: ND 1.3 Increase fiber and fluid intake

ND 1.2 High calorie, high protein diet

ND 5.7 Initiate meals on wheels

Education: E-1.2 Provide examples of high fiber, high protein foods, and high calcium foods

ND – 6.5 Develop regular schedule for taking iron supplements

Counseling: C-2.5 Discuss social support

C-2.4 Discuss fluid needs and how to practically incorporate them into daily meal plans

Coordination of Care: Contact psychologist to review ongoing depression and meds, make arrangements for dental clinics, refer to social worker for community and financial resources

**Monitoring and Evaluation:** Assess po intake of kilocalories, PRO, and fluid. Monitor weight and labs. Review intake and activity logs. Monitor for changes in BMI over time, fewer infections, and improved quality of life.

- Develop a targeted therapeutic approach to skeletal muscle loss and muscle strength in older persons (Thomas, 2007).
- Establish a nutritional plan according to patient prognosis (Table 10-23).

### FOOD AND NUTRITION

- Monitor physical exam and clinical status to determine needed dietary changes.
- **Mild malnutrition:** Provide sufficient calories and protein, gradually increasing to meet needs. Diet should provide adequate carbohydrate (CHO) and caloric intake to spare protein and correct weight loss. Use tube feeding or CPN, if appropriate (see Section 17). Vitamin-mineral supplementation is recommended.
- **Severe malnutrition or cachexia:** Start treatment with intravenous glucose. Gradually add lactose-treated milk and soft, easily tolerated solids. Provide high-biologic value proteins with sufficient calories that are adequate to use nitrogen effectively. Avoid overfeeding (use 20–25 kcal/kg, progressing gradually to 35–40 kcal/kg). Add a vitamin-mineral supplement, particularly including thiamin. Provide enteral feeding, if needed; start with continuous versus intermittent or bolus feedings at a slow rate until serum electrolyte levels are stable.
- Practical suggestions for improving intake in debilitated patients include liberalizing previous diet restrictions where safe and appropriate, addressing impaired dentition and swallowing, addressing physical and cognitive deficits, encouraging family and friends to provide favorite foods, addressing poor consumption of specific foods, and providing appropriate nutrient supplements (Harris and Fraser, 2004).
- Oral nutritional supplements are feasible in nutritionally depleted patients, particularly between meals.

**TABLE 10-22** Selected Biochemical Changes Observed in Severe Protein–Energy Malnutrition (PEM)

Body Composition	Energy Malnutrition	Protein Malnutrition/ Edema
Total body water	High	High
Extracellular water	High	Higher
Total body potassium	Low	Lower
Total body protein	Low	Low
<b>Serum or plasma</b>		
Transport proteins (transferrin, ceruloplasmin, retinol-, cortisol-, and thyroxine-binding proteins, beta-lipoproteins) <sup>a</sup>	Normal or low	Low
Enzymes such as amylase, alkaline phosphatase	Normal	Low
Transaminase	Normal or high	High
C-reactive protein	Varies by condition	Varies
<b>Liver</b>		
Glycogen	Normal or low	Normal or low
Urea cycle enzymes and other enzymes	Low	Lower
Amino acid synthesizing enzymes	High	Not as high

<sup>a</sup>Note. Inflammatory processes and their effects on hepatic protein metabolism (albumin, transferrin, and transthyretin) have been identified. Serum hepatic protein levels correlate with *severity* of illness but do not accurately measure effectiveness of nutritional repletion (Fuhrman et al, 2004). Evaluate their value cautiously.

**REFERENCES**

Fuhrman MP, et al. Hepatic proteins and nutrition assessment. *Am Diet Assoc.* 104:1258, 2004.  
 Torun B, Viteri F. Protein-energy malnutrition. In: Warren K, Mahmood A, eds. *Tropical and geographical medicine*. 2nd ed. New York: McGraw-Hill, 1990.

- Assure adequate intake of vitamin D<sub>3</sub> from sunlight exposure, diet, and supplements to support gene expression and health.
- Treatment of vitamin D deficiency in otherwise healthy patients with 2000–7000 IU vitamin D per day should be sufficient to maintain year-round 25(OH)D levels in the range of 40–70 ng/mL (Cannell and Hollis, 2009).

**Common Drugs Used and Potential Side Effects**

- Medications that are often used to increase intake by stimulating appetite include oxandrolone (Oxandrin), megestrol acetate (Megace), cyproheptadine HCl (Periactin), and dronabinol (Marinol).
- Experimental therapies for treating cachexia include nonsteroidal antiinflammatory drugs, tumor necrosis factor alpha antagonists, tetrahydrocannabinol, growth hormone, ghrelin, oxandrolone, and omega-3 fatty acids (Gullett et al, 2009). Comparing oxandrolone, strength training, and nutrition alone, strength training is most cost effective and improves quality of life more than nutrition alone or oxandrolone (Shevitz et al, 2005).

**Herbs, Botanicals, and Supplements**

- Herbs and botanical supplements should not be used without discussing it with the physician.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Emphasize the importance of gradual refeeding.
- Discuss the complicating effects of malnutrition. Unless nutritional therapy is aggressive, infection and sepsis are major risks, and surgery becomes life threatening. PEM can increase fistula formation, reduce recovery and wound healing after surgery, and lead to pneumonia or poor drug tolerance.
- Allow patients to participate in feeding decisions. Set goals and help plan together with family.

**Patient Education—Food Safety**

Use of tube feeding or CPN at home warrants training to prevent foodborne illnesses. Handwashing, counter sanitation, and sterile techniques are important in handling these products and the administration kits.

**TABLE 10-23 Poor Prognosis and Consequences of Not Feeding a Patient**

Clinical manifestations of PEM relate to length of time, extent of nutritional deprivation, and prior health status. There are serious detrimental effects on every organ. "When maintained on a prolonged semi-starvation diet, otherwise healthy individuals experience a **loss of heart tissue** that parallels their loss of body mass. Respiratory rate, vital capacity, and minute volume of ventilation also decrease. These **changes in pulmonary function** are thought to result from reduced basal metabolic rate that accompanies starvation. In addition, **liver function declines, kidney filtration rates decline, and nearly every aspect of the immune system is compromised**. Defective ability to fight bacterial and viral infections occurs. Starvation therefore leads to **increased susceptibility to infection, delayed wound healing, reduced rate of drug metabolism, and impairment of both physical and cognitive function**. If starvation is prolonged, complications develop, **leading eventually to death**" (Sullivan, 1995).

Other consequences of not feeding an individual who *will not* or *cannot* eat orally in sufficient amounts include

- **Dehydration** with increased risk of urinary tract infections, fever, swollen tongue, sunken eyeballs, decreased urine output, constipation, nausea, vomiting, decreased blood pressure, mental confusion, and electrolyte disturbances.
- **Decreased awareness** of environment from decreased glucose availability for the brain.
- **Development of new or additional pressure ulcers** over bony prominences from lack of sufficient protein, calorie, vitamin, and mineral intakes and decreased body fat.
- **Decreased ability to participate in activities of daily living** (self-feeding, dressing, bathing, toileting).
- **Low body weight or rapid, involuntary weight loss**, which are highly predictive of illness and imminent death. The elderly are particularly unable to regain weight after a stress situation.

#### REFERENCE

Sullivan D. The role of nutrition in increased morbidity and mortality. *Clin Geriatr Med*. 11:663, 1995.

*Poor prognosis may be seen in individuals with the following conditions who also have PEM:*

Age <6 months

Cachexia from chronic renal failure

Clinical jaundice or elevated serum bilirubin level

Circulatory collapse: cold hands and feet, weak radial pulse, diminished consciousness

Deficit in weight for height >30% or in weight for age >40%

Dehydration and electrolyte disturbances, particularly hypokalemia and severe acidosis

Extensive exudative or exfoliative cutaneous lesions or deep pressure ulcers

Hypoglycemia

Hypothermia

Infections, particularly bronchopneumonia or measles

Petechiae or hemorrhagic tendencies (purpura is usually associated with septicemia or a viral infection)

Persistent tachycardia, signs of heart failure, or respiratory difficulty

Severe anemia with clinical signs of hypoxia

Stupor, coma, or other alterations in awareness

Cachexia is characterized by maladaptive responses such as anorexia, elevated basic metabolic rate, wasting of lean body tissue, and underutilization of fat tissue for energy. Inflammation secondary to cytokines is significant.

## REFEEDING SYNDROME

### NUTRITIONAL ACUITY RANKING: LEVEL 4

#### DEFINITIONS AND BACKGROUND

The effects of starvation are extensive and negatively affect the pituitary gland, thyroid gland, adrenal glands, gonads, and bones (Usdan et al, 2008). Refeeding syndrome (RFS) refers to these various metabolic abnormalities that may complicate carbohydrate and protein administration in undernourished patients, as in anorexia nervosa or head and neck cancer. Other conditions that can lead to refeeding syndrome can be found in Table 10-24.

During refeeding, insulin release is stimulated by the presence of carbohydrate and protein in the gut. Insulin plays a key role in the switch from using up body stores to using food; it stops the release of fat from stores and the production of glucose from protein. In refeeding, the increase in insulin lowers glucagon levels. With gluconeogenesis, glycogenolysis, and fatty acid mobilization, glucose is taken up rapidly into the cells. Phosphorus is driven inside the cells; the result is a dangerous hypophosphatemia. Adenosine triphosphate (ATP) levels drop, with major effects on the cardiac, pulmonary, CNS, hematological, and muscular systems. This process also stops sodium excretion and causes

fluid retention in the first few days of refeeding or when caloric intake is increased.

The typical patient who experiences RFS has been malnourished for days to weeks and develops hypophosphatemia and, occasionally, hypokalemia and hypomagnesemia when administered a carbohydrate load in the form of glucose-concentrated fluids, total parenteral nutrition, tube feedings, or an oral diet (Marinella, 2009). Overwhelming cardiovascular and pulmonary manifestations can accompany refeeding with carbohydrate in chronically malnourished patients (Miller, 2008). Increases in heart rate, blood pressure, oxygen consumption, cardiac output, and an expansion of plasma volume are seen. The response is dependent on the amount of calories, protein, and sodium administered, and the malnourished heart can easily be given a metabolic demand that is too high for it to supply.

Stressed, critically ill patients may be at risk of refeeding following short periods of fasting (Miller, 2008). RFS usually occurs within 4 days of starting to feed again. The respiratory muscle, reduced in mass and ATP content by malnutrition, is unable to respond to the increased workload imposed by aggressive nutrition support. Excess carbon dioxide production and increased oxygen consumption can result from giving too much glucose and overfeeding. A person with malnutrition-induced respiratory muscle wasting can get short of breath and cannot sustain an increased ventilatory drive. Pulmonary edema may develop in some due to increased water load, and this may lead to respiratory failure. Clearly, RFS syndrome is a life-threatening, underdiagnosed but treatable condition (Gariballa, 2008).

Precipitous falls in electrolyte levels in persons with diabetes that occur due to intracellular shifts are a result of the anabolic effects of insulin doses (Parrish, 2009). This form of refeeding is common but not always recognized.

Problems with sodium derangements may lead to heart failure. When potassium shifts into cells, hypokalemia and arrhythmias can occur. When magnesium shifts intracellularly, tetany and seizures may be seen. Thiamin deficiency must be prevented during refeeding, because it is a cofactor in carbohydrate metabolism, important for both the heart and the brain. With thiamin deficiency, there can be signs such as mental confusion, ataxia, muscle weakness, edema,

**TABLE 10-24 Conditions with High Risk for Refeeding Syndrome**

Alcoholism
Anorexia nervosa
Chronic underfeeding
Hepatic failure
Malabsorption from GI damage or chronic use of phosphate binders such as aluminum-containing antacids or sucralfate
Morbid obesity with massive weight loss from fasting
Protein-energy malnutrition
Prolonged fasting
Prolonged parenteral nutrition
Respiratory alkalosis

muscle wasting, tachycardia, and cardiomegaly. Wernicke's encephalopathy can be precipitated by carbohydrate feeding in thiamine-deficient patients.

The gut is also affected by malnutrition, where it begins to atrophy. Activity of the brush border enzymes and pancreatic enzyme secretion return to normal with refeeding, but it requires a period of readaptation to food to minimize GI complaints such as diarrhea, nausea, and vomiting.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Refeeding syndrome is not genetically derived.

Clinical/History	Temperature	Na <sup>+</sup>
Height	Rhabdomyolysis	Chol, Trig
Weight	pCO <sub>2</sub> , pO <sub>2</sub>	H & H
BMI	Respiratory	Serum Fe
Desirable BMI	insufficiency	Red blood cell
Percentage of usual weight	or failure	dysfunction
History of weight changes	Dizziness	Ca <sup>++</sup>
Diet history	Spontaneous diarrhea	BUN, Creat
I & O		Partial pressure of carbon dioxide (pCO <sub>2</sub> )
Anorexia	<b>Lab Work</b>	Partial pressure of oxygen (pO <sub>2</sub> )
Bone pain	Serum phos (low?)	
Edema	Mg <sup>++</sup> (low?)	
Tachycardia	K <sup>+</sup> (low?)	
	Gluc	

## INTERVENTION

### OBJECTIVES

- Correct starvation without overloading the system with nutrients of any type. Use less than full levels of calorie and fluid requirements. Weight gain is not a goal during the first week.
- Advance calories and volume with careful monitoring of cardiac and respiratory side effects.
- Increase nutrition support slowly while assuring adequate amounts of electrolytes. Check electrolytes 2–3 times daily until stable. Organ function and fluid balance also need to be monitored daily during the first week and less frequently after that time.
- Distinguish between constitutional thinness and malnutrition since the causes are different, as are risks for RFS.
- Monitor for neurological, hematological, and metabolic complications of hypokalemia, hypophosphatemia, and hyperglycemia. Prevent sudden death.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Excessive Energy Intake—Refeeding Syndrome

**Assessment Data:** A 60-year old female with a 4-month history of poor dietary intake; connective tissue disease leading to myositis and dysphagia; respiratory failure needing mechanical ventilation. Low baseline electrolyte concentrations, including potassium, magnesium, calcium, and phosphate, and low serum albumin. Twelve hours after starting nasogastric tube feeding, she developed a cardiac arrest from which she was successfully resuscitated. Repeated attempts to wean her from the ventilator failed. BMI low at 16. Clinical nutrition team made the diagnosis of refeeding syndrome.

**Nutrition Diagnosis:** Excessive energy intake related to 4-month history of poor oral food and beverage intake as evidenced by diet history and respiratory failure with need for ventilator dependency.

**Intervention:** Food-nutrient delivery: high-protein, high-fat, low-carbohydrate diet, multivitamin and trace-element supplements, and electrolyte infusion. Education: role of proper pace of refeeding in someone who has been starving recently.

**Monitoring and Evaluation:** Monitor labs 2–3 times daily until labs improve (potassium, magnesium, calcium, and phosphate). Evaluate readiness for ventilator weaning after intake is managed and gradually increased over 14–21 days. Monitor for improvements in weight and BMI.

## FOOD AND NUTRITION

### Refeeding an Adult

- Avoid malnutrition—intervene early and use D5 (5% dextrose) with any saline infusion when patients are designated NPO or are on limited diets for procedures/surgery (Parrish, 2009).
- Start patients at 15–20 cal/kg for the first 3 days, but also start enteral nutrition or total parenteral nutrition at low infusion rates (Parrish, 2009). Feeding can be gradually increased and be up to desired levels by day 7.
- Protein should be started slowly (1.2 g/kg actual weight) and increased gradually to 1.5 g/kg to protect and restore some lean body mass.
- At first, restrict carbohydrate (CHO) intake to 150–200 g/d to prevent a rapid insulin surge. CHO in parenteral nutrition (PN) should be initiated at 2 mg/kg/min (about 150–200 mg/d). Provide insulin as needed to keep blood glucose within a normal range and to protect nutritional stores.
- Fat calories should make up the difference.
- Refeeding results in expansion of the extracellular space, and fluid must be given carefully during the first few days to weeks of refeeding. Weight gain greater than 1 kilogram in the first week is due to fluid retention. Fluid may need to be restricted to 800 to 1000 cc/d. Increases in blood pressure, heart rate, and respiratory rate may be early signs of fluid excess. Adjust when edema exists (e.g., fluid restriction according to I & O, tachycardia, peripheral edema).
- Rather than using boluses of potassium, phosphate, and magnesium via the enteral access, intravenous replacement can be slower and better tolerated (Parrish, 2009).

- Adjust electrolytes depending on laboratory values. Sodium must be given carefully to prevent overexpansion of the extracellular fluid. Additional phosphorus is required; 250–500 mg/d for up to 5–7 days may be needed to replenish. Potassium serum levels should be in the high normal range with 80 to 120 mEq/d needed.
- Magnesium and thiamin should also be given. Supplement with other vitamins and minerals as needed. Excesses are not required.

### Refeeding a Child (Tips from the World Health Organization)

- Refeeding in a child should be through oral or tube feeding, not intravenous feedings. Use 100 kcal/kg actual weight; protein as 1–1.5 g/kg; 100–130 ml/g fluid daily. Breastfeeding may continue, but formula may be given first.
- Starter formula may be made with 300 milliliters of cow's milk, 100 grams of sugar, 20 milliliters of oil, 20 milliliters of electrolyte/mineral solution, and water to make 1000 milliliters. Feed the child every 2 hours at first, gradually decreasing to every 3 hours over the first week. If intake does not reach the 80 kcal/kg goal, then night tube feeding may be needed.
- Return of an appetite is often a first sign that the rehabilitative phase has begun; this may take a week. Continue a gradual increase to avoid heart failure. Increase each feed by 10 milliliters until some remains uneaten, usually around intakes of 200 ml/kg/d.
- After a gradual transition, give frequent feeds with unlimited amounts; 150–220 kcal/kg/d and 4–6 g/kg/d of protein are reasonable estimates. Catch-up formula can be made using 880 milliliters of milk, 75 grams of sugar, 20 milliliters of oil, 20 milliliters of electrolyte/mineral solution, and water to make 1000 milliliters.
- Sensory stimulation and emotional support is also a part of the therapy, so there is a need to provide tender loving care and a cheerful, stimulating environment. Structured play therapy for 15–30 minutes a day and physical activity as soon as the child is well enough are also important.
- The World Health Organization promotes healthy pregnancy in order to avoid chronic disease later in life (WHO, 2009). There is an association between low growth in the first year and an increased risk of CHD. Blood pressure has been found to be highest in those with retarded fetal growth and greater weight gain in infancy.
- Studies of children and health risk have found that the thinnest children, if they became obese as adults, have a greater risk of developing chronic diseases (WHO, 2009). With anorexia nervosa, short stature, osteoporosis, and infertility may be long-lasting complications (Usdan et al, 2008). Short stature may be associated with an increased risk of CHD, stroke, and even diabetes.

### Common Drugs Used and Potential Side Effects

- Monitor specific medications used and their side effects (e.g., gastrointestinal distress).
- Insulin is used to correct hyperglycemia levels. Monitor blood glucose levels as refeeding occurs.
- In clinical practice, it is not uncommon to give patients a 100-mg thiamine bolus daily for 3 days when they are at risk for refeeding syndrome (Francini-Pesenti, 2009; Parrish, 2009). Give the other B-complex and vitamins as well (Mehanna et al, 2009).
- Advances in leptin, ghrelin, and endocannabinoid systems may provide therapeutic breakthroughs. Ghrelin facilitates nutritional restoration and lowering serum leptin may be needed to avoid RFA (Stoving et al, 2009).

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing it with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Provide nutrition education to focus on adequate nutrient intake.
- Consider referral if food insecurity is a concern.
- Offer guidelines according to a discharge intervention plan for use at home or elsewhere. The physician may suggest long-term medication use or therapies.
- Encourage research in this area since evidence is lacking (Mehanna et al, 2009).

### Patient Education—Food Safety

There are no specific food handling techniques that are unique to malnutrition. However, use of tube feeding or CPN at home warrants training to prevent infections.

## OVERVIEW—RHEUMATIC DISORDERS

Adapted from: Porth CM. *Pathophysiology: Concepts of altered health states*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 1998.

Some rheumatic diseases involve connective tissues and others may be caused by autoimmune disorders, where the body attacks its own healthy cells and tissues. See Table 11-1. Rheumatic disorders include osteoarthritis (OA), rheumatoid arthritis (RA), juvenile RA, bursitis, tendonitis, infectious arthritis, spondyloarthropathies, polymyositis, psoriatic arthritis, systemic lupus erythematosus, scleroderma, polymyalgia rheumatica, polyarthritis nodosa, giant cell arteritis, gout, and fibromyalgia. Typically, treatment of these disorders includes a rheumatologist who specializes in the treatment of disorders that affect joints, soft tissue, bones and connective tissues.

Arthritis represents a group of more than 100 different rheumatic diseases that cause stiffness, pain, swelling in the joints, muscles, ligaments, tendons or bones. Over 15% (40 million) of Americans have some form of arthritis. *Spondylosis* is OA of the spine. *Infectious arthritis* is caused by bacterial invasion spread from nearby joints following chickenpox, rubella, or mumps. Autoimmune disorders, Crohn's disease, and psoriasis may cause *seronegative arthritis*. *Mixed connective tissue disease* shows features of RA, cutaneous systemic sclerosis, inflammatory myopathies and Raynaud's syndrome.

Mast cells and basophils are involved in several inflammatory and immune events and are known to produce a broad spectrum of cytokines (Rasheed et al, 2009). The activation of nuclear transcription factor- $\kappa$ B is linked with arthritis, osteoporosis, and psoriasis. The cytokine tumor necrosis factor

<sup>a</sup>When the immune system does not work right, the immune cells can mistake the body's own cells as invaders and attack them; these are called autoimmune diseases. In this table a sample list of body systems affected by autoimmune rheumatic disorders. Adapted from: National Institutes of Health (NIH). NIH Publication No. 02-4858. Available at <http://www.niams.nih.gov/hi/topics/autoimmune/autoimmunity.htm>.

alpha (TNF $\alpha$ ) plays a key role in chronic inflammatory and rheumatic diseases.

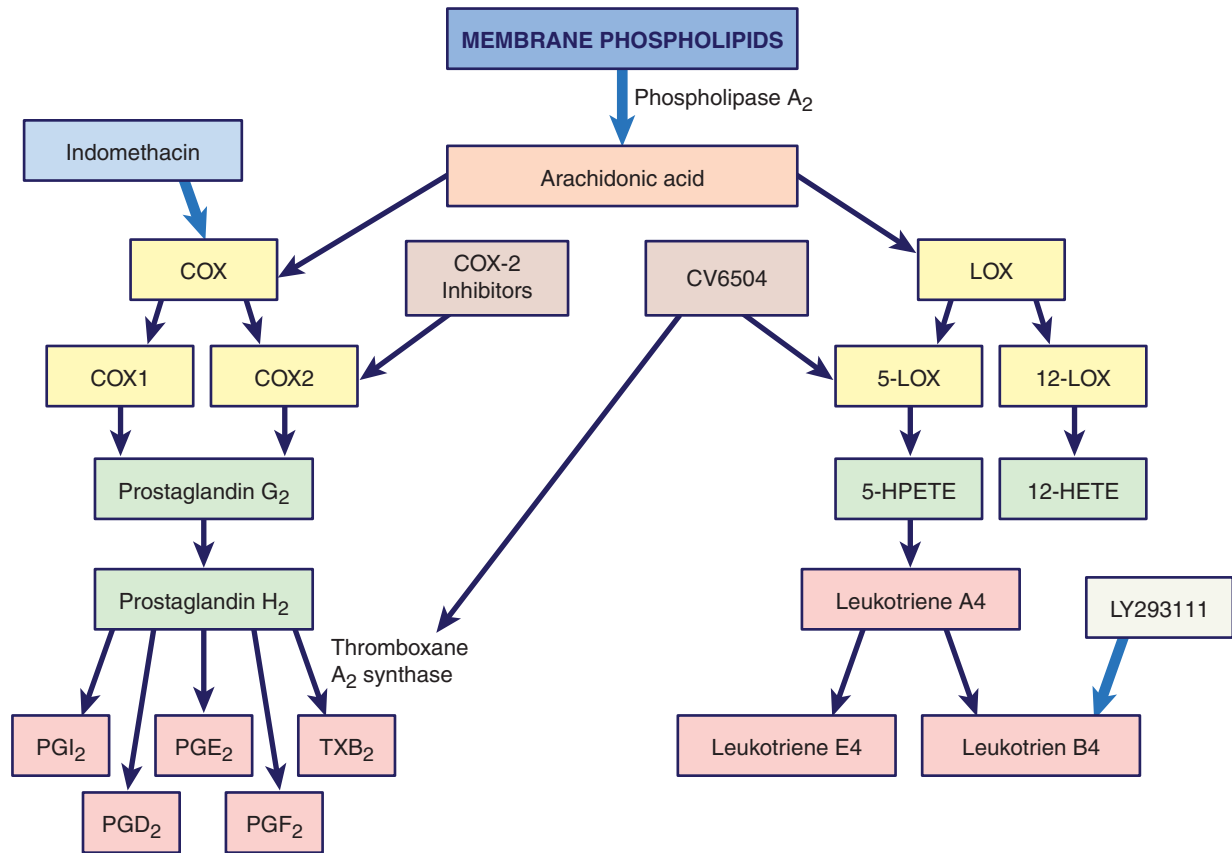

Early recognition and treatment of these disorders are important. RA, juvenile idiopathic arthritis, the seronegative spondyloarthropathies, and lupus may have skeletal pathology (Walsh et al, 2005) and an inflammatory atherosclerosis. A multidisciplinary, multipronged approach is best. Physical and occupational therapies are beneficial for maintaining as much independence as possible in these conditions.

Most rheumatic conditions are managed by use of nonsteroidal anti-inflammatory drugs (NSAIDs) and TNF $\alpha$  antagonists. Etanercept, infliximab, and adalimumab significantly reduce symptoms and improve both functionality and quality of life (Braun et al, 2006; Nash and Florin, 2005). Fortunately, research is on-going for the autoimmune diseases. Gene profiling is helpful, especially in pediatrics (Jarvis, 2005). Osteoimmunology is a new branch of medical science, and anti-inflammatory therapies promise new treatments.

## Role of Inflammation and Fatty Acids

Excessive and inappropriate inflammation contributes to acute and chronic human diseases. It is characterized by the production of inflammatory cytokines, arachidonic

acid-derived eicosanoids (prostaglandins, thromboxanes, leukotrienes, and other oxidized derivatives), other inflammatory agents (e.g., reactive oxygen species), and adhesion molecules (Calder, 2006). Three major types of omega-3 fatty acids are ingested in foods: alpha linolenic acid (ALA), eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA). The body converts ALA to EPA and DHA, which are readily used by the body. Omega-3 fatty acids help reduce inflammation, while omega-6 fatty acids tend to promote inflammation. The precursor ALA does not appear to exert anti-inflammatory effects at achievable intakes (Calder, 2006).

A balance between omega-3 and omega-6 fatty acids in the diet is needed. The proper balance helps maintain and even improve health; one to four times more omega-6 fatty acids than omega-3 fatty acids is desirable, yet people who follow a Western diet consume a higher percentage of omega-6 fatty acids than they should.

Long-chain omega-3 polyunsaturated fatty acids (PUFAs) act by replacing arachidonic acid as an eicosanoid substrate, inhibiting arachidonic acid metabolism; by altering the expression of inflammatory genes through effects on transcription factor activation; and by leading to anti-inflammatory mediators known as resolvins (Calder, 2006).

### Role of Phytochemicals and Total Diet

Phytochemicals known for their ability to protect tissue also appear to block the activity of an enzyme that triggers inflammation in joints. See Table 11-2.

### Complementary and Alternative Medicine (CAM) Therapies

Controlled scientific studies of many patients can prove that a particular treatment is beneficial or that an apparent improvement is incidental. The important consideration is that treatment should do no harm.

Some studies have been done in alternative therapies, particularly diet in the treatment of arthritis, but none have shown any real long-term benefit. Patients often do benefit from complementary therapies, either because the treatment truly works or because of psychological (placebo) effects. While there is evidence of benefit for vitamin C, vitamin D, and nutraceuticals such as glucosamine, chondroitin, S-adenosylmethionine, ginger, and avocado/soybean unsaponifiables (McAlindon, 2006), specific diets and herbal or botanical products should only be used with medical consultation.

While the best nutrition-based strategy for promoting optimal health and reducing the risk of chronic disease is to wisely choose a wide variety of foods, additional nutrients from supplements can help some people meet their nutrition needs (American Dietetic Association, 2009). Physicians reported familiarity with acupuncture (80%), yoga (74%), and Tai-Chi (72%) yet almost all of their patients use CAM therapies (Mak et al, 2009). It is logical, then, that dietetics practitioners must keep up to date on the efficacy, safety, and the regulatory issues in order to provide the best advice.

**TABLE 11-2** Phytochemicals and Dietary Factors Affecting Rheumatic Disorders

Component	Foods or Ingredients	Role
Cruciferous vegetables: broccoli, cauliflower, cabbage, bok choy	Sulforaphane	Boost phase 2 enzymes
Dairy products, low fat	To be identified; vitamin D?	Protective factors against gout (Choi, 2005).
Fruits: pomegranate, cranberry	Anthocyanins, tannins; ellagic acid; resveratrol; quercetin; vitamins A, C; selenium	Potent anti-inflammatory activity (Rasheed et al, 2009).
Long-chain polyunsaturated fatty acids	EPA and DHA	Replace arachidonic acid as an eicosanoid substrate, inhibiting arachidonic acid metabolism. Alter expression of inflammatory genes through effects on transcription factor activation, leading to anti-inflammatory mediators termed resolvins (Calder, 2006).
Mediterranean diet	Resveratrol, olive oil, lower intake of red meat	Protects against severity of rheumatoid arthritis (Choi, 2005).
Spices	Turmeric (curcumin) Red pepper (capsaicin) Cloves (eugenol) Ginger (gingerol) Cumin, anise, and fennel (anethol) Basil, rosemary (ursolic acid) Garlic (diallyl sulfide, ajoene, S-allylmercaptocysteine)	Interrupts pathway for transcription factor- $\kappa$ B (Aggarwal and Shishodia, 2004).
Vitamin D	Hormone affects over 2000 genes	Needed for healthy immune system, gene expression, strong bones.
Total protein and purine-rich vegetables	Neutral	Do not tend to promote gout (Choi, 2005).
Vitamin E, beta-carotene, and retinol.	Neutral	Have NOT been shown to halt the progression of rheumatic disorders
Red meats, seafood, beer, and liquor	Undesirable	Tend to promote symptoms of gout, inflammatory polyarthritis, or rheumatoid arthritis (Choi, 2005).

## OVERVIEW—BONE DISORDERS

Adapted from: Moore KL, Agur AMR. *Essential Clinical Anatomy*, 2nd ed. Baltimore. Lippincott Williams & Wilkins

Bones are living, growing, and changing parts of the body. The human skeletal system consists of bones, cartilage, ligaments, and tendons and accounts for about 20% of the body weight. Osteoblasts are bone-forming cells, osteoclasts resorb or break down bone, and osteocytes are mature bone cells. The osteoblast is an endocrine cell type.

There is a reciprocal regulation of bone and energy metabolism by leptin and osteocalcin. Leptin inhibits insulin secretion by beta cells while osteocalcin favors it (Hinoi et al, 2009). Leptin deficiency leads to increased osteoblast activity and increased bone mass. Expression of the *Esp* gene, exclusive to osteoblasts, regulates glucose homeostasis and adiposity through controlling osteoblastic secretion of osteocalcin (Wolf, 2008). Osteocalcin deficiency leads to decreased insulin and adiponectin secretion, insulin resistance, higher serum glucose levels, and increased adiposity (Wolf, 2008). This recently understood concept has implications for diabetes and the metabolic syndrome.

There are 206 bones in the adult skeleton. The two types of bone tissue (compact and spongy) differ in density. Bone strength is derived from quantity (density and size) and quality (structure, consistency, and turnover). Bone mass is dependent upon individual genetic background. Adequate nutrient intake is needed from birth to achieve maximal bone mass and to prevent osteoporosis later in life.

The trace elements, calcium and phosphorus, are involved in skeletal growth. Parathyroid hormone (PTH) regulates calcium and bone homeostasis; it is expressed in the placenta, regulates the placental expression of genes involved in calcium and other solute transfer, and may directly stimulate placental calcium transfer (Simmonds et al, 2010).

Magnesium and fluoride are matrix constituents while zinc, copper and manganese are components of enzymatic systems involved in matrix turnover. A sufficient protein intake, along with adequate calcium, supports stronger

**TABLE 11-3 Recommendations for Prevention of Osteoporosis**

- Get the recommended amounts of calcium and vitamin D<sub>3</sub> for age and sex; use supplements when diets are inadequate.
- Maintain a healthy weight and be physically active 30+ minutes a day for adults and 60+ minutes a day for children, including weight-bearing activities to improve strength and balance.
- Minimize the risk of falls by removing items that might cause tripping, improving lighting, and encouraging regular exercise and vision tests to improve balance and coordination.
- Risks for patients of all ages should be evaluated by health care professionals. Obtain bone density tests for women over the age of 65 and for any man or woman who suffers even a minor fracture after the age of 50. "Red flags" for someone is at risk include a history of multiple fractures, those who take certain medications, and those who have a disease that can lead to bone loss.
- A BMD test is used to detect osteoporosis before fractures occur, predict chances of future fractures, or determine rate of bone loss and monitor the effects of treatment. The DEXA scan is most common.
- Normal BMD: within 1 standard deviation (SD) of a "young normal" adult.
  - Low bone mass (osteopenia): BMD is between 1 and 2.5 SD below that of a "young normal" adult.
  - Osteoporosis: BMD is 2.5 SD or more below that of a "young normal" adult.

bone density; this fact contradicts past suggestions that high-protein diets deplete bone strength.

Changes in bone turnover markers may become accurate predictors of fracture risk. Assessing risk factors for low bone mass is important in monitoring the etiology of fracture in older individuals (Kelsey et al, 2006). In general, women's bone health has been studied more extensively than that of men. Studies on the predictors of fractures in men are needed, such as bone architecture, morphology, biochemical markers of bone turnover, and hormonal levels (Szulc et al, 2005).

Vitamins are important. Vitamin D<sub>3</sub> plays a role in calcium metabolism. Vitamins C and K are cofactors of key enzymes for skeletal metabolism. Another indicator of bone health is heart health. There are similar pathophysiological mechanisms underlying cardiovascular disease (such as dyslipidemia, oxidative stress, inflammation, hyperhomocysteinemia, hypertension, and diabetes) and low bone mineral density (BMD). Sufficient folic acid, vitamins B<sub>6</sub> and B<sub>12</sub> can help improve bone health by lowering elevated homocysteine levels. Antioxidant nutrients, including vitamins A and C and selenium, play a role in bone health.

While calcium is widely recognized for bone health, other minerals are equally important. Iron promotes production of collagen in bone structure; 18 mg is most protective for women but balance is also critical as too much iron may throw off calcium balance. Finally, silicon in the form of choline-stabilized orthosilicic acid is the bioavailable form that enhances calcium and vitamin D<sub>3</sub> in bone health.

Omega-3 fatty acids such as EPA help increase levels of calcium in the body, deposit calcium in the bones, and improve bone strength. People who are deficient in EFAs EPA and gamma linolenic acid (GLA) are more prone to bone loss.

Former U.S. Surgeon General Richard H. Carmona (2005) warned in a landmark report that, by 2020, half of all American citizens older than 50 would be at risk for fractures from osteoporosis and low bone mass if immediate action is delayed by individuals at risk, doctors, health systems, or policymakers. At least 10 million Americans over the age of 50 have osteoporosis, another 34 million are at risk for developing osteoporosis, and roughly 1.5 million people have suffered a bone fracture related to osteoporosis. About 20% of senior citizens who suffer a hip fracture die within a year of fracture; another 20% of individuals with a hip fracture end up in a nursing home. Hip fractures account for 300,000 hospitalizations each year. See Table 11-3 for recommendations to prevent osteoporosis.

# ANKYLOSING SPONDYLITIS (SPINAL ARTHRITIS)

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Carol Mattson Porth, *Pathophysiology Concepts of Altered Health States*, 7th ed. Philadelphia: Lippincott Williams & Wilkins, 2005.

### DEFINITIONS AND BACKGROUND

Among the 100 different rheumatic diseases that affect the joints and muscles is a group of five called **spondyloarthropathies**. These include ankylosing spondylitis, reactive arthritis (Reiter's syndrome), psoriatic arthritis or spondylitis, spondylitis of inflammatory bowel disease, and undifferentiated spondyloarthropathy. Spondylitis is inflammation of the joints linking the vertebrae (a fused spine is not uncommon). Spondylitis affects about 300,000 Americans and is more common in Caucasians than in African Americans. The condition is most common in men aged 16–35 years and may run in families.

In **ankylosing spondylitis**, inflammation of connective tissue recedes but leaves hardened and damaged joints that fuse together the bones of the spinal column. The sacroiliac joints generally are affected first. Symptoms and signs include chronic lower back pain, early morning stiffness in the lower back where the lower spine is joined to pelvis, vague chest pains, tender heels, weight loss, anemia, anorexia, slight fever, recurring iritis or reddened eyes, valvular heart disease. Pain may occasionally start in the knees and shoulders. There is a strong link between the bowel and the osteo-articular system, notably with the HLA-B27 gene where there are symptoms such as abnormal antigen presentation,

the presence of autoantibodies against specific antigens shared by the colon and other extra-colonic tissues, increased intestinal permeability, osteoporosis and osteomalacia secondary to IBD (Rodriguez-Reyna et al, 2009).

Elevated tumor necrosis factor alpha (TNF $\alpha$ ) is believed to be one of the causes of inflammation and bone destruction (Braun et al, 2006); therefore, anti-TNF therapy is effective (Barkham et al, 2005). Exercise to strengthen muscles that tend to cause pain on stooping or bending may be useful to relieve lower back pain. Attention to good posture will reduce some types of pain. Surgery may be needed to replace a joint or to relieve pain.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Genetic marker HLA-B27 can be detected in these individuals.

#### Clinical/History

Height  
Weight  
Body mass index (BMI)  
Weight changes  
Anorexia  
Fever?  
Lower back pain  
Pain in knees or shoulders  
Iritis or reddened eyes  
X-rays

Erythrocyte sedimentation rate (ESR) (high)  
C-reactive protein (CRP)  
Ca<sup>++</sup>, Mg<sup>++</sup>  
Na<sup>+</sup>, K<sup>+</sup>  
Alkaline phosphatase (Alk phos)  
Blood urea nitrogen (BUN)  
Creatinine (Creat)  
Phosphorus (P)

Hemoglobin and hematocrit (H & H)  
Aspartate aminotransferase (AST)  
Alanine aminotransferase (ALT)  
Serum folate and B<sub>12</sub>  
Homocysteine levels  
Vitamin D<sub>3</sub> status (serum 25-OHD)

#### Lab Work

HLA-B27 gene test (positive in 90%)

### INTERVENTION

#### OBJECTIVES

- Reduce pain, inflammation, and disease activity; support improved functioning and ability to work or to maintain quality of life.
- Correct anorexia, nausea, poor intake or weight loss, anemia, or fever where present.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Unintentional Weight Loss

**Assessment:** Loss of 15 lb this past 6 months, much pain and inflammation with ankylosing spondylitis, taking numerous medicines that cause GI distress and anorexia.

**Nutrition Diagnosis (PES):** Unintentional weight loss (NC-1.4) related to pain, inflammatory processes, and GI distress and evidenced by 15-lb unplanned weight loss in past 6 months.

**Interventions:**

Food and Nutrient Delivery: ND 1.2 Alter diet as tolerated. ND 32.3 and 32.4 Initiate vitamin and mineral supplementation.

Education: E-1.2 Discuss ways to increase energy and nutrient density in food choices.

Counseling: C 2.2 Agree to goal of consuming only nutrient-dense foods for the coming month until next visit. C-2.3 Keep a food diary for one month.

**Monitoring and Evaluation:** Review food diary after 1 month. Monitor weight for resolution of weight loss; goal is gain of 1–2 lb weekly.

- Improve ability to participate in physical activities of choice to maintain lean body mass.

## FOOD AND NUTRITION

- A normal diet is useful. Support gradual weight loss, if needed, to normalize weight. Some patients claim relief while using a vegetarian diet with less red meat.
- Preferred foods should be offered to stimulate appetite.
- Increase intake of foods rich in antioxidants such as vitamins E and C, selenium, and fish oils for rich sources of omega-3 fatty acids. Sufficient calcium and vitamin D are also important.
- Include phytochemicals derived from spices such as turmeric (curcumin); red pepper (capsaicin); cloves (eugenol); ginger (gingerol); cumin, anise, and fennel (anethol); basil and rosemary (ursolic acid); garlic (diallyl sulfide, S-allylmercaptocysteine, ajoene); and pomegranate (ellagic acid) (Aggarwal and Shishodia, 2004).

## Common Drugs Used and Potential Side Effects

- Sulfasalazine, methotrexate, azathioprine, cyclosporine, leflunomide, and tumor necrosis factor-alpha blocking agents can be considered as first-line therapy but there are possible harmful effects on intestinal integrity, permeability, and even on gut inflammation (Rodriguez-Reyna et al, 2009).

- Etanercept (Enbrel), an anti-TNF therapy, may improve mobility and quality of life (Braun et al, 2006; Davis et al, 2005; Temel et al, 2005). Infliximab (Remicade), another monoclonal antibody, also targets TNF $\alpha$  and provides clinical improvement. Upper respiratory infections, psoriatic rashes, and allergic reactions can occur.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician. Ginger, corn, pineapple, and pigweed have been recommended; no clinical trials prove efficacy.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Exercise is crucial, especially swimming, to relieve back pain.
- Patient should practice deep breathing exercises for pain relief. Stretching and strengthening exercises also are important.
- Patient will likely find that sleeping on a hard bed, supine, is most helpful.
- Discuss role of energy intake for weight control.

## Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# GOUT

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Rubin E MD and Farber JL MD. *Pathology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 1999.

### DEFINITIONS AND BACKGROUND

Uric acid is the end product of purine metabolism. Because humans have lost hepatic uricase activity, this leads to uniquely high serum uric acid concentrations when compared with other mammals. About 70% of daily urate disposal occurs via the kidneys; in 5–25% of the human population, impaired renal excretion leads to hyperuricemia.

Gout is a disorder of sudden and recurring attacks of painful arthritis with inflamed joints (usually the big toe, ankle, knees, and feet). Hyperuricemia promotes deposition of monosodium urate crystals in the joints and tendons. Gout affects more than 1% of adults in the United States and is the most common form of inflammatory arthritis among men (Saag and Choi, 2006). The disease tends to affect men between the ages of 30 and 50 years and is often hereditary.

Risks include genetic factors; high intake of seafood and red meats (Choi et al, 2005; Johnson et al, 2005) as well as beer and fructose (Doherty, 2009). Higher intakes of coffee, low-fat dairy products, and vitamin C are associated with lower risk (Doherty, 2009). See Table 11-4 for other etiologies of hyperuricemia. Gout prevalence increases in direct association with age, metabolic syndrome, hypertension, and use of thiazide diuretics (Saag and Choi, 2006). There is increased incidence in postmenopausal women, with polyarticular onset, hand involvement, and development of tophi (Ene-Stroescu and Gorbien, 2005). Tophi are hard lumps of urate crystals that are deposited under the skin around the joints and may be permanent.

Acute attacks may be triggered by surgery, sudden and severe illness, fasting, chemotherapy, or joint injury. Acute gout most commonly affects the first metatarsal joint of the foot, but other joints may also be involved. The joint swells, and skin turns warm, red, purplish, and shiny. Severe pain usually occurs, more so at night.

Gout progresses from asymptomatic hyperuricemia to acute gouty arthritis, intercritical gout (intervals between acute attacks), and finally to chronic tophaceous gout. Tophi

**TABLE 11-4 Acquired Causes of Hyperuricemia**

Cause	Description
<b>Increased urate production</b>	
Nutritional	Excess ethanol or fructose intake
Hematological	Myeloproliferative and lymphoproliferative disorders, polycythemia
Drugs	Ethanol, cytotoxic drugs, vitamin B <sub>12</sub> (treatment of pernicious anemia)
Miscellaneous	Obesity, psoriasis, hypertriglyceridemia
<b>Decreased renal excretion of urate</b>	
Drugs	Ethanol, cyclosporine (Sandimmune), thiazides, furosemide (Lasix) and other loop diuretics, ethambutol (Myambutol), pyrazinamide, aspirin (low-dose), levodopa (Larodopa), nicotinic acid (Nicolar)
Renal	Hypertension, polycystic kidney disease, chronic renal failure (any etiology)
Metabolic/endocrine	Dehydration, lactic acidosis, ketosis, hypothyroidism, hyperparathyroidism
Miscellaneous	Obesity, sarcoidosis, toxemia of pregnancy

Adapted from: Harris M, et al. Gout and hyperuricemia. *Am Fam Physician*. 59:925, 1999.

may develop if the condition goes untreated. Although attacks of gout can subside in a few days, repeated attacks can cause permanent joint damage, and the disease often results in substantial disability and frequent medical care.

Treatment includes the pain-relieving NSAIDs and, for more serious outbreaks, corticosteroids. Most patients with gout eventually require long-term treatment with medications that lower blood uric acid levels. Patients with asymptomatic hyperuricemia should lower their urate levels by changes in diet or lifestyle.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** About 10% of people with hyperuricemia develop gout. Genetic variants within the transporter gene, SLC2A9 (GLUT9), affect both fructose and uric acid transport. Other renal urate transporters have been identified, including URAT1.

Clinical/History	Obesity	Urate crystals in urine
Height	Swollen, painful big toe (podagra)	Use of thiazide diuretics?
Weight		
BMI	Arthritis	

Tophus, suspected or proven	Birefringent crystals in the synovial fluid	Ca <sup>++</sup> , Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup>
Asymmetrical swelling within a joint on X-ray	BUN (increased) Cholesterol (Chol) Triglycerides (increased?)	Albumin (Alb) Creat Glucose (Gluc) AST, ALT Vitamin D <sub>3</sub> status (serum 25-OHD)
<b>Lab Work</b>		
CRP		
Uric acid (increased)		

## INTERVENTION

### OBJECTIVES

- Lower bodily stores of uric acid crystal deposits to prevent the inflammatory processes and structural alterations. Increase excretion of urates and force fluid intake to prevent uric acid kidney stones.
- Data from NHANES III show a remarkably high prevalence of the metabolic syndrome among individuals with gout, along with an increased risk of myocardial infarction and cardiovascular mortality (Hak and Choi, 2008). Encourage lifestyle changes including reduction in energy intake, weight, alcohol intake, red meat intake.
- Promote gradual weight loss. In the obese, controlled weight management has the potential to lower serum urate (Schlesinger, 2005).
- Correct any existing dyslipidemia and prevent complications such as renal disease, hypertension, and stroke.

### FOOD AND NUTRITION

- A low-fat, high-carbohydrate (CHO) diet increases excretion of urates. Vegetables such as peas, mushrooms,

cauliflower, and spinach yield a protective effect (Choi, 2005).

- Develop a weight loss plan if needed.
- Avoid excessive intake of seafood such as anchovies, sardines, caviar, and herring. Reduce intake of beef, pork, duck, bacon, turkey, and ham.
- Ensure a high-fluid intake, especially water and skim milk. Nonfat milk, low-fat yogurt, dairy products, fruits such as cherries, and high intakes of vegetable protein may reduce serum urate (Schlesinger, 2005).
- Use of 4+ cups of coffee per day should be recommended (Choi and Curhan, 2007).
- Exclude alcoholic beverages (Schlesinger, 2005) and fructose or sugar-sweetened soft drinks (Choi et al, 2008).
- Use antioxidant-rich foods such as pomegranate, raspberries, and strawberries.

### Common Drugs Used and Potential Side Effects

- Uricosuric drugs: Probenecid (Benemid) and sulfinpyrazone (Anturane) block renal absorption of urates. Serum uric acid levels should be kept below 360  $\mu\text{mol/L}$  (6 mg/dL). Use adequate fluid.

Anorexia, nausea, vomiting, and sore gums may result.

- The medication febuxostat (Uloric) shows promise.
- Xanthine oxidase inhibitors: Allopurinol (Aloprim) blocks uric acid formation. Adequate intake of fluid is needed. Mild gastrointestinal (GI) upset, taste changes, or diarrhea can occur; take after meals. Febuxostat is even more effective than allopurinol; side effects are transient (Schumacher, 2005).
- During more serious outbreaks, NSAIDs, colchicine (Colcrys), and corticosteroids (prednison) may be prescribed for short-term use.
- Medications that can increase uric acid levels include hydrochlorothiazide (a diuretic) and some transplantation medications (cyclosporine and tacrolimus). Monitor for signs of gout.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Celery, avocado, turmeric, cat's claw, chiso, and devil's claw have been recommended; there are no clinical trials that prove efficacy.
- Vitamin C shows some effectiveness; 1000 mg may be beneficial in preventing gouty attacks (Gao et al, 2008).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The inflammatory response may be suppressed by omega-3 fatty acids from fish oils and from walnuts, flaxseed, and cherries. Use these foods several times a week.
- Alcohol, beef, sardines, anchovies, and pork may precipitate a gouty attack (Choi et al, 2005). Otherwise, there is little need for a traditional "low purine" diet (Hayman and Marcason, 2009).

### SAMPLE NUTRITION DIAGNOSES

#### Excessive Alcohol Intake

**Assessment Data:** Diet history and food records, medication history, alcohol and fluid intake.

**Nutrition Diagnosis (PES):** Excessive alcohol intake related to consuming large amounts of alcohol (36 oz whiskey daily) as evidenced by recent painful flare of gout with hyperuricemia.

**Intervention:** Food-nutrient delivery—Decrease alcohol intake (ND 3.3). Education: Discuss role of proteins, alcohol, diet, fluid intake, and medications in managing gout. Counseling: Motivational interviewing and goal setting with patient (C 2.1, 2.2) to implement recommended lifestyle modifications into daily plan.

**Monitoring and Evaluation:** Evaluation of alcohol intake records; improvement in symptoms of gout. Monitor need for additional education/counseling. Evaluate for decrease in uric acid levels and lower frequency of gouty attacks.

- Weight loss may be helpful, but avoid fasting. Instruct patient to lose weight gradually.
- Discuss the importance of adequate fluid ingestion. Recommend coffee intake (Choi and Curhan, 2007). Avoid sugar-sweetened soft drinks and fructose, but diet soft drinks are acceptable (Choi et al, 2008; Hak and Choi, 2008).
- Aim to drink at least a half gallon of water and skim milk daily.

### Patient Education—Food Safety

If enteral or parenteral nutrition is needed, sanitation and handwashing are essential.

## IMMOBILIZATION

### NUTRITIONAL ACUITY RANKING: LEVEL 2

#### DEFINITIONS AND BACKGROUND

Extended periods of immobilization, for various reasons, may be nutritionally depleting. Patients with orthopedic injuries may lose 15–20 lb from stress, immobilization, trauma, and bed rest. Prolonged immobilization and nonuse of lower and upper limb muscles may cause atrophy. Nitrogen depletion can be extensive. A large nitrogen loss and high protein oxidation can be related to extensive injury and elevated energy expenditure.

Unloading of weight-bearing bones induced by immobilization has significant impacts on calcium and bone metabolism. Immobilization hypercalcemia involves nausea, vomiting, abdominal cramps, constipation, headache, and lethargy.

Persons with physical disabilities frequently are nonambulatory and have bone loss due to immobility. Prevention of osteoporosis and related fractures in this population includes calcium and vitamin D supplementation and risk-based screening. With careful attention to functional capacity enhancements, bone mass can be restored (Rittweger et al, 2005).

In older individuals, sarcopenia is the result of excessive loss of muscle mass and strength, loss of mobility, neuromuscular impairment, and balance failure. Falls and fractures can lead to immobilization, which induces more loss of muscle mass.

One final group at risk for the consequences of immobilization are those individuals who are in intensive care units (ICU) for a prolonged period. There is a need for physical therapy, as possible, to avoid a long recovery.

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Immobilization is usually from injury or other nongenetic causes, but may be a side effect of certain diseases with a genetic origin, such as spina bifida.

Clinical/History	Dual-energy	Lab Work
Height or arm length/knee length	x-ray absorptiometry (DEXA)	H & H
Weight	Decreased range of motion?	Alb
BMI	Contractures; stiff joints?	Transthyretin, retinol-binding protein (RBP)
Weight changes	Blood clots	CRP
Triceps skinfold (TSF)	Pressure ulcers	Nitrogen (N) balance
Midarm muscle circumference (MAMC)	Constipation	Ca <sup>++</sup>
Midarm circumference (MAC)	Indigestion, anorexia?	(increased?)
	Depression?	Parathormone (PTH)
	Change in quality of life?	

Urinary $\text{Ca}^{++}$ (high?)	Alk phos $\text{Mg}^{++}$	BUN, Creat $\text{Na}^+$ , $\text{K}^+$
Vitamin $\text{D}_3$ status (serum 25-OHD)	Red blood cell (RBC) count	

## INTERVENTION

### OBJECTIVES

- Correct negative nitrogen balance from increased losses (perhaps up to 2–3 g of nitrogen per day) to prevent pressure ulcers and infections. Moderate exercise is beneficial in altering the inflammatory milieu associated with immobility, and in improving muscle strength and physical function (Truong et al, 2009).
- Correct anorexia, indigestion, constipation.
- Prevent deossification and osteoporosis of bones. Prevent hypercalcemia from low serum levels of albumin, which normally binds calcium.
- Prevent kidney and bladder stones, urinary tract infections.
- Provide adequate fluid intake to aid excretion of nutrients.
- Prevent constipation, impactions, and obstruction.
- Prevent anemias that result from inadequate nitrogen balance.
- Prevent venous thrombosis (McManus et al, 2009).
- Improve or sustain a positive quality of life.

## FOOD AND NUTRITION

- Diet should provide adequate intake of high-biological value proteins to correct nitrogen balance. An intake of 1.2 g protein/kg body weight is often recommended. Provide adequate energy to spare protein; use sufficient carbohydrates and fats, including 1–2% total kilocalories as essential fatty acids (EFAs).
- Encourage adequate intake of calcium since a high-protein diet raises the body's calcium requirements. Increased

### SAMPLE NUTRITION DIAGNOSES

#### Physical Inactivity

**Assessment Data:** Diet history, food records, medication history, fluid intake. New paraplegia following motorcycle accident.

**Nutrition Diagnosis (PES):** Physical inactivity (NB 2.1) related to paraplegia as evidenced by inability to walk voluntarily after motorcycle accident.

**Intervention:** Food-nutrient delivery—Offer food preferences to maintain desired intake; monitor calcium and protein intake in particular. Education: Discuss importance of physical therapy and nutrition in maintaining as much lean body mass as possible.

**Monitoring and Evaluation:** Evaluate ability to tolerate sufficient physical therapy to maintain adequate skin integrity, muscle mass, and urinary tract function; ability to achieve desirable nitrogen and calcium balance.

intake of phosphorus during the first few weeks may be useful.

- Diet should provide a high-fluid intake.
- Intake of vitamin C and zinc should be adequate to protect against skin breakdown.
- Diet should provide adequate amounts of fiber to prevent constipation. Avoid overuse of fiber in cases where there is impaction.

## Common Drugs Used and Potential Side Effects

- Medications may be used to treat underlying conditions; they may have side effects that contribute to nutrient losses.
- Take pain medications as directed to maintain relief of pain, rather than only taking them when you feel very badly.
- Immobilization-induced hypercalcemia affects bone metabolism in Parkinson's disease; this inhibits secretion of PTH, which in turn suppresses 1,25-dihydroxyvitamin D production (Sato et al, 2005). These abnormalities may be corrected by the suppression of bone resorption with bisphosphonate; supplementations of calcium and vitamin D should be avoided in these patients (Sato et al, 2005).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain that calcium and nutrient intakes will have to be monitored for patients who will be tube fed or on a liquid diet for extended periods of time.
- Explain the need for adequate fiber and fluid (2–3 L) to prevent constipation, urinary tract infections, and so on. Early ambulation is the best treatment possible.
- Because prolonged bed rest in the ICU affects the development of ICU-acquired weakness, early mobility requires a reduction in heavy sedation and bed rest (Truong et al, 2009). Identify strengths and limitations, and alternate rest periods with activity. Do range of motion exercises every day.
- Monitor and report to a physician any symptoms such as pain and fatigue upon movement, new numbness in legs or arms, loss of motor strength, increased weakness, loss of bowel or bladder control, increased pain on movement.

### Patient Education—Food Safety

If enteral or parenteral nutrition is needed, sanitation and handwashing are essential.

## LUPUS

## NUTRITIONAL ACUITY RANKING: LEVEL 2

## DEFINITIONS AND BACKGROUND

Lupus is an autoimmune disorder that involves areas of inflammation of the joints, tendons, other connective tissues, and skin. A pathologic CD4+T cell subset with impaired extracellular signal-regulated kinase (ERK) pathway signaling, DNA hypomethylation, and consequent aberrant gene expression contributes to disease pathogenesis (Gorelik and Richardson, 2010).

There are four types of lupus: neonatal, discoid, systemic, and drug induced. The systemic form (SLE) is the most common. One to two million people have lupus, especially Latino, African American, and Native American women, with onset in the late teens to thirties. For most people, lupus is a mild disease affecting only a few organs; for some, it may cause serious and even life-threatening problems. Because lupus has symptoms that mimic other disorders, careful diagnosis is important. Lupus may show symptoms similar to those of celiac disease.

Infections can bring on a lupus flare, increasing the risk of even more infections. Other environmental factors that may trigger the disease include antibiotics (especially sulfa and penicillin), other drugs, and exposure to phthalate in toys, plastics, and beauty products.

Active lupus contributes to coronary heart disease (CHD) risk (Haque et al, 2010). Premature cardiovascular disease in SLE patients is a consequence of inflammation. Type I interferons stimulate the cascade of atherosclerotic development, starting with endothelial damage and abnormal vascular repair (Von Feldt, 2008).

SLE is characterized by autoantibodies to nuclear antigens and immune complex deposition in organs such as the kidney (Gorelik and Richardson, 2010). Lupus nephritis is the term for this form of kidney disease that occurs. About a third of patients with lupus will develop it, requiring medical evaluation and nutritional management.

A cure for lupus is not yet possible, but treatments allow a more normal life. The use of methotrexate can reduce the dependency on steroids, which is desirable (Fortin et al, 2008). Antioxidant interventions have been studied extensively and show promise. Finally, supplementation with fish oil may reduce symptomatic disease activity.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Persons with close family members who have lupus have a 10 times greater frequency than the general population. Alleles in the TYK2 gene have been associated with SLE as well as multiple sclerosis.

<b>Clinical/History</b>	Achy joints (arthralgia)	Antibodies to double-stranded DNA
Height	Swollen and painful joints (nonerosive arthritis)	Serum copper (increased)
Weight	Protein or cellular casts in urine	Total protein (decreased)
BMI	Swollen ankles	WBC (decreased)
BP	Dry eyes	Gluc (increased)
I & O	Easy bruising	Low platelet count
Fever over 100°F	<b>Lab Work</b>	H & H, serum ferritin (decreased)
Seizures and cognitive dysfunction	LE prep	Transferrin
Butterfly rash across cheeks and nose	ESR or CRP (elevated?)	Chol (increased)
Skin rashes, red raised patches	Complement protein test (C3, C4, CH50, CH100)	BUN, Creat
Photosensitivity	INR, abnormal blood clotting	Specific gravity, urine (decreased)
Painless mouth or nose ulcers	Positive anti-nuclear antibody test (ANA)	Alb, transthyretin
Pale or purple fingers from cold or stress (Raynaud's syndrome)		Ca <sup>++</sup> , Mg <sup>++</sup>
Unusual hair loss		Na <sup>+</sup> , K <sup>+</sup>
Pleuritis or pericarditis		Vitamin D <sub>3</sub> status (serum 25-OHD)
Fatigue, prolonged		

## INTERVENTION

### OBJECTIVES

- Counteract steroid therapy; replenish potassium and nutrient reserves.
- Reduce fever and replace nutrient losses and weight loss.
- Control disease manifestations.
- Manage cardiac effects. Accelerated atherosclerosis and premature CHD are recognized complications (Haque et al, 2010). Pericarditis is also common, with shortness of breath and chest pain.
- Rule out gluten intolerance.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Drug–Nutrient Interaction

**Assessment Data:** Weight and medical histories; medications; altered lab values for calcium, potassium. Complaints of swollen ankles and fluid retention.

**Nutrition Diagnosis (PES):** Drug–nutrient interaction related to prolonged use of corticosteroids for lupus as evidenced by osteopenia, low serum calcium and potassium, negative nitrogen balance and sodium–fluid retention.

**Intervention:** Food–nutrient delivery—Alter dietary intake to increase protein-rich foods, sources of potassium and calcium; decrease sodium intake. Education about the importance of managing specific nutrients while taking steroid medications (i.e., protein, calcium, potassium) and decreasing sodium-rich foods. Counseling about how to apply the DASH diet principles, which may be helpful.

**Monitoring and Evaluation:** Fewer complaints of swollen ankles and fluid retention; improved lab values related to calcium, potassium, and nitrogen balance studies.

- Prevent or manage infections, such as urinary tract infections, shingles, respiratory infections such as colds, yeast infections, salmonella and herpes.

## FOOD AND NUTRITION

- Diet should be adequate in protein and energy during fever.
- When renal disease is present, diet should be adjusted. Check lab values regularly.
- Alter diet, if needed, to lower blood pressure (BP) levels or excess weight. Mildly restrict sodium intake and monitor for potassium and phosphorus changes.
- Dietary nutrients may modify clinical course of disease. Vitamin C intake may prevent the occurrence of active disease; use a multivitamin–mineral supplement.
- Anemia is often present. Vitamin B<sub>12</sub>, dietary fiber, iron, calcium, and folate may be low in the diets of lupus patients. However, avoid excessive doses of supplements; use DRI levels.
- Use a nutrient-rich diet that includes nuts, fish and fish oils, olive oil, fruits, vegetables, and whole grains that are rich in phytochemicals, omega-3 fatty acids, and antioxidants. Include phytochemicals derived from spices (see Table 11-2).
- If gluten intolerance is present, provide a gluten-free nutrition plan.

### Common Drugs Used and Potential Side Effects

- Benlysta (belimumab), is a new drug developed specifically for people with systemic lupus. Many other drugs are in clinical trials.

- Steroid therapy may cause sodium retention, hyperglycemia, potassium and calcium depletion, and negative nitrogen balance. Side effects include weight gain, a round face, acne, easy bruising, fractures or osteoporosis, hypertension, cataracts, hyperglycemia or onset of diabetes, increased risk of infection, and stomach ulcers. Fish oil supplements may allow gradual reduction in use of steroids.
- Methotrexate (Rheumatrex) confers an advantage in participants with moderately active lupus by lowering daily prednisone dose and slightly decreasing lupus disease activity (Fortin et al 2008).
- Corticosteroid and cytotoxic drugs affect the immune system over time, making the individual prone to more infections. Immunosuppressive agents such as azathioprine (Imuran) and cyclophosphamide (Cytoxan) or methotrexate are used to control the overactive immune system but they have GI side effects.
- NSAIDs and acetaminophen may be useful.
- Sunscreens are needed to protect against the sun's harmful rays; there are no systemic side effects.
- Antimalarials, such as chloroquine (Aralen) or hydroxychloroquine (Plaquenil), may be used for skin and joint symptoms of lupus. Side effects are rare and consist of occasional diarrhea or rashes. Chloroquine can affect the eyes. Hydroxychloroquine may cause anorexia, nausea, abdominal cramps, and diarrhea.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Coumestrol, a natural phytoestrogen, may relieve some symptoms.
- Use of indoles, conjugated linolenic acid (CLA), and vitamins C, E, and D may be beneficial.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Ensure patient has an adequate intake of fluids during febrile periods.
- Explain which foods are sources of sodium and potassium in the diet.
- Adequate rest is needed during flare-ups.
- Cortisone creams may be needed for persistent skin rashes. Sunblock should be used outdoors.
- Discuss how to manage diet for elevated blood glucose; insulin may be needed. Carbohydrate counting may be useful.
- Regular doctor visits and lab tests are important, especially blood and urine testing.
- Dietary strategies for the prevention of obesity, osteoporosis, and dyslipidemia deserve attention. Weight loss plans may be needed.

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# MUSCULAR DYSTROPHY

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Actually a group of nine disorders, muscular dystrophy (MD) involves a hereditary condition with progressive degenerative changes in the muscle fibers, leading to weakness and atrophy. Most of the disorders are described in Table 11-5.

Muscular biopsy is required for the definitive diagnosis of the specific congenital type. BMI should be used with caution for the evaluation of the nutritional status of patients with Duchenne MD (DMD); assessment of the compartmental distribution of muscle and fat are more sensitive. Extremely elevated serum creatine kinase (CK) levels may indicate muscle disease. In the late stages, fat and connective tissue may replace muscle fibers.

Patients with MD may be prone to nutrient deficiency due to mobility limitations or oropharyngeal weakness (Motlagh et al, 2005). Micronutrient requirements are yet to be determined but, as a result of corticosteroid treatment, vitamin D and calcium should be supplemented (Davidson and Truby, 2009).

Many patients demonstrate inadequate nutrient intake of protein, energy, vitamins (especially E), and minerals (calcium, selenium, and magnesium), and significant correlations exist between measures of strength and copper and water-soluble vitamins (Motlagh et al, 2005).

Delayed growth, short stature, muscle wasting, and increased fat mass are characteristics that impact on nutritional status and energy requirements (Davidson and Truby, 2009). There may be loss of muscle mass, wasting, which may be hard to see because some types of MD cause a build-up of fat and connective tissue that makes the muscle appear larger (pseudohypertrophy).

Gene therapy, gene silencing, and cell therapy are potential therapies for MD patients. Some evidence exists supporting supplementation with creatine monohydrate to improve muscle strength (Davidson and Truby, 2009). Creatinine as a marker of renal function has limited value in DMD because of reduced muscle mass. There is potential value of cystatin C as a biomarker for monitoring renal function (Violett et al, 2009).

The prognosis of MD varies according to type and progression. Some cases may be mild and very slowly progressive, with a normal lifespan. Other cases may have more marked progression of muscle weakness, functional disability, and loss of ambulation. Life expectancy often depends on the degree of progression and late respiratory deficit. In DMD, death often occurs in the late teens or early twenties. Rehabilitation, orthopedic, respiratory, cardiovascular, gastroenterology, nutrition, pain issues, as well as general surgical and emergency-room considerations are essential to address (Bushby et al, 2010).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Dystrophinopathies are due to a genetic defect of the protein dystrophin. Genetic counseling is advised when there is a family history of MD. Note that DMD can be detected by genetic studies performed during pregnancy.

Clinical/History	Eyelid drooping (ptosis)	(LDH), increased
Height	Dysphagia?	Cystatin C
Weight	Drooling	Myoglobin-urine/serum
BMI (use only with other parameters)	Chewing difficulty?	Creat (often decreased)
MAC, MAMC, TSF	Hand-to-mouth coordination	Aldolase, AST (altered)
Muscle weakness	Electromyography (EMG)	BUN
Apparent lack of coordination	Electrocardiography (ECG)	N balance
Progressive crippling	DEXA	Alb, transthyretin
Scoliosis?		CRP
Contractures of the muscles around the joints	<b>Lab Work</b>	H & H, serum ferritin
Clubfoot or clawhand?	Muscle biopsy	Serum P
Hypotonia	Creatine phosphokinase (CPK), increased?	Gluc
Loss of mobility	Lactate dehydrogenase	AST, ALT
		Ca <sup>++</sup> , Mg <sup>++</sup>
		Na <sup>+</sup> , K <sup>+</sup>
		Vitamin D <sub>3</sub> status (serum 25-OHD)

**TABLE 11-5** Types of Muscular Dystrophy and Nutritional Implications

Type of MD	Comments	Nutritional Implications
Becker muscular dystrophy (BMD)	Very similar to DMD (see below), but onset is later (adolescence or adulthood). BMD patients live longer.	Weakness makes it difficult for self-feeding.
Congenital muscular dystrophy (CMD)	Caused by genetic mutations affecting some of the proteins necessary for muscles and some proteins related to the eyes and/or brain. Onset is at or near time of birth. Indicators include generalized muscle weakness with possible joint stiffness or looseness. Depending on the type, CMD may involve spinal curvature, respiratory insufficiency, mental retardation or learning disabilities, eye defects, and seizures.	Weakness makes it difficult for self-feeding.
Distal muscular dystrophy (DD)	DD is caused by a mutation in any of at least seven genes that affect proteins necessary to the function of muscles; it is usually passed on as an autosomal dominant or autosomal recessive trait. DD (Miyoshi form) first shows signs between ages 40 and 60 years, with weakness and muscle wasting of the hands, forearms, and lower legs; it progresses slowly.	Weakness and muscle wasting of the hands and forearms make self-feeding difficult.
Duchenne muscular dystrophy (DMD)	DMD primarily affects young boys, who inherit the disease through their mothers (X-linked recessive). Also called pseudohypertrophic. Caused by absence of dystrophin, a protein that helps keep muscle cells intact. DMD is the most severe form of dystrophinopathy. Aggressive forms appear in age 2–3, with frequent falls, difficulty in getting up from sitting or lying position. Generalized weakness and muscle wasting affect hip, thigh, shoulder, and trunk muscles first; large calf muscles. Weakness in lower leg muscles, resulting in difficulty running and jumping; waddling gait; mild mental retardation or scoliosis, in some cases. Survival is rare after the late twenties.	Facial muscles are involved; patient cannot suck, close lips, bite, chew, or swallow. DMD eventually affects all voluntary muscles, the heart, and lung muscles.
Emery-Dreyfus muscular dystrophy (EDMD)	EDMD is caused by gene mutations that produce emerin, lamin A, or lamin C, which are proteins in the membrane that surrounds the nucleus of each muscle cell. Onset in childhood, usually by age 10. Weakness and wasting of shoulder, upper arm, and shin muscles and joint deformities are common. Disease usually progresses slowly. Frequent cardiac complications are common, and a pacemaker may be needed.	Self-feeding becomes difficult.
Fascioscapulohumeral muscular dystrophy (FSHMD)	FSHMD (also called Landouzy-Dejerine) begins in childhood to early adulthood, with facial muscle weakness and weakness and wasting of the shoulders and upper arms. Caused by a missing piece of DNA on chromosome 4, it progresses slowly with some periods of rapid deterioration. Usually evident by age 20, it may span many decades. Inheritance is autosomal dominant, which means it can be passed on by either parent. It is considered to be the most common form.	Self-feeding becomes difficult; loss of skeletal muscle occurs. Abdominal muscles are affected.
Limb-girdle muscular dystrophy (LGMD)	LGMD is caused by a mutation in any of at least 15 different genes that affect proteins necessary for muscle function. LGMD has an onset in late childhood to middle age. Weakness and wasting affects shoulder and pelvic girdles first. Progression is slow, with cardiopulmonary complications often occurring in later stages of the disease. It is inherited as an autosomal recessive, autosomal dominant trait.	Self-feeding becomes difficult.
Myotonic dystrophy (MyD)	MyD (Steinert's disease) has onset anywhere from birth to middle age. Congenital myotonic form is more severe. Generalized weakness and muscle wasting affect the face, feet, hands, and neck first. Delayed relaxation of muscles after contraction. Progression is slow, sometimes spanning 50–60 years. Inheritance is autosomal dominant; there is a repeated section of DNA on either chromosome 19 or chromosome 3. Individuals with MyD have long faces and drooping eyelids; men have frontal baldness.	Progression is slow. Often complicated by diabetes. Prone to nutritional deficiencies from associated dysmotility of the entire GI. Handgrip is significantly lower; knee extension is higher compared to other dystrophies (Motlagh et al, 2005).
Oculopharyngeal muscular dystrophy (OPMD)	OPMD has onset in early adulthood to middle age. It affects muscles of eyelids (causing droopy eyelids) and throat. It progresses slowly, with swallowing problems common. Inheritance is autosomal dominant, and onset is usually in the fourth or fifth decade. The gene that is defective in OPMD is called the <i>poly(A) binding protein2</i> gene; extra amino acids in the protein made from the defective <i>PABP2</i> gene cause the protein to clump together in the muscle cell nuclei, interfering with cell function. OPMD can be diagnosed with a DNA test.	Swallowing difficulty is common. Tube feeding should be considered before wasting occurs.

Type of CMD	Cause	Inheritance Pattern
Merosin-deficient CMD	Lack of merosin (laminin 2) or other defect leading to merosin deficiency	Chromosome 6 gene Other genes
Ullrich CMD	Abnormalities in collagen 6	Chromosome 2 or 21 genes, recessive or dominant
Bethlem myopathy	Abnormalities in collagen 6	Chromosome 2 or 21 genes, dominant
Integrin-deficient CMD	Lack of integrin alpha 7	Chromosome 12 gene, recessive
Fukuyama CMD (FCMD)	Lack of fukutin	Chromosome 9 gene, recessive
Muscle-eye-brain disease (MEB)	Lack of POMGnT1, fukutin or fukutin-related protein	Chromosome 1, 9, or 19 genes, recessive
Walker–Warburg syndrome (WWS)	Lack of POMT1, POMT2, fukutin or fukutin related protein	Chromosome 9, 14, or 19 genes, recessive
CMD with rigid spine syndrome	Lack of selenoprotein N1	Chromosome 1 gene, recessive

## INTERVENTION

### OBJECTIVES

- Encourage patient to lead a relatively active life; exercise programs can help prevent contractures.
- Prevent obesity, from inactivity; obesity complicates physical therapy.
- Encourage activities other than eating to prevent dependency on food as a source of pleasure.
- Malnutrition is a serious threat, especially with respiratory muscle weakness. Monitor nutritional intake and deficits

on a regular basis. Prevent aspiration pneumonia or nasal regurgitation. Use a multidisciplinary approach, especially for feeding difficulties such as texture modification and supplemental feeding (Davidson and Truby, 2009).

- Avoid constipation because fecal impaction is frequent.
- Prevent osteoporosis and fractures, which can occur in this population.
- Manage long-term consequences, such as cardiomyopathy or respiratory failure.

### FOOD AND NUTRITION

- Work with the MyPyramid food guidance system as a basic guide. Check patient's BMI and adjust intake accordingly. Use a low-energy diet if necessary to control or lessen obesity. Some patients' requirements may be 30% lower than normal (Munn et al, 2005).
- Use foods that are easy to chew and swallow for DMD, such as pureed or blenderized foods. Tube feed only if necessary.
- Provide adequate fiber (prune juice, bran and other whole grains, fruits, and vegetables) if constipation becomes a problem.
- Ensure adequate intake of fluid to prevent fecal impaction, dehydration, and related effects.
- Adequate sodium chloride is important (Yoshida et al, 2006). Manage carefully if there are cardiac side effects or problems with BP.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal GI Function—Constipation

**Assessment Data:** Weight and physical activity histories. Medical history, medications and lab values. Complaints of chronic constipation and GI discomfort. Diet hx showing low fiber and intake of <4 cups of fluid per day to avoid the need to urinate.

**Nutrition Diagnosis (PES):** Abnormal GI function related to constipation and physical inactivity as evidenced by infrequent evacuation, hard stools, and GI discomfort.

**Intervention:** Food and Nutrient Delivery—Increase fluid and fiber sources from tolerated foods such as whole grain cereals, fresh fruits, and vegetables. Educate about the desirable foods and fluid intake. Counsel about the importance of daily range of motion and physical exercises. Coordinate care with other disciplines according to needs, including PT, OT, nursing, medical team.

**Monitoring and Evaluation:** Alleviation of constipation. No further complaints of GI discomfort related to infrequent stooling pattern.

### Common Drugs Used and Potential Side Effects

- The myotonia (delayed relaxation of a muscle after a strong contraction) may be treated with medications

such as phenytoin or quinine. Side effects can include folic acid depletion.

- Early introduction of steroids can exacerbate weight gain in a population already susceptible to obesity (Davidson and Truby, 2009).
- It may be useful to try beta<sub>2</sub>-adrenergic agonists, which can increase muscle mass. Albuterol may be needed for some individuals prior to exercise and strength training.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

Approximately 50% of children are on herbal preparations, 30% of adolescents take herbal medications, and 70% of adults use some aspect of complementary medicine (Buehler, 2007).

- Green tea extract may improve muscle health by reducing or delaying necrosis by an antioxidant mechanism (Dorchies et al, 2006).
- Traditional Chinese medicine has been advocated for treatment of types of MD, but studies are needed to identify active ingredients.
- Supplementation with creatine monohydrate may improve muscle strength (Davidson and Truby, 2009).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Provide low-calorie snack tips for patients who are obese.
- Help patient modify food textures to meet needs.
- Discuss problems related to inactivity or weight gain.
- Discuss the importance of adequate fluid intake.
- Discuss methods to prevent aspiration and pneumonia.
- Comprehensive management strategies can improve function, quality of life, and longevity (Bushby et al, 2010). Work with the occupational therapist and other therapists to maintain optimal levels of function.

## Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# MYOFASCIAL PAIN SYNDROMES: FIBROMYALGIA AND POLYMYALGIA RHEUMATICA

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

Adapted from: William J. Koopman, Larry W. Moreland, *Arthritis and Allied Conditions A Textbook of Rheumatology*, 15th ed. Philadelphia: Lippincott Williams & Wilkins, 2005.

## DEFINITIONS AND BACKGROUND

**Myofascial pain syndromes** are a group of disorders characterized by aching pain and stiffness in soft tissues, including muscles, tendons, and ligaments. In the United States, **fibromyalgia (FM)** is estimated to occur in 2% of adults (Mease, 2005). Diagnosis is difficult, and the etiology is not clear. Corticotropin-releasing hormone (CRH) and substance P (SP) are found in increased levels in the cerebral spinal fluid (CSF) of FM patients, and increased interleukin (IL)-6 and IL-8 are found in the serum where they release proinflammatory and neurosensitizing molecules (Lucas et al, 2006).

FM, or “fibrositis,” is a central sensitivity syndrome with abnormalities in the peripheral, central, sympathetic nervous systems, and the hypothalamo–pituitary–adrenal axis stress response system (Mease, 2005). Etiology theories abound, including inadequate sleep, physical or psychological trauma, or exposure to viruses such as hepatitis B or C, or HIV infection. Serotonin and dopamine levels may be lower than normal. Insulin-like growth factor-1 (IGF-1) levels may also be low; they are a surrogate marker for low growth hormone secretion during stage 3 and 4 of sleep, when tissue repair occurs (Rosenzweig and Thomas, 2009).

FM causes widespread pain and stiffness either throughout the body or localized along the spine. Persistent symptoms may be disruptive but are not life threatening. Symptoms include sleep disturbance, depression, fatigue, headaches, irritable bowel syndrome, numbness in the hands and feet, and mood disorders. Acupuncture may offer relief (Martin et al, 2006).

**Polymyalgia rheumatica (PMR)** affects people over age 70 years, usually women. It causes aching, severe muscle stiffness, and pain. Symptoms start suddenly and may affect several areas in the neck, shoulders, hips, and/or thighs. It

usually goes away with treatment but may reoccur. Symptoms include mild joint stiffness and swelling, face pain, anemia, extreme fatigue, unintentional weight loss, and anorexia. The cause of PMR is not known but may be related to aging. Diagnosis is difficult. Many people with PMR also have giant-cell arteritis with double vision, severe headaches, or vision loss. Low-dose corticosteroids may be needed for up to a year (Hernandez-Rodriguez et al, 2009).

Treatment of myofascial pain disorders may include exercise, medications such as glucocorticoids and NSAIDs, a healthy diet rich in antioxidants, and adequate rest. Massage and cognitive behavioral therapy (CBT) are helpful (Mease, 2005). After a warm-water swimming program, a significant decrease in IL-8, IFN $\gamma$ , and CRP has been noted (Ortega et al, 2009). Use of a phytochemical-rich diet results in a decrease in joint stiffness and pain as well as an improvement in self-reported quality of life. Plant foods are rich natural sources of antioxidants (quercetin, myristin, and kaempferol) in addition to fiber and other nutrients. A vegan diet often shows highly increased serum levels of beta- and alpha-carotenes, lycopene, lutein, and vitamins C and E.

Rapid-paced discovery is taking place in genetics, patient assessment, new therapeutic targets, and novel methods of treatment delivery (Williams and Clauw, 2009). The best multidisciplinary team includes a rheumatologist, physical therapist, exercise therapist, dietitian, and massage therapist (Lemstra and Olszynski, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** A multigenic or genome-wide approach may be needed to alter individualized pain therapy according to the patient’s genotype. For example, DRD2 polymorphisms decrease the functioning of the dopaminergic reward system; this could cause an individual to require more pain medicine. Research is ongoing to determine whether individuals with FM have the genetic tendency toward lower pain thresholds.

<b>Lab Work</b>	Trig, Chol Alb, transferritin	Alk phos Vitamin D <sub>3</sub> status (serum 25-OHD)
CRP or ESR (may be high)	BUN, Creat	
Plasma adreno- medullin (high in PMR)	Ca <sup>++</sup> , Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup> Gluc	

## INTERVENTION

### OBJECTIVES

- Relieve pain. Acupuncture, massage, cognitive-behavior therapy (CBT) and varied exercises may be recommended (Assefi et al, 2005; Rosenzweig and Thomas, 2009).
- Lose weight, if obese.
- Correct underlying problems such as hypertension.
- Support lifestyle changes, including stress reduction, relaxation techniques, and exercise.
- Prevent blindness in PMR when there is giant-cell arteritis.

### FOOD AND NUTRITION

- Use a balanced diet. The MyPyramid food guidance system is another useful tool for planning a healthy diet. Include phytochemicals; dietary quercetin should be encouraged (Lucas et al, 2006). Table 11-2 is also a useful reference.
- A vegan diet may be beneficial with berries, fruits, vegetables, roots, nuts, germinated seeds, and sprouts.
- A weight loss plan may be needed.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Intake of Bioactive Substances

**Assessment Data:** Weight and physical activity histories. Medical history, medications and lab values. Much pain; diagnosed FM. Diet hx and 3-day food record shows intake of <2 fruits and vegetables daily. No food allergies.

**Nutrition Diagnosis (PES):** Inadequate intake of bioactive substances related to low intake of fruits and vegetables as evidenced by diet history and intake records.

**Intervention:** Food and Nutrient Delivery—Provision of more spices, fruits, vegetables and juices. Education about the role of antioxidants, spices, and phytochemicals in reducing inflammation and the possibility of lessening pain symptoms. Counseling about menus, recipes and cooking tips for including more bioactive ingredients. Encourage intake of fish oils, walnuts, fatty fish such as salmon for omega-3 fatty acids.

**Monitoring and Evaluation:** Diet Hx showing improved intake of spices (such as turmeric, cumin, cinnamon), cocoa and coffee, fruits including berries and apples and pomegranates, vegetables such as broccoli and cabbage on a daily and weekly basis. Fewer complaints of overt pain.

- Increased intake of omega-3 fatty acids may help to reduce inflammation and relieve pain in some individuals. Increase intake of fatty fish, walnuts, and flaxseed.

## Common Drugs Used and Potential Side Effects

- Medications that decrease pain and improve sleep may be prescribed. Low doses of tricyclic antidepressants (amitriptyline, Elavil; cyclobenzaprine, Flexeril) and the serotonin-3 receptor antagonist tropisetron may be helpful (Lucas et al, 2006; Rosenzweig and Thomas, 2009). Opioids, NSAIDs, sedatives, muscle relaxants, and antiepileptics have been used to treat FMS (Mease, 2005).
- Pregabalin (Lyrica) and duloxetine (Cymbalta) are used in FMS. Milnacipran (Savella) is a dual norepinephrine and serotonin reuptake inhibitor that has been shown to be safe (Arnold et al, 2009; Mease et al, 2009).
- Opioids are not recommended for FM (Rosenzweig and Thomas, 2009).
- For PMR, a trial of low-dose corticosteroids is given, usually in the form of 10–15 mg of prednisone (Deltasone, Orasone) per day. Side effects may include sleeplessness, weight gain, loss of nitrogen and calcium, cataracts, thinning of the skin, easy bruising. NSAIDs, such as ibuprofen (Advil, Motrin) and naproxen (Naprosyn, Aleve), are ineffective in the treatment of PMR.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician. CAM is popular for musculoskeletal conditions. Some CAM modalities show significant promise, such as acupuncture (Martin et al, 2006). Excellent resources are available on the Internet from the National Center for Complementary and Alternative Medicine (<http://nccam.nih.gov>).
- Magnesium; sulfur compounds such as SAmE, dimethylsulfoxide (DMSO), taurine, glucosamine, and chondroitin sulfate; and reduced GSH may have clinical applications in the treatment of FMS; controlled trials are needed.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Aerobic exercise, patient education and CBT are quite effective. Daily exercise will be important for strengthening weak muscles. Exercise adherence can help reduce the need for pain medications (Lemstra and Olszynski, 2005).
- Discuss weight management, as needed.
- Discuss the role of omega-3 fatty acids in reduction of inflammation.

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# OSTEOARTHRITIS AND DEGENERATIVE JOINT DISEASE

**NUTRITIONAL ACUITY RANKING: LEVEL 1–2**

Adapted from: Cohen BJ. *Medical Terminology*, 4th ed. Philadelphia. Lippincott Williams & Wilkins 2003.

**DEFINITIONS AND BACKGROUND**

OA may be primary (in older individuals) or may follow an injury or disease involving the articular surfaces of synovial joints. The joint may lose its normal shape and bone spurs may grow on the edges of the joint. OA is a common health problem in populations over age 40 years, and it is a leading cause of pain and disability. OA mostly affects cartilage where the surface layer breaks down and wears away. The hands, knees, hips, and spine are most commonly affected.

Over 40 million Americans report that they have arthritis and many indicate that it limits their daily activities. High serum concentrations of tumor necrosis factor are associated with lower physical function and more pain, stiffness, and physical disability. Over a third of adults with arthritis experience limitations in their ability to work.

Treatments for OA combine nonpharmacological modalities, pharmacological agents, and surgical procedures. Exercise, weight control, rest, and relief from stress on joints, nondrug pain relief, and various types of complementary

medical techniques may be useful. Continuous passive motion (CPM), massage, and heat treatments may be used. Surgery is reserved for those persons for whom other treatments have been unsuccessful.

Weight loss is a primary treatment for OA for individuals who are obese. Obesity is a significant risk factor for and contributor to increased morbidity and mortality from chronic diseases, including OA (Pi-Sunyer, 2009). Overweight causes strain on joints and should be managed early by health professionals (Gasbarrini and Piscaglia, 2005). An average weight loss of 5% in overweight and obese older patients brings an 18% gain in overall function (Messier et al, 2005), and a 10% weight loss improves function by 28% (Christensen et al, 2005).

While vitamins A, C, and E have major roles in modulating oxidative stress, immune responses, and cell differentiation, controlled trials found that these vitamins do not halt progression of OA (Choi, 2005). Vitamins D and K play a protective role (Bergink et al, 2009; Oka et al, 2009). Diets rich in omega-3 fatty acids may reduce joint stiffness and pain, increase grip strength, and enhance walking pace. Pomegranate fruit extracts can block interleukin-1 $\beta$  (IL-1 $\beta$ ) enzymes that contribute to cartilage destruction and OA. Finally, cadgerin-11 is a protein that contributes to joint destruction and a related fabric has been developed for cartilage replacement.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** OA is the breakdown and inflammation of joint cartilage, usually brought on by aging and repetitive joint usage. OA and cardiovascular disease share age and obesity as risk factors, but may also be linked by pathogenic mechanisms involving metabolic abnormalities and systemic inflammation (Puenpatom and Victor, 2009).

Vitamin D<sub>3</sub> status (serum 25-OHD)

## SAMPLE NUTRITION CARE PROCESS STEPS

### Overweight

**Assessment Data:** Weight and physical activity histories; symptoms diary; medical history, medications, and lab values.

**Nutrition Diagnosis (PES):** Overweight with joint pain related to eating double portions at lunch and dinner meals as evidenced by diet history and BMI of 29.

**Intervention:** Food and Nutrient Delivery—Offer choices of lower fat and low energy foods and snacks. Educate about the role of excess weight and joint pain. Counsel and offer weight management tips, tips for dining out or snacking. Coordinate care with referral to physical therapy for exercises to reduce pain and stiffness in affected joints.

**Monitoring and Evaluation:** Weight changes, food intake records, symptoms diary.

## INTERVENTION

### OBJECTIVES

- Control pain and improve joint function. If joint replacement is necessary, prepare for surgery accordingly.
- Maintain a normal body weight. If needed, weight loss may be beneficial to lessen pressure on weight-bearing joints.
- Maintain an active lifestyle as much as possible.
- Encourage patient (especially if older) to consume adequate amounts of vitamins D and K, protein and calcium from a healthy, nutrient-dense, antioxidant-rich diet.
- Maintain integrity of cartilage in affected joints. Omega-3 fatty acids may reduce the activity of enzymes that destroy cartilage. Include fish oils and certain plant seed oils that impact immune and inflammatory responses as precursors of eicosanoids.

### FOOD AND NUTRITION

- Use a calorie-controlled diet if obesity is present. Use of a meal replacement may help to promote weight loss.
- The inflammatory response may be suppressed by an increase in omega-3 fatty acids, as found in fatty fish (mackerel, herring, and salmon) and from walnuts and flaxseed. Use these foods several times a week.
- Calcium is found in dark green, leafy vegetables, such as kale and broccoli; canned sardines and salmon with bones; fortified orange juice; milk and dairy products, such as cheese and yogurt; fortified bread, tofu or soy milk.
- Vitamin C is needed for healthy collagen and cartilage. Good sources include citrus fruits, bell peppers, tomatoes, watermelon, strawberries, and kiwifruit.
- Low dietary vitamin D intake increases the risk of progression of knee OA, particularly in subjects with low baseline BMD (Bergink et al, 2009). Include vitamin D from sardines, herring, fish-liver oil; butter and cream; egg yolks; liver; fortified cow's milk and dairy

products, such as cheese and yogurt; and fortified cereals.

- Vitamin K may be found in leafy greens such as kale, Swiss chard, broccoli, spinach, raw parsley. It is also found in small amounts in olive, soybean or canola oils and in mayonnaise.
- Boron may help OA. Sources include apples, legumes, leafy vegetables, carrots, pears, grapes, and some drinking water.
- Include plenty of phytochemicals. Pomegranates and cranberries are especially protective because of the ellagic acid. See Table 11-2.

## Common Drugs Used and Potential Side Effects

- Because of GI risks (including ulcer complications) and cardiovascular risks, including hypertension and thrombotic events associated with NSAIDs, acetaminophen is the first choice anti-inflammatory agent (Berenbaum, 2008). Table 11-6 gives more details on medicines used for OA. Evaluate risks as well as benefits for all drug therapies.

**TABLE 11-6 Medications Commonly Used for Osteoarthritis**

Medication	Comments	Side Effects
Anti-inflammatory drugs, nonsteroidal (NSAIDs)	Indomethacin (Indocin), aspirin piroxicam (Feldene), naproxen (Naprosyn), nabumetone (Relafen) and Ibuprofen (Advil, Motrin) may be recommended.	Nausea, GI distress, anorexia, flatulence, or vomiting can occur. Take with food. Prolonged use may cause GI bleeding or ulcers. Indomethacin may also cause renal failure, or diarrhea; naprosen may cause heartburn or increased risk of cardiovascular disease.
COX-2 Inhibitors	Cyclooxygenases are needed for the synthesis of prostaglandins. The COX-2 enzyme mediates inflammation and pain. Celecoxib (Celebrex) is the only FDA-approved drug at this time.	These agents may promote increased risk of heart attack and stroke. Rofecoxib (Vioxx) and valdecoxib (Bextra) were removed from the market in 2004 and 2005.
Misoprostol (Cytotec)	Misoprostol reduces stomach acid if NSAIDs are used.	Abdominal cramps may occur.
Frankincense (Boswellia frereana)	Interestingly, this herb may lessen arthritic pain. Epi-lupeol is the principal constituent of B. frereana. B. frereana prevents collagen degradation, and inhibits the production of pro-inflammatory mediators (Blain et al, 2010).	Fewer side effects than glucosamine and chondroitin.
Glucosamine sulfate and chondroitin	Glucosamine reduces cartilage damage and decreases pain associated with osteoarthritis. Taken with chondroitin, it may help relieve symptoms of osteoarthritis. Some pills do not contain sufficient levels to be effective; check brand with <a href="http://www.consumerlab.com">www.consumerlab.com</a> to select the best choice.	Glucosamine can increase blood glucose levels and aggravate shellfish allergy because it is made from these shells. Chondroitin may alter blood clotting activity in a manner similar to that of aspirin.
Hyaluronic acid substitutes (viscosupplements)	These injections are designed to replace a normal component of the knee joint involved in joint lubrication and nutrition.	A series of injections are required. When used with methotrexate, the benefits may be greater (Homma et al, 2009).
Omega-3 fatty acids	Supplementation causes a decrease in both degradative and inflammatory aspects of chondrocyte metabolism.	May increase effects of blood-thinning drugs and herbs.
Steroids	Corticosteroids may cause sodium retention; calcium, nitrogen, and potassium depletion; truncal obesity; and hyperglycemia.	Corticosteroids may have a short-term effect in osteoarthritis (Bellamy et al, 2005). Injections are required.
Topical pain relievers (Zostrix, Icy Hot, Therapeutic Mineral Ice, Aspercreme, and Ben Gay)	Creams and rubs stimulate nerve endings to relieve pain; deplete the amount of neurotransmitter (substance P) that sends pain messages to the brain; and block prostaglandins that cause pain and inflammation.	No internal side effects.
Tramadol (Ultram)	Pain reliever that is prescribed when over-the-counter medications do not provide relief.	Potentially addictive.

**TABLE 11-7 Side Effects of Herbs Commonly Used for Arthritis**

<b>Bromelain</b>	May increase effects of blood-thinning drugs and tetracycline antibiotics.
<b>Echinacea</b>	Might counteract immunosuppressant drugs, such as glucocorticoids, taken for lupus and rheumatoid arthritis; might increase side effects of methotrexate.
<b>Evening primrose oil</b>	Can counteract the effects of anticonvulsant drugs.
<b>Folic acid</b>	Interferes with methotrexate.
<b>Gamma linoleic acid (GLA)</b>	May increase effects of blood-thinning drugs and herbs.
<b>Garlic</b>	Can increase effects of blood-thinning drugs and herbs
<b>Ginger</b>	Can increase nonsteroidal anti-inflammatory drug (NSAID) side effects and effects of blood-thinning drugs and herbs.
<b>Ginkgo</b>	May increase effects of blood-thinning drugs and herbs.
<b>Ginseng</b>	May increase effects of blood-thinning drugs, estrogens, and glucocorticoids; should not be used by those with diabetes; may interact with monoamine oxidase (MAO) inhibitors.
<b>Kava</b>	Can increase effects of alcohol, sedatives, and tranquilizers.
<b>Magnesium</b>	May interact with blood pressure medications.
<b>S-adenosylmethionine (SAME)</b>	SAME may rebuild eroded joint cartilage. Enteric coating is needed because of gastrointestinal (GI) side effects.
<b>Soy and avocado extracts</b>	Antioxidant effects in reducing the symptoms of osteoarthritis; avoid excessive use in patients with hormonal cancers.
<b>St. John's wort</b>	May enhance effects of narcotics, alcohol, and antidepressants; increases risk of sunburn; interferes with iron absorption.
<b>Valerian</b>	May enhance effects of sedatives and tranquilizers.
<b>Vitamin E</b>	Gamma-tocopherol may worsen osteoarthritis; alpha-tocopherol is better.
<b>Zinc</b>	Can interfere with glucocorticoids and other immunosuppressive drugs.

Note: Herbs and botanical supplements should not be used without discussing with physician. Excerpted from The Arthritis Foundation's guide to alternative therapies, Web site accessed December 6, 2009, at <http://www.arthritis.org>.

## Herbs, Botanicals, and Supplements

- Boswellia frereana (frankincense) suppresses cytokine-induced matrix metalloproteinase expression and production of pro-inflammatory molecules; studies are on-going (Blain et al, 2010).
- Glucosamine sulfate combined with omega-3 fatty acids may reduce OA symptoms, including morning stiffness and pain in hips and knees (Gruenwald et al, 2009). Undenatured type II collagen (UC-II) may be more effective in the treatment of OA than glucosamine and chondroitin (Crowley et al, 2009).
- Green tea's anti-inflammatory properties and ginger may aid in pain relief.
- Table 11-7 provides a description of some side effects of products often used for OA.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Physical and occupational therapies, diet, and exercise play an extremely important role. Long-term exercise and dietary weight loss are most effective. Acupuncture may be used to relieve pain.
- Because OA allows muscles around the joints to become weak, exercise and stretching should be suggested to maintain flexibility. Repetitive, high-impact movements are not recommended whereas Tai Chi helps balance and protects bones. Exercises include a series for strengthening, aerobic, agility, and range of motion. Long-term

weight training, walking programs, swimming, and flexibility exercises are helpful.

- Encourage patient to avoid fad diets for "arthritis cure." Ensure that the patient's diet is balanced and includes all nutrients. A weight-loss plan may be needed.
- To alleviate stress on the joints, pharmacological and behavioral techniques with self-monitoring, should be included (Berkel et al, 2005).
- Pain initiates and exacerbates sleep disturbance; therefore, improving the sleep of OA patients helps to reduce the pain (Vitello et al, 2009). Transcutaneous electrical nerve stimulation (TENS) directs mild electric pulses to nerve endings that lie beneath the skin in the painful area; it block messages to the brain and by modifies pain perception. CBT is also useful.
- Focus on abilities and strengths rather than on disabilities and weaknesses.

## Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

## OSTEOMYELITIS

### NUTRITIONAL ACUITY RANKING: LEVEL 1–2

#### DEFINITIONS AND BACKGROUND

Acute osteomyelitis may be caused by localized infection of the long bones or injury to bone and surrounding soft tissue. *Staphylococcus aureus* is implicated in most patients with acute osteomyelitis; *S. epidermidis*, *S. aureus*, *Pseudomonas aeruginosa*, *Serratia marcescens*, and *Escherichia coli* may be found in the chronic form. When a bone is infected, the bone marrow swells and compresses against the rigid outer wall of bone, and blood vessels may be compressed or die; abscesses may form. Osteomyelitis and inflammatory arthritis affect many children (Pruthi and Thapa, 2009).

Some diseases predispose patients to osteomyelitis, including diabetes mellitus, sickle cell disease, acquired immunodeficiency virus (AIDS), intravenous drug abuse, alcoholism, chronic steroid use, immunosuppression, and chronic joint disease. Use of prosthetic orthopedic devices and recent orthopedic surgery or open fracture may also place a patient at risk for osteomyelitis. Patients with diabetes mellitus with poor glucose control may experience infections of the lower extremities, from superficial cellulitis to deep soft tissue infections and osteomyelitis. Because osteomyelitis is prevalent after diabetic foot ulcers, careful treatment is crucial to avoid amputation (Schinabeck and Johnson, 2005).

Prompt treatment is important. If not treated properly, the condition may become chronic with a poor prognosis. Treatment generally involves evaluation, staging, determination of etiology, antimicrobial therapy, and debridement or stabilization of bone. In children, serious musculoskeletal infections include osteomyelitis, septic arthritis, pyomyositis, and necrotizing fasciitis (Frank et al, 2005).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Deficiency of the interleukin-1-receptor antagonist (DIRA) promotes neonatal osteomyelitis, an autosomal recessive autoinflammatory disease caused by mutations in IL1RN (Aksentijevich et al, 2009).

Clinical/History	Local swelling, redness	White blood cell (WBC) count (increased)
Height	Contractures in affected extremities	Gluc
Weight	Magnetic resonance imaging (MRI)	Alb, transthyretin
BMI	Bone densitometry or x-rays	BUN, Creat
Intake and output (I & O)	Pressure ulcers or lesions with a sinus tract?	Alk phos
BP		AST, ALT
Bone pain		Ca <sup>++</sup> , Mg <sup>++</sup>
Sudden, acute pain in joints near the infection		Na <sup>+</sup> , K <sup>+</sup>
Fever, chills		Vitamin D <sub>3</sub> status (serum 25-OHD)
Tachycardia, diaphoresis		
Nausea	<b>Lab Work</b>	
Dehydration, electrolyte imbalance	CRP and ESR (increased)	

**SAMPLE NUTRITION CARE PROCESS STEPS****Underweight**

**Assessment Data:** Weight and physical activity histories. Medical history, medications, and lab values.

**Nutrition Diagnosis (PES):** Underweight related to poor nutrition quality of life and inadequate oral intake as evidenced by insufficient pain medicine before meals and BMI of 18.

**Intervention:** Food and nutrient delivery—offer nutrient and energy-dense favorite foods. Educate about the benefits of gaining weight to tolerate medical therapies more effectively, to gain energy, and to improve nutritional quality of life. Coordinate timing of medicines with meals to assure that pain medicine is given 20–30 minutes before meals.

**Monitoring and Evaluation:** Weight gain in 3–6 months; improved timing of meals with pain medicine to decrease anorexia at mealtime.

**INTERVENTION****OBJECTIVES**

- Characterize and treat the infection. Prevent further infection, dehydration, and other complications.
- Promote recovery and healing of any skin lesions or pressure ulcers.
- Correct defective blood flow to allow nutrients and oxygen to reach all tissues.
- Control serum glucose and alleviate hyperglycemia with insulin if needed.
- Correct anorexia, poor intake, weight loss, nausea and vomiting where present.

**FOOD AND NUTRITION**

- Encourage adequate fluid intake.
- Maintain a normal to high intake of calories, protein, zinc, vitamin A, and vitamin C in particular. A multivitamin–mineral supplement may be needed.
- With diabetes, control carbohydrate to promote more effective healing.

**Common Drugs Used and Potential Side Effects**

- For optimal results, antibiotic therapy must be started early, with antimicrobial agents administered parenterally

for at least 4–6 weeks if needed. Vancomycin or amphotericin B may be used; monitor for side effects related to timing and meals.

- Analgesics may be used for pain. GI distress is a common side effect.

**Herbs, Botanicals, and Supplements**

- Herbs and botanical supplements should not be used without discussing with physician.
- It is reasonable to include phytochemical-rich foods each day. See Table 11-2.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Discuss role of nutrition in wound healing, immunity, and other conditions related to this disorder.
- Discuss signs that may indicate reversal of status or recovery, such as increased fever, elevated glucose levels, additional infections, more redness in affected areas.
- Promote use of nutrient-dense foods that are rich in antioxidants, phytochemicals, protein, zinc and vitamins.

**Patient Education—Food Safety**

- If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used. Infection control is extremely important to avoid additional microbial contamination.

# OSTEOMALACIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Yochum TR and Rowe LJ. *Yochum and Rowe's Essentials of Skeletal Radiology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 2004.

### DEFINITIONS AND BACKGROUND

**Osteomalacia**, adult rickets, causes softening and demineralization of the bone from insufficient vitamin D. Osteomalacia may occur in conjunction with bone loss and hip fractures. It more commonly results from intestinal malabsorption as from Crohn's disease, colon resection, cystic fibrosis, celiac disease, or chronic use of anticonvulsants. It is also seen in kidney failure, liver disease, and some types of cancer. Severe vitamin D deficiency leads to secondary hyperparathyroidism, increased bone turnover and losses.

Derangements in serum phosphate level result in osteomalacia (Saito and Fukumoto, 2009). Matrix extracellular phosphoglycoprotein (MEPE) inhibits mineralization; altered expression is associated with oncogenic osteomalacia and hypophosphatemic rickets (Boskey et al, 2010). In addition, deficient actions of fibroblast growth factor, FGF23, result in hypophosphatemic osteomalacia; FGF23 works as a hormone (Saito and Fukumoto, 2009).

Osteomalacia often occurs in older people, in dark-skinned individuals who live in northern latitudes, and in those who have limited sunlight exposure. Vitamin D is produced in response to sun exposure, so the process works faster in pale individuals. Sun exposure of about 15 minutes without sunscreen a few times a week is needed. Darker skinned individuals may need to take supplements.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** The vitamin D receptor (VDR) is responsible for the expression of over 900 genes, or about 3% of the human genome.

Clinical/History	Lab Work	PTH Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup> Serum phos Alk phos (increased) Alb, transferritin CRP BUN, Creat
Height	Serum P	
Weight	(decreased)	
BMI	Serum Ca <sup>++</sup>	
Bone pain, aches	(decreased)	
Softened, deformed bones	Urinary Ca <sup>++</sup>	
Muscular weakness, listlessness	Vitamin D <sub>3</sub> (serum 25-OHD): normal >30 ng/mL;	
Numbness of arms, feet	low between 15 and 30 ng/mL;	
Easy bone fractures	very low at less than 15 ng/mL	
Bone densitometry, DEXA		
Bone biopsy		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Vitamin D Intake

**Assessment Data:** Weight, physical activity histories, medical history, medication use, lab values. Limited sunlight exposure; works indoors in a sedentary job. Complaints of bone pain. Low serum vitamin D<sub>3</sub> at 17. Diet Hx shows limited to no intake from milk and milk products, dislike of fish, no use of multivitamin supplements.

**Nutrition Diagnosis (PES):** Inadequate vitamin D intake related to limited sunlight exposure, indoor job, and diet low in vitamin-D rich foods as evidenced by low serum vitamin D levels.

**Intervention:** Food-nutrient delivery—Encourage intake of more fortified dairy products, fish; use daily supplement containing the active form of vitamin D (cholecalciferol) in dose as prescribed by physician. Educate about the need to get sunlight exposure (20 minutes without sunscreen) several times weekly. Counsel about ways to use vitamin-D rich foods in menu planning and recipes that are acceptable to patient and/or family members.

**Monitoring and Evaluation:** Serum levels of 25-hydroxyvitamin D (25-OHD) at more desirable level after 2–3 months. Patient statement of acceptance of foods rich in vitamin D, such as cream soups and casseroles made with milk. No further signs of osteomalacia.

## INTERVENTION

## OBJECTIVES

- Provide correct amount of calcium, phosphorus, and vitamin D<sub>3</sub>. Include other nutrients that support bone health; meet DRI levels. See Table 11-8.
- Prevent or reverse, if possible, bone density loss resulting from calcium loss in the bone matrix.
- Prevent heart disease and stroke, which may be consequences of severe vitamin D deficiency.

## FOOD AND NUTRITION

- Diets should be high in calcium; adults will need 1200–1500 mg. If patient is lactose intolerant, try Lactaid

or other forms of lactose-free milk, broccoli, greens, and other sources of calcium.

- Vitamin D is administered at high levels. Dietary sources include fish (particularly salmon, tuna, and mackerel) and fish liver oils. Small amounts are found in egg yolk and beef liver.
- Potassium, magnesium, vitamins C and K and other potentially important nutrients should be highlighted.

## Common Drugs Used and Potential Side Effects

- Monitor treatment with calcium salts to prevent hypercalcemia; use with plenty of liquids. Avoid taking with iron supplements or bulk-forming laxatives. High-calcium diets may reduce zinc absorption and balance and may, therefore, increase zinc intake.

TABLE 11-8 Nutrients and Bone Health

Nutrient	Comments
Alcohol	Moderate drinking (1–2 glasses of wine daily) is associated with increased trochanteric bone mineral density (BMD), but higher intakes may be associated with lower BMD. Heavy alcohol consumption may be linked to tobacco use, poor dietary habits, and poor bone health.
B-complex vitamins	Folic acid and vitamins B <sub>6</sub> and B <sub>12</sub> help to lower homocysteine when elevated.
Boron	Some role but not clearly defined.
Caffeine	Over 300 mg/d of caffeine can negatively impact the vitamin D receptor gene ( <i>VDR</i> ), and the Site Testing Osteoporosis Prevention and Intervention Trial (STOP-IT) found that greater amounts of caffeine affect BMD negatively (Rapuri et al, 2007). Limit intake to three cups of coffee daily and five servings of caffeinated soft drinks or tea; be sure to include adequate amounts of calcium.
Calcium and vitamin D	Dietary supplementation with calcium (1200 mg or more) and vitamin D (800–1000 IU) supports strong bone matrix, moderately reduces bone loss, and reduces the incidence of fractures. Vitamin D may actually be more important than calcium.
Copper	Copper is integral to the process of cross-linking of collagen and elastin molecules, and may have other roles in bone cells as well. Copper is found in meat, poultry, shellfish, organ meats; chocolate; nuts; cereal grains; dried legumes and dried fruits.
Dietary Fiber	A high intake of dietary fiber may interfere with calcium absorption; this may impact vegans, who consume 50 or more grams of fiber per day.
Iron	Iron is important for collagen maturation, and has other roles in osteoblasts and osteoclasts. Iron is found in organ meats, such as liver, kidney, heart; seafood; lean meat, poultry; dried beans; egg yolks; dried fruits; dark molasses; whole-grain and enriched breads or cereals.
Magnesium	Low intakes of magnesium contribute to bone loss. More than 50% of the total magnesium in the body is found in the bone, mostly in bone fluids. Magnesium is found in seeds, nuts; legumes; milled cereal grains; dark-green leafy vegetables such as spinach, broccoli, turnip greens, dark lettuces; milk.
Manganese	Manganese is necessary for the formation of bone matrix and is found in whole grains, nuts, legumes, tea, instant coffee, fruits, and vegetables.
Phosphorus	Meat, poultry, fish, eggs; cereals, grains; legumes; milk and dairy products, nuts.
Protein	70–100 g/d provides more bone building. Avoid larger doses, which can lead to excessive urinary calcium losses.
Silicon	There may be a role for silicon in stimulation of collagen synthesis and osteoblast differentiation. Intake of biologically active silicon, orthosilicic acid, enhances bone density and may help to preserve bone mass (Devine et al, 2005).
Sodium	Excesses can increase calcium excretion. Avoid using salt at the table, and limit total intake to 2400 mg/d.
Soy	Soy seems to be protective against fractures. Isoflavones increase bone density; use dietary sources.
Vitamin A	Too much retinal (not derived from the carotenoids found in plant sources) may contribute to hip fractures, especially in postmenopausal Caucasian women. Preformed vitamin A is found in liver, milk fat, fortified skim milk, eggs.
Vitamin C	Part of collagen, which supports healthy bone structure. Tissues saturate at 200 mg, therefore large doses are wasted.
Vitamin K	Supports osteocalcin for bone strength, reduces urinary calcium excretion, and modifies bone matrix proteins. A low intake of this fat-soluble vitamin increases the risk for bone fracture. Supplement with 120 µg if needed. Vitamin K is found in dark-green leafy vegetables, dairy products, meat, and eggs.
Zinc	The enzymes in osteoblasts require zinc in order to synthesize collagen. Zinc is found in animal products such as meat, fish, poultry; fortified and whole-grain cereals; milk and milk products; shellfish; liver. Zinc is also found in dry beans; nuts.

## REFERENCES

Devine A, et al. Protein consumption is an important predictor of lower limb bone mass in elderly women. *Am J Clin Nutr*. 81:1423, 2005.

- Anticonvulsant therapy, tranquilizers, sedatives, muscle relaxants, and oral diabetic agents may deplete vitamin D. Phosphate binders with aluminum may precipitate osteomalacia; calcium carbonate may be useful, but do not take it with whole grains, bran, high-oxalate foods, or iron tablets.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Many doctors believe that between 1000–2000 IU of vitamin D per day may be needed to maintain adequate serum levels of this hormone. The upper limit for vitamin D is 10,000 IU per day.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain which foods are good sources of vitamin D. Encourage use of cholecalciferol (vitamin D<sub>3</sub>) and not vitamin D<sub>2</sub>.
- Encourage patient to spend time in the sun for skin synthesis of vitamin D; 15–20 minutes may be needed, after which use a sunscreen to avoid sunburn.

- A spoonful of cod liver oil contains about 1300 IU of vitamin D; an 8-oz glass of fortified milk contains about 100 IU.
- Vegetarians who avoid dairy products may be at risk for calcium and vitamin D depletion; discuss alternative sources from diet or from necessary supplementation.

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

## OSTEOPENIA AND OSTEOPOROSIS

### NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Smeltzer SC, Bare BG. *Textbook of Medical-Surgical Nursing*, 9th ed. Philadelphia: Lippincott Williams & Wilkins, 2000.

### DEFINITIONS AND BACKGROUND

**Osteopenia** is a decrease in the amount of calcium and phosphorus in the bones. It is identified by a decrease in bone density, which is evident through a DEXA scan. It can occur in premature infants or in adults as a result of long-term inflammatory bowel disease, especially Crohn's disease, or from low BMI. Plasma 25-hydroxyvitamin D (25-OHD) is the most sensitive indicator of BMD and clinical vitamin D<sub>3</sub> status.

**Osteoporosis** is the most common bone disease in humans; it is characterized by low bone mass, structural deterioration, and decreased bone strength in an estimated 10 million Americans (NOF, 2009).

The aging population is highly affected. Seven percent of non-Hispanic white and Asian men aged 50 and older are estimated to have osteoporosis, and 35% are estimated to have low bone mass. Men are especially vulnerable when they have renal failure, smoke, or take medications on a regular basis, such as anticonvulsants, corticosteroids, or barbiturates.

The World Health Organization (2009) defines osteoporosis as a BMD value that is 2.5 standard deviations or more below the mean of a young adult of the same sex. The lower the BMD, the greater the fracture risk. Osteoporosis can be a silent disease until a fragility fracture occurs at the hip and proximal humerus, when significant physical disability can result.

**TABLE 11-9 Risk Factors for Osteoporosis***Factors That Cannot Be Changed*

Advanced age	History of fracture in a first-degree relative
Caucasians (e.g., Northern European and Asian)	Low body mass index (BMI) and low muscle mass
Female gender	Personal history of fracture after age 50 years
Family history of osteoporosis	

*Factors That Might Be Altered*

Anorexia nervosa	Hypogonadism, as from low estrogen levels or anorexia nervosa
Current smoking	Lifetime diet low in calcium (poor diet, excess fiber)
Depression, past or current	Low testosterone levels in men
Diabetes	Low vitamin D intake or sunlight exposure
Estrogen deficiency (premature menopause, amenorrhea)	Sedentary lifestyle or extended bed rest (immobilization)
Excessive use of alcohol	Use of chemotherapy, tamoxifen, glucocorticoids, lithium, and some anticonvulsants
Homocysteine, elevated plasma levels	Total parenteral nutrition, long-term use
Hypertension	

*Conditions or Diseases That May Lead to Osteoporosis*

AIDS/HIV	Gastrectomy	Liver disease, severe	Primary biliary cirrhosis
Amyloidosis	Gaucher's disease	Lymphoma or leukemia	Rheumatoid arthritis
Ankylosing spondylitis	Hemochromatosis	Malabsorption syndromes	Spinal cord transection
Celiac disease	Hemophilia	Mastocytosis	Stroke
Chronic obstructive pulmonary disease	Hyperparathyroidism	Multiple myeloma	Thalassemia
Congenital porphyria	Hypophosphatasia	Multiple sclerosis	Thyrotoxicosis
Cushing's syndrome	Idiopathic scoliosis	Osteomalacia	Tropical sprue
<b>Diabetes, type 1</b>	<b>Inflammatory bowel disease</b>	Pernicious anemia	

Women can lose up to 20% of their bone mass in the 5–7 years following menopause; 50% of will experience an osteoporotic fracture at some point in time. About 20% of postmenopausal white women in the United States have osteoporosis and 1.5 million fractures occur annually, especially of the hip and spine. Falls are associated with a high risk of frailty fractures (Schwartz et al, 2005).

Spinal or vertebral fractures may lead to loss of height, severe back pain, and spinal deformities such as kyphosis or stooped posture. Hip fractures require hospitalization and major surgery; they impair the ability to walk and may cause disability or death. By 2050, the annual number of hip fractures is expected to triple (World Health Organization, 2009).

Awareness and management of risk factors is important for preventing osteoporosis and the related disability. Both genetic and lifestyle factors play a role. A family history of hip fracture carries a twofold increased risk of fracture among descendants; genetic factors play a major role in BMD and in osteoporosis risk (Ferrari, 2008). Yet BMD is just one of many contributors to bone strength and fracture risk reduction. Dairy, fruit, and vegetable intakes have

emerged as an important modifiable protective factor for bone health (Tucker, 2009). Women may lose bone during lactation if their diets are low in calcium and other nutrients. Magnesium, potassium, vitamin C, vitamin K, several B vitamins, and carotenoids are important (Tucker, 2009); see Table 11-8.

In the skeleton, interleukin-1 protein causes an increase in the number and activity of osteoclastic cells—the cells that break down bone tissue. Depression and elevated plasma homocysteine levels are also associated with osteoporosis. See Table 11-9 for the full list of risk factors for osteoporosis.

Physical activity has different effects depending on its intensity, frequency, and duration, and the age at which it is started, with greater effects in adolescence and as a result of weight-bearing exercise. In addition, diet contributes significantly. Building strong bones during childhood and adolescence can be the best defense against developing osteoporosis later. By about age of 20, most women have acquired 98% of total bone mass. Acquisition of a high peak bone mass (reaching genetic potential) by 30 years of age helps reduce bone losses later in life.

Markers of bone turnover can be used to predict the rate of bone loss in post-menopausal women and can also be used to assess the risk of fractures (Eastell and Hannon, 2008). Markers of bone formation include serum bone alkaline phosphatase, total osteocalcin and the procollagen type I N-terminal propeptide assay (Eastell and Hannon, 2008).

Serotonin can serve as a marker for low bone mass. Circulating levels of the neurotransmitter serotonin are inversely associated with bone mass in women; this may have implications when using SSRIs. Bone formation is inhibited by serotonin in the gut. Inactivation of the leptin receptor in serotonergic neurons identifies a molecular basis for the common regulation of bone and energy metabolisms (Yadav et al, 2009). A drug that stops the gut from synthesizing serotonin may be able to reverse severe bone loss and prevent osteoporosis.

Measurements of the urinary excretion of N- and C-terminal cross-linked telopeptides and of serum C-terminal cross-linked telopeptides are sensitive and specific for bone resorption (Eastell and Hannon, 2008). These measures are as important as measurement of BMD.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Genes coding for the LDL-receptor related protein 5 (LRP5), estrogen receptor alpha (ESR1), and osteoprotegerin, OPG (TNFRSF11b) are known to pose a risk for osteoporosis (Ferrari, 2008). In a large-scale study, single nucleotide polymorphisms (SNPs) from nine gene loci (ESR1, LRP4, ITGA1, LRP5, SOST, SPP1, TNFRSF11A, TNFRSF11B, and TNFSF11) were associated with BMD, but not always in a predictable manner (Richards et al, 2009).

<b>Clinical/History</b>	Mg <sup>++</sup>	TSH
Height	Na <sup>+</sup> , K <sup>+</sup>	Total
Weight	Vitamin D <sub>3</sub>	testosterone
BMI	status (serum	in men
Back pain	25-OHD)	Serum homocysteine
BP	Alb	Serum folate
Bone densitometry, DEXA	CRP	and vitamin B <sub>12</sub>
	PTH (useful in some patients)	
<b>Lab Work</b>	Serum P	
Ca <sup>++</sup>	(decreased	
Urinary Ca <sup>++</sup> (24 hours)	with hyperparathyroidism)	

## INTERVENTION

### OBJECTIVES

- Preserve height, support independence, and improve functional status. Prevent fractures (Tussing and Chapman-Novakofski, 2005).

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Vitamin Intake

**Assessment Data:** Food records, DEXA scan showing two deviations below normal. Weight and physical activity histories. Medical history, medications, and lab values.

**Nutrition Diagnosis (PES):** Inadequate intake of vitamin D (NI5.9.1.3) related to poor diet, no food sources, and no use of supplements as evidenced by very low BMD on DEXA.

**Intervention:** Food and Nutrient Delivery: ND 1.3—add calcium containing beverages and foods, vitamin-D rich foods, adequate protein. ND 3.2.3.3—Supplement use for Vitamin D.

**Education:** E 2.2—Educate patient concerning calcium and vitamin D food and beverage sources to meet needs along with supplement, sunlight exposure 10–30 min/d, protein needs, increased physical activity.

**Counseling:** Good sources of vitamin D from diet and supplements, meal planning and shopping tips, dining out guide, referral to Meals-on-Wheels or other social agencies as appropriate, appropriate role for sunshine exposure.

**Monitoring and Evaluation:** Improvements in dietary and supplemental intake of vitamin D as shown in food records, lab values. DEXA scan report showing no further decline, and a slight improvement in risk level. No fractures.

- Optimize bone health: choose a balanced diet rich in calcium and vitamin D; use weight-bearing and resistance-training exercises. Follow a healthy lifestyle with no smoking.
- Decrease precipitating factors, such as use of anticonvulsants or corticosteroids, lactase deficiency, low intake of fruits and vegetables and dairy, calcium malabsorption, sedentary lifestyle, and low BMI. Provide adequate time for evaluating improvement (6–9 months at least).
- Assure adequate intake of protein. Rather than having a negative effect on bone, protein intake appears to benefit bone status, particularly in older adults (Tucker, 2009).
- Intake of magnesium, potassium, fruit, and vegetables is positively associated with bone health and total bone mass.

## FOOD AND NUTRITION

- Advise all patients to consume adequate amounts of calcium ( $\geq 1200$  mg/d, including supplements if necessary) and vitamin D. Women after menopause or over age 65 years will need 1500 mg calcium daily. To fulfill the requirement, 1 quart of milk daily can be consumed. If fluid milk is not consumed, dry skim milk powder can be added to many foods. Aged cheeses and yogurt are sources as well.
- Calcium supplements can be used if dairy products are not tolerated; calcium absorption averages approximately 30–40% from most sources See Table 11-10. Space the supplements throughout the day; take no more than 500–600 mg two or more times daily with meals. Use with vitamin D and magnesium.
- For vitamin D, choose fortified milk, cod liver oil, egg yolks, and fatty fish. Supplements may be needed. Do not exceed 10,000 IU/d.

**TABLE 11-10 Tips on Calcium Supplements<sup>a</sup>**

Product	Source of Calcium (mg)	No. of Tablets/Day to Provide About 900–1000 mg Calcium Per Tablet
Caltrate 600	Carbonate (600 mg)	1.5
Os-Cal 500	Carbonate from oyster shell (500 mg)	2
Os-Cal 500 + Vitamin D	Carbonate from oyster shell (500 mg)	2
Posture (600 mg)	Phosphate (600 mg)	1.5
Posture-Vitamin D	Phosphate (600 mg)	1.5
Citracal	Citrate (200 mg)	5
Citracal + Vitamin D	Citrate (315 mg)	3
Citracal Liquitab	Citrate (500 mg)	2
Tums 500 mg	Carbonate from limestone (500 mg)	2
Tums E-X	Carbonate from limestone (300 mg)	3.5
Tums Ultra	Carbonate from shell (400 mg)	2.5
Calcet + Vitamin D	Carbonate, lactate, gluconate (300 mg)	3.5
Fosfree	Carbonate, gluconate, lactate (175 mg)	6

<sup>a</sup>Excesses of calcium supplements can cause hypercalcemia; monitor intakes carefully and take no more than 500–600 mg two or more times daily with meals. Avoid taking with iron supplements. Use extra water with supplements. Excess vitamin D can cause vitamin D calcinosis. Rates of calcium absorption vary, and dietary sources are the best absorbed; calcium maleate is also well absorbed. Elemental calcium varies in different supplements, as follows:

1. Calcium carbonate (Tums, Roxane, Os-Cal, Calciday, Oyst-Cal, Oystercal, Caltrate) contains 40%. Calcium carbonate temporarily decreases gastric acidity, which is needed for calcium absorption. Tricalcium phosphate provides 39%.
2. Calcium chloride contains 36%.
3. Bone meal or Dolomite contains 33% but should be avoided as it also contains lead.
4. Calcium acetate (Phos-Ex, PhosLo) contains 25%.
5. Calcium citrate (Citracal) contains 21%.
6. Calcium lactate contains 13%.
7. Calcium gluconate contains 9%.

Updated from: Shils M, et al, eds. *Modern nutrition in health and disease*. Baltimore: Lippincott Williams & Wilkins, 1999.

- Extra protein may be needed (Devine et al, 2005; Tucker, 2009).
- For sufficient intake of vitamin B<sub>12</sub>, include dairy products, meat, poultry, fish, and fortified cereals.
- Isoflavones may also be beneficial; use two to three servings of soy foods daily.
- If patient is obese, use a nutrient-rich, calorie-controlled diet that provides adequate protein, vitamins, calcium, and other minerals. Adequate manganese, vitamins C and K, potassium, and magnesium should be consumed to meet at least the DRI levels. Include fruits and vegetables that contribute to bone health.
- Assure that folic acid and vitamins B<sub>6</sub> and B<sub>12</sub> are adequate, especially if serum homocysteine levels are elevated.
- Sodium must be controlled. Keep sodium within desired limits while increasing potassium and magnesium.
- Beware of excesses of wheat bran because phytates may increase calcium excretion.
- Caffeine from coffee does not seem to be a problem if calcium (as from milk) is consumed in adequate amounts. However, cola drinks should be limited (Tucker, 2009).
- Moderate alcohol intake shows positive effects on bone, particularly in older women (Tucker, 2009).

achieve recommended intake from dietary sources (see Table 11-11). Side effects may include abdominal pain, anorexia, constipation, vomiting, nausea or dry mouth.

- Oral doses of vitamin D<sub>3</sub> in the range of 1800 to 4000 IU per day may be needed to take serum levels up to 75 to 110 nmol/L (Bischoff-Ferrari et al, 2010).
- Oral alendronic acid is the reference drug for menopausal women with osteopenia. It may be used with parathormone as well, but this has a 2-year limit (Black et al, 2005). See Table 11-12 for more guidance.
- The once monthly injections of risenedronate (150 µg) are beneficial for those for which daily or weekly dosing is a challenge (Rackoff, 2009). Bone markers can be used to monitor the efficacy of antiresorptive therapy such as hormone-replacement therapy, raloxifene and bisphosphonates (Eastell and Hannon, 2008).
- SSRIs have been associated with lower BMD and increased rates of bone loss, as well as increased rates of fracture (Haney et al, 2010). Their use should be closely monitored.

### Herbs, Botanicals, and Supplements

#### Common Drugs Used and Potential Side Effects

- Adequate calcium is crucial; supplementation in bio-available forms is necessary in individuals who do not

- Herbs and botanical supplements should not be used without discussing with physician.
- Cabbage, pigweed, dandelion, avocado, and parsley have been recommended, but have not shown efficacy.

**TABLE 11-11 Medications Commonly Used for Management of Osteoporosis<sup>a</sup>**

Medication Comments	Effects	Comments
Bisphosphonates: risedronate (Actonel); alendronate (Fosamax)	Effective agents for reducing vertebral and nonvertebral fracture risk. Alendronate is approved for the treatment of osteoporosis in men. Alendronate and risedronate are approved for use by men and women with glucocorticoid-induced osteoporosis. Zoledronic acid is under study. Bisphosphonates inhibit atherogenesis.	Risedronate may cause dysphagia, esophageal ulcer, and stomach ulcer. Take on an empty stomach 30 minutes before meals; sit upright. Take additional vitamin D and calcium. Headache, gastrointestinal (GI) distress, diarrhea, nausea, constipation, and rash may occur, although rarely. Alendronate may cause metallic taste, nausea, diarrhea, and decreased potassium and magnesium. Avoid in severe renal disease, pregnancy, or breastfeeding. Nausea, heartburn, irritation or pain of the esophagus, anorexia, vomiting, dysphagia, sensation of fullness, and constipation or diarrhea may occur.
Calcitonin-salmon (Miacalcin)	Bone loss is reduced, and bone mass increases, although not in the hip. A modest increase in bone mass occurs.	200 IU/d, the recommended regimen, reduces vertebral fracture risk by 33% in women with low bone mass. Calcitonin makes calcium more available to bones. It is given as an injection or nasal spray; it may cause allergic reactions and flushing of the face and hands, urinary frequency, anorexia, nausea, constipation, or skin rash.
Calcitriol (1,25-dihydroxyvitamin D)	Active form of vitamin D hormone that increases GI absorption of calcium from the gut, kidney reabsorption of calcium, stimulates bone resorption, decreases PTH production, and stimulates skeletal osteoblasts/osteoclasts. Larger doses than the DRI for vitamin D may be needed; 700–800 IU may be beneficial along with 500–1200 mg calcium (Cranney et al, 2007).	Anorexia, abdominal cramping, headache, lethargy, nausea, weight loss, and weakness may result from larger doses.
Ibandronate (Boniva)	Ibandronate is used to treat or prevent osteoporosis in women after menopause; it may increase bone mass by slowing loss of bone.	Should not be taken if hypocalcemia is a problem.
PTH (teriparatide; Forteo)	PTH is the only anabolic osteoporosis agent available for clinical use to lower vertebral fracture incidence by triggering formation of new bone.	Use only in ambulatory patients.
Raloxifene (Evista)	Significantly reduces vertebral fracture risk but not nonvertebral fracture risk.	Protects against thin, weak bones and fractures; also lowers serum cholesterol by 7% and low-density lipoprotein (LDL) by 11%. It may trigger menopausal symptoms, including hot flashes, but is less likely to have an estrogen-like increase in cancer risk.
Sodium fluoride	The slow-release form may increase bone formation and decrease the risk of fractures.	In patients with mild-to-moderate osteoporosis, long-term supplements with fluoride plus calcium result in lower rates of vertebral fracture than supplementation with calcium alone. Intake of fluoride in drinking water at 1 ppm does not appear to be associated with increased risk of hip fracture. Side effects may include abdominal pain, diarrhea, nausea, vomiting.
Statins	Statins, agents that reduce atherogenesis, stimulate bone formation.	Cardiovascular disease and low bone mineral density have some common etiologies.

<sup>a</sup>The FDA approves calcitonin, alendronate, raloxifene, and risedronate for the treatment of postmenopausal osteoporosis; alendronate, risedronate, and raloxifene are approved for the prevention of the disease. Current pharmacological options for osteoporosis prevention and/or treatment are bisphosphonates (alendronate and risedronate), calcitonin, estrogen and/or hormone therapy, parathyroid hormone (PTH 1–34), and raloxifene.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Prevention is the best medicine. Encourage patient to stand upright, rather than sit or recline, as often as feasible. Measures to decrease fall frequency and to slow down the rapid life pace of healthy people with low bone mass should prevent some fractures (Kelsey et al, 2005).
- Change a sedentary lifestyle. Regular resistance and high-impact exercise, contributes to development of high peak bone mass and may reduce the risk of falls in older individuals (Moayeri, 2008). Aerobic and strengthening exercises are helpful as well.
- Walking or running is beneficial. However, excessive weight-bearing exercise can cause amenorrhea in premenopausal women when a low-calorie diet is consumed.

**TABLE 11-12 Features of Rheumatic Arthritis**

Tender, warm, swollen joints
Symmetrical pattern of affected joints
Joint inflammation <i>often</i> affecting the wrist and finger joints closest to the hand
Joint inflammation <i>sometimes</i> affecting other joints, including the neck, shoulders, elbows, hips, knees, ankles, and feet
Fatigue, occasional fevers, a general sense of not feeling well
Pain and stiffness lasting for more than 30 minutes in the morning or after a long rest
Symptoms that last for many years
Variability of symptoms among people with the disease

Source: National Institute of Arthritis and Musculoskeletal and Skin Diseases. Available at [http://www.niams.nih.gov/Health\\_Info/Rheumatic\\_Disease/default.asp#ra\\_14](http://www.niams.nih.gov/Health_Info/Rheumatic_Disease/default.asp#ra_14).

- An educational osteoporosis prevention program with hands-on activities can increase self-efficacy (Tussing and Chapman-Novakofski, 2005). Explain that calcium absorption declines with age and that adequate calcium and vitamin D are important throughout life. The overall benefit of healthful eating must be strongly emphasized. Consider calcium and vitamin D supplementation in the elderly.
- Describe importance of the use of milk, cheeses, yogurt, broccoli, kale and other greens, and soybeans. Provide recipes and shopping tips.
- Decrease the use of tobacco. Use only moderate amounts of alcohol.
- Caffeine poses a minimal risk unless it replaces calcium-containing beverages; BMD is not affected by caffeine if at least 1 glass of milk is consumed daily.
- Encourage adequate exposure to sunlight (10–30 min/d). Avoid sunburn and overexposure, with its risks of skin cancer.
- Remind all teenagers that osteoporosis is “kid stuff;” maintenance of weight-bearing activity is important during the growing years. Intake of carbonated beverages instead of milk is a big concern.
- Some mineral waters are excellent sources of calcium; bioavailability is good.
- Avoid long-term use of high doses of retinol from fortified foods or supplements.
- Persons with previous fractures are at risk and should be monitored carefully for osteoporosis. The National Osteoporosis Foundation supports an Awareness and Prevention Month in May of each year.

- When steroids are used, check on bone density changes; there is a high incidence of osteoporosis.
- Note that improvements in BMD may take up to 3 years to note improvement (Compston, 2009).

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# PAGET'S DISEASE (OSTEITIS DEFORMANS)

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

### DEFINITIONS AND BACKGROUND

Paget's disease of the bone (PDB) is a disorder of skeletal remodeling, where areas on bone grow abnormally, enlarging and becoming soft. It is of unknown etiology, with excessive bone destruction and repairing. Of all persons older than 50 years of age, 3% have an isolated lesion; actual clinical disease is much less common. PDB is the second most common bone disease in the world. A systematic laboratory screening including serum alkaline phosphatase of an older subject complaining of bone pain, articular pain, or back pain is a strategy to improve the diagnosis of PDB (Varenna et al, 2009).

The disease tends to run in families. Genetic analysis indicates that 40% of patients with Paget's disease have an affected first-degree relative. Approximately 3 million Americans have the disease; it rarely occurs before age 40. Juvenile Paget's disease is very debilitating. Osteoclasts are larger than normal and increased in size (Deftos, 2005). Juvenile Paget's disease usually presents in infancy or childhood and results in progressive deformity, growth retardation, and deafness.

The disease is higher in frequency in people who are aged 65 or older. There is a slight male predominance. Prognosis is good in mild cases.

Sarcoma can also be found in this population (Mankin and Hornicsek, 2005). There has been a decline in incidence of this complication but where it does occur, prognosis is still poor (Mangham et al, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** There seem to be strong ties to European ancestry in Paget's disease, including Australia and New Zealand. A majority of cases harbor germline mutations in the *SQSTM1*, Sequestosome1 gene (Merchant et al, 2009).

Clinical/History		Lab Work
Height	Headaches	
Weight	Tickening of long bones	Alk phos (increased)
BMI	Bowing of limbs	Urinary $\text{Ca}^{++}$ (altered)
Deep "bone pain"	Reduced height	Vitamin D <sub>3</sub> status (serum 25-OHD)
Joint pain, neck pain	Spontaneous fractures	Uric acid (UA), elevated?
Skull enlargement	X-rays (denser, expanded bones)	
Hearing loss	Bone scans	

PTH (abnormal) $\text{Ca}^{++}$ , $\text{Mg}^{++}$ $\text{Na}^{+}$ , $\text{K}^{+}$	Alb, transferritin CRP Transferrin Serum P	H & H Serum B <sub>12</sub> Radiolabeled bisphosphonate
---	--	---

### INTERVENTION

#### OBJECTIVES

- Prevent complications, especially related to the nervous system (e.g., fractures, spinal stenosis, paraplegia, cardiac failure, and deafness).
- Prevent side effects of drug therapy.
- Promote full recovery when possible.
- Differentiate from other conditions with bone lesions.
- Alleviate anemia and other complications.

#### FOOD AND NUTRITION

- Adequate protein is important, with adequate calories to spare protein.
- Adequate levels of calcium and vitamins C and D may be needed.
- To correct anemia, monitor serum levels of iron and vitamin B<sub>12</sub> to determine need for an altered diet.

#### Common Drugs Used and Potential Side Effects

- Drugs that inhibit bone resorption—bisphosphonates (etidronate, pamidronate, clodronate, or alendronate)—

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### Abnormal Nutritional Labs

**Assessment Data:** Weight and physical activity histories. Medical history, medications, abnormal lab values for alk phos, uric acid, serum vitamin D<sub>3</sub>, and PTH.

**Nutrition Diagnosis (PES):** Abnormal nutritional labs related to metabolic changes from Paget's disease as evidenced by increased alk phos, altered urinary calcium, abnormal PTH, elevated uric acid levels, diagnosis of anemia, and bone pain.

**Intervention:** Treatment with bisphosphonates to alter serum and urinary labs; careful monitoring for side effects affecting intake and appetite. Food-nutrient delivery—Correct iron-deficiency anemia from poor intake and disease process.

**Monitoring and Evaluation:** Improvement in serum lab values; resolution of anemia; decreased bone pain.

may be used to slow the progression. Bisphosphonates are pyrophosphate analogs that bind to bone at active sites of remodeling. The bisphosphonate zoledronic acid (Zometa), given in a single injection, yields a rapid and long-lasting improvement in bone health (Reid et al, 2005). The nitrogen-containing BPs pamidronate (Aredia) and zoledronic acid (Zometa) are capable of causing bisphosphonate-associated osteonecrosis of the jaw (Grewal and Fayans, 2008).

- Risedronate (Actonel) can cause dysphagia, esophageal ulcer, and stomach ulcer. Take on an empty stomach 30 minutes before meals; consume additional vitamin D and calcium. Headache, diarrhea, nausea, constipation, and rash may occur, although they are rare.
- Osteoprotegerin may be used in managing the juvenile form of Paget's disease (Cundy et al, 2005).
- Thyrocalcitonin or synthetic calcitonin may be used to decrease passage of calcium from bones to bloodstream. Methods of administration include a nasal spray. Monitor for nausea or vomiting.
- Analgesics may be needed for pain.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Unusual bone diseases may be associated with use of Chinese herbs.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss appropriate dietary alterations for patient's condition, individualized for the current condition and status. Include good food sources of calcium, B-complex

vitamins, iron, protein, and vitamin D. Monitor carefully, if supplements are used, in addition to dietary guidance.

- Discuss side effects for the specific drugs ordered.

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

## POLYARTERITIS NODOSA

### NUTRITIONAL ACUITY RANKING: LEVEL 1–2

### DEFINITIONS AND BACKGROUND

Polyarteritis nodosa (PAN) is characterized by necrotizing inflammation of medium- or small-sized arteries without glomerulonephritis or vasculitis in arterioles, capillaries, or venules (Colmegna and Maldonado-Cocco, 2005). Viral infections such as hepatitis B may trigger it.

In PAN, arteries become inflamed in several organs, causing damage in brain, heart, liver, GI tract, or renal tissues. Renal involvement develops and is accompanied by hyper-

tension in half of patients. PAN also commonly involves the gut (abdominal angina, hemorrhage, perforation), heart (myocarditis, myocardial infarction), or eye (scleritis); rupture of renal or mesenteric microaneurysms can also occur. PAN is two to three times more common in men and usually develops between ages 40 and 50 years. Rarely, it occurs after a Hepatitis-B vaccination.

It is fatal if not treated. Treatment includes use of prednisone, plasmapheresis to remove immune complexes, and antiviral therapy (lamivudine) for the hepatitis B infection.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Medium-sized artery vasculitides that occur in childhood manifest mostly as PAN, with high morbidity and mortality rates (Dillon et al, 2009). PAN is likely to have a genetic connection; MEFV is one gene under study.

<b>Clinical/History</b>	Myalgias, weakness	Hepatitis B antigen or antibody in serum
Height	Neuropathy	
Weight	Hematuria	
BMI	Fatigue	Ca <sup>++</sup> , Mg <sup>++</sup>
Weight loss >4 kg since onset of illness	Rash, nodules or Raynaud's disease	Na <sup>+</sup> , K <sup>+</sup>
Hematuria	Biopsy of medium vessels	Alb, transthyretin
Edema		BUN, Creat (elevated but not from dehydration)
Chest pain		Transferrin
Tachycardia		H & H
Shortness of breath	<b>Lab Work</b>	Vitamin D <sub>3</sub> status (serum 25-OHD)
Fever?	ESR (elevated)	
Abdominal pain	CRP	
BP (elevated)	Glucose	

## INTERVENTION

### OBJECTIVES

- Treat as soon as possible to decrease heart and renal damage.
- Improve appetite and intake.
- Prevent weight loss.
- Increase calorie intake when there is fever.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Oral Food and Beverage Intake

**Assessment Data:** Weight and physical activity histories. Medical history, medications, and lab values.

**Nutrition Diagnosis (PES):** Inadequate oral food and beverage intake related to anorexia, fever and abdominal pain as evidenced by weight loss of 3 kg in 8 weeks.

**Intervention:** Food-Nutrient delivery—Offer preferred foods, enhanced with energy kilocalories from milk powder, fats, etc. Educate about how to manage nausea; suggest small, frequent meals throughout the day and liquids separate from meals. Coordinate care with nursing, medical teams if medications are needed.

**Monitoring and Evaluation:** Resolution of weight loss; no further losses. Improvement in nausea and abdominal pain.

- Reduce edema, anorexia, hypertension, and other effects of the disorder.

### FOOD AND NUTRITION

- A high-energy intake may be beneficial in case of weight loss.
- A normal to high protein intake generally is required.
- Fluid or sodium intake may be limited with hypertension, kidney disease, or edema or with use of steroids.
- Include phytochemicals derived from spices such as turmeric (curcumin); red pepper (capsaicin); cloves (eugenol); ginger (gingerol); cumin, anise, and fennel (anethol); basil and rosemary (ursolic acid); garlic (diallyl sulfide, S-allylmercaptocysteine, and ajoene); and pomegranate (ellagic acid) (Aggarwal and Shishodia, 2004).

### Common Drugs Used and Potential Side Effects

- Steroids such as prednisone may be used for 2 weeks. Side effects of long-term use include negative nitrogen and potassium balances; decreased calcium and zinc levels; CHO intolerance; and excessive sodium retention. With weight gain, a calorie-controlled diet may be useful.
- Pain relievers may be needed; monitor individually for side effects such as GI distress.
- Immunosuppressive cyclophosphamide may be used; long-term effects can reduce the ability to fight infections. Corticosteroids plus cyclophosphamide is the standard of care, in particular for patients with more severe disease, in whom this combination prolongs survival (Colmegna and Maldonado-Cocco, 2005).
- Infliximab may be used as an alternative agent for the treatment of patients with PAN refractory to conventional therapy (Al-Bishri et al, 2005).

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss alternate dietary guidelines as appropriate for medications and side effects of the disease.
- Discuss sources of nutrients as appropriate for the ordered diet. Provide guidance on enhancing nutrient and energy density from meals and snacks.
- With abdominal pain and GI bleeding, PAN occasionally is mistaken for inflammatory bowel disease. Be certain to see a trained specialist as needed.

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# RHABDOMYOLYSIS

**NUTRITIONAL ACUITY RANKING: LEVEL 3****DEFINITIONS AND BACKGROUND**

Rhabdomyolysis (RML) is a clinical and biochemical syndrome resulting from skeletal muscle injury with release of myoglobin into the plasma and breakdown of muscle fibers with release into the circulation. Some of these changes are toxic to the kidney, often resulting in kidney damage or acute renal failure. A disturbance in myocyte calcium homeostasis takes place.

RML may occur in infants, toddlers, and adolescents who have inherited enzyme deficiencies of carbohydrate or lipid metabolism, DMD, or malignant hyperthermia. RML may also occur from extensive muscle damage as from a crushing injury, major burn, electrical shock, toxins, bacterial infections, excessive exercise (Olpin, 2005), seizures, alcoholism, overdose of cocaine, or use of drugs such as cholesterol-reducing statins. The most common causes of RML in adults include crush injury, overexertion, alcohol abuse, use of certain medicines, and toxic substances. Postoperative RML in bariatric surgery occurs with prolonged muscle compression; potential consequences may lead to death (de Menezes Ettinger et al, 2005).

Muscle pain caused by RML may involve specific symptoms of groups of muscles or may be generalized throughout the body. Muscles in the calves and the lower back are commonly affected but each patient is different. Early complications of RML include severe hyperkalemia with cardiac arrhythmia and arrest. The most serious late complication is acute renal failure.

RML can be defined with CK values exceeding 10–25 times the upper limit of normal irrespective of renal function (Linares et al, 2009). Management of suspected drug-induced myopathy should include immediate discontinuation of the offending agent and supportive care (Mor et al, 2009).

inherited myopathies. Elevated CK levels have been found with a high-density SNP genotype in a p.Trp3X allele; this mutation is associated with a mild Becker phenotype of MD (Flanigan et al, 2009).

**Clinical/History**

Height  
Weight  
BMI  
Weight gain (unintentional)  
I & O  
Tea-colored urine  
Temperature  
BP (elevated)  
Exposure to toxic substances or chronic alcohol use  
Use of medications such as statins  
Muscle tenderness

Weakness of the affected muscles  
Muscle stiffness or aching (myalgia)  
Seizures  
Joint pain  
Fatigue  
Abnormally dark colored urine from excretion of myoglobin

**Lab Work**

Serum myoglobin test (positive)  
Urinary casts or hemoglobin  
Ca<sup>++</sup>, Mg<sup>++</sup>  
Na<sup>+</sup>  
K<sup>+</sup> (may be high from muscle breakdown)  
Alb,  
transferritin  
CRP  
BUN  
Creat  
Transferrin  
H & H  
UA (elevated)  
Vitamin D<sub>3</sub> status (serum 25-OHD)

**ASSESSMENT, MONITORING, AND EVALUATION****CLINICAL INDICATORS**

**Genetic Markers:** RML may occur in infants, toddlers, and adolescents who have inherited enzyme deficiencies of carbohydrate or lipid metabolism or who have

**INTERVENTION****OBJECTIVES**

- Preserve renal function.
- Eliminate myoglobin out of the kidneys with early and aggressive hydration. Medicines may also be needed to make the urine more alkaline.
- Treat kidney failure or hyperkalemia if needed.

**FOOD AND NUTRITION**

- Hydration needs with muscle necrosis may approximate the massive fluid volume needs of a severely burned patient.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Excessive Physical Activity**

**Assessment Data:** Weight and physical activity histories. Medical history with diagnosis of RML.

**Nutrition Diagnosis (PES):** Excessive physical activity related to 2-hour workouts twice daily as evidenced by complaints of weakness, muscle stiffness and tenderness, and very high CPK levels.

**Intervention:** Education about a more desirable level of physical activity to lessen strain on muscles. Counseling about nutrition for athletics and maintenance of other healthy habits, including adequate rest and sleep. Physical activity logs.

**Monitoring and Evaluation:** Improvement in muscle stiffness and tenderness; CPK levels returning to a normal range. Physical activity logs showing workouts no longer than 30 minutes twice daily.

- Special dietary advice is required if there is renal disease or the need for dialysis.
- It is important to offer advice according to the medical condition that preceded RML. Avoidance of fasting, feeding with a high-carbohydrate and low-fat diet, and intravenous drip infusion soon after every onset of RML may be needed for children (Korematsu et al, 2009).

**Common Drugs Used and Potential Side Effects**

- Statins block the enzyme in the liver that is responsible for making cholesterol, hydroxy-methylglutaryl-coenzyme A reductase (HMG-CoA reductase).
- Despite the withdrawal of cerivastatin because of fatal RML, the risk of this complication with other statins is extremely low (Waters, 2005). Options for managing statin myopathy include statin switching, particularly to fluvastatin or low-dose rosuvastatin; nondaily dosing regimens; nonstatin alternatives, such as ezetimibe and bile acid-binding resins; and coenzyme Q10 supplementation (Joy and Hegele, 2009).
- Diuretic therapy may be needed if there is hypertension.
- If there is hyperkalemia, calcium chloride or calcium gluconate may be used.

**Herbs, Botanicals, and Supplements**

- Health care practitioners must take an active role in identifying patients who are using CAM and provide appropriate patient education (Gabardi et al, 2007). Herbs and botanical supplements should not be used without

discussing with physician. There are 17 dietary supplements that have been associated with direct renal injury, CAM-induced immune-mediated nephrotoxicity, nephrolithiasis, RML with acute renal injury, and hepatorenal syndrome (Gabardi et al, 2007).

- Even brief exposure to atorvastatin causes a marked decrease in blood coenzyme Q10 concentration, with commonly reported adverse effects of exercise intolerance, myalgia, and myoglobinuria.

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Discuss alternate dietary guidelines as appropriate for medications and side effects of the disease.
- Discuss how to use diet and exercise to manage high serum cholesterol if this information has not been given before. Reinforce what the patient has been doing well.
- After damage to any muscles, extra fluid is needed to dilute urine and to eliminate myoglobin. Among soldiers, RML occurs in 25% of those who are injured (Carter et al, 2005).

**Patient Education—Food Safety**

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# RHEUMATOID ARTHRITIS

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: Strickland JW, Graham TJ. *Master Techniques in Orthopaedic Surgery: The Hand*, 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2005.

### DEFINITIONS AND BACKGROUND

RA is a chronic polyarthritis mainly affecting the smaller peripheral joints and is accompanied by general ill health. Crippling deformities can occur. Of all cases, 75% are women. Most patients are between ages 20 and 40, and RA affects over 1.3 million Americans. To diagnose RA, symptoms must have been present for at least 6 weeks; see Table 11-12.

The cause of RA is increased inflammatory cytokine production, such as from mast cells, interleukin-6, tumor necrosis factor alpha (TNF $\alpha$ ), and acute-phase proteins. Inflammation of synovial tissues is the dominant manifestation. Antibodies against IgG and collagen are noted. Hand involvement and knees or ankles/feet are involved in most. Table 11-13 provides a list of the variant forms of RA.

Some studies show an improvement in RA symptoms over the short term with a diet high in omega-3s or fish oil supplements. Omega-3 fatty acids reduce tenderness in joints, decrease morning stiffness, and reduce the amount

**TABLE 11-13 Variant Forms of Rheumatic Arthritis (RA)**

Condition	Background	Nutritional Implications
Juvenile RA (JRA)	JRA causes joint inflammation and stiffness for more than 6 weeks in a child 16 years of age or less. It is classified into three types, depending on symptoms, number of joints involved, and presence or absence of antibodies in the blood. Pauciarticular JRA is most common and affects mainly the knees. The polyarticular form affects 30% of children with JRA. Still disease is the systemic form; it tests negative for the usual antibodies, may affect internal organs, may become chronic in adulthood and affects 20% of children with JRA. Both genetic factors and environmental factors, such as a virus, can trigger JRA. Because JRA often affects knees, limping can occur. Salicylates, gold salts, or glucocorticoids may be used.	Children suffering from JCA may have reduced serum levels of beta-carotene, retinol, and zinc.
Sjögren's syndrome	Dry eyes and dry mouth occur as a result of insufficient production of lacrimal and salivary secretions. Artificial tears and glucocorticoids may be needed. Sjögren's syndrome is relatively common and affects 4 million Americans, mostly women. It is most often related to RA, lupus, scleroderma, or polymyositis. Debilitating pain and fatigue can occur. Sensitivity to sunlight is common; sunscreen is helpful.	Plan meals and use artificial saliva for easier swallowing. Chewing sugar-free gum can stimulate saliva production if any is available. Gel-based saliva substitutes are useful. Sip water often, and avoid caffeinated drinks, which can be dehydrating. Drink water during meals to help with swallowing. Mouth infections are common; use good oral hygiene. With dry mouth or dysphagia, there is a risk for aspiration pneumonia. Weight loss and digestive problems are common.
Felty's syndrome	Felty's syndrome only affects about 1% of RA patients. This is a triad of RA, granulocytopenia, and splenomegaly. Painful, stiff, and swollen joints occur. Infections, leg ulcers, burning eyes, and anemia also can complicate the condition. Sometimes, splenectomy is indicated; drug therapy may be helpful to others.	Fever, weight loss, and brown pigmentation may occur. If immunosuppressive drugs are used, monitor for side effects.
Rheumatoid vasculitis	Rheumatoid vasculitis can be life threatening and usually occurs in patients with severe deforming arthritis and a high titer of rheumatoid factor. A majority have a strong human leukocyte antigen relationship. Vasculitic lesions include rheumatoid nodules, small nail fold infarcts, and purpura. Fatigue, weight loss, fever, organ ischemia, CNS infarctions, myocardial infarction, and peripheral neuropathy can occur.	Corticosteroids are the usual treatment. D-penicillamine and prednisone generally are used.

of medication needed; they also downregulate T-cell proliferation. People with RA who eat 4 oz of fish every day have less morning stiffness, swollen joints, and all-around pain. Fish oil and aspirin are blood thinners, and they should not be taken together for a long time.

Supplements of GLA, as from borage oil, may reduce generation of mediators of inflammation and attenuate symptoms but may cause potentially harmful increases in serum arachidonic acid unless EPA is also used. GLA increases prostaglandin E levels, which increase cyclic adenosine monophosphate (cAMP) levels which, in turn, suppress TNF $\alpha$  synthesis.

Epidemiological studies suggest that the antioxidant potential of dietary carotenoids may protect against the oxidative damage that can result in inflammation (Pattison et al, 2005). Proper antioxidant nutrients provide defense against increased oxidant stress. Supplementation of folate and vitamin B<sub>12</sub> is needed in patients treated with methotrexate to reduce side effects and to offset elevated plasma homocysteine.

Complications of RA may include osteoporosis and chronic anemia. Calcium and vitamin D reduce the bone loss in patients who take steroids. An iron supplement may prevent anemia, and serum ferritin levels may be low. Patients benefit from a basic dietary supplement.

Higher intakes of meat and total protein and lower intakes of fruit, vegetables, and vitamin C are associated with an increased risk of RA (Choi, 2005). However, dietary factors such as fruit, coffee, long-chain fatty acids, olive oil, vitamins A, E, C, and D, zinc, selenium, and iron need to be studied over a longer time period (Pedersen et al, 2005).

Rheumatoid cachexia, loss of muscle mass and strength and increase in fat mass, is very common in patients with RA and persists even after joint inflammation improves (Roubenoff, 2009). Cardiovascular disease is a concern. Body composition studies are as important as BMI and other traditional assessment measures (Elkan et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** B cell, cytokine and inflammation response, and antigen presentation pathways are associated with RA; this confirms the known biological mechanisms for auto-immunity (Ballard et al, 2009).

Clinical/History	Pain and	Lab Work
Height	stiffness >30	RBC
Weight	minutes in	CRP
BMI	the morning	LE prep
Temperature	or after a	Creat (may be
	long rest	decreased)
	Food allergies	

ESR (increases with inflammation)	Ceruloplasmin (may be increased)	Alb, transthyretin
ANA	H & H	Gluc
Rheumatoid factor (RF)	Serum ferritin	BUN
Antistreptococcal antibody titer	Serum B <sub>12</sub>	Ca <sup>++</sup> , Mg <sup>++</sup>
Immunoglobulins (may be elevated in Sjögren's)	Transferrin	Na <sup>+</sup> , K <sup>+</sup>
	Serum folate, RBC folate	Vitamin D <sub>3</sub> status (serum 25-OHD)
	Serum copper	

## INTERVENTION

### OBJECTIVES

- Preserve a high level of physical and social functioning to promote good quality of life; reduce the effects of pain and swelling.
- Maintain satisfactory nutritional status; malnutrition and loss of lean body mass are common in this condition. Monitor weight changes.
- Simplify meal preparation.
- Support the immune system. Consume foods rich in antioxidants, such as carotenoids (Pattison et al, 2005), vitamin E, selenium, and vitamin D. A vegetarian diet may have significant benefits.
- Promote adequate growth in children who have RA; stunting can occur from glucocorticoids.
- Promote return of fat-free body mass and improvement in muscle strength.
- Restrict sodium intake, if needed.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Drug–Nutrient Interaction

**Assessment Data:** Weight and physical activity histories. Medical history, medications and lab values. DEXA scan results.

**Nutrition Diagnosis (PES):** Food-Medication interaction (NC-2.3) related to corticosteroid use secondary to diagnosis of RA as evidence by abnormal Ca<sup>++</sup> level <8.4, DEXA scan at 80% of desirable range for age, perimenopausal status, low calcium and vitamin D intake from diet history.

**Intervention:** Food-Nutrient Delivery—include extra calcium-rich foods. Education about use of steroid therapy and its impact on nutritional status. Counseling about good sources of calcium and vitamin D from diet and supplements, meal planning and shopping tips, dining out guide, referral to Meals-on-Wheels or other social agencies as appropriate. Coordinate care with nursing and physician to administer calcium and vitamin D supplements at different time than corticosteroids to help increase absorption.

**Monitoring and Evaluation:** Improvements in dietary and supplemental intake of vitamin D and calcium as shown in food records, lab values, and DEXA scan report.

- Modify patient's diet if hyperlipidemia is present or if there is elevated homocysteine.
- Avoid or correct constipation.

## FOOD AND NUTRITION

- Use a high-protein and high-calorie diet if patient is malnourished. Cachexia is common (Marcora et al, 2005).
- A diet that lessens inflammation is useful; olive oil should be used often because it contains oleocanthal, a natural anti-inflammatory agent.
- Eating fatty fish, such as salmon, sardines, mackerel, hering, and tuna, two times per week is suggested. In addition to fatty fish, other good sources of omega-3s include flaxseed, walnuts, soy, canola oils. Try to acquire 3–6 g of omega-3 fatty acids per day for 4 months.
- An uncooked vegan diet may be useful, with berries, fruits, vegetables, roots, nuts, and seeds; see Table 11-2. There is improvement in RA when eating a lactovegetarian, vegan, or Mediterranean diet (Skoldstam et al, 2005).
- Adequate fluid, fiber, vitamins, and minerals are important. Use foods high in beta-carotene, lutein lycopene, selenium, vitamins C and E; choose nutrient-dense foods. Antioxidants such as beta-cryptoxanthin (as from one glass of freshly squeezed orange juice daily) can reduce the risk of developing RA (Pattison et al, 2005).
- Increase vitamin D intakes to decrease the incidence and severity of RA. Provide adequate intake of calcium, magnesium, B-complex vitamins, potassium, and zinc.
- Increase folic acid if methotrexate is used; enhance diet or encourage folic acid supplements.
- Provide meals that are easy to tolerate when the drugs being used cause gastric irritation. Avoid acidic or highly spiced foods if needed.
- With dysphagia, tube feed or use soft/thick, pureed foods as needed.
- Identify and eliminate any food allergens. Individualize the diet accordingly.

## Common Drugs Used and Potential Side Effects

- With biologic therapies, such as TNF inhibitors, many patients with RA have seen significant improvement in symptoms, function, and quality of life (Barton et al, 2009). See Table 11-14.

**TABLE 11-14 Medications Used in Rheumatoid Arthritis**

Medications	Uses/Effects	Side Effects	Monitoring
Analgesics and nonsteroidal anti-inflammatory drugs (NSAIDs)	Analgesics relieve pain; NSAIDs relieve pain and reduce inflammation.	Upset stomach, peptic ulcer, bleeding, renal failure. Use of NSAIDs may increase rate of miscarriage for pregnant women.	For all traditional NSAIDs: avoid drinking alcohol or using blood thinners; avoid if there is sensitivity or allergy to aspirin or similar drugs, kidney or liver disease, heart disease, high blood pressure, asthma, or peptic ulcers.
Acetaminophen		Usually no side effects when taken as directed.	Not to be taken with alcohol or with other products containing acetaminophen. Not to be used for more than 10 days unless directed by a physician.
Aspirin: buffered, plain	Aspirin is used to reduce pain, swelling, and inflammation, allowing patients to move more easily and carry out normal activities. It is generally part of early and ongoing therapy.	Upset stomach; tendency to bruise easily; ulcers, pain, or discomfort; diarrhea; headache; heartburn or indigestion; nausea or vomiting.	Doctor monitoring is needed. Not used for children in whom Reye's syndrome is a risk, but otherwise useful in lessening inflammation.
Traditional NSAIDs: ibuprofen, ketoprofen, naproxen	NSAIDs help relieve pain within hours of administration in dosages available over the counter (available for all three medications). They relieve pain and inflammation in dosages available in prescription form (ibuprofen and ketoprofen). It may take several days to reduce inflammation.	For all traditional NSAIDs: abdominal or stomach cramps, pain, or discomfort; diarrhea; dizziness; drowsiness or light-headedness; headache; heartburn or indigestion; peptic ulcers; nausea or vomiting; possible kidney and liver damage (rare).	For all traditional NSAIDs: avoid drinking alcohol or using blood thinners; avoid if there is sensitivity or allergy to aspirin or similar drugs, kidney or liver disease, heart disease, high blood pressure, asthma, or peptic ulcers.
Cyclo-oxygenase (COX)-2 inhibitor NSAIDs: celecoxib, valdecoxib	COX-2 inhibitors, such as traditional NSAIDs, block COX-2, an enzyme in the body that stimulates an inflammatory response. Unlike traditional NSAIDs, however, they do not block the action of COX-1, an enzyme that protects the stomach lining. Vioxx was withdrawn by FDA.	Stomach irritation, ulceration, and bleeding may occur. Caution is advisable for patients with a history of bleeding or ulcers, decreased renal function, hepatic disease, hypertension, or asthma.	Doctor monitoring for possible allergic responses to valdecoxib and celecoxib is important.

(continued)

**TABLE 11-14 Medications Used in Rheumatoid Arthritis (continued)**

Medications	Uses/Effects	Side Effects	Monitoring
Corticosteroids	These are steroids given by mouth or injection. They are used to relieve inflammation and reduce swelling, redness, itching, and allergic reactions.	Increased appetite, indigestion, nervousness, or restlessness.	For all corticosteroids, advise the doctor if there is presence of the following: fungal infection, history of tuberculosis, underactive thyroid, herpes simplex of the eye, high blood pressure, osteoporosis, or stomach ulcer.
Methylprednisolone, prednisone	These steroids are available in a pill form or as an injection into a joint. Improvements are seen up to 24 hours after administration. There is potential for serious side effects, especially at high doses. They are used for severe flares or when the disease does not respond to NSAIDs and disease-modifying antirheumatic drugs.	Osteoporosis, mood changes, fragile skin, easy bruising, fluid retention, weight gain, muscle weakness, onset or worsening of diabetes, cataracts, increased risk of infection, and hypertension.	Doctor monitoring for continued effectiveness of medication and for side effects is needed.
Disease-modifying antirheumatic drugs (DMARDs)	These are common arthritis medications. They relieve painful, swollen joints and slow joint damage, and several DMARDs may be used over the disease course. They take a few weeks or months to have an effect and may produce significant improvements for many patients. Exactly how they work is still unknown.	Side effects vary with each medicine. DMARDs may increase risk of infection, hair loss, and kidney or liver damage.	Doctor monitoring allows the risk of toxicities to be weighed against the potential benefits of individual medications.
Azathioprine	This drug was first used in higher doses in cancer chemotherapy and organ transplantation. It is used in patients who have not responded to other drugs and in combination therapy.	Cough or hoarseness, fever or chills, loss of appetite, lower back or side pain, nausea or vomiting, painful or difficult urination, unusual tiredness or weakness.	Avoid with allopurinol or kidney or liver disease. May decrease immunity; contact doctor immediately with chills, fever, or a cough. Regular blood and liver function tests are needed.
Cyclosporine	This medication was first used in organ transplantation to prevent rejection. It is used in patients who have not responded to other drugs.	Bleeding, tender, or enlarged gums; high blood pressure; increase in hair growth; kidney problems; trembling and shaking of hands.	Avoid with sensitivity to castor oil (if receiving the drug by injection), liver or kidney disease, active infection, or high blood pressure. Using this drug may make you more susceptible to infection and certain cancers. Do not take live vaccines while on this drug. Avoid St. John's wort and echinacea.
Hydroxychloroquine	It may take several months to notice the benefits of this drug, which include reducing the signs and symptoms of rheumatoid arthritis.	Diarrhea, eye problems (rare), headache, loss of appetite, nausea or vomiting, and stomach cramps or pain.	Doctor monitoring is important, particularly with an allergy to any antimalarial drug or a retinal abnormality.
Gold sodium thiomalate (Ridaura)	This was one of the first DMARDs used to treat rheumatoid arthritis.	Redness or soreness of tongue; swelling or bleeding gums; skin rash or itching; ulcers or sores on lips, mouth, or throat; irritation on tongue. Monitor joint pain 1 or 2 days after injection.	Avoid with lupus, skin rash, kidney disease, or colitis. Periodic urine and blood tests are needed to check for side effects.
Leflunomide	This drug reduces signs and symptoms and slows structural damage to joints caused by arthritis.	Bloody or cloudy urine; congestion in chest; cough; diarrhea; difficulty, burning, or painful urination or breathing; fever; hair loss; headache; heartburn; loss of appetite; nausea and/or vomiting; skin rash; stomach pain; sneezing; and sore throat.	Doctor must monitor for the following: active infection, liver disease, known immune deficiency, renal insufficiency, or underlying malignancy. Regular blood tests, including liver function tests, are needed. Leflunomide must not be taken during pregnancy; it may cause birth defects in humans.

(continued)

**TABLE 11-14 Medications Used in Rheumatoid Arthritis (continued)**

Medications	Uses/Effects	Side Effects	Monitoring
Methotrexate (Rheumatrex)	This drug can be taken by mouth or by injection and results in rapid improvement (it usually takes 3–6 weeks to begin working). It is very effective, especially in combination with infliximab or etanercept. It produces more favorable long-term responses compared with DMARDs such as sulfasalazine, gold sodium thiomalate, hydroxychloroquine and may be used in pediatrics.	Abdominal discomfort, chest pain, chills, nausea, mouth sores, painful urination, sore throat, and unusual tiredness or weakness.	Doctor monitoring is important, particularly with an abnormal blood count, liver or lung disease, alcoholism, immune system deficiency, or active infection. Methotrexate must not be taken during pregnancy because it may cause birth defects in humans. Avoid Echinacea. Extra folic acid is needed.
Sulfasalazine	This drug suppresses the immune system.	Abdominal pain, aching joints, diarrhea, headache, sensitivity to sunlight, loss of appetite, nausea or vomiting, and skin rash.	Doctor monitoring is important, particularly with allergy to sulfa drugs or aspirin or with a kidney, liver, or blood disease.
Biological response modifiers	These drugs selectively block cytokines, which play a role in inflammation. Long-term efficacy and safety are uncertain.	Increased risk of infection, especially tuberculosis. Increased risk of pneumonia, and listeriosis (a foodborne illness caused by the bacterium <i>Listeria monocytogenes</i> ).	Avoid eating undercooked foods (including unpasteurized cheeses, cold cuts, and hot dogs) to reduce listeriosis while taking biological response modifiers.
Tumor necrosis factor inhibitors: etanercept (Enbrel), golimumab (Simponi), infliximab (Remicade), and adalimumab (Humira)	Highly effective for treating patients with an inadequate response to DMARDs. Often prescribed in combination with methotrexate. Etanercept requires subcutaneous injections twice weekly. Infliximab is taken intravenously (IV) during a 2-hour procedure, along with methotrexate. Adalimumab requires injections every 2 weeks.	<i>Etanercept</i> : pain or burning in throat, redness, itching, pain, and/or swelling at injection site, runny or stuffy nose. <i>Infliximab</i> : abdominal pain, cough, dizziness, fainting, headache, muscle pain, runny nose, shortness of breath, sore throat, vomiting, wheezing. <i>Adalimumab</i> : redness, rash, swelling, itching, bruising, sinus infection, headache, nausea. <i>Golimumab</i> : respiratory infection, sore throat and nasal congestion.	Doctor monitoring is important, particularly with active infection, exposure to tuberculosis, or a central nervous system disorder. Evaluation for tuberculosis is necessary before treatment begins.
Interleukin-1 inhibitor: anakinra (Kineret)	This medication requires daily injections. Long-term efficacy and safety are uncertain.	Redness, swelling, bruising, or pain at the site of injection; headache; upset stomach; diarrhea; runny nose; and stomach pain.	Doctor monitoring is required.
Selective Costimulation Modulator: Abatacept	Abatacept is given intravenously in a 30-minute infusion. It may be given alone or with DMARDs.	Cough, dizziness, headache, infections, sore throat.	Doctor monitoring is needed.
CD20 Antibody: Rituximab	This medication is for people whose rheumatoid arthritis has not responded to other biologic agents. It is given by two IV infusions 2 weeks apart. It is given with methotrexate.	Abdominal pain, chills/shivering, fever, headache, infection, itching.	Doctor monitoring is needed.
Other medications	Pilocarpine hydrochloride (Salagen) and cevimeline (Evoxac).	Available to treat dry mouth associated with Sjögren's syndrome. They stimulate the salivary glands.	

Adapted from: National Institutes of Health. Health topics. Accessed December 19, 2009 at [http://www.niams.nih.gov/Health\\_Info/Rheumatic\\_Disease/default.asp#ra\\_16](http://www.niams.nih.gov/Health_Info/Rheumatic_Disease/default.asp#ra_16).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician. Some people have tried acupuncture and other alternatives to traditional medicine, but it is important not to neglect regular health care or treatment of serious symptoms. Female patients tend to use alternative treatments for RA more than males; psychosocial intervention may be beneficial.
- With borage oil, concomitant NSAID use may undermine the effects. Borage oil is contraindicated in pregnancy given the teratogenic and labor-inducing effects of prostaglandin E agonists.
- St. John's wort and echinacea should not be used with cyclosporine or methotrexate.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Adoption of a Mediterranean diet confers health benefits in this population because of greater consumption of fruits and vegetables, lower consumption of animal products, and use of olive oil, which modulates immune function (Wahle et al, 2005). Inclusion of omega-3 fatty acids is also important (Berbert et al, 2005); herring, salmon, sardines, tuna, and mackerel are good dietary sources.
- No evidence exists to prove that foods from the nightshade family (potatoes, tomatoes, eggplant, and sweet and hot peppers) should be excluded.
- Encourage nutrient-dense foods. If intake is poor, a vitamin–mineral supplement may be needed. Dietary quinones, phenolics, vitamins, amino acids, isoprenoids, and other compounds in functional foods have become very popular (Losso and Bawadi, 2005).
- Instruct patient about simplified planning and preparation tips. Sandwiches, prepared meals, pre-cut fruits and vegetables are easy to use. Cook double portions and freeze leftovers for another day.
- Discourage quackery and substitute sound health practices.
- Carbohydrate intolerance occurs because of chronic inflammation and use of steroids; planning must reflect individual needs.
- A support group may be helpful for coping.
- Physical therapy and exercise are beneficial for most patients. Strengthening exercises may help improve patient's ability to walk and may decrease joint pain and fatigue. Dynamic exercise is beneficial in RA (Hurkmans et al, 2009).
- Check on bone density; there is a high incidence of osteoporosis when steroids are used.

## Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# RUPTURED DISC

## NUTRITIONAL ACUITY RANKING: LEVEL 1

### DEFINITIONS AND BACKGROUND

Determining the cause of back pain is complicated as it is often multifactorial; anatomical abnormalities are common in the spine and may not necessarily translate into clinical symptoms (Sheehan et al, 2010).

A slipped or ruptured disc is called a cervical radiculopathy, herniated intervertebral disc, lumbar radiculopathy, or prolapsed intervertebral disc. In this condition, slipping or prolapse of a cervical or lumbar disc occurs, with neck, shoulder, or low back pain accordingly. Degenerating changes in the disks begin around 30 years of age. Overweight and obesity increase the risk of low back pain and the need for medical attention (Shiri et al, 2010).

With **lumbar radiculopathy**, ambulation may be painful, and limping can occur. Muscular weakness, severe back pain that radiates to buttocks or legs and feet, pain that worsens with coughing or laughing, tingling or numbness in legs or feet, and muscle contractions or spasms may also result. With **cervical radiculopathy**, neck pain in back and sides is deep; pain may radiate to shoulders, upper arms, or forearms and worsens with coughing or laughing. Spasm of neck muscles and pain that worsens at night may occur.

A laminectomy surgically removes the lamina of a vertebra. Percutaneous automated discectomy (PAD) surgery can be performed in some cases; this surgery breaks up the disc and removes fragments. There is no convincing medical evidence to support routine use of lumbar fusion, but it may be useful in patients with associated spinal deformity, instability, or associated chronic low-back pain (Resnick et al, 2005). Surgery for radiculopathy with herniated lumbar disc and symptomatic spinal stenosis is associated with short-term benefits compared to nonsurgical therapy, though benefits diminish with long-term follow-up in some trials (Chou et al, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** This condition is acquired and not genetic.

<b>Clinical/History</b>	Myelography	Na <sup>+</sup> , K <sup>+</sup>
Height	Discography	Alb, transthyretin
Weight	Spinal or	BUN, Creat
BMI	neck x-rays	Alk phos
I & O	Nerve	Gluc
BP	conduction	Vitamin D <sub>3</sub>
Constipation	velocity test	status (serum
Edema		25-OHD)
MRI or computed	<b>Lab Work</b>	
tomography	H & H	
(CT) scan	Ca <sup>++</sup> , Mg <sup>++</sup>	

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal GI Function

**Assessment Data:** Weight and physical activity histories. Medical history and medications.

**Nutrition Diagnosis (PES):** Abnormal GI function related to constipation and infrequent stooling pattern as evidenced by GI distress and evacuation every 3–4 days.

**Intervention:** Food-nutrient delivery—Assure intake of adequate fluid and fiber at all meals. Education—Discuss tips for alleviating constipation through use of specific foods rich in fiber (fruits, vegetables, whole grains, beans and legumes). Coordinate care—Work with nursing and physicians to determine if any medications that cause constipation can be changed, or if some type of laxative can be added.

**Monitoring and Evaluation:** Improvement in bowel habits; alleviation of constipation.

### INTERVENTION

### OBJECTIVES

- Maintain adequate rest and activity levels, as assigned by physician.
- Prevent weight gain from decreased activity.
- Encourage adequate hydration.
- Prevent constipation and straining.
- Assist with feeding, if patient is in traction.
- Relieve pain and promote healing.

### FOOD AND NUTRITION

- A regular diet generally is sufficient. For some, a strict energy-controlled diet may be beneficial to promote weight loss.
- Increased fluid and fiber intake can be helpful to reduce constipation. Fresh fruits and vegetables, dried beans, legumes, whole grains, bran, and other foods may be needed.

### Common Drugs Used and Potential Side Effects

- Anti-inflammatory drugs may be used. NSAIDs are used for long-term pain control, but narcotics may be given if the pain does not respond. Nausea, GI distress, and anorexia may result. Follow directions regarding when to take (e.g., before or after meals).
- Analgesics may be helpful to relieve pain. Chronic use of aspirin may cause GI bleeding.
- Muscle relaxants may be ordered. GI distress or nausea can occur.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Instruct patient regarding effective methods of relieving constipation.
- Discuss role of nutrition and exercise in health maintenance. Weight loss may be needed.
- After surgery, the role of nutrition in wound healing should be discussed.

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# SCLERODERMA (SYSTEMIC SCLEROSIS)

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

Adapted from: Goodheart HP, MD. *Goodheart's Photoguide of Common Skin Disorders*, 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2003.

### DEFINITIONS AND BACKGROUND

Scleroderma is a chronic disease characterized by fibrosis and autoantibodies. Approximately 2% of the population in Europe and North America suffers from disorders such as scleroderma (Chen and von Mikecz, 2005). Genetic, immunological, hormonal, and environmental factors are considered to be triggers (Molina and Shoenfeld, 2005).

The diffuse form affects a large area of the skin and several organs; it is also called **systemic sclerosis** (SSc). In SSc, pathological deposition of fibrous connective tissue in the skin and visceral organs occurs. Fibrosis involves an increase of hydroxylysine aldehyde collagen cross-linkages as well as an increase in inflammatory cytokines (Brinckmann et al,

2005). The GI tract is affected, and Raynaud's syndrome (ischemia of fingers) is common.

The limited form of scleroderma affects the skin and sometimes the lungs. The CREST syndrome (**limited cutaneous sclerosis**) is less severe than SSc and causes less internal organ damage. Calcium deposits, Raynaud's phenomenon, esophageal dysfunction, skin damage on fingers, and telangiectasia form the acronym for CREST.

As the disease progresses, large areas of the skin or just the fingers (sclerodactyly) may be affected. Skin on the face tightens and causes a mask-like appearance. Spider veins (telangiectasia) occur on the fingers, chest, face, lips, or tongue. Calcium deposits can occur on the fingers or other bony areas; sores or contractures may result from the scarring. Scarring of the esophagus may be especially detrimental, causing blockage or even cancer. Lungs can be affected, leading to shortness of breath with exercise.

Neurological involvement consists of epilepsy, central nervous system vasculitis, peripheral neuropathy, vascular malformations, headache, and neuroimaging abnormalities; ocular manifestations include uveitis, xerophthalmia, glaucoma, and papilledema (Zulian et al, 2005). SSc is characterized by vasculopathy, inflammation, vasospasm, microvascular involvement is common; an increased prevalence of distal peripheral artery disease in the digits has been found (Hetterna et al, 2008).

**Scleroderma renal crisis** (SRC) occurs in 5–10% of SSc patients, who may present with an abrupt onset of hypertension, acute renal failure, headaches, fevers, malaise, hypertensive retinopathy, encephalopathy, and pulmonary edema (Denton et al, 2009). Multiple organ system dysfunction may occur. Pulmonary hypertension, heart failure, and respiratory failure cause serious morbidity and mortality. There is no known cure, and SSc can be fatal.

There seems to be an increased prevalence of celiac disease in patients with scleroderma (Rosato et al, 2009). Both disorders require careful management. Current therapies for scleroderma target the immune system, with the goal of reducing inflammation, ischemic injury to the involved organs, and secondary tissue injury and fibrosis (Hennes and Wigley, 2007).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Genetic factors contribute to disease susceptibility; transforming growth factor- $\alpha$  is a cytokine that contributes to fibroblast activation, collagen overproduction, and pathological tissue fibrosis (Varga, 2008). T-cell polarization is implicated in the lung disease of SSc (Boin et al, 2008).

<b>Clinical/History</b>	Nausea, vomiting	Gluc
Height	Diarrhea, constipation	Prothrombin time (PT)
Weight	Skinfold measurements	Alb, transthyretin
BMI		CRP
I & O		GFR
Weight loss		BUN, Creat
Fever?		Homocysteine
BP		$\text{Ca}^{++}$ , $\text{Mg}^{++}$
Thickening, swelling of the ends of the fingers	<b>Lab Work</b> ANA (high) RF (high) LDL Cholesterol (elevated)	$\text{Na}^+$ , $\text{K}^+$ Alk phos Vitamin D <sub>3</sub> status (serum 25-OHD)
Dysphagia	Trig (may be low)	Fecal fat test, hydrogen breath
Heartburn	Anti-tTG antibody	test for malabsorption
Fibrosis of salivary and lacrimal glands	Serum folate H & H	
Abdominal pain, flatulence	Serum B <sub>12</sub>	

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Difficulty Swallowing

**Assessment Data:** Weight, medical history, medications. Low salivation and difficulty swallowing.

**Nutrition Diagnosis (PES):** Difficulty swallowing related to low saliva production as evidenced by fibrosis, inability to swallow solids.

**Intervention:** Food-Nutrient Delivery—Alteration in food choices to liquefy meals and make them easier to swallow. Educate about the use of saliva substitutes, more fluids, altered food choices as needed. Counseling about when to request changes, such as tube feeding.

**Monitoring and Evaluation:** Improvement in swallowing and tolerance for meals. No weight loss.

## INTERVENTION

### OBJECTIVES

- Prevent or correct protein-energy malnutrition and nutrient deficiencies.
- Correct xerostomia where present; decreased saliva, dysphagia, and difficulty in chewing will result.
- Monitor dysphagia with esophageal involvement; alter method of feeding as needed.
- Counteract vitamin B<sub>12</sub> and fat maldigestion and absorption, which may be common.
- Monitor hypomotility and gastroparesis; alter fiber intake as appropriate. For many patients, nutritional support and relief of symptoms remain the primary management goals.
- Improve quality of life and reduce fatigue; allow return to work or maintenance of energy levels.

### FOOD AND NUTRITION

- Diets high in energy (30–40 kcal/kg) and adequate to high in protein are often necessary. A soft diet with moistened foods and extra fluids is useful. Add fiber if constipation is a problem (such as adding crushed bran to hot cereal).
- Small, frequent feedings may be needed. Tube feed if patient is dysphagic or has obstruction.
- Use parenteral nutrition if GI tract is highly affected, with intractable diarrhea and severe malabsorption.
- If there is celiac sensitivity, omit gluten from the diet.
- Reduce lactose if intolerance occurs. Extra calcium may be needed if lactose is not tolerated orally.
- Give supplements of fat- and water-soluble vitamins.
- With hypertension and multiple organ system dysfunction, reduced sodium or fluid restriction may be needed.

### Common Drugs Used and Potential Side Effects

- Topical or systemic corticosteroids, vitamin D analogs (calcitriol and calcipotriol), photochemotherapy, laser therapy, antimalarials, phenytoin, D-penicillamine, and colchicine all have varying degrees of success. Topical tacrolimus cream is an immunosuppressive antibiotic.
- Interstitial lung disease can be treated with cyclophosphamide, vascular disease of the lungs and digits with endothelin receptor antagonists, and general symptoms with phosphodiesterase inhibitor sildenafil or prostacyclins (Hennes and Wigley, 2007).
- Early, aggressive treatment with angiotensin-converting enzyme inhibitors helps with a renal crisis (Denton et al, 2009).
- Anti-inflammatory agents, such as steroids, are often used in SSc. Monitor for nitrogen and calcium losses, altered electrolyte levels, and elevated glucose levels. Correct diet accordingly.
- Antihypertensives usually are needed; monitor BP results. Potassium supplements may or may not be required; determine need according to medication selected.
- Trental (pentoxifylline) is used for Raynaud's syndrome to improve circulation. Anorexia or GI distress may result.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- For Raynaud's disease, evening primrose, ginkgo, mustard, garlic, borage, and red pepper have been suggested, but there are no clinical trials that prove effectiveness.
- CAM is frequently used to treat stress-related disorders such as scleroderma; some merit can be noted (Hui et al, 2009).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Artificial saliva (Xero-Lube) or lemon glycerine may be useful.
- Chew sugarless gum.
- If eating orally, adequate chewing time will be required.
- Consume adequate fluids. Choose moist foods or foods with sauces/gravies.
- For heartburn, keep head elevated after meals; decrease or limit intake of chocolate, caffeine, fatty foods, alcohol, citrus, and tomatoes.
- Physical therapy and exercise may help maintain muscle strength but cannot totally prevent joints from locking into stiffened positions.

### Patient Education—Food Safety

If enteral or parenteral nutrition is used, careful sanitation and handling techniques must be taught and used.

# Hematology: Anemias and Blood Disorders

## CHIEF ASSESSMENT FACTORS

- Anorexia
- Beefy, Red Tongue or Magenta Tongue; Other Signs of Nutrient Deficiencies
- Blood Type
- Bruising
- Concurrent Asthma, Cancer, Cerebrovascular Disease, Hemorrhage, Myocardial Infarction, Renal Disease
- Dietary Habits: Use of Heme and Nonheme Iron, Vitamin and Mineral Deficiencies, Protein Intake, Vegan Lifestyle
- Exposure to Lead Paint, Other Toxins
- Family History of Allergies, Anemias, Cancer, Immune Disorders, and Leukemias
- Fatigue
- History of Alcohol and Nicotine Use
- Infections, Sepsis
- Lymphadenopathy
- Medication Use (Prescriptions, Over-the-Counter) and Use of Herbal or Botanical Medications
- Occupational or Environmental Exposure to Toxic Substances
- Previous Blood Disorder, Bleeding Tendencies, Blood Transfusion, or Exposure to Radiation
- Surgery, Especially Gastric, Hepatic, or Renal

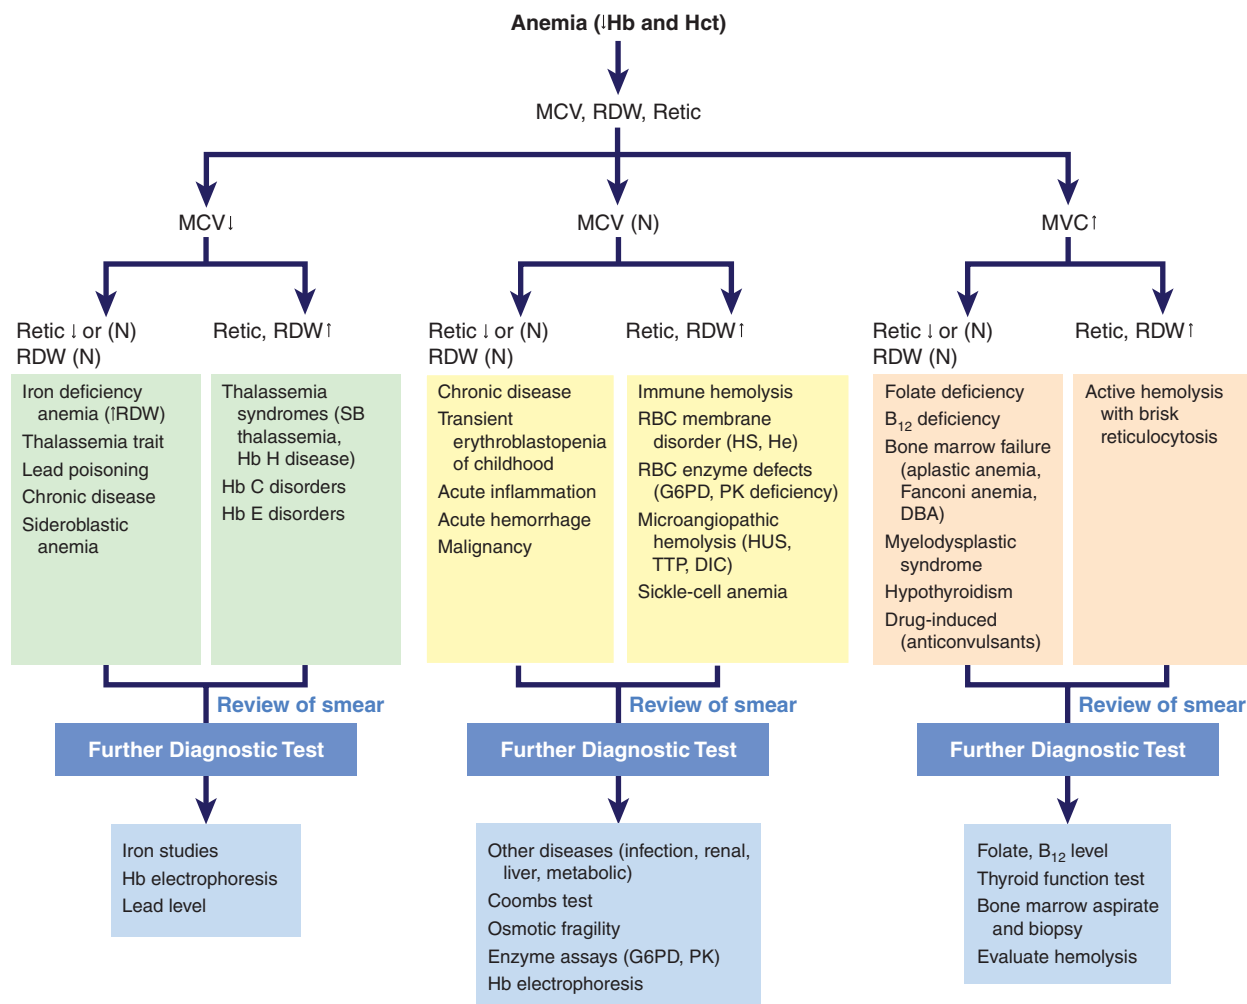

## GENERAL INFORMATION ABOUT ANEMIAS

Blood contains plasma and cells. Plasma is clear and yellow and makes up 55% of blood. It contains proteins, nutrients, hormones, and electrolytes. White cells, red blood cells (RBCs), and platelets make up the remaining 45% of blood. The white cells fight infection, platelets are necessary for blood clotting, and RBCs carry oxygen throughout the body. Hepcidin, the main iron regulatory hormone, is made primarily in hepatocytes in response to liver iron levels, inflammation, hypoxia, and anemia (Munoz et al, 2009). Erythropoietin is the hormone that stimulates RBC production. The erythrocyte life span is 120 days, after which the cells are destroyed by the spleen. Anemias are a set of hematological disorders with a reduced number of RBCs, reduced amount of hemoglobin (Hgb), or reduced number of volume-packed RBCs (hematocrit [Hct]). Excessive bleeding, decreased RBC production, and increased RBC destruction may lead to anemias. The main consequences of these disorders include hypoxia and decreased oxygen-carrying capacity. Overall, anemias affect over 3.4 million people in the United States. Chronic disease and iron deficiency are the most common causes. Other causes of anemias include peptic ulcers, inflammation, infection, cancers, gastritis, liver

disease, renal disease, hypothyroidism, history of blood transfusions, blood coagulation disorders, and poor diet. Generally, Hgb, serum iron, TIBC or UIBC, and serum ferritin will establish iron status. In conditions due to blood cell production or cancers, other tests or procedures are needed to determine the cause for abnormal iron levels. These may include a complete blood count (CBC) with differential, zinc protoporphyrin (ZPP) immunological tests, hormone tests, reticulocyte count, C-reactive protein (CRP), sedimentation rate (SED rate), B<sub>12</sub> or folate levels, genetic testing, tissue biopsy, MRI, ultrasound, bone marrow aspiration, blood smears, urine or fecal sampling, scopes (endoscope or colonoscopy), and tests associated with specific diseases or conditions that can have anemia or iron overload.

Anemias can be encountered with generalized or specific nutritional deficiencies (Table 12-1). The nutritional anemias are caused by deficits, but not all anemias require nutritional intervention. Use caution when evaluating single laboratory results; most anemias have a specific profile. For example, iron and copper participate in one-electron exchange reactions; the same property that makes them essential also generates free radicals that can be seriously deleterious to cells (Arredondo and Nunez, 2005). Table 12-2 provides some key definitions that are used to describe anemias.

Red cell distribution width (RDW), a measure of heterogeneity in the size of circulating erythrocytes, is associated with some chronic diseases and predicts mortality.

**TABLE 12-1 Nutritional Factors in Blood Formation**

Protein
Iron
Vitamin C
Vitamin E
Folic acid
Vitamin B <sub>6</sub>
Vitamin B <sub>12</sub>
Vitamin K
Copper
Riboflavin (minute amounts)

Inadequate intakes of many nutrients are now known to contribute to several chronic diseases. Folic acid and vitamin B<sub>12</sub> are among the key nutrients involved. Vitamin B<sub>12</sub> deficiency, iron or folate deficiency, chronic gastrointestinal (GI) bleeding, and myelodysplastic syndrome are causes of anemia in the elderly. Anemias are more common in the hospitalized elderly than among those who live independently.

Iron is an essential micronutrient as it is required for adequate erythropoietic function, oxidative metabolism, and cellular immune responses (Munoz et al, 2009). Yet it is one of the most frequently lacking nutrients in both developing and developed countries. Iron-deficiency anemia (IDA) affects about 25% of infants worldwide. Adults, especially menstruating women, are also susceptible. Laboratory tests provide evidence of iron depletion in the body, or reflect iron-deficient red cell production; the appropriate combination of these laboratory tests help establish a correct

**TABLE 12-3 Iron Tests**

Hemoglobin	Reflects the level of functional iron. Low levels can indicate iron-deficiency anemia or ACD. Hemoglobin values help determine if anemia is present and if a blood donation can be done
Serum ferritin	Measures the amount of iron in storage. One ferritin molecule can hold as many as 4500 iron atoms. Ferritin can be elevated when a person has an infection or inflammatory condition
Serum iron (Fe)	Free or unbound iron in serum. Ideal range is 40–180 µg/dL. Measurement is best done fasting because serum iron is sensitive to foods or supplements recently consumed, time of day, and menstruation
Transferrin	Iron-binding and transport protein that can bind to and transport two molecules of iron. Transferrin carries iron through the bloodstream to the bone marrow, the liver, and ferritin. Transferrin is no longer measured directly by most physicians, instead TIBC is used
TIBC	Demonstrates the iron-binding ability of transferrin. Serum iron divided by TIBC × 100% provides the transferrin-iron saturation percentage (Tsat%), which is also called iron saturation. Normally, Tsat% is 25–35%. Higher numbers are suggestive of iron loading. Lower numbers are suggestive of iron-deficiency anemia

From: Iron Overload Disease Association, <http://www.irondisorders.org/Forms/irontests.pdf>, accessed December 21, 2009.

diagnosis of ID status and anemia (Munoz et al, 2009). Table 12-3 lists some relevant tests and Table 12-4 lists common signs and symptoms of anemias.

Up to 10% of young women in developed countries are iron deficient. The problem is not easily resolved by adopting

**TABLE 12-2 Definitions**

Acute anemia	Precipitous drop in the RBC population due to hemolysis or acute hemorrhage
Anemia	Reduction in the number of circulating RBCs, the amount of hemoglobin, or the volume of packed RBCs (Hct)
Chronic anemia	Anemia that lasts 2 months or longer
Hypochromia	Blood condition in which there is a low level of hemoglobin and color
Hyperchromia	Blood that is excessively pigmented
Microcytic anemia	Usually caused by or resulting in iron deficiency; RBCs are small in size
Macrocytic anemia	Folic acid or vitamin B <sub>12</sub> insufficiency; RBCs are larger than usual
Megaloblastic anemia	Anemias in which there are large, nucleated abnormal RBCs that are irregular in shape, from pernicious anemia or use of certain immunosuppressive or antitumor drugs
Normocytic anemias	Inhibition of marrow by infection or chronic disease; RBCs are of usual size
Normochromia	Blood with a normal color and level of hemoglobin

**TABLE 12-4 General Signs and Symptoms of Anemia**

- Anorexia
- Ascites
- Bowel irregularity
- Chest pain, palpitations
- Coldness of extremities
- Dizziness, especially postural
- Dyspnea, especially exercise intolerance
- Decreased libido or impotence
- Decreased urine output
- Difficulty sleeping or concentrating
- Fatigue, weakness, irritability
- Headache
- Mental status changes
- Pale conjunctiva
- Tachycardia
- Thirst
- Tinnitus
- Vertigo, syncope

## Comparing Disorders of Iron

IRON PANEL TESTS	Serum Iron	Serum Ferritin	Transferrin Iron Saturation Percentage	Total Iron Binding Capacity (TIBC)	Transferrin	Hemoglobin
Hemochromatosis	↑	↑	↑	↓	↓	NORMAL
Iron Deficiency Anemia	↓	↓	↓	↑	↑	↓
Sideroblastic Anemia	↑	↑	↑	↓	↓	↓
Thalassemia	↑	↑	↑	↓	↓	↓
Porphyria Cutanea Tarda (PCT)	↑	↑	↑	↓	↓	NORMAL
Anemia of Chronic Disease (ACD)	↓	↑ OR NORMAL	↓	↓	↓	↓
African Siderosis (AS)	↑	↑	↑	↓	↓	NORMAL
Vitamin B <sub>12</sub> Deficiency (pernicious anemia)	↑ OR NORMAL	↑ OR NORMAL	↑ OR NORMAL	↓ OR NORMAL	↓ OR NORMAL	↓

an iron-rich diet because absorption varies greatly. Although the absorption of dietary iron (1–2 mg/d) is regulated tightly, it is balanced with losses (Munoz et al, 2009). Dietary heme iron is important and more readily absorbed than nonheme iron derived from vegetables and grains. Most heme is absorbed in the proximal intestine.

Inherited Hgb disorders, such as sickle cell anemia and thalassemia, can be attributed to the effects of natural selection. In environments in which malaria was common, carriers were protected and survived to have more children.

## ANEMIAS

## ANEMIA OF CHRONIC DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 2

## DEFINITIONS AND BACKGROUND

Anemia of chronic disease (ACD) is the condition of impaired iron utilization where functional iron (Hgb) is low, but tissue iron (such as in storage) is normal or high. ACD is known as anemia of inflammation (AI). Low Hgb,

low total iron-binding capacity (TIBC), and low transferrin with elevated ferritin are identified. ACD is the second most common type of anemia after anemia of iron deficiency; it results in increased morbidity and mortality of the underlying disease (Agarwal and Prchl, 2009). ACD is seen in a wide range of chronic autoimmune, cancerous or leukemic,

inflammatory, and infectious disease conditions. In rheumatoid arthritis, ACD and iron-deficiency anemia coexist, resulting from GI bleeding due to the use of many drugs. ACD is also found in approximately 50% of patients with lupus (Giannouli et al, 2006). In aging and heart failure, chronic anemia is common.

Hepcidin is the iron regulatory peptide that is synthesized in the liver to suppress iron absorption and utilization. Synthesis is suppressed by anemia, hypoxia, and erythropoiesis, and induced by inflammatory cytokines such as interleukin-6 (Matsumoto et al, 2009). ACD is characterized by macrophage iron retention induced by cytokines and hepcidin. Excess hepcidin causes proteolysis of the cellular iron exporter, ferroportin, trapping iron in macrophages, and iron-absorbing enterocytes (Ganz and Nemeth, 2009). Because circulating hepcidin levels affect iron traffic, its determination may aid to differentiate between ACD and iron-deficiency anemia to select an appropriate therapy (Theurl et al, 2009).

Hgb improvement is an independent predictor of quality of life improvement in anemic patients, yet supplementation with iron for those with ACD can be harmful and even result in death. Levels of erythropoietin are reduced in ACD. The genetically engineered form (epoetin) can correct anemia caused by cancer in about 50–60% of patients and may improve survival in HIV infection.

Epoetin can eliminate the need for transfusions but is very expensive.

Successful treatment of the underlying disease improves ACD, but if not possible, treatment with erythropoietic agents (ESAs), supplemented with iron if necessary, is helpful in many cases (Agarwal and Prchl, 2009). ESAs are safe and may forestall some of the target-organ damage (Nurko, 2006).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Modifications of hepcidin gene expression suggest a key role for hepcidin in iron homeostasis. HAMP is the gene that encodes hepcidin.

<b>Clinical/History</b>	Headache, irritability	Hgb and Hct (H & H) (high)
Height		
Weight		
Body mass index (BMI)	<b>Lab Work</b>	Serum ferritin (high)
Diet history	Complete blood count (CBC)	Serum Fe
Intake and output (I & O)	RBC count	Glucose (Gluc)
Blood pressure (BP)	Serum hepcidin level	Transferrin (low)
Fatigue and weakness	Total iron-binding capacity (TIBC) (low)	Albumin (Alb)
		C-reactive protein (CRP)

## SAMPLE NUTRITION CARE PROCESS STEPS

### Abnormal Nutritional Laboratory Values

**Assessment Data:** Weight, BMI normal. Hgb is low at 10; ferritin is normal. GI bleeding and pain.

**Nutrition Diagnoses (PES):** Abnormal nutritional laboratory values related to chronic anemia and high doses of medications for lupus as evidenced by low Hgb, normal serum ferritin, and GI bleeding.

**Interventions:** Food-nutrient delivery—encourage nutrient-dense foods and frequent snacks; avoid fasting. Education about low-calorie, nutrient-dense foods and timing with medications. Counseling about timing of medications with food to reduce GI bleeding. Coordinate care with medical and nursing teams to review medications and determine which, if any, could be changed to reduce impact on GI tract.

**Monitoring and Evaluation:** No additional GI bleeding or distress. Resolution or improvement of anemia. Hgb closer to normal.

## INTERVENTION

### OBJECTIVES

- Prevent infections or sepsis.
- Reduce fever and excessive inflammation.
- Lessen bleeding tendencies and hemorrhages.
- Ensure adequate periods of rest. Simplify meal planning if needed.
- Prepare for bone marrow transplantation, if needed.
- Prevent further complications and decline in organ functioning.

### FOOD AND NUTRITION

- Provide a balanced diet that is easily prepared, with six small feedings.
- Provide extra fluid unless contraindicated.
- If steroids are used, limiting sodium intake may be needed.
- Correct iron overload where present.

## Common Drugs Used and Potential Side Effects

- Genetically engineered erythropoietin (epoetin) is often used; given weekly, it can improve quality of life and levels of energy.
- Avoid iron supplements in this condition; they can be harmful and even result in death.
- Corticosteroids may be used. Watch side effects of chronic use such as elevated serum sodium levels, decreased potassium and calcium levels, and negative nitrogen balance. Hyperglycemia may occur; alter diet accordingly.
- Antibiotics may be required when infections are present. Monitor for GI distress and other effects.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Alpha tocopherol and N-acetylcysteine have been recommended, but more controlled studies are needed.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss needs of the patient, which are specific for signs, symptoms, and side effects of any medications.
- Discuss nutritious meal planning. If patient has diabetes, heart failure, or cirrhosis, counsel specifically for those issues.
- Correcting anemia in heart failure patients improves quality of life and exercise capacity in both men and women (Fox and Jorde, 2005). Once improvement is noted, activity levels can be increased.
- Counsel about reduction of iron overload if present. For example, iron-fortified cereals and oral supplements containing iron should be avoided. Increase grains, fruits, vegetables, cheese, and dairy foods; use fewer heme iron sources.

- Being female is often independently associated with lower Hgb, so assess using sex-specific laboratory values (Fox and Jorde, 2005).

### Patient Education—Food Safety

If tube feeding or central parenteral nutrition (CPN) is needed, careful handwashing procedures should be followed.

# ANEMIAS IN NEONATES

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

**Anemia of prematurity (AOP)** is a normocytic, normochromic anemia that presents with very low Hgb and low erythropoietin level. Inadequate RBC production may occur, and the average life span of these cells is about 35–50 days (compared with 120 days for adults). Three causes of AOP include inadequate RBC production, shortened RBC life span, or blood loss. AOP is very common among those born prematurely, where prevalence may be as high as 50% in those born before 32 weeks of gestation. It is also especially common in those born with weight below 1500 g (Haiden et al, 2006).

**Hemolytic disease of the newborn** (erythroblastosis fetalis) is a condition in which RBCs are broken down or destroyed more rapidly than normal, causing hyperbilirubinemia, anemia, or death; hemolytic disease of the newborn may occur in Rh-positive babies born to Rh-negative mothers (Merck Manual, 2009). Critically ill, extremely premature infants develop anemia because of intensive laboratory blood testing and undergo multiple RBC transfusions in the early weeks of life (Widness et al, 2005). Poor weight gain, apnea and tachypnea, lethargy, tachycardia, and pallor are symptoms.

Reducing anemia in infants may be a preventive measure to lower disease burden from infectious disease in this

vulnerable population (Levy et al, 2005). Nutritional deficiencies of vitamin E, vitamin B<sub>12</sub>, and folate exaggerate the degree of anemia. Vitamin E supplementation, however, when given to preterm infants, does not reduce the severity of this anemia. Administration of vitamin B<sub>12</sub> and folate with erythropoietin and iron may enhance erythropoietin-induced erythropoiesis more than erythropoietin alone (Haiden et al, 2006).

When detected early in pregnancy, iron-deficiency anemia is associated with a greater risk of preterm delivery (Scholl, 2005). However, it is important not to overdo iron intake. High levels of Hgb, Hct, and ferritin are associated with an increased risk of fetal growth restriction, preterm delivery, and preeclampsia (Scholl, 2005).

**Diamond-Blackfan anemia (DBA)** (erythrogenesis imperfecta or congenital hypoplastic anemia) is a rare blood disorder characterized by deficiency of RBCs at birth. Other symptoms including slow growth, abnormal weakness, fatigue, pallor, characteristic facial abnormalities, protruding shoulder blades, abnormal shortening of the neck due to fusion of cervical vertebrae, hand deformities, and congenital heart defects. DBA may be inherited as either an autosomal dominant or recessive genetic trait, where the body's bone marrow produces little or no RBCs. A genetic error on chromosome

19 is associated with about 25% of cases, and there is a family history of the disorder in 10–20% of cases.

DBA affects approximately 600–700 million people worldwide but can be difficult to identify. The symptoms may also vary greatly, from very mild to severe and life threatening. DBA is usually diagnosed within the first 2 years of life, sometimes even at birth, on the basis of symptoms. The diagnosis of this anemia might not be recognized right away, however, because it is rare.

The first line of treatment for DBA is prednisone. About 70% of children with DBA will respond to this life-long treatment, where the medication stimulates the production of more RBCs. If steroids do not work, the next treatment is blood transfusions. Regular blood transfusions will provide RBCs but can lead to iron overloading. Normally, the body uses iron when making new RBCs, but since the person with DBA is not making many cells, the iron builds up. The person then needs to take medication that takes the excess iron out of the body. The only cure available for DBA is bone marrow transplantation. Stem-cell transplantation with human leukocyte antigen (HLA)-matched stem cells has been used for DBA (Kuliev et al, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Anemia in a newborn may be caused by a genetic condition such as congenital hypoplastic anemia. In DBA, a genetic alteration on chromosome 19 has been noted.

<b>Clinical/History</b>	Fatigue and pallor I & O	Serum Fe and ferritin Gluc Alb CRP
Height		
Weight		
BMI		
Diet history	<b>Lab Work</b>	Serum folic acid
Slow growth in child (low height–weight percentiles)	CBC RBC count H & H (>2 standard deviations below mean for age)	and B <sub>12</sub> K <sup>+</sup> , Na <sup>+</sup> Calcium
BP		
Weakness		

## INTERVENTION

### OBJECTIVES

- Provide improved oxygenation for tissues.
- Prevent infections or sepsis. Reduce fevers or excessive inflammation.
- Control hyperglycemia or other side effects of treatments.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Vitamin-Mineral Intake

**Assessment Data:** Low birth weight (1450 g), poor suck. Lab work shows low Hgb and serum B<sub>12</sub>; diagnosis of anemia. Pallor, listlessness, and tachycardia.

**Nutrition Diagnoses (PES):** Inadequate vitamin and mineral intake related to poor suck and low birth weight as evidenced by lab work with low Hgb and serum B<sub>12</sub>. Inadequate weight gain.

**Interventions:** Nutrient delivery—specialized infant formula with added calories and administration of vitamin B<sub>12</sub>, folate, erythropoietin and iron.

**Monitoring and Evaluation:** Improvement in heart rate, growth, and pallor. Resolution of anemia.

- Prevent further complications.
- Support growth.

## FOOD AND NUTRITION

- Provide an appropriate formula that is easily prepared, with small feedings given frequently.
- Provide extra fluid unless contraindicated.

## Common Drugs Used and Potential Side Effects

- If corticosteroids are used, watch side effects of chronic use such as elevated serum sodium levels, decreased potassium and calcium levels, and negative nitrogen balance. Hyperglycemia may occur; alter diet accordingly. Besides diabetes, glaucoma, bone weakening, and high blood pressure can occur, and the medication may suddenly stop working for that person at any point in time.
- Antibiotics may be required when infections are present. Monitor for gastrointestinal distress and other side effects.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss needs of the patient, which are specific for signs and symptoms and for side effects of any medications.
- Discuss nutritious meal planning.
- If patient has diabetes, counsel specifically for nutritional management.
- Activity levels must be restricted to avoid accidents or falls that could promote bleeding.
- Referral to the Women, Infants, and Children (WIC) Program can be beneficial. WIC programs are helpful in

improving Hgb concentration among young children (Altucher et al, 2005). Age-specific values should be used to assess progress:

#### Age-Specific Values for Hemoglobin and Hematocrit

Age	Hb (g/dL)	Hct (%)
28-week gestation	14.5	45
32-week gestation	15	47
Term	16.5	51
1–3 days	18.5	56
2 weeks	16.6	53

## ANEMIA OF RENAL DISEASES

### NUTRITIONAL ACUITY RANKING: LEVEL 2

#### DEFINITIONS AND BACKGROUND

**Anemia of renal disease** occurs in both acute and chronic renal disease. This type of anemia is often normochromic, normocytic, and sometimes microcytic. When the kidneys become diseased, scar tissue forms and prevents the cells that make erythropoietin from functioning. The buildup of uremic toxins and decreased erythropoietin production adversely affects erythropoiesis. The accumulation of toxic metabolites, which are normally excreted by the kidneys, shortens the life span of circulating RBCs. Management is complicated by a vicious circle of cardiorenal anemia syndrome in which CKD, heart failure, and anemia exacerbate each other (Besarab et al, 2009).

There is an inverse relationship between blood urea nitrogen (BUN) levels and RBC life span, but there is also diminished renal production of erythropoietin. If no cause for anemia other than chronic kidney disease is detected on the basis of the workup and the serum creatinine is  $\geq 2$  mg/dL, anemia is most likely due to erythropoietin deficiency; measurement of serum erythropoietin levels is not needed.

Anemia usually starts during the third stage of renal disease, when glomerular filtration rate (GFR) is below 60 cc/minute but before dialysis has started. Short daily hemodialysis and daily home nocturnal hemodialysis can control blood pressure and manage anemia in this population (Pierratos, 2005). Correction of anemia appears to improve cardiac function and quality of life without a greater risk for adverse events (Besarab et al, 2009).

#### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** In disorders such as type-2 diabetes, chronic kidney disease is common. Anemia may be present and cause fatigue and difficulty with daily activities such as climbing stairs.

Clinical/History	Lab Work	
Height	CBC and RBC	<sup>a</sup> Transferrin saturation
Weight	count	(serum iron $\times 100 \div$
BMI	Serum Fe	TIBC)
Diet history	Hgb (may be	$<20\%$ ?
BP	$<12$ g/dL)	<sup>b</sup> Reticulocyte
I & O	Hct (often	hemoglobin
Weakness	$<33\%$ )	content
Fatigue and	Serum ferritin:	(CHr)
pallor	(100 absolute	Serum soluble
Dizziness	deficiency;	transferrin
Difficulty	overload	receptor
concentrating	$>800$ ng/dL	(sTfR)—
Shortness of	TIBC	elevated?
breath		

Gluc	Test for occult	Creatinine
Alb	blood	(Creat)
CRP	Blood urea	
Serum folic acid	nitrogen	
and B <sub>12</sub>	(BUN)	

<sup>a</sup>The best indicator for iron availability for erythropoiesis.

<sup>b</sup>Half-life of reticulocytes is 1 day; it represents immediate availability of bone marrow iron.

## INTERVENTION

### OBJECTIVES

- Prevent infections or sepsis. Reduce fever and excessive inflammation.
- Prevent further complications such as heart failure. Fluid may accumulate and build up in the lungs and liver.
- Support growth in children.
- Improve energy level and decrease fatigue, irritability, and infections.

### FOOD AND NUTRITION

- Provide a balanced diet that is easily prepared, with small feedings given frequently.
- Provide extra fluid unless contraindicated.
- Provide sufficient foods rich in iron and B-vitamins, as appropriate (depending on laboratory values, current status, predialysis, or dialysis).

## Common Drugs Used and Potential Side Effects

- Iron therapy is effective in 30–50% of patients with CKD. A serum ferritin concentration of 100–500 ng/mL is the target during oral and IV iron therapy for predialysis and

peritoneal dialysis patients. IV administration and a target serum ferritin concentration of 200–500 ng/mL is recommended for hemodialysis patients (Besarab et al, 2009; Grabe, 2007).

- Erythropoietin Stimulating Agents (ESAs) are given when Hgb falls below 10 g/dL. Epoetin (EPO) is used when oral iron therapy fails (Nurko, 2006). This can be given every week, or every 2 weeks, or monthly. The two formulations of EPO, epoetin alpha (ProCrit) and darbepoetin (Aranesp, DPO), are effective. Longer half-life of darbepoetin alpha permits administration on a once-monthly basis in patients with CKD and anemia (Grabe, 2007). A recent addition is methoxypolyethylene glycol-epoetin beta (Mircera) that has a longer half-life and can be given every 2 weeks.
- Iron deficiency and inflammation are possible causes of inadequate response to ESAs (Grabe, 2007). In the iron-replete patient with an inadequate response to epoetin, the following conditions should be evaluated and treated, if reversible: infection or inflammation (AIDS, lupus); chronic blood loss; aluminum toxicity; hemoglobinopathies (thalassemias, sickle cell anemia); folate or vitamin B<sub>12</sub> deficiency; multiple myeloma; malnutrition; or hemolysis.
- Ferric gluconate maintains Hgb and allows lower epoetin doses in anemic hemodialysis patients with low TSAT and ferritin levels up to 1200 ng/mL (Kapoian et al, 2008).
- Parenteral iron is reserved for dialysis patients or those who are intolerant of oral iron. Iron dextran (In-FeD, Dexferrum), sodium ferric gluconate (Ferrlecit), and iron sucrose (Venofer) are available. Ferumoxytol is a new IV iron preparation for CKD (Schwenk, 2010). Iron dextran may cause serious allergic reactions.
- Vitamin C helps increase absorption. Dairy and antacids decrease absorption.
- Docusate helps alleviate constipation. Iron supplements can darken stools.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. Because the use of CAM is increasing among children and adults with chronic illnesses, efforts should be made to identify those therapies that are beneficial, harmless, and cheap for possible integration with conventional therapy (Oshikoya et al, 2008). Adverse side effects are possible.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss needs of the patient that are specific for signs and symptoms and side effects of any medications.
- Discuss simplified, but nutritious, meal planning.
- If patient has diabetes, heart failure, or cirrhosis, counsel specifically for nutritional management.
- Activity levels must be restricted to avoid accidents or falls that could promote bleeding.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Vitamin Intake

**Assessment Data:** CKD with low erythropoietin production; Hgb >12 and Hct >33% with EPO. Serum folic acid and vitamin B<sub>12</sub> levels remain low. Physical signs of vitamin deficiency.

**Nutrition Diagnoses (PES):** Inadequate vitamin intake related to poor oral intake as evidenced by diet history, recent anorexia, low serum levels of B<sub>12</sub> and folate, and minimal use of prescribed water-soluble vitamins.

**Interventions:** Food-Nutrient Delivery—In addition to EPO and iron, use vitamin B<sub>12</sub> and folic acid supplements. Educate about the need to use the supplements daily and to retest lab work every 3–6 months. Counseling about good food sources of folic acid and vitamin B<sub>12</sub>.

**Monitoring and Evaluation:** Lab work showing normal B<sub>12</sub> and folic acid levels. Fewer complaints of fatigue; no physical signs of vitamin deficiency.

- People who take EPO shots should have regular tests to monitor their Hgb. If it climbs above 12 g/dL, their doctor should prescribe a lower dose of EPO.

### Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

## APLASTIC ANEMIA AND FANCONI'S ANEMIA

### NUTRITIONAL ACUITY RANKING: LEVEL 1

### DEFINITIONS AND BACKGROUND

**Aplastic anemia** is a rare bone marrow disorder with normocytic, normochromic anemia in which normal marrow is replaced with fat. Aplastic anemia, myelodysplastic syndromes, and paroxysmal nocturnal hemoglobinuria (PNH) occur when the bone marrow stops making healthy blood-forming stem cells that produce RBCs, white blood cells, and platelets. Telomeres, repeat sequences at the ends of chromosomes, are protective chromosomal structures that shorten with every cell cycle; aplastic anemia is associated with inherited mutations in telomere repair or protection genes (Calado, 2009).

In about 50% of cases, the cause may be inherited or due to autoimmunity. In other cases, exposure to toxic agents (e.g., radiation, heavy metals, inorganic arsenic) or use of drugs (e.g., phenylbutazone, chloramphenicol, anticonvulsants) may be the cause. Use of interferon-gamma (IFN- $\gamma$ ) may be responsible for certain aspects of the pathology seen in bone marrow failure syndromes, including aplastic anemia (Zeng et al, 2006). Signs and symptoms are listed in Table 12-5.

Treatment includes blood transfusion, preventive antibiotics, careful handwashing, hormone therapy, immunosuppressive therapy, and medications to enhance bone marrow cell production. Severe aplastic anemia (SAA) is life threatening and can be treated with bone marrow transplantation, immunosuppressive therapy, and high-dose cyclophosphamide (Brodsky et al, 2009). Resolution of iron overload (such as serum ferritin >1000 ng/mL) should be addressed before transplant because it may lead to lethal infections (Storey et al, 2009).

**Fanconi's anemia (FA)** is a rare, genetic disorder characterized by multiple congenital anomalies, progressive bone marrow failure, and an increased prevalence of leukemia or liver cancer (Fagerlie and Bagby, 2006). FA is characterized

by delayed bone marrow failure with progression to aplastic anemia. It may be apparent at birth or between ages 2 and 15 and is characterized by deficiency of all bone marrow elements including RBCs, white blood cells, and platelets (pancytopenia). FA is associated with cardiac, kidney, or skeletal abnormalities as well as vitiligo or patchy, brown discolorations (pigmentation changes) of the skin. There are

**TABLE 12-5 Signs and Symptoms of Aplastic or Fanconi's Anemias**

Blood in stool
Bronzing of skin (café au lait spots)
Dizziness
Headache, irritability
Hemorrhagic diathesis (gums, nose, GI tract, urinary tract, vagina)
Hemosiderosis with resulting cirrhosis, diabetes, heart failure
Increasing fatigue and weakness
Increasing or persistent infections
Irritability
Missing or horseshoe kidney (FA)
Missing or misshapen thumbs (FA)
Nausea
Oral thrush or lesions
Petechiae, ecchymosis
Scoliosis
Skeletal anomalies of spine, hips, ribs (FA)
Slow thought processes, headache
Small head, low birth weight (FA)
Tachycardia, tachypnea, dyspnea
Waxlike pallor

several different subtypes, each of which results from abnormal mutations of different genes. Prognosis is poor among those individuals with low blood counts. Treatment of FA involves transfusions, bone marrow transplantation, or gene therapy. FA patients do not tolerate radiation well and are prone to cancers, even after transplantation. Currently, life span is not long; many children do not survive to adulthood.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** In Caucasians, genetic variations in IFNG may be found. Mutations TERC and TERT genes are also seen in aplastic anemia. The FANCM or FNACJ gene mutations are responsible for some forms of Fanconi's anemia.

Clinical/History	Lab Work	White blood cell (WBC) count (<1500)
Height	RBC count (decreased)	Alb,
Weight	Prothombin	transferritin
BMI	time (PT)	CRP
Diet history	Serum Fe	Alanine amino-
BP	Gluc	transferase
GI problems	Granulocytes (decreased)	(ALT)
See Table 12-5 also	Transferrin	Aspartate
Bone marrow biopsy	H & H	aminotrans-
Ultrasound	Platelets (decreased)	ferase (AST)
Hand x-ray or CT scan		Bilirubin

## SAMPLE NUTRITION CARE PROCESS STEPS

### Self-Feeding Difficulty

**Assessment Data:** Low BMI, medical hx with diagnosis of Fanconi's anemia, misshapen thumbs with difficulty holding utensils.

**Nutrition Diagnoses (PES):** Self-feeding difficulty (NB-2.6) related to hand deformity as evidenced by low BMI and difficulty consuming enough at mealtimes.

**Interventions:** Food-nutrient delivery—add extra kilocalories to foods and recipes, such as extra fats and carbohydrates. Include extra protein-rich foods as tolerated between meals. Serve finger foods and beverages that can be taken through a straw (milkshake, eggnog). Educate parents about changes in menus and foods for greater intake of nutrient and energy-dense foods. Counsel for ways to enhance self-feeding with use of adaptive feeding equipment.

**Monitoring and Evaluation:** Improvement in BMI over time and better intake from nutrient and energy-dense foods. Enhanced skills using adaptive feeding tools.

## INTERVENTION

## OBJECTIVES

- Prevent infections or sepsis. Reduce fevers.
- Reduce bleeding tendencies and hemorrhages.
- Ensure adequate periods of rest.
- Prepare for splenectomy or bone marrow transplantation.
- Prevent further complications, where possible, and decline in cardiovascular and hepatic functions.

## FOOD AND NUTRITION

- Replenish nutrient stores.
- Provide a balanced diet that is easily prepared, with six small feedings.
- Provide extra fluid unless contraindicated (35 cc/kg or more).
- If patient has mouth lesions, avoid excesses of hot or cold foods, spicy or acidic foods, or foods with rough textures.
- If steroids are used, limit sodium intake.

## Common Drugs Used and Potential Side Effects

- Growth factors (erythropoietin, G-CSF, and GM-CSF) may help to improve blood counts.
  - Corticosteroids may be used. Side effects of chronic use include elevated serum glucose and sodium levels, decreased potassium and calcium levels, and negative nitrogen balance.
- High-dose cyclophosphamide is highly effective therapy for SAA, but large randomized controlled trials are necessary to compare with either bone marrow transplantation or use of antithymocyte globulin and cyclosporine (Brodsky et al, 2009).
- Antibiotics may be required for infections; monitor for GI distress and other side effects.
- Aspirin should be avoided because it may aggravate blood losses. Other drugs that may aggravate the condition include chloramphenicol, phenylbutazone, sulfa drugs, and ibuprofen. Each of these has specific GI side effects that should be monitored (see index for more information).
- A list of drugs that can cause acquired aplastic anemia is found at [http://www.wrongdiagnosis.com/a/aplastic\\_anemia/medic.htm#medication\\_causes\\_list](http://www.wrongdiagnosis.com/a/aplastic_anemia/medic.htm#medication_causes_list)

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss needs of the patient, which are specific for signs and symptoms and for side effects of any medications.
- Discuss simplified, but nutritious, meal planning.

- If patient has diabetes, heart failure, or cirrhosis, counsel specifically to those issues for nutritional management.
- Activity levels must be restricted to avoid accidents or falls that could promote bleeding.
- Genetic counseling is advised for parents who wish to have more children.

### Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

# COPPER DEFICIENCY ANEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Copper has a role in the production of Hgb (the main component of RBCs), myelin (the substance that surrounds nerve fibers), elastin, collagen (a key component of bones and connective tissue), and melanin (a dark pigment that colors the hair and skin). It is required for the function of over 30 proteins, including superoxide dismutase, ceruloplasmin, lysyl oxidase, cytochrome c oxidase, tyrosinase, and dopamine beta-hydroxylase (Arredondo and Nunez, 2005).

One third of the total body pool of copper is found in skeletal muscle; one third is found in brain and liver; the final third is found in bone and other tissues. Copper is also found in trace amounts in all tissues in the body and is excreted primarily in the bile.

Copper is needed in minute amounts for the formation of Hgb. The metabolism of copper and iron are closely related. Systemic copper deficiency generates cellular iron deficiency, which results in diminished work capacity, reduced intellectual capacity, diminished growth, alterations in bone mineralization, and diminished immune response (Arredondo and Nunez, 2005). Copper deficiency also results in reduced activity of white blood cells and reduced thymus hormone production, thus resulting in increased infection rates.

Marginal deficits of this element can contribute to the development and progression of a number of disease states including cardiovascular disease and diabetes (Li et al, 2005; Urui-Adams and Keen, 2005). Homocysteine thiolactone accumulates when homocysteine is high; it inhibits lysyl oxidase, which depends on copper to catalyze cross-linking of collagen and elastin in arteries and bone. A copper deficiency should, therefore, be avoided. Betaine, copper, folate,

pyridoxine, and vitamin B<sub>12</sub> have proven to be beneficial in lowering serum homocysteine levels. Overall, supplementation with 3–6 mg of copper per day can improve copper status in otherwise healthy individuals; increased intake could reduce the risk of atherosclerosis by promoting improved fibrinolytic capacity (Bugel et al, 2005).

Copper, along with zinc and iron, is an essential metal for normal central nervous system development and function. Imbalances can result in neuronal death (apoptosis), which may contribute to Alzheimer's disease, Parkinson's disease, amyotrophic lateral sclerosis (ALS), and Huntington's disease. Imbalances can also result in neuron deaths in traumatic brain and spinal cord injury, stroke, and seizures (Levenson, 2005).

People with poor intake of protein or whose diets are very high in milk may become deficient in copper or iron. Infants fed on all cow's milk diet without copper supplements may develop copper deficiency. Acquired copper deficiency may be a delayed complication of gastric surgery.

Zinc supplementation (150 mg/d) or vitamin C (1500 mg or more) will reduce copper absorption and increase the potential for anemia. Other conditions that can lead to copper deficiency include burns, pancreatic or liver disease, kidney disease, diarrhea, and prematurity.

Bicytopenia (anemia and neutropenia) with normal platelet count is a feature of hematological disorders caused by copper deficiency; abnormalities improve within a few months after copper supplementation therapy (Nagano et al, 2005). Ceruloplasmin (Cp) is a copper-containing plasma protein with an important role in iron homeostasis; levels are low when copper intake is deficient.

Hospitalized patients should be evaluated carefully. Although enteral feedings contain adequate concentrations

of trace elements, problems with bioavailability may occur, and patients receiving long-term enteral feeding should be monitored to avoid anemia and leukopenia (Ito et al, 2005; Oliver et al, 2005). Copper supplementation is essential in parenteral nutrition to prevent an adverse effect of deficiency; requirements in CPN amount to 0.3 mg/d in adults and 20 µg/kg body wt/d in infants or children (Shike, 2009). Nutritional deficiencies that can occur in otherwise asymptomatic normally growing children are often overlooked (Suskind, 2009). If present, they have a significant impact on the health of the child.

Another area for careful review is bariatric surgery. Serum copper levels should be monitored in patients with a neurologic syndrome, who have undergone gastric bypass surgery (Naismith et al, 2009; Griffith et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Copper anemias are acquired.

Clinical/History	Ceruloplasmin	Serum zinc
Height	(low)	(Zn) (often elevated)
Weight	H & H	Homocysteine
BMI	Serum Fe	Alb,
Diet history	Serum ferritin	transferrin
BP	(increased)	CRP
See Table 12-6	Macrocytic, hypochromic anemia	Retinol-binding protein (RBP)
<b>Lab Work</b>	Platelets	
CBC	(normal)	
Serum copper (low)	Erythropoietin levels	
	(elevated)	

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Mineral Intake

**Assessment Data:** Nutritional laboratories showing low-serum copper and Cp with high-serum zinc. Previous bariatric surgery (>1 year) with recent medical visit. Other laboratories are normal. Diet hx reveals low intake of copper from foods.

**Nutrition Diagnoses (PES):** Inadequate mineral intake of copper related to significant decrease in total food consumed each day for past year post-gastric bypass surgery as evidenced by low-serum Cu and Cp levels and regular use of Zn supplements.

**Interventions:** Education about ways to enhance copper from meals and snacks. Decrease use of single-Zn supplements and use a multivitamin-mineral supplement that contains copper.

**Monitoring and Evaluation:** Improved serum Cu and Cp levels after 3 months; better intake of copper-rich foods. Serum Zn within normal range.

**TABLE 12-6 Symptoms of Copper Insufficiency and Anemia**

Anorexia
Bone fractures
Cardiovascular disease, increased serum cholesterol levels
Diarrhea
Dermatitis or loss of pigmentation of skin, pallor
Edema
Fatigue
Growth retardation
Hair loss
Irregular heart rhythms
Labored respiration, decreased oxygen delivery
Nerve conduction problems
Neurological and immunological abnormalities in newborns if mothers are deficient (Urui-Adams and Keen, 2005).
Myeloneuropathy and myelopathy
Poor collagen formation, decreased wound healing
Reduced red blood cell function
Reduced thyroid function
Shortened red cell life span
Skeletal defects from bone demineralization
Skin sores
Weakness

## INTERVENTION

### OBJECTIVES

- Correct copper deficiency and documented anemias.
- Instruct patient regarding good sources of protein, iron, and copper to prevent recurrences.
- Monitor use of zinc in supplements, diet, and enteral or parenteral sources to avoid overdosing and related copper depletion.

## FOOD AND NUTRITION

- Good sources of copper include oysters, liver, nuts, dried legumes, and raisins. A typical diet provides about 2- to 3-mg copper/d, about half of which is absorbed. A supplement of 3- to 6-mg copper may be useful in adults.
- Protein should be at least 1 g/kg for adults; iron intake should be adequate for age and sex.
- Monitor use of multivitamin-mineral supplements to avoid large doses of zinc. Ascorbic acid can act as a pro-oxidant in the presence of metals such as iron or copper; large doses are not recommended.
- Monitor tube-fed patients to ensure that they are receiving sufficient amounts of copper (Ito et al, 2005; Oliver et al, 2005).

**TABLE 12-7 Food Sources of Copper**

Blackstrap molasses
Black pepper
Chicken
Chocolate (unsweetened or semisweet baker's chocolate and cocoa)
Enriched cereals (bran flakes, raisin bran, shredded wheat)
Fruits (such as cherries, dried fruits, bananas, grapes)
Legumes (such as soybeans, lentils, navy beans, and peanuts)
Nuts and nut butters (cashews, filberts, macadamia nuts, pecans, almonds, and pistachios)
Organ meats (beef liver, kidneys, and heart)
Potatoes
Seafood (oysters, squid, lobster, mussels, crab, and clams)
Seeds (pumpkin)
Tea
Vegetables (avocado, mushrooms, potatoes, sweet potatoes, tomatoes)
Whole grains

### Common Drugs Used and Potential Side Effects

- Cupric sulfate is one brand of injectable copper supplement. Copper gluconate is given orally. Beware of excesses, which can be indicated by black or bloody vomit, bloody urine, diarrhea, heartburn, loss of appetite, lower back pain, metallic taste, nausea (severe or continuing), pain or burning while urinating, vomiting, yellow eyes or skin, dizziness or fainting, severe headache, or even coma.
- Do not refrigerate this supplement. Discard when outdated.
- Avoid taking copper supplements with nonsteroidal anti-inflammatory drugs (NSAIDs), birth control pills, allopurinol, estrogen hormones, or cimetidine.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Have patient avoid fad diets. Monitor vegetarian (non-heme iron) diets carefully.
- Zinc in large doses may deplete copper levels; discuss use of mineral supplements. (Rowan and Lewis, 2005).

- Patients at risk for copper deficiency should be counseled on how to avoid this condition. For example, patients with muscular dystrophy may not consume adequate amounts, and muscle strength can diminish as a result (Motlagh et al, 2005).
- Discuss foods that are good sources of protein, iron, and copper; see Table 12-7.
- Be aware that some denture creams contain a high amount of zinc that could be a concern (Spain et al, 2009).

### Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

# FOLIC ACID DEFICIENCY ANEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Three steps for metabolism of dietary folic acid to the bioavailable form.

### DEFINITIONS AND BACKGROUND

Folic acid is composed of a pterin ring connected to *p*-aminobenzoic acid (PABA). Humans do not generate folate because they cannot synthesize PABA. The amino acid histidine is metabolized to glutamic acid. Formiminoglutamic acid (FIGLU) is an intermediary in this reaction, and tetrahydrofolic acid is the coenzyme that converts it to glutamic acid. Under normal conditions, sufficient intake of dietary histidine can prevent anemia. When dietary intake of histidine is diminished or urinary excretion is greatly increased, anemia results. Folate deficiency depletes histidine through increased urinary excretion.

Folic acid is needed for the synthesis of DNA and maturation of RBCs. Deficiency of folate can lead to many clinical abnormalities, including macrocytic anemia, cardiovascular diseases, birth defects, and carcinogenesis (including colorectal cancer). Folic acid-deficiency anemia generally is caused by inadequate diet, intestinal malabsorption, alcoholism, or pregnancy (Table 12-8).

Folic acid deficiency yields a hyperchromic, macrocytic, megaloblastic anemia. Because similar hematological changes occur with vitamin B<sub>12</sub> deficiency, it is important to check the serum levels of vitamin B<sub>12</sub> along with folate tests. Folate is best

measured by RBC folate because serum levels are misleading and reflect more recent intake.

Homocysteine elevation is a risk factor for vascular and thrombotic disease. Genetic and acquired influences have been evaluated. While neural tube defects result from maternal

Folic acid anemic cells are hypochromic and macrocytic. Adapted from: *Anderson's Atlas of Hematology*; Anderson, Shauna C., PhD. Copyright 2003, Wolters Kluwer Health/Lippincott Williams & Wilkins.

 Surgery

Medications that interact with folic acid:

- Antiepileptic drugs (AED): phenytoin, carbamazepine, primidone, valproic acid, phenobarbital, and lamotrigine impair folate absorption and increase the metabolism of circulating folate
- Capecitabine: Folinic acid (5-formyltetrahydrofolate) may increase the toxicity of Capecitabine
- Dihydrofolate reductase inhibitors (DHFRIs): DHFRIs block the conversion of folic acid to its active forms, and lower plasma and red blood cell folate levels. DHFRIs include aminopterin, methotrexate, sulfasalazine, pyrimethamine, triamterene, and trimethoprim. Administer leucovorin at the same time
- Nonsteroidal anti-inflammatory drugs (NSAIDs): NSAIDs inhibit some folate dependent enzymes. NSAIDs include ibuprofen, naproxen, indomethacin, and sulindac
- Cholestyramine, Colestipol, Cycloserine, Isotretinoin, oral contraceptives, Methylprednisolone, pancreatic enzymes, Pentamidine, Sulfasalazine either decrease folic acid absorption or increase excretion
- Smoking and alcohol: reduced serum folate levels may occur

folate insufficiency in the periconceptual period, there are also inborn errors of folate metabolism that aggravate the problem.

DNA methylation occurs by transfer of a methyl group from S-adenosylmethionine (SAM) to cytosine (Abdolmaleky et al, 2004). SAM serves as a methyl group donor in important functions such as changing norepinephrine to epinephrine, chromatin remodeling, RNA inhibition and modification, and DNA rearrangement (Abdolmaleky et al, 2004). Prenatal intakes of folic acid, vitamin B<sub>12</sub>, choline, and betaine influence the degree of DNA methylation (Waterland and Jirtle, 2004). Methylation affects adult susceptibility to asthma, cancer, autism, bipolar disease, Alzheimer's disease, stroke, and schizophrenia.

Folate deficiency can result in congenital neural tube defects and megaloblastic anemia; inadequacy is associated with high blood levels of the amino acid homocysteine,

which has been linked with the risk of arterial disease, dementia, and Alzheimer's disease (Malouf et al, 2008). Decreasing or low levels of folic acid may also be associated with depression in older adults.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Congenital folate malabsorption, methylenetetrahydrofolate reductase (MTHFR) deficiency, and formiminotransferase deficiency are genetic defects. MTHFR deficiency causes neurological problems even without megaloblastic anemia. MTHFR polymorphisms on chromosome 1 affect 10% of the world's population, especially Caucasians. Varied DNA methylation patterns influence the biological response to food components and vice versa (Milner, 2006).

Clinical/History	Lab Work	
Height	RBC folate	Serum Fe (increased)
Weight	(<140 ng/mL) – best	Mean cell volume (MCV)
BMI	Serum folate (<3 ng/mL)	Leukopenia, WBC
Diet history	MTHFR alleles?	Urinary formimino-glutamic acid (FIGLU) after histidine load
BP	Mild	Serologic testing for parietal cell and intrinsic factor (IF) antibodies (vs. Schilling test)
I & O	hyperhomocystinemia (15–25 mmol/L)	
Weight loss	Moderate hyperhomocystinemia (26–50 mmol/L)	
Anorexia, malnutrition	Low RBC H & H	
Smooth and sore red tongue	CBC (macrocytic cells)	
Diarrhea	Transferrin	
Fatigue, lethargy	Serum B <sub>12</sub>	
Poor wound healing		
Coldness of extremities		
History of alcohol abuse?		

## INTERVENTION

### OBJECTIVES

- Increase folate in diet and supplemental folic acid to alleviate anemia.
- Improve diet to provide nutrients needed to make RBCs: folate and other B-complex vitamins, iron, and protein. Instruct patient to correct faulty diet habits if relevant.
- Check for malabsorption syndromes (celiac disease, blind-loop syndrome, congenital or acquired megacolon, Crohn's disease) and correct these as far as possible through use of medications and other treatments.
- Monitor serum folic acid status regularly.

registered trademark of Merck; Deplin is one brand, containing 7.5 mg of L-methylfolate.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Vitamin C promotes absorption of folate from foods. See Table 12-9 for a list of folate sources.
- Pregnant women should receive appropriate counseling; 30% may have a folate deficiency. Daily needs increase by approximately 200 µg over the adult requirements of 400 µg. Folate protects against neural tube defects in the first trimester.

**TABLE 12-9 Folic Acid Sources**

Source	Folic Acid (µg)
Breakfast cereals fortified with 100% of the DV	400
Beef liver, cooked, braised, 3 ounces	185
Black-eyed peas, immature, cooked, boiled, half cup	105
Spinach, frozen, cooked, boiled, half cup	100
Great Northern beans, boiled, half cup	90
Asparagus, cooked, four spears	85
Broccoli, cooked, half cup	84
Rice, white, long-grain, parboiled, enriched, cooked, half cup	65
Vegetarian baked beans, canned, one cup	60
Spinach, raw, one cup	60
Green peas, frozen, boiled, half cup	50
Broccoli, chopped, frozen, cooked, half cup	50
Egg noodles, cooked, enriched, half cup	50
Avocado, raw, all varieties, sliced, half cup sliced	45
Peanuts, all types, dry roasted, 1 ounce	40
Lettuce, Romaine, shredded, half cup	40
Wheat germ, crude, two tablespoons	40
Tomato Juice, canned, 6 ounces	35
Orange juice, chilled, includes concentrate, three-fourth cup	35

Derived from: NIH Fact Sheet, <http://ods.od.nih.gov/factsheets/folate.asp>, accessed December 27, 2009.

- Women who have a folic acid allele in the MTHFR gene may need to use a special brand of supplement, such as Neevo ([pamlabs.com](http://pamlabs.com)) during pregnancy.
- Large intakes of folic acid (>1 mg/d) can cure the anemia but may mask a correlated vitamin B<sub>12</sub> anemia; monitor carefully. 5-methyl THFA enters cells via a diverse range of folate transporters where it may be demethylated to THFA, the active form. Because vitamin B<sub>12</sub> is required in this conversion, its absence traps folic acid in its inactive form as 5-methyl THFA.
- In seniors with low vitamin B<sub>12</sub> status, high-serum folate is associated with anemia and cognitive impairment but when not vitamin B<sub>12</sub> status was normal; however, high-serum folate was associated with protection against cognitive impairment (Morris et al, 2009).
- Attractive meals may help appetite. Fad and restrictive diets should be avoided.
- Alcoholic beverages interfere with folate metabolism and absorption.
- Food folates are oxidized easily and destroyed by lengthy cooking; advise patients accordingly.

### Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

# HEMOLYTIC ANEMIAS

## NUTRITIONAL ACUITY RANKING: LEVELS 2–3

### DEFINITIONS AND BACKGROUND

In **hemolytic anemia**, RBCs have an abnormal membrane, which results in hemolysis. RBCs are destroyed faster than they can be produced in bone marrow. In severe cases in infancy, encephalomalacia can result. The incidence of all types of hemolytic anemias is 4 in 100,000 persons in the United States. Treatment may involve splenectomy or steroid use. Most are not affected specifically by vitamin E.

Types of hemolytic anemias include Hgb-SC disease, hemolytic anemia due to glucose-6-phosphate dehydrogenase (G6PD) deficiency, hereditary elliptocytosis, hereditary spherocytosis, idiopathic autoimmune hemolytic anemia, nonimmune hemolytic anemia caused by chemical agents, and secondary immune hemolytic anemia. This text covers aplastic anemia, sickle cell anemia, and thalassemia. Table 12-10 describes some of these types of anemias.

Dizziness	Fatigue, intolerance for exercise	Hgb in urine
Edema	Heart murmur	Hemosiderin in urine
Pallor		TIBC
Nosebleeds, bleeding gums		Bilirubin (elevated)
Dark urine	<b>Lab Work</b>	Transferrin
Jaundice, splenomegaly	RBC (low)	Gluc
Puffy eyelids	Hgb (low)	AST (increased)
Weakness, confusion	Reticulocyte count (increased)	Blood test for G6PD
Chills	Serum alpha-tocopherol levels	CRP

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Some types of hemolytic anemia have genetic links.

<b>Clinical/History</b>	BMI	BP
Height	Diet history	Tachycardia
Weight	Growth percentile	Shortness of breath

### INTERVENTION

### OBJECTIVES

- Prevent further complications.
- Correct anemia or deficits of nutrients, such as vitamin E.

### FOOD AND NUTRITION

- Provide diet as usual for age and sex.
- Avoid excesses of iron.
- Ensure adequate intake of vitamin E and zinc, which may become deficient. Good sources of vitamin E include wheat germ, almonds, sunflower seeds, sunflower or safflower oil, peanut butter, peanuts, corn oil, spinach, broccoli, and

**TABLE 12-10** Types of Hemolytic Anemia

Type	Description
Acquired autoimmune hemolytic anemia	A rare autoimmune disorder characterized by the premature destruction of RBCs. Normally, RBCs have a life span of 120 days before the spleen removes them, but in this condition, RBCs are destroyed prematurely. Bone marrow production of new cells can no longer compensate. This anemia occurs in individuals who previously had a normal RBC system. Patients with autoimmune hemolytic anemia usually are associated with thrombosis
Familial hemolytic jaundice (spherocytic anemia)	A hereditary anemia in which RBCs are shaped like spheres rather than their normal, donut-like shape. Jaundice and anemia occur from destruction of the abnormal cells by the spleen. Surgical removal of the spleen usually is indicated. There is no permanent cure
Glucose-6-phosphate dehydrogenase (G6PD) deficiency anemia	This anemia is seen in about 10% of African-American males in the United States and is also common in persons from the Mediterranean area or Asia. The severity differs among different populations. In the most common form in the African-American population, the deficiency is mild, and the hemolysis affects primarily older RBCs. In Caucasians, G6PD deficiency tends to be more serious because even young red blood cells are affected. It affects millions of people worldwide, especially in malaria-prone areas
Hereditary nonspherocytic hemolytic anemia	A group of rare genetic blood disorders characterized by defective RBCs (erythrocytes) that are not abnormally “sphere shaped” (spherocytes). Membranes of RBCs, abnormal metabolism of a chemical contained in hemoglobin (porphyrin), and deficiencies in certain enzymes such as G6PD or pyruvate kinase are thought to be the cause of these disorders
Vitamin E-sensitive hemolytic anemia	This condition may occur in infants who receive polyunsaturated fatty acids (PUFAs) without adequate vitamin E. Children with cystic fibrosis should be screened for vitamin E-deficient hemolytic anemia

## SAMPLE NUTRITION CARE PROCESS STEPS

## Unintentional Weight Loss

**Assessment Data:** BMI 20, recent weight loss 10#. GI distress and pallor noted. Diagnosis of hemolytic anemia with splenectomy planned.

**Nutrition Diagnoses (PES):** Unintentional weight loss related to GI distress and loss of appetite as evidenced by recent weight loss of 10# in 6 weeks.

**Interventions:** Prepare for splenectomy; use nutrient-dense and energy-rich foods as tolerated, such as milkshakes or eggnogs with or between meals. Educate patient about ways to enhance food intake while not feeling well.

**Monitoring and Evaluation:** Postoperative evaluations; return of appetite and improved intake. No further weight loss; eventual weight regained.

soybean oil. Good sources of zinc include oysters, beef shank, crab, pork, chicken, lobster, baked beans, cashews, and yogurt.

## Common Drugs Used and Potential Side Effects

- For hemolytic anemia that is sensitive to vitamin E deficiency, water-soluble vitamin E (alpha-tocopherol) is likely to be given daily. Avoid taking with an iron supplement, which could interfere with utilization.
- Persons with G6PD deficiency need to avoid exposing themselves to certain medicines such as aspirin (acetylsalicylic acid), certain antibiotics used to treat infections, fava beans, and mothballs.
- Medicines can improve autoimmune hemolytic anemia (AIHA). Where prednisone is used, monitor for side effects. Monoclonal antibody therapy such as rituximab is used in difficult cases; it appears to be a safe and effective option (Hoffman, 2009).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Flavonoid preparations, marketed for a variety of effects and generally safe, should be evaluated carefully because there have been reports of toxic flavonoid–drug interactions, hemolytic anemia, and other problems (Galati and O'Brien, 2004).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- For hemolytic anemia that is sensitive to vitamin E deficiency, discuss, in layman's terms, the role of vitamin E in lipid oxidation and utilization. Discuss sources of polyunsaturated fatty acids (PUFAs) and why excesses should be controlled. Discuss sources of vitamin E in the diet; natural sources are more bioavailable than synthetic sources.
- Discuss exercise tolerance and ability to eat sufficient amounts of food as related to fatigue.

## Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

## IRON-DEFICIENCY ANEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2

## DEFINITIONS AND BACKGROUND

Hgb transports oxygen to the tissues and carbon dioxide back to the lungs where it is exhaled. Hgb levels are influenced by sex, age, altitude, and smoking. In the adult male and the elderly, iron deficiency is usually caused by chronic blood loss. In children and women, low intake of iron may be a problem. The nutrient most commonly deficient in the world is iron. Iron deficiency affects two billion people, mostly in developing countries (Lynch, 2005).

IDA results from inadequate intake, impaired erythropoiesis or absorption of iron, blood loss, or demands from closely repeated pregnancies (Table 12-11). Serious systemic consequences include impaired cognitive function, koilonychia, and impaired exercise tolerance. Hct is the measure of RBCs in a given volume of blood, packed by centrifuge. Transferrin is the carrier protein that picks up iron from the intestines.

Absorption of iron occurs in the ferrous form; storage is in the liver, spleen, and bone marrow. See Table 12-12 for

**TABLE 12-11 Stages of Iron Deficiency**

Stages of Iron Deficiency	Indicator	Diagnostic Range
Stage 1 Depletion of iron stores	Stainable bone marrow iron Total iron binding capacity Serum ferritin concentration	Absent >400 µg/dL <12 µg/L <20 µg/L + low Hb or Hct indicates iron deficiency
Stage 2 Early functional iron deficiency	Transferrin saturation Free erythrocyte protoporphyrin Serum transferrin receptor	<16% >70 µg/dL erythrocyte >8.5 mg/L
Stage 3 Iron deficiency anemia	Hemoglobin concentration Mean cell volume	<12 g/dL <80 fL

Adapted from: Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicon, Vanadium, and Zinc (2002), Iron, p. 302 Food and Nutrition Board (FNB), Institute of Medicine (IOM).

content of iron in various body sources. Approximately 90% of the body's store of iron is reused. Diet replaces iron lost through sweat, feces, and urine. The duodenum (upper small intestine) is where iron is best absorbed. Damage or surgery of the duodenum can greatly inhibit total iron absorption, thus leading to greater risk of deficiency. Table 12-13 describes factors that can modify iron absorption.

IDA is the final stage of a long period of deprivation. Serum ferritin (storage form) is the most useful test to differentiate IDA from ACD. Iron deficiency is relatively common in toddlers, adolescent girls, and women of childbearing age. Ingestion of cow's milk causes occult intestinal blood loss in young infants. The Hgb content of reticulocytes (young RBCs) is a good indicator of iron deficiency and IDA in children. Risk of iron deficiency may be underestimated in high-risk populations.

Postpartum anemia is associated with breathlessness, tiredness, palpitations, and maternal infections, and blood transfusions and iron supplementation have been used in the treatment of IDA. Erythropoietin may be useful.

**TABLE 12-12 Normal Iron Distribution in the Body**

Forms	Men (mg iron/kg BW)	Women (mg iron/kg BW)
Storage—ferritin	9	4
Storage—hemosiderin	4	1
Transport protein: transferrin	<1	<1
Functional hemoglobin	31	31
Functional myoglobin	4	4
Enzymes	2	2
TOTAL	50	42

Based on data from: Insel P, Turner R, Ross D. *Nutrition*. Sudbury, MA: Jones & Bartlett Publishers, 2001.

**TABLE 12-13 Factors That Modify Iron Absorption**

Factor	Description
Physical state (bioavailability)	Heme > Fe <sup>2+</sup> > Fe <sup>3+</sup>
High gastric Ph	Hemigastrectomy, vagotomy, pernicious anemia, histamine H <sub>2</sub> -receptor blockers, calcium-based antacids
Disruption of intestinal structure	Crohn's disease, celiac disease (nontropical sprue)
Inhibitors	Phylates, tannins, soil clay, laundry starch, iron overload
Competitors	Cobalt, lead, strontium
Facilitators	Ascorbate, citrate, amino acids, iron deficiency

From: Information Center for Sickle Cell and Thalassemic Disorders. Iron deficiency. Available at <http://sickle.bwh.harvard.edu/fe-def.html>.

Celiac disease may be present in children and is associated with IDA (Goel et al, 2005). In persistent IDA, screening for celiac disease (anti-tissue transglutaminase antibodies), autoimmune gastritis (gastric, anti-parietal, or anti-IF antibodies), and *Helicobacter pylori* (IgG antibodies and urease breath test) is recommended (Hershko and Ronson, 2009).

Because menstruation increases iron losses each month, women of childbearing age tend to become iron deficient. When there is not enough Hgb, free erythrocyte protoporphyrin (FEP) accumulates. Athletes are also at risk for iron deficiency. Recreational athletes should be screened for iron deficiency using serum ferritin, serum transferrin receptor, and Hgb (Sinclair and Hinton, 2005).

As many as 25% of children and 20% of those seen in mental health clinics have pica, which is characterized by persistent and compulsive cravings to eat nonfood items. Pica can occur in pregnant women, in autism, and in persons with brain injuries. Pica is seen in about half of patients with iron deficiency; it is a consequence of iron deficiency and is relieved by iron supplementation.

Exposure to lead also has a significant effect on Hgb and Hct levels. Serum levels above 50 mcg/dL are a problem. Lead poisoning reduces Hgb production, causes iron deficiency, and elevates FEP as the precursor.

Poor intake of vitamins A, B<sub>12</sub>, C, and E, folic acid, and riboflavin is also linked to the development and control of IDA. Multiple micronutrient (MMN) supplementation during pregnancy reduces the risk of low birth weight, small-for-gestational age, and anemia; MMN supplementation improves CD4 counts and HIV-related morbidity and mortality in adults (Allen et al, 2009).

When Hgb levels are seriously low, the heart is particularly vulnerable. Anemia in heart failure patients is associated with reduced exercise tolerance, increased heart failure hospitalizations, and increased all-cause mortality (Stamos and Silver, 2009). Whole-blood transfusion or IV iron may be needed. Iron fortification of food is also a cost-effective method for reducing the prevalence of nutritional iron deficiency. In populations where young children are routinely fed cooked rice daily, fortifying it with iron helps improve iron status (Beinner et al, 2010).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutations in a type-II serine protease, matriptase-2/TMPRSS6, are associated with severe iron deficiency caused by inappropriately high levels of hepcidin expression; hemojuvelin is a cell surface protein that regulates hepcidin expression (Lee, 2009).

<b>Clinical/History</b>	Flatulence, vague abdominal pains	Mean cell Hgb (MCH) (decreased)
Weight		Mean cell Hct (MCHC) (decreased)
BMI	Anorexia	CBC (every 3–6 months after initial)
Diet history	Diarrhea	Transferrin (increased)
BP	Glossitis, stomatitis	MCV (<80)
I & O	Ankle edema	RBC (small, microcytic, hypochromic)
Pallor	Tingling in extremities	WBC/ differential (increased)
Brittle, spoon- shaped fingernails (koilonychia)	Palpitations	TIBC (increased >350 µg/dL)
Stool examina- tion for occult blood	Alopecia	Reticulocyte count
Impaired cogni- tive function	<b>Lab Work</b>	Serum copper
Blue sclerae	Ferritin (decreased stores in liver, spleen, bone marrow; levels are <20 g/L)	Cholesterol (Chol)
Impaired exercise tolerance	Serum iron (low)	Test for <i>H. pylori</i>
Weakness, fatigue	H & H (Hgb is more sensitive)	
Vertigo		
Headache, irritability		
Heartburn		
Dysphagia		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Harmful Beliefs About Food

**Assessment Data:** Diet hx indicates pica during this pregnancy. Mom states that “the starch is good for my baby.” Eats starch after each meal. Twenty-weeks pregnant; age 19. Low H & H.

**Nutrition Diagnoses (PES):** Harmful beliefs/attitudes (NB-1.2) about food or nutrition-related topics.

**Interventions:** Initial/Brief nutrition education (N.I.2.2) to provide basic nutrition-related educational about food and foods rich in iron; reasons to discontinue eating starch and to begin taking a prenatal vitamin. Counseling—work with client to set goals for a healthier pregnancy.

**Monitoring and Evaluation:** Improvement in H & H. Discontinuation of pica. Positive pregnancy outcome.

## INTERVENTION

### OBJECTIVES

- Alleviate cause of the anemia and associated anorexia.
- Provide adequate oral iron to replace losses or deficits, especially heme sources of protein (liver, beef, oysters, lamb, pork, ham, tuna, shellfish, fish, and poultry).
- Provide an acid medium to favor better absorption. Enhancers include gastric juice and ascorbic acid. Food sources of vitamin C should be included daily.
- Monitor and correct pica, including geophagia (clay eating), amylophagia (starch eating), ice eating, or any lead exposure.
- Avoid or correct constipation.
- Screen for IDA or sports anemia in athletes (Sinclair and Hinton, 2005).
- Reduce iron inhibitors, such as excessive fiber (as in whole grains), phytic acid (as in spinach, bran, legumes, and soy products), tannins in tea, and polyphenols in coffee or red wine. In many developing countries, cereal and legume-based diets contain low amounts of bioavailable iron, which may increase the risk of iron deficiency (Zimmermann et al, 2005).

### FOOD AND NUTRITION

- If IDA is related to inadequate iron in diet, usually adding three portions of lean red meat (heme iron sources) per week, along with all other essential vitamins and minerals, will correct the anemia. The average mixed diet contains approximately 6 mg of iron per 1000 kcal. Iron absorption increases as stores become depleted. Good sources of iron include liver, dried beans, egg yolks, kidney, lean beef, dark meat of chicken, salmon, tuna, dried fruits, enriched whole-grain cereals, molasses, and oysters.
- Heme iron is found readily in beef, pork, and lamb; consume with fruit or fruit juice. Heme iron is absorbed well, regardless of other foods in the diet.
- Nonheme iron absorption is greatly affected by other foods. Absorption of nonheme iron is best in the presence of foods rich in vitamin C or with heme-containing sources. Increase intake of vitamin C (oranges, grapefruit, tomatoes, broccoli, cabbage, baked potatoes, strawberries, cantaloupe, and green peppers), especially with an iron supplement.
- Detect pica and discuss with patient. Pica substance may displace other important foods, leading to nutrient malnutrition. The ingested substance may also be toxic.
- Tea, coffee, wheat brans, and soy products tend to inhibit absorption of nonheme iron. Monitor use carefully; avoid excesses.

### Common Drugs Used and Potential Side Effects (Table 12-14)

- If anemia is caused by an increased demand for iron such as a growth spurt (toddlers, adolescents) or pregnancy, oral supplementation may be necessary; inorganic

**TABLE 12-14 Medications to Correct Iron-Deficiency Anemia**

Medication	Description
Ferrous salts (Feosol, Fer-In-Sol, Mol-Iron) or tablets (Feostat, Fergon, Feosol)	Prolonged-release ferrous sulfate (Slow Fe) improves iron absorption with fewer side effects than standard ferrous sulfate pills. Other forms include ferrous fumarate (Femiron, Feostat, Fumerin, Hemocyte, Ircon) and ferrous gluconate (Fergon, Ferralet, Simron). These may cause gastric irritation and constipation.
Enteric-coated or sustained-release iron	More expensive and often carry the iron past maximal absorption site in the upper intestine.
Heme iron (Proferrin Forte)	This is a medical food that contains heme iron plus folic acid. It is absorbed regardless of achlorhydria, and has fewer GI side effects than IV or ferrous iron sources. It can be taken with or without meals.
Parenteral or IV iron	Can be administered by injection or infusion. This therapy is reserved for cases of trauma where blood loss is life threatening and is not used for insufficiency due to inadequate dietary iron intake. Imferon can be given intramuscularly, if oral iron is not tolerated; pain and skin discoloration may result.

iron in ferrous form (50–200 mg/d for adults; 6 mg/kg for children) combined with increased consumption of heme-rich sources of iron. This is best absorbed on an empty stomach, but with food if there are GI side effects.

- Iron pills should be taken 2 hours before or after other medications. Iron can inhibit the effectiveness of thyroid medications, antibiotics, and some antidepressant drugs. Once ingested, it is imperative that the stomach contains acid to dissolve the iron salt; if taking antacids or H<sub>2</sub> blockers such as cimetidine (Tagamet), the iron salt will not dissolve.
- The amount of elemental iron contained in iron pills will vary. A 325-mg supplement is probably made of ferrous fumarate or gluconate, with only 100 mg of elemental iron per pill.
- Heme iron supplements (such as Proferrin) can be taken with meals, unlike ionic iron preparations, which must be taken on an empty stomach between meals. However, individuals with allergies to beef, milk, or other dairy products should not be given Proferrin.
- It takes 4–30 days to note improvements after iron therapy, especially in Hgb levels. Hgb should rise 0.1–0.2 g/dL/day after the fifth day of treatment; then should rise 2.0 g/dL/week for 3 weeks. Iron therapy should be continued for at least 2 months after the Hgb has returned to normal to replenish the iron stores.
- Iron stores are replaced after 1–3 months of treatment. Increased supplementation in normal individuals can cause additional, unnecessary iron to go into storage, reflected by ferritin elevation.
- Aspirin or corticosteroids can cause GI bleeding or peptic ulceration. Vitamin C and nutrient levels may be decreased.
- Some medications, including antacids, can reduce iron absorption. Iron tablets may also reduce the effectiveness of other drugs, including the antibiotics tetracycline, penicillamine, and ciprofloxacin and the anti-Parkinson's drugs methyldopa, levodopa, and carbidopa. Wait 2 hours between doses of these drugs and iron supplements.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Hgb is made from protein, iron, and copper. RBCs are made from vitamin B<sub>12</sub>, folacin, and amino acids. Explain which foods are good sources of iron, protein, vitamin C, and related nutrients.
- Temporary changes in stool color (green or tarry and black) are common with supplements; this is not cause for alarm. To avoid side effects of supplements, take them with meals or milk; food iron has fewer side effects.
- Foods and substances that can interfere with the absorption of iron include calcium, tannins, which are found in coffee, tea, grapes, red wine, purple or red rice, and bran fiber or chocolate. Avoid excesses of oxalates, alkalis, and antacids; discuss sources. Iron supplementation is best taken 2 hours after consuming these substances.
- The average American diet contains 10–20 mg of iron daily, roughly 10% of which is absorbed. Avoid overdosing with iron supplements. The body can only synthesize 5–10 mg of Hgb per day, and excesses may work against the immune system.
- Local or systemic infections interfere with iron absorption and transport.
- In children under age 2, limit milk intake to no more than 500 mL/d for better iron status.
- Explain nonfood pica—clay, starch, plaster, paint chips—and the relationship with nutrition. In food pica in which singular foods are eaten instead of balanced meals, the foods chosen are often crunchy or brittle. Excessive consumption of lettuce, ice, celery, snack chips, and chocolate has been noted; after iron supplementation, cravings often subside.
- Iron deficiency may be partly induced by plant-based diets containing low levels of poorly bioavailable iron (Kesa and Oldewage-Theron, 2005). Young people who follow a vegan diet should have their iron status monitored closely.
- Use culturally appropriate nutrition counseling. In some cultures, boys may be fed iron-rich foods preferentially over girls; counseling should be designed to improve intake by girls (Shell-Duncan and McDade, 2005).

### Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

## MALARIA AND PARASITIC ANEMIAS

### NUTRITIONAL ACUTY RANKING: LEVEL 1

Adapted from: Rubin E MD and Farber JL MD. *Pathology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 1999.

## DEFINITIONS AND BACKGROUND

Gastrointestinal infestation by parasitic worms that feed on blood (hookworm) or on nutrients (tapeworm) may occur, especially in tropical or subtropical areas. Intestinal parasites that affect nutrition in particular include soil-transmitted helminths, *Giardia duodenalis*, *Entamoeba histolytica*, other parasites such as the coccidia, *Schistosoma* sp., and malarial parasites. Iron deficiency is found to be correlated with these parasites in tropical countries (Shell-Duncan and McDade, 2005).

The neglected infections of poverty are parasitic, bacterial, and viral infections that disproportionately affect impoverished populations in the United States; these include Chagas disease, cysticercosis, congenital cytomegalovirus (CMV), toxocariasis, toxoplasmosis, and trichomoniasis (CDC, 2009). Toxoplasmosis is considered to be the third leading cause of death attributed to foodborne illness in the United States (CDC, 2009).

**Malaria** is a bloodborne, parasitic infection transmitted by mosquitoes. It kills more than 1 million people annually, especially in Africa. Pregnant women, children, and immunocompromised individuals have the highest rates of morbidity and mortality (Schantz-Dunn and Nour, 2009). More than 1000 cases of malaria are reported to the Centers for Disease Control and Prevention each year in the United States. Travelers or immigrants present with fever, chills, nausea, vomiting, headache, abdominal pain, severe anemia, and acute renal failure (Vicas et al, 2005).

Risks for miscarriage, intrauterine demise, premature delivery, low birth-weight neonates, neonatal death, severe anemia, and maternal death are high among pregnant women with malaria (Schantz-Dunn and Nour, 2009). Between 150 and 300 children die each hour from malaria (Bremar, 2009). For those who survive, neurologic impairment, anemia, hypoglycemia, and low birth weight imperil normal development and survival (Bremar, 2009).

Malaria can be prevented with appropriate drugs, bednets treated with insecticide, and effective educational outreach. Resistance of *Plasmodium falciparum* to drugs and Anopheles mosquitoes to insecticides has stimulated discovery and development of artemisinin-based combination treatments (ACTs) and other drugs, long-lasting insecticide-treated bednets (with synthetic pyrethroids) and a search for nontoxic, long-lasting, affordable insecticides for indoor residual spraying (Bremar, 2009). A malaria vaccine is under development (Greenwood, 2008).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Congenital CMV is passed from mother to infant during pregnancy.

<b>Clinical/History</b>	BMI	I & O
Height	Diet history	Fatigue
Weight	BP	

Abdominal discomfort	<b>Lab Work</b>	TIBC
Nausea, vomiting	Hgb (often <5 g/dL)	Alb
Fever	Hct	Serum folic acid
Irritability	Serum Fe	CRP
Pica?	Ferritin	Transferrin
	Serum B <sub>12</sub>	Gluc
		Serum Cu
		Serum Zn

## INTERVENTION

### OBJECTIVES

- Correct anemia from blood losses; eliminate parasitic infestation.
- Prevent GI tract perforation or obstruction, when likely to exist.
- Improve nutritional status and appetite. Parasitic infections affect the intake of food, subsequent digestion and absorption, metabolism, and nutrient storage and cause subtle micronutrient deficiency, such as vitamin A deficiency.
- Prevent low birth weight and other adverse effects in pregnant or postpartum women and their infants.

### FOOD AND NUTRITION

- A diet high in protein, B-complex vitamins, and iron may be appropriate. Provide adequate energy to meet individual's needs for anabolism where needed.
- Foods rich in heme iron and vitamins C and A should be included in meals served or planned. Iron inhibitors should be excluded from diet as far as possible until recovery is complete.
- Include plenty of other nutrient-dense foods, such as good sources of zinc and other micronutrients (Table 12-15).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal GI Function

**Assessment Data:** Weight loss, GI distress, Hgb <5, temperature averaging 101 degrees F. Dx of parasitic infection *Giardia* from drinking water at a campsite.

**Nutrition Diagnoses (PES):** Abnormal GI function related to parasitic infection of *Giardia* as evidenced by fever, low Hgb <5, GI distress, and weight loss.

**Interventions:** Food–Nutrient delivery—offer tolerated foods and beverages. Suggest use of a multivitamin–mineral supplement. Educate about risks of drinking potentially contaminated water from various sources.

**Monitoring and Evaluation:** Improvement in Hgb level; return of lost weight. Resolution of *Giardia*.

**TABLE 12-15** Micronutrient Deficiencies in Parasitic Anemias such as Malaria

Micronutrient	Deficiency Effects
Vitamin A	Increased susceptibility to malarial anemia, altered iron metabolism, deficit of retinol for synthesis of acute phase reactants
Vitamin C	Impaired T-lymphocyte response, delayed cutaneous hypersensitivity, impaired complement function, reduced phagocytic function
Vitamin E	Impaired T-lymphocyte response, altered B-cell function and impaired humoral response, delayed cutaneous hypersensitivity, impaired cytokine function or production, reduced phagocytic function; deficiency can contribute to oxidant damage to erythrocytes, leading to hemolysis, but deficiency can make the parasite more vulnerable to oxidation generated with some antimalarial drugs
Riboflavin	Decreased iron absorption, increased erythrocyte fragility, depressed erythropoiesis; deficiency may protect against malaria by diminished parasite multiplication and growth
Folate	Impaired erythropoiesis; deficiency may protect against malaria through impaired parasite metabolism
Copper	Involvement in acute phase response to infection
Iron	Impaired erythropoiesis, decreased T-lymphocyte response, altered B-cell function and impaired humoral response, delayed cutaneous hypersensitivity, impaired cytokine function or production, reduced phagocytic function; deficiency and associated microcytosis may reduce malaria parasite multiplication. Avoid excesses.
Selenium	Unknown role
Zinc	Impaired immune function including decreased T-lymphocyte response, altered B-cell function and impaired humoral response, delayed cutaneous hypersensitivity, impaired cytokine function or production, reduced phagocytic function; can contribute to increased parasitemia

From: Nussenblatt V, Semba, RD. Micronutrient malnutrition and the pathogenesis of malarial anemia. *Acta Trop.* 82:321, 2002; and Scrimshaw NS, Sangiovanni JP. Synergism of nutrition, infection, and immunity: an overview. *Am J Clin Nutr.* 66:464S, 1997.

### Common Drugs Used and Potential Side Effects

- Artemisinin combination therapy replaces ineffective chloroquine and sulphadoxine pyrimethamine for first-line treatment of malaria and for the provision of long-lasting, insecticide treated bednets (Greenwood, 2008).
- If needed, oral or parenteral iron may be given to correct anemia more rapidly. Beware of excessive use of oral supplements because of their potential side effects with iron overloading; monitor all sources (including iron-enriched foods).

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss ways to prevent further parasitic infestations, as with small children playing in soil. Pregnant women must be particularly careful, especially in developing countries where malaria, hookworm, and other parasites are common.
- Discuss ways to prepare foods high in necessary nutrients and methods to increase bioavailability (e.g., combining orange juice at breakfast with an iron-fortified cereal, etc.). In vulnerable populations, use fortified beverages to correct micronutrient deficiency.
- In areas of malaria transmission, anemia is apparent from the first few months of life, and there is a great need to target interventions at pregnant women and infants, which are the groups at highest risk. Food-fortification programs can be very beneficial.

### Patient Education—Food Safety

- Avoid eating raw fish or meats.
- Washing vegetables thoroughly before eating them and cooking meat to recommended temperatures to avoid toxoplasmosis (CDC, 2009).
- If tube feeding or CPN is needed, careful handwashing procedures should be followed.
- To prevent the spread of CMV, do not share food, drinks, or eating utensils with young children. Wash hands with soap and water after touching diapers or saliva.

MEGALOBLASTIC ANEMIAS: PERNICIOUS OR VITAMIN B<sub>12</sub> DEFICIENCY

## NUTRITIONAL ACUITY RANKING: LEVEL 2

## DEFINITIONS AND BACKGROUND

**Megaloblastic anemias** affect the nervous system if left untreated. Deficiency of folate and vitamin B<sub>12</sub> changes in the concentrations of metabolites, such as methylmalonic acid and homocysteine.

**Pernicious anemia** (PA) is a macrocytic anemia caused by a vitamin B<sub>12</sub> deficiency and intrinsic factor (IF). PA is thought to be an autoimmune disorder and is often found with other disorders such as thyroid or diabetes. The anti-parietal cell antibodies test measures the presence of antibodies against gastric parietal cells. Long-standing *Helicobacter pylori* infection probably plays a role with the irreversible destruction of the gastric body mucosa (Lahner and Annibale, 2009).

The three forms of PA are congenital PA, juvenile PA, and adult-onset PA. The forms are based on the age at onset and the precise nature of the defect causing impaired vitamin B<sub>12</sub> utilization (e.g., absence of IF). PA affects 1–2% of older individuals. Defective RBC production occurs, caused by a lack of IF of the stomach. IF helps vitamin B<sub>12</sub> produce RBCs. IF is present in gastric juice and binds to B<sub>12</sub>. Once bound, IF changes and becomes less susceptible to digestion; this protects B<sub>12</sub> and allows its absorption from gastric juice. When IF is not available, B<sub>12</sub> cannot be properly absorbed. Vitamin B<sub>12</sub> deficiency and achlorhydria have a detrimental effect on bone strength. Having PA increases the risk for hip fracture, even after treatment (Merryman et al, 2009).

**Vitamin B<sub>12</sub>-deficiency anemia** may take 5–6 years to appear; this megaloblastic anemia is a reversible form of ineffective hematopoiesis. There may be almost 800,000 older adults in the United States who have undiagnosed and untreated vitamin B<sub>12</sub> deficiency. It is often masked by high folate intakes. Hidden blood loss, gastric atrophy, and poor dietary intake should be addressed (Table 12-16).

The Schilling test is no longer used. Serologic testing for parietal cell and IF antibodies are used instead. With normal absorption, the ileum absorbs more vitamin B<sub>12</sub> than the body needs and excretes excess into the urine. With impaired

absorption, however, little or no vitamin B<sub>12</sub> is excreted into the urine. Low serum levels cannot identify all cases of vitamin B<sub>12</sub> deficiency; serum methylmalonic acid level may also be needed. Holotranscobalamin (holoTC), when compared with the other markers of vitamin B<sub>12</sub> deficiency, shows promise for diagnosing early vitamin B<sub>12</sub> deficiency (Hvas and Nexø, 2005).

Adequate selenium intake plays an important role in maintaining vitamin B<sub>12</sub> adequacy. Glutathione forms a complex called glutathionylcobalamin, which could protect against diseases related to vitamin B<sub>12</sub> depletion.

Areas of research include intermittent vitamin B<sub>12</sub> supplement dosing and better measurements of the bioavailability of vitamin B<sub>12</sub> from fermented vegetarian foods and algae. Vegetarians are at risk for vitamin B<sub>12</sub> deficiency (Allen, 2008). Vitamin B<sub>12</sub> anemia is corrected by the use of oral cyanocobalamin.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Human leukocyte antigen-DR genotypes suggest a role for genetic susceptibility in PA (Lahner and Annibale, 2009). In congenital PA, IF is missing. Nearly all people with PA test positive for anti-parietal cell antibodies.

Clinical/History	Postural hypotension?	Diarrhea
Height	Fatigue	Constipation
Weight	Flatulence,	Anorexia
BMI	nausea, and	Tachycardia, car-
Diet history	vomiting	diomegaly
Weight loss?		Achlorhydria

TABLE 12-16 Risks and Causes of Pernicious Anemia or Vitamin B<sub>12</sub>-Deficiency Anemia

Pernicious Anemia	Vitamin B <sub>12</sub> -Deficiency Anemia
High risk: Family history of pernicious anemia; African, Scandinavian, or Northern European descent; autoimmune endocrine disorders	High risk: Vegans; elderly; persons with intestinal malabsorption or gastric atrophy or hypochlorhydria; stomach removal surgery; drug use (colchicine, neomycin); metabolic disorders (homocystinuria methylmalonic aciduria); breastfed infants of vitamin B <sub>12</sub> -deficient mothers; poor diet in infancy or pregnancy
Causes: Autoimmune endocrine diseases such as type 1 diabetes, hypoparathyroidism, Addison's disease, hypopituitarism, testicular dysfunction, Graves' disease, chronic thyroiditis, myasthenia gravis, secondary amenorrhea, vitiligo, gastric surgery, anorexia nervosa, or bulimia nervosa	Causes: Poor intake of extrinsic factor (vitamin B <sub>12</sub> ). Chronic alcoholism. <i>Helicobacter pylori</i> infection with diminished production of intrinsic factor. Hidden blood loss. Fish tapeworm. Reduced intestinal absorption, as with celiac disease or Crohn's disease

Glossitis with beefy, red tongue	MCV, MCHC, MCH (increased)	TIBC
Lemon yellow or waxy skin	Macrocytic/nucleated cells	Urinary methylmalonic acid
Numbness or tingling in hands and feet	Reticulocyte count (low)	Serum folate
Impaired sense of smell	Hct (low)	Serum homocysteine (elevated?)
	Lactate dehydrogenase (LDH) (increased)	Holotranscobalamin (holoTC)
<b>Lab Work</b>	CBC (altered platelets and WBC count)	Bilirubin
Parietal cell and IF antibodies	Gastrin (increased)	Transferrin
RBCs		
Serum B <sub>12</sub>		

## INTERVENTION

### OBJECTIVES

- Alleviate the etiology of anemia, where possible.
- Provide foods that will not hurt a sore mouth. Glossitis decreases the desire to eat.
- Correct patient's anorexia.
- Prevent neurological defects if treatment is delayed or insufficient; depression, psychosis, and mania can appear.
- Where present, correct PA; prevent progression to gastric cancer. PA requires vitamin B<sub>12</sub> injections.
- Prevent or correct hyperhomocysteinemia.

## FOOD AND NUTRITION

- Diet should make liberal use of high biological value (HBV) proteins. Good sources of vitamin B<sub>12</sub> include liver,

other meats, fish, poultry, eggs, milk, cheese, yogurt, fortified products such as cereals, and soy milk. The daily average intake is 2–30 mg.

- Supplement diet with iron, vitamin C, folic acid and other B vitamins, copper, and selenium.
- If patient has a sore mouth, use a soft or liquid diet with fewer spicy or acidic foods.

## Common Drugs Used and Potential Side Effects

- Vitamin B<sub>12</sub> deficiency is effectively treated with oral vitamin B<sub>12</sub> supplementation. Crystamine or Rubramin PC is cyanocobalamin in drug form for vitamin B<sub>12</sub> deficiency.
- For PA, vitamin B<sub>12</sub> injections are given weekly until remission, after which six to eight injections yearly will suffice. For some, vitamin B<sub>12</sub> supplements may be as effective as injections; high doses, such as 1000 µg, are needed daily for about 18 months.
- Trinsicon contains vitamin B<sub>12</sub>, ferrous fumarate, vitamin C, folacin, and IF. It is less effective when taken with dairy products.
- Some medications that conflict with vitamin B<sub>12</sub> absorption include chloramphenicol, proton pump inhibitors, histamine 2 inhibitors, and metformin.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- True vegan diets do not contain vitamin B<sub>12</sub>; it is found only in animal foods. Include eggs, meat, fish, shellfish, cheese, milk, milk products, or use B<sub>12</sub> fortified soy products. Some fad diets may also be low in vitamins and protein; monitor intake carefully.
- PA develops after total gastrectomy unless vitamin B<sub>12</sub> is administered. The problem may also occur in patients with partial gastrectomy or gastric bypass. Lifelong vitamin B<sub>12</sub> replacement or injections are necessary.
- Avoid fatigue; plan simple meals and snacks.
- Megaloblastic B<sub>12</sub> anemia may occur in elderly; careful food choices are essential.
- Breastfed infants of vitamin B<sub>12</sub>-deficient mothers are at risk for severe developmental abnormalities, growth failure, and anemia. Counseling for lactating women is important.

## Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

## For More Information

- Medline—Pernicious Anemia  
<http://www.nlm.nih.gov/medlineplus/ency/article/000569.htm>
- Pernicious Anemia  
<http://www.med.unc.edu/medicine/web/perniciousanemia.htm>

## SAMPLE NUTRITION CARE PROCESS STEPS

### Abnormal Nutrition Laboratories

**Assessment Data:** PA with low serum vitamin B<sub>12</sub>, Hgb, and Hct; elderly resident in long-term care facility.

**Nutrition Diagnoses (PES):** Altered nutrition-related laboratories related to resident's body inability to produce IF and to absorb cobalamin as evidence by abnormal vitamin B<sub>12</sub> <200 pg/mL, Hgb <12 gm/dL, and Hct <37%.

**Interventions:** Food and nutrient delivery—provide resident with foods/beverages with vitamin C such as orange juice, citrus fruits, and melon to be consumed at every meal to aid with iron absorption. Resident will eat two scrambled eggs at breakfast to increase vitamin B<sub>12</sub>. Coordinate care with nursing and medical staff to administer vitamin B<sub>12</sub> shots and support with adequate dietary intake.

**Monitoring and Evaluation:** Monitor monthly laboratories; goal vitamin B<sub>12</sub> >200 pg/mL, Hgb >12, and Hct >38%.

- Vitamin B<sub>12</sub> Deficiency Anemia

# SIDEROBLASTIC ANEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinicopathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

## DEFINITIONS AND BACKGROUND

Sideroblastic anemias are a group of blood disorders characterized by an impaired ability of the bone marrow to produce normal RBCs. Inherited sideroblastic anemia comprises several rare anemias due to heterogeneous genetic lesions, all characterized by the presence of ringed sideroblasts in the bone marrow (Camaschella, 2009).

Abnormal RBCs called sideroblasts are found in the blood of people with these anemias. This anemia is a microcytic, hypochromic anemia similar to that caused by iron deficiency, except that serum iron is normal or elevated. The iron inside RBCs is inadequately used to make Hgb, despite adequate or increased amounts of iron. Therapy comprises application of antioxidants, vitamins, iron, bone marrow-stimulating factors, or substitution of cells (Finsterer, 2007).

The disease X-linked sideroblastic anemia with ataxia is due to a mutation in the protein transporter that is thought to transfer iron clusters from the mitochondrion to the cytoplasm (Napier et al, 2005). Another name for the congenital type of anemia is hereditary iron-loading anemia.

X-linked sideroblastic anemia (delta-aminolevulinic acid synthase deficiency) is vitamin B<sub>6</sub> responsive that responds to high pyridoxine doses (Clayton, 2006). Pyridoxal phosphate is the cofactor for over 100 enzyme-catalyzed reactions in the body. Vitamin B<sub>6</sub> is the main vitamin for processing amino acids and is also needed to make melatonin, serotonin, and dopamine.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Mutations in the mitochondrial carrier family gene SLC25A38 cause nonsyndromic autosomal recessive congenital sideroblastic anemia (Petkau, 2009). The enzyme directly relevant to sideroblastic anemia is ALAS-2 or ALAS-e on the X chromosome. However, most sideroblastic anemias are acquired.

<b>Clinical/History</b>	Dizziness	Transferrin saturation (often elevated)
	Decreased tolerance for exercise	Serum folic acid
Height		Serum homocysteine
Weight		WBC
BMI		Serum Fe, ferritin
Diet history	<b>Lab Work</b>	Serum Cu
BP	Serum B <sub>6</sub> levels	
I & O	Hgb (low at 4–10 g/dL)	
Alcohol or drug toxicity?	RBC	
Fatigue		

## INTERVENTION

## OBJECTIVES

- Identify causes and solutions.
- Remove any precipitating factors, such as specific drugs or alcohol use.
- Correct problems, such as suppression of bone marrow, iron loading, and anemia.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Inadequate Vitamin Intake

**Assessment Data:** Diagnosis of sideroblastic anemia, pyridoxine-responsive. BMI normal. Complaints of fatigue and poor exercise tolerance. Diet indicates intake of B<sub>6</sub>-rich foods to be infrequent. Lab work with high transferrin saturation, Hgb of 6, and low serum B<sub>6</sub> levels.

**Nutrition Diagnoses (PES):** Inadequate vitamin intake (B<sub>6</sub>) related to X-linked genetic defect and low dietary intake as evidenced by diet and medical histories.

**Interventions:** Trial of 100- to 200-mg pyridoxine by mouth. Counseling about foods rich in vitamin B<sub>6</sub>.

**Monitoring and Evaluation:** Improvement in symptoms (less fatigue and better exercise tolerance). Lab work showing improvement in serum B<sub>6</sub> and Hgb, and lower transferrin saturation levels.

## FOOD AND NUTRITION

- A diet high in vitamin B<sub>6</sub> may be beneficial with medication. Potatoes, bananas, raisin bran cereal, lentils, liver, turkey, and tuna are good sources of vitamin B<sub>6</sub>.
- Protein and carbohydrate (CHO) intake should be adequate, and energy should also be adequate to spare protein. Folic acid and copper may also be needed.
- Alcohol intake should be severely limited.
- Balanced meals and snacks, as necessary, may be helpful.

## Common Drugs Used and Potential Side Effects

- Vitamin B<sub>6</sub> may be ordered; age-dependent doses are specified. The National Academy of Sciences performed an analysis of vitamin B<sub>6</sub> studies. It is usually safe at intakes of up to 100 mg/d in adults, but neurological side effects can sometimes occur at or above that level. Vitamin B<sub>6</sub> toxicity damages sensory nerves, leading to numbness in the hands and feet as well as difficulty walking.
- Chloramphenicol may cause drug-induced bone marrow suppression, resulting in sideroblastic anemia. Isoniazid,

busulfan, penicillamine, and cycloserine can cause abnormal vitamin B<sub>6</sub> metabolism. Monitor for gastrointestinal side effects.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss adequate sources of all needed nutrients such as vitamin B<sub>6</sub>, especially if deficiency caused the anemia.
- Discuss attractive menu planning and balancing of meals because appetite and intake may be poor chronically. Discuss snacks and frequency.

## Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

## HEMOGLOBINOPATHIES

## SICKLE CELL ANEMIA

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinicopathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

## DEFINITIONS AND BACKGROUND

Sickle cell disease (SCD) is the most common genetic disorder of the blood. SCD involves anemia that is hereditary and hemolytic. Cells in SCD are crescent shaped and become rigid; they lodge themselves in the capillaries of the peripheral-blood system outside the heart. The sickling of RBCs occurs when partially or totally deoxygenated Hgb molecules distort their normal disk shape, producing stiff, sticky, sickle-shaped cells that obstruct small blood vessels; this causes vaso-occlusion as well as deprivation of oxygen to body tissues (Edwards et al, 2005). Everyone with SCD has chronic hemolytic anemia, vasculopathy, vaso-occlusive disease, acute and chronic organ damage, and shortened life span (Steinberg, 2008).

SCD has several forms including sickle cell anemia, sickle cell Hgb C disease, and sickle cell thalassemia disease. It is usually detected within the first year of life. Routine use of daily antibiotics until 5 years of age, immunization of children with pneumococcal vaccine, annual influenza vaccination after 6 months of age, and meningococcal vaccination after 2 years of age are important preventive measures (Mehta et al, 2006).

The largest population in the world with sickle cell anemia is in Africa. While this condition most commonly

affects blacks of African descent, it is also found in people of Middle Eastern, East Indian, and Mediterranean origin. About 100,000 Americans have SCD (~1 in every 400–500 African-Americans). Carrier frequency varies, with high rates associated with zones of high malaria incidence. Carriers are often protected against malaria.

Patients with SCD are at risk for delayed growth and sexual maturation; acute and chronic pulmonary dysfunction; stroke; aseptic necrosis of the hip, shoulders, or both; sickle cell retinopathy; dermal ulcers; and severe chronic pain (Edwards et al, 2005). The homozygous state (SS) is associated with complications and a reduced life expectancy.

Chronic anemia, pallor, and jaundice result because sickled cells do not last as long as normal blood cells. Bone marrow functions at six times the normal rate. Because there are fewer cells, the blood is thinner or anemic. When RBCs are destroyed, bilirubin is released into the blood and turns the whites of the eyes to a shade of yellow.

Inadequate dietary intakes of folate are common, whereas vitamin B<sub>12</sub> intakes are usually adequate. Low RBC folate levels may occur. Serum total homocysteine (tHcy) levels may be elevated in this population; greater intakes than normal of folate may be needed. Elevated tHcy levels contribute to

thrombosis, a frequent event in this population. Children with sickle cell anemia have lower vitamin B<sub>6</sub> concentrations.

Infants and children who have SCD are at risk for nutritional deficiencies and loss of body mass during acute illness. Suboptimal vitamin A intake is common, with more frequent hospitalizations and poor growth. Low serum vitamin D status is highly prevalent in children with SCD; vitamin D status is associated with season and dietary intake. Prepubertal children with SCD may have zinc deficiency and may benefit from zinc supplementation.

There is an underlying defect in lipid metabolism associated with SCD, manifested during the fasting state; this abnormality in lipid homeostasis has the potential to alter RBC membrane fluidity and function in SCD patients (Buchowski et al, 2007). Individuals with SCD have reduced levels of EPA and DHA in red cells, platelets, and mononuclear cells due to peroxidation from compromised antioxidant competence (Ren et al, 2008). Because dietary omega-3 fatty acids reduce prothrombotic activity, include omega-3 fatty acids in diet and in supplemental form.

Cellular and tissue damage is caused by hypoxia, oxidant damage, inflammation, abnormal intracellular interactions, and reduced nitric oxide bioavailability (Steinberg, 2008). Young children with SCD are at a very high risk of stroke, with microvascular occlusion and painful episodes (Adams, 2007).

Aggressive antibiotic therapy and transfusions can save lives. Transfusion is indicated for symptomatic anemia and specifically to prevent stroke, during acute stroke, and for acute chest syndrome (Roseff, 2009). Although life saving, transfusion therapy has resulted in the majority of sickle cell anemia patients being at risk for iron overloading and hemosiderosis-induced organ damage (Vichinsky et al, 2005). Iron overload has become easier to manage with the introduction of an oral iron chelator (Adams, 2007).

Acute chest syndrome, triggered by infections and fat clots in the lungs, is the leading cause of death in sickle cell anemia. Treatment includes hydroxyurea therapy to decrease the frequency of painful episodes and hematopoietic cell transplantation (Mehta et al, 2006). Bone marrow transplantation requires a perfect match from a sibling. Because patients with SCD have problems with surgery, including prolonged bleeding, vitamin K should be given preoperatively (Raffini et al, 2006). Use of transcranial Doppler ultrasonography helps identify asymptomatic, at-risk children who should be considered for chronic blood transfusions (Mehta et al, 2006).

Studies of gene expression are bringing new solutions. Human progenitor cell (from bone marrow, peripheral blood stem cells, or umbilical blood) transplant can cure the disease and is used for patients with severe disease for whom conventional therapy may not be effective (Roseff, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Sickle cell anemia is an autosomal recessive disease caused by a mutation in the *hemoglobin*

*beta gene (HBB)* found on chromosome 11p15.5. Genetic studies have identified regions on chromosome 6q23 and BCL11 A on chromosome 2p16 that account for 20–50% of the common variation in fetal Hgb levels in patients with sickle cell anemia (Thein et al, 2009). SNPs have also been found in KCNK6 (Sebastiani et al, 2009).

Clinical/History	Lab Work	Serum
Height	CBC, WBC	creatinine
Weight	Sickle cell test	N balance
BMI	Hgb (often low)	Alb
Diet history	Hct	CRP
BP	Serum Fe	Cholesterol
I & O	(increased	Triglycerides
Chronic anemia,	from	(Trig)
pallor	hemolysis)	(decreased)
Jaundice	RBP	MCV
Bone pain	(decreased)	Serum ferritin
Abdominal	Bilirubin	Partial pressure
pain	tHcy (often	of oxygen
Breathlessness	elevated)	(pO <sub>2</sub> )
Lower leg	Transferrin	Partial pressure
ulcers	saturation	of carbon
Casts or blood in	Serum folic acid	dioxide
urine	and B <sub>12</sub>	(pCO <sub>2</sub> )
Excessive thirst	Serum and	Uric acid
CT scan or MRI	urinary zinc	(increased)
		PT and INR

## INTERVENTION

## OBJECTIVES

- Supplement diet with missing nutrients. Correct any malnutrition.
- Reduce oxygen debt and hemolytic crises.
- Reduce painful cramps, liver dysfunction, cholelithiasis, jaundice, and hepatitis.
- Lessen likelihood of pressure ulcers, infections, and renal failure. Infections may include pneumonia, cholecystitis, osteomyelitis, or urinary tract infections.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Involuntary Weight Loss

**Assessment Data:** Weight pattern, percent desirable body weight, diet history, problems with meal planning or shopping, financial challenges.

**Nutrition Diagnosis (PES):** Involuntary weight loss related to sick cell anemia with inadequate caloric intake as evidenced by 10% loss of usual body weight in the last 2 months.

**Intervention:** Nutrition counseling, encouraging energy-dense foods and favorites. Coordination of care with referral to social service agencies for help with meal preparation and delivery.

**Monitoring and Evaluation:** Weight records, improvements in appetite and intake.

**TABLE 12-17 Equation to Predict Energy Needs in Adolescents with Sickle Cell Disease**

Basal energy requirements are higher in adolescents with sickle cell anemia than in healthy control subjects (Buchowski et al, 2002)

Males: REE (kcal/d) =  $1305 + 18.6 \times \text{weight (kg)} - 55.7 \times \text{hemoglobin (g/dL)}$

REE (kJ/d) =  $5461 + 77.7 \times \text{weight (kg)} - 233.2 \times \text{hemoglobin (g/dL)}$

Females: REE (kcal/d) =  $1100 + 13.3 \times \text{weight (kg)} - 30.2 \times \text{hemoglobin (g/dL)}$

REE (kJ/d) =  $4603 + 55.6 \times \text{weight (kg)} - 126.2 \times \text{hemoglobin (g/dL)}$

- Maintain adequate hydration.
- Promote normal growth and development, which tend to be stunted in children.
- Prevent chronic hypoxia, which can lead to lower intellectual performance.
- Improve quality of life and ability to participate in the activities of daily life.

## FOOD AND NUTRITION

- Include food sources of omega-3 fatty acids; vitamins D, C, A, B<sub>12</sub>, and B<sub>6</sub>; folic acid; and HBV proteins; ensure adequate zinc and riboflavin.
- Estimate fluid and energy needs; increase diet as needed (Table 12-17).
- A multivitamin–mineral supplement should be recommended; one without excess iron is important when transfusions are used. Avoid excesses of iron, including from tube feedings or parenteral nutrition.
- Energy deficits are common in this population. Nightly tube feeding can help to improve nutritional status. While supplementation with arginine has been suggested, more studies are needed.

## Common Drugs Used and Potential Side Effects

- Pain medicines (such as ibuprofen) may be used. Monitor for all side effects and GI distress.
- Hydroxyurea therapy (Droxia, Hydrea) can be used to increase Hgb production.
- Rofecoxib is a cyclo-oxygenase-2 (COX-2) inhibitor approved for pain and has been tested in children with no adverse effects.
- Rituximab may be used to prevent delayed hemolytic transfusion reaction disorder in SCD.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- A phytochemistry, Niprisan, may reduce episodes of SCD crisis associated with severe pain.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Indicate which foods are good sources of folic acid, HBV proteins, zinc, riboflavin, and vitamins A, C, D, E, B<sub>6</sub>, and B<sub>12</sub>.
- Discuss ways for easy meal preparation because fatigue tends to be a problem.
- Quality of life is often decreased among adults with SCD, and health professionals should try to offer assistance that will help improve this quality (McClish et al, 2005).

## Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

# THALASSEMIAS

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinicopathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

### DEFINITIONS AND BACKGROUND

The thalassemias are inherited hematologic disorders caused by defects in the synthesis of one or more of the Hgb chains. Alpha thalassemia is caused by reduced or absent synthesis of alpha globin chains, and beta thalassemia is caused by reduced or absent synthesis of beta globin chains (Muncie and Campbell, 2009). Hemolysis and impaired erythropoiesis occur.

Collectively, the thalassemias are among the most common inherited disorders. Alpha-thalassemic syndromes have an increased frequency in African, American Indian, and Asian populations. Beta thalassemia is well recognized in persons of Greek and Italian descent; Cooley's or Mediterranean anemia is most severe. The beta thalassemias are more common and are a worldwide clinical problem due to an increasing immigrant population (Hahalis et al, 2005).

Silent carriers of alpha thalassemia and persons with alpha or beta thalassemia trait are asymptomatic and require no treatment. Alpha thalassemia intermedia (Hgb H disease) causes hemolytic anemia (Muncie and Campbell, 2009). The RBCs are fragile and contain abnormal Hgb.

Beta thalassemia major causes hemolytic anemia, poor growth, and skeletal abnormalities during infancy. Symptoms can begin as early as 3 months of age. In the first year or two of life and in the absence of transfusion, a child can demonstrate severe anemia and expansion of the facial and other bones. These children may be pale or jaundiced, have a poor appetite, fail to grow normally, and have an enlarged spleen, liver, or heart. The incidence of gallstones is unusually common in this population. Affected children will require regular lifelong blood transfusions (Hahalis et al, 2005).

Blood transfusions and increased gastrointestinal iron absorption result in iron overload and tissue damage. If splenomegaly occurs, a splenectomy may be needed. Excess iron accumulates, leading to liver, heart, and pituitary damage and failure of these organs. Cardiac complications caused by iron deposition, such as cardiomyopathy, are major causes of death (Hahalis et al, 2005). Chelation therapy may be needed.

Recent advances have been beneficial. Bone marrow transplants can be curative for some children with beta thalassemia major. Cord blood is the blood that remains in the umbilical cord and placenta following birth; it is a rich source of stem cells that reproduce into RBCs for the immune system. Stem cell transplantation offers opportunities for individuals with thalassemia to lead a more normal life.

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** In thalassemia, variations are caused by the severity of the genetic mutations. In thalassemia major or intermedia, reduction in the number of alpha globin genes can ameliorate the disease phenotype; conversely, excess alpha globin genes convert beta thalassemia trait to a clinical picture of thalassemia intermedia (Rund and Fucharoen, 2009). An increase in Hgb F level is variably associated with the presence of beta thalassemia trait. Levels relate to the presence of a polymorphism in the (G)gamma-158 (C>T) gene (Mosca et al, 2009).

Clinical/History	Quantitative	TIBC
Height	Hgb A2 and	(decreased)
Weight	Hgb F	Thyroid-
BMI	Serum Fe	stimulating
Diet history	(increased)	hormone
BP	FEP	(TSH)
Growth failure	Transferrin iron	Thyroxine (T4)
Jaundice	saturation	Alkaline
I & O	percentage	phosphatase
Leg ulcers	(increased)	(Alk phos)
Bone	Serum lead	Gluc
abnormalities	Transferrin	Vitamin B <sub>12</sub>
Enlarged spleen	(decreased)	Serum zinc
Hypogonadism	Superconduct-	Alb
Anemia	ing Quantum	CRP
Jaundice	Interference	Hypopara-
	Device	thyroidism
	(SQUID)	
<b>Lab Work</b>	Serum ferritin	
RBC, CBC	(increased)	
H & H (low?)		

### INTERVENTION

#### OBJECTIVES

- Offer temporary relief with blood transfusions; this will improve hematological status with oxygen availability.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Unintentional Weight Loss**

**Assessment Data:** Growth failure in 6-year old, weight loss of 3# in past 12 months. Poor oral intake and anorexia. Hx of thalassemia intermedia, diagnosed at age 2.

**Nutrition Diagnoses (PES):** Unintentional weight loss related to poor oral intake as evidenced by weight loss of 3# in past year and growth failure (previously 40th percentile, now at 25th percentile for age).

**Interventions:** Food–nutrient delivery: enhance meals and snacks with high-density foods such as milkshakes with dry milk powder and peanut butter added. Educate parents about ways to enhance energy and nutrient density in meals and snacks. Counsel about when to contact the physician (e.g., signs of jaundice, additional weight loss, or chronic anorexia).

**Monitoring and Evaluation:** Improved intake of energy-dense foods and beverages. Growth chart improving over past 3–6 months, closer to 40th percentile again.

Correct side effects of iron overloading from the necessary transfusions.

- Correct failure to thrive and GI problems.
- Prevent slow or stunted growth. Impaired growth is a problem in children.
- Reduce or correct infections. Promote healing of any ulcerations.
- Manage any hyperglycemia.

## FOOD AND NUTRITION

- A diet high in quality protein, energy, B-complex vitamins (especially folic acid and vitamin B<sub>12</sub>), and zinc will be beneficial. To prevent iron overloading, avoid use of multivitamin–mineral supplements that contain iron and vitamin C in large amounts.
- Provide adequate fluid intake.
- If hyperglycemia and diabetes are present, use carbohydrate counting and other accepted techniques for managing glucose levels.

## Common Drugs Used and Potential Side Effects

- Iron-chelating therapy with deferoxamine in patients with thalassemia major has dramatically improved the prognosis

of this disease (Taher et al, 2005). Side effects include allergic reactions, tinnitus, and erythematous rash. Overchelation may cause growth retardation and mineral deficiency.

- Oral iron-binding agents are capable of preventing dietary iron absorption from the diet; oral chelator deferiprone (Ferriprox) is one.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss ways to improve nutritional intake, when deficient.
- Discuss importance of diet in the maintenance of hematological health.
- Persons with thalassemia should be referred for preconception genetic counseling. Women with alpha thalassemia trait should consider chorionic villus sampling to diagnose infants with Hgb Bart's, which increases the risk of toxemia and postpartum bleeding (Muncie and Campbell, 2009).

## Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

## OTHER BLOOD DISORDERS

## BLEEDING DISORDERS: HEMORRHAGE AND HEMOPHILIA

## NUTRITIONAL ACUITY RANKING: LEVEL 2

## DEFINITIONS AND BACKGROUND

The circulatory system is a closed system, with low volume and high pressure. It provides efficient delivery of nutrients to all tissues. When there is volume loss, a large decrease in nutrient delivery occurs.

**Hemorrhage** is the excessive discharge of blood from a ruptured vessel. Bleeding (bright red in spurts from an artery; dark red and steady flow from a vein) can be external, internal, or into skin or other tissue. When massive, a hemorrhage can cause such symptoms as rapid, shallow breathing; cold, clammy skin; thirst; visual disturbances; and extreme weakness. Loss of more than 20% of blood volume causes hypotension and tachycardia; loss of more than 1 quart of blood may lead to shock. Peptic ulcer, hemophilia, spontaneous liver rupture, or stroke may lead to a hemorrhage. In some cases, surgery may be necessary. In chronic myelogenous leukemia (CML), a slowly progressive disease, platelets are increased in number and easy bleeding occurs.

To stop a hemorrhage, blood must clot properly. Blood clots when its fibrinogen is converted to fibrin by action of thrombin. Vitamin K works as a coenzyme that converts glutamic acid to gamma-carboxyglutamic acid; this helps to bind calcium and is required for the activation of the seven vitamin K-dependent clotting factors in the coagulation cascade (Table 12-18).

**Hemophilia** is an inherited bleeding disorder. Diagnosis may be early in life, or later after surgery or trauma. In severe cases, serious bleeding may occur without any cause. While internal bleeding may occur anywhere, bleeding into joints is common. Standard treatment involves replacing the missing clotting factor. In pregnant women who carry the trait, a C-section is often recommended. **Von Willebrand disease** is the most common hereditary bleeding disorder,

where bleeding gums, abnormal menstrual bleeding, nose bleeds, and bruising are the symptoms. Desamino-8-arginine vasopressin (DDAVP) is given to raise the levels of von Willebrand factor, which reduces the bleeding tendency.

The immune response to coagulation factors VIII or IX with formation of inhibitory antibodies complicates the treatment of hemophilia; regulatory T cells (Treg) are an important component of the mechanism by which tolerance is maintained (Cao et al, 2009). New gene therapy and immune tolerance protocols are under study.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Hemophilia A, which affects 80–90% of cases, shows a mutation in the FVIII gene. People with Hemophilia B have low or missing levels of clotting factor IX. Hemophilia affects mostly males, although women carry the trait.

Clinical/History	Temperature I & O	Excessive or easy bleeding
Height	Blood in urine	Excessive
Weight	or stool?	bruising
BMI	Petechiae	Nose bleeds
Diet history	Hemophilic	Abnormal
BP	arthropathy	menstrual
Pulse		bleeding

**TABLE 12-18** Blood Clotting Factors That Involve Nutrition

The coagulation cascade involves a series of steps that stop bleeding through clot formation. Vitamin K-dependent coagulation factors are synthesized in the liver. Consequently, severe liver disease results in lower blood levels of vitamin K-dependent clotting factors and an increased risk of uncontrolled bleeding (hemorrhage). The following factors involve nutrition:

- I. Fibrinogen
- II. Prothrombin
- III. Thromboplastin
- IV. Calcium

In hemostatic (bleeding) disorders, it is important to evaluate for bleeding problems in the family history, history of heavy menses or easy bruising, and prior blood transfusions. Bleeding disorders include a number of conditions in which people tend to bleed longer. Clotting involves about 20 different plasma proteins (clotting factors). Normally, clotting factors form fibrin that stops bleeding. In bleeding disorders, the process does not occur normally. Some bleeding disorders are present at birth (hemophilia and von Willebrand's disease), or they can be acquired (such as vitamin K deficiency, severe liver disease, use of anticoagulant drugs or prolonged use of antibiotics, bone marrow problems, leukemia, pregnancy-associated eclampsia, or snake bite). In these disorders, vision loss can occur from bleeding into the eye, or anemia may result, or there may be neurological problems or even death. Gene therapy may one day be available to treat the bleeding disorders.

<b>Lab Work</b>	Thrombin time	Transferrin
Coagulation testing	(thrombin added to plasma, and time to clot measured)	RBC

		Serum Fe
		Serum folic acid and B <sub>12</sub>
		TIBC
		(increased)
		Creatinine
		CRP

## INTERVENTION

### OBJECTIVES

- Medical management is designed to control bleeding, take care of the underlying cause of the bleeding, and replace lost blood. Transfusions may be needed. Less severe hemorrhages may require iron, vitamin B<sub>12</sub>, and folic acid to help replace RBCs.
- Support erythropoiesis.
- Control intestinal impact of gastrointestinal bleeding, which can cause a protein overload.
- Prevent hypovolemic shock (low cardiac output, decreased blood pressure, and decreased urinary output) from uncontrolled bleeding.

### FOOD AND NUTRITION

- Ensure that diet is rich in proteins, iron, folic acid, vitamin B<sub>12</sub>, and copper.
- Check need for vitamin K. Patients with intestinal or liver disease may become deficient. If medications to replace

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Vitamin Intake

**Assessment Data:** Bleeding disorder (Hemophilia A) with easy bruising and blood in urine and stool. Currently taking Alphanate; scheduled for dental surgery in 2 weeks. Serum vitamin K levels low. Diet hx shows little intake of any vitamin K-rich foods.

**Nutrition Diagnoses (PES):** Inadequate vitamin K intake related to hereditary bleeding disorder and minimal dietary intake as evidenced by low serum vitamin K levels, easy bruising and blood in urine and stool even while taking Alphanate.

**Interventions:** Food-nutrient delivery; identify foods that could be included and tolerated. Educate about the sources of vitamin K from diet. Counsel about multivitamin-mineral supplements that contain a desired dose of vitamin K (10–120 µg per dose).

**Monitoring and Evaluation:** Fewer episodes of blood in urine and stool; less easy bruising. Tolerance for multivitamin-mineral supplement and foods. Improved serum levels of vitamin K. No difficulty with dental surgery and excessive bleeding.

**TABLE 12-19 Food Sources of Vitamin K**

Food	Serving	Vitamin K (µg)
Kale, raw	One cup (chopped)	547
Broccoli, cooked	One cup (chopped)	420
Parsley, raw	One cup (chopped)	324
Swiss chard, raw	One cup (chopped)	299
Spinach, raw	One cup (chopped)	120
Leaf lettuce, raw	One cup (shredded)	118
Watercress, raw	One cup (chopped)	85
Soybean oil	One tbsp	26
Canola oil	One tbsp	20
Mayonnaise	One tbsp	12
Olive oil	One tbsp	7

Source: U.S. Department of Agriculture. USDA national nutrient database for standard reference, release 16. Available at [http://www.nal.usda.gov/fnic/foodcomp/Data/SR16/wtrank/wt\\_rank.html](http://www.nal.usda.gov/fnic/foodcomp/Data/SR16/wtrank/wt_rank.html).

vitamin K are used, diet should provide a balance without excess. Monitor content of meals or enteral feedings and multivitamin supplements carefully to ensure that all RDAs are met without excesses (Table 12-19).

### Common Drugs Used and Potential Side Effects

- Avoid aspirin, NSAIDs, and other blood thinners. Oral anticoagulants, such as Warfarin, inhibit coagulation through antagonism of the action of vitamin K. Inadequate gamma-carboxylation of vitamin K-dependent proteins will inhibit clot formation. Patients taking these drugs are cautioned against consuming very large or highly variable quantities of vitamin K in their diets; they need a reasonably constant dietary intake.
- If vitamin K is needed, it is available in multivitamins and other supplements in doses that range from 10 to 120 µg per dose.
- Alphanate (antihemophilic factor) is approved to decrease bleeding in patients with bleeding diseases who must have surgery or other invasive procedures. People with hemophilia and their families can be taught to give factor VIII concentrates at home at the first signs of bleeding. XYNTHA is a new recombinant factor VIII product for both the control and prevention of bleeding episodes and surgical prophylaxis.
- FEIBA therapy, consisting of activated prothrombin complex concentrate (aPCC) and recombinant activated factor VII (rFVIIa), is effective and safe for reducing bleeding in hemophilia A (Valentino, 2009).

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Potential adverse effects of high vitamin E intakes in humans, such as bleeding, are not clear (Hathcock et al, 2005).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Blood donors should be alerted to the need to replace daily iron intake by 0.7 mg for a year. Every pint is equivalent to 250 mg of iron lost.
- Discuss adequate dietary replacement for lost nutrients. A multivitamin–mineral supplement may be indicated.

### Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

# HEMOCHROMATOSIS AND IRON OVERLOAD

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Rubin E MD and Farber JL MD. *Pathology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 1999.

## DEFINITIONS AND BACKGROUND

**Hereditary hemochromatosis (HH)** is one of the most common autosomal recessive disorders among Caucasians. One in 200–400 individuals of Northern European ancestry is at risk for hemochromatosis (Camaschella and Merlini, 2005). It is also common in Hispanics or people of Mediterranean descent and is 10 times more common in males than

females. Irish Americans and African-Americans have double the usual frequency. Tragically, hemochromatosis remains underdiagnosed.

In hemochromatosis, iron stores are deposited in excess, often from excess intake or liver/pancreatic diseases, renal dialysis, or frequent and long-term transfusions. Healthy people may accumulate up to 1 g of iron, but people with this condition accumulate 15–30 g. Increased iron absorption leads to excessive accumulation of iron deposits within cells of the liver, heart, pituitary gland, pancreas, and other organs, gradually causing tissue damage.

Because hemochromatosis has many possible symptoms, it often goes undiagnosed. However, early detection is important and may prevent organ failure that can occur if it is left untreated. Long-term complications include liver cirrhosis, diabetes, cardiomyopathy, hypogonadism, arthropathy, skin pigmentation, and susceptibility to liver cancer (Camaschella and Merlini, 2005) (Table 12-20).

**Iron overload** patients may have diagnoses other than HH: non-alcoholic fatty liver disease (NAFLD), chronic hepatitis C, and chronic alcohol use are most common (Dever et al, 2009). Iron toxicity can also occur in aplastic anemia, chronic hemolytic anemia, porphyria cutanea tarda, sideroblastic anemia, thalassemias, diabetes, rheumatoid arthritis, or transfusional iron overload. Sometimes, individuals with Alzheimer's or Parkinson's disease may have heavy metal toxicities that contribute to an iron overload. Free iron is destructive to cells, and too much iron can be a carcinogen because cancer cells need it for their DNA synthesis. With chronic kidney disease, keep serum ferritin levels below 500 ng/dL.

**Porphyrias** are rare disorders caused by lack of the enzymes necessary for production of heme; this causes heme precursors, porphyrins, to accumulate in the bone marrow, liver, and bloodstream (MedlinePlus, 2009). The porphyrins may also

**TABLE 12-20 Facts About Hemochromatosis**

1. Undetected or untreated excess iron kills after inflicting injury to a variety of body organs. The physician's concern must be to detect any excess iron instead of establishing the diagnosis
2. Some literature suggests treatment when ferritin alone is elevated. Giving blood does no harm and, instead, is beneficial to health. About one fourth of patients have low hemoglobin; treatment is the same unless the anemia is so severe that blood transfusions are required. Severely anemic patients require iron removal by an iron chelator, Desferal
3. Iron overloading is preventable. When diagnosis is in doubt, the patient should begin a trial of weekly phlebotomies at the blood bank. Four to 6 weeks will usually provide the answer, and getting rid of a little excess iron will improve health
4. The patient should be taken to the blood bank upon the physician's order for weekly phlebotomies
5. A liver biopsy is not always necessary, and waiting can delay important treatment. DNA testing is not useful because it cannot detect all of the known mutations
6. When iron levels test low, the cause must be found. It is dangerous to medicate with iron without testing first and then finding the reason for any deficiency
7. Symptoms vary. Chronic fatigue, arthritis, anemia (iron-loading anemia is one symptom), and elevated liver enzymes must not be ignored. Hemoglobin level does not indicate iron status. A disorder of thyroid or any part of the body can be a symptom of iron overload
8. Excess iron lowers immunity. Many diseases (such as cancer, hepatitis, and AIDS) will show a poor outcome unless any excess iron is removed. Excess iron stored in the brain exacerbates severity in Alzheimer's, multiple sclerosis, Lou Gehrig's disease, Parkinson's disease, psychological problems, autism, and other diseases

Adapted from: Iron Overload Diseases Association, <http://www.ironoverload.org/>, accessed December 23, 2009.

be excreted in the urine or stool. Most porphyrias are hereditary, but attacks may also be triggered by drugs, alcohol, hormones, or infections.

**Acute, hepatic porphyrias** affect the nervous system. Symptoms include nerve damage with pain or paralysis, abdominal pain and liver damage, red or brown urine, anxiety and delirium, muscle pain or weakness, numbness or tingling, tachycardia, loss of deep tendon reflexes, low blood pressure, and electrolyte imbalances. Constipation or diarrhea may occur. A diet high in carbohydrate (55–60% of total kilocalories) and beta carotene may be beneficial (MedlinePlus, 2009).

**Porphyria cutanea tarda (PCT)** can occur without an inherited enzyme deficiency. The porphyrins accumulate in the liver and skin, causing photosensitivity, skin damage, and cirrhosis. Phlebotomy removes excess iron, and chloroquine or hydroxychloroquine removes the excess porphyrins from the liver (Anderson, 2007).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** HH is recessive, requiring the gene from two carrier parents. There are several types of genetic hemochromatosis: type I or classic (HHC); type II a, b, or juvenile (JHC); type III or transferrin receptor mutation; and type IV or ferroportin mutation. Iron overload can also occur in individuals with the HFE C2824 gene in 1 out of 200 people.

<b>Clinical/History</b>	BMI	I & O
Height	Diet history	Bronzing of the skin
Weight	BP	

Profound fatigue (in HH)	Enlarged spleen	Serum Cu (increased)
Arthralgia (in HH)	Hypothyroidism	Alb
Loss of body hair	Depression	Serum Fe
Loss of libido	Liver biopsy	Ferritin (increased >1000 ng/mL?)
Lack of menstruation or early menopause	Bone marrow studies	Hgb (desirable = 10 g/dL)
Abdominal pain	<b>Lab Work</b>	Hct (desirable = 30–35%)
Chronic intermittent diarrhea	Transferrin-Iron Saturation Percentage <sup>a</sup> (normal 25–35%)—best test	Gluc
Irregular heartbeat	TIBC	Serum B <sub>6</sub>
Cardiomegaly with congestive failure	(normal, 12–45%)	Serum B <sub>12</sub>
Hepatomegaly	Transferrin (increased)	Serum folic acid
		Thyroid tests
		Liver function tests
		CRP

<sup>a</sup>Divide total serum iron by TIBC for percentage of tissue saturation (TS). Divide the serum iron level by TIBC for percentage of transferrin saturation.

### INTERVENTION

### OBJECTIVES

- Remove excess iron from body (usually with phlebotomies of 500 mL weekly, performed by the physician over several months). Then therapy is repeated several times annually for rest of the life.
- Prevent liver cancer, heart attack, or stroke by unloading storage iron as fast as possible; keep serum ferritin at low normal range.
- If excess iron intake is a chronic problem, discontinue use in supplements and fortified foods (such as iron-fortified cereals). Read labels carefully.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Excessive Mineral Intake

**Assessment Data:** Male with transferrin-iron saturation percentage (46%), ferritin (160 ng/mL), elevated H & H. Diagnosis of iron overloading. Diet hx reveals high intake of animal proteins and heme iron (about 20 g/day).

**Nutrition Diagnoses (PES):** Excessive iron intake related to diet high in animal proteins and heme iron as evidenced by transferrin-iron saturation percentage (46%), ferritin (160 ng/mL), elevated H & H.

**Interventions:** Food–nutrient delivery—encourage more vegetarian meals and fewer ounces of meats at mealtime. Educate about the role of heme iron intake in iron overloading disorders. Counsel and provide meal planning tips and portion guides for intake of meats.

**Monitoring and Evaluation:** Improvement in serum laboratories (transferrin-iron saturation percentage, ferritin, and H & H) with levels closer to normal. Diet hx reveals improved intake of 8–10 g/day.

- Teach principles of nutrition and menu planning to incorporate adequate intake of other nutrients that may be depleted with excessive phlebotomies (e.g., folate and other B-complex vitamins, protein).

## FOOD AND NUTRITION

- Provide a normal diet unless renal or hepatic function is altered. Do not consume foods or take supplements high in vitamin C. Read cereal labels and avoid those with 100% or more of the daily allowance for iron and vitamin C. A low-iron diet is not recommended.
- Ensure adequate protein and sufficient energy intake to meet estimated needs and activity levels.
- Avoid alcohol because of potential damage to a vulnerable liver.

## Common Drugs Used and Potential Side Effects

- Avoid use of multivitamin supplements that contain iron and vitamin C because these can increase iron absorption.

- An iron chelator may be needed, such as deferoxamine (DFO). This is given intravenously 8–12 hours for up to five times in a week. It can be neurotoxic.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- All blood relatives of the patient must be evaluated and monitored yearly for iron overloading.
- Genetic testing of other family members is also recommended for those with inherited type.
- Discuss avoidance of alcohol and raw seafood. *Vibrio vulnificus* in some raw seafood kills people every year; many are those with undetected iron overload.
- Discuss nutrient sources as appropriate for the individual.

## Patient Education—Food Safety

- If tube feeding or CPN is needed, careful handwashing procedures should be followed.
- Avoid eating raw seafood.

## POLYCYTHEMIA VERA

## NUTRITIONAL ACUITY RANKING: LEVEL 1

## DEFINITIONS AND BACKGROUND

Polycythemia vera (PV) is a chronic, progressive disease in which increased blood volume and increased erythrocyte production occur. Other names include erythremia,

Osler–Vasquez disease, and polycythemia rubra vera. Hematological disorders like PV can result in elevated levels of cobalamin, which is released during hepatic cytolysis.

The cause of PV is unknown, and the disease is considered a hematological malignancy. The disease develops

slowly and may progress to acute myelogenous leukemia. The average age at diagnosis is 50–60 years. Incidence is highest among those of Jewish ancestry, occurring in 2 of 100,000 of the population. Increased viscosity of the blood and number of platelets result in a high risk for clot formation and stroke, hemorrhage, or myocardial infarction.

Patients with PV frequently develop hyperhomocysteinemia due to discrete depletion of cobalamin or folate; vitamin therapy should be considered. With treatment, individuals with this condition may live for 15–20 years. Phlebotomy or medications may be used.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The somatic V617 F mutation in the Janus kinase (JAK) 2 gene, which causes a valine to phenylalanine substitution at position 617, has recently been found in the majority of patients with PV (Meyer, 2009).

Clinical/History		
Height	Dusky reddish skin on face and hands	Erythropoietin (low)
Weight	Hemorrhagic tendency	TIBC
BMI	Seizures, confusion	Erythrocyte sedimentation rate (ESR)
Diet history	Splenomegaly	Leukocyte Alk phos
I & O	Tinnitus	Serum ferritin
BP (hypertension?)	Paresthesias	Gluc
Belching, fullness	Gout	RBC (7–12 million)
Flatulence		Oxygen saturation >92%
Peptic ulcer?	<b>Lab Work</b>	CRP
Constipation	Hgb (>18 g/dL)	Alb, transthyretin
Headache	Hct (>52% for men; >47% for women)	CRP
Vertigo	Platelets (elevated)	Chol, Trig
Lassitude	Leukocytes (elevated)	BUN, Creat
Tinnitus	Serum B <sub>12</sub> (elevated)	Uric acid (elevated)
Pruritus after bathing		Bone marrow biopsy
Transient blurred vision, diplopia		
Dyspnea		
Chest pain		

## INTERVENTION

### OBJECTIVES

- Prepare patient for phlebotomy by ensuring adequate nutrient stores.
- Prepare, as needed, for chemotherapy or radiation therapy, which may be provided.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Abnormal GI Function

**Assessment Data:** BMI 20. Constipation, flatulence, history of gastric bleeding, and ulceration.

**Nutrition Diagnoses (PES):** Abnormal GI function related to discomfort and pain as evidenced by constipation, flatulence, GI ulceration, and bleeding.

**Interventions:** Food–nutrient delivery—use comfort foods and adequate CHO, fiber, and fluid intake; reduce acidic foods and items not well tolerated. Educate about good nutrition and inclusion of B-complex vitamins. Counsel about individualizing tolerance for medications with appropriate food, fluid, and snacks.

**Monitoring and Evaluation:** Daily use of prescribed medications. Improvement in GI function; resolution of constipation and flatulence. No additional GI bleeding.

- Correct or control condition.
- Manage any side effects such as heart failure, peptic ulcer disease, gastric bleeding, gout, leukemia, and seizures.

## FOOD AND NUTRITION

- A high CHO diet with preferred foods and balanced meals should be offered. Monitor for the need for vitamin or mineral supplementation. Include foods rich in beta carotene.
- Extra fluids will be helpful (35–40 mL/kg, unless contraindicated, as with heart failure).
- Changes in dietary texture or content may be needed if radiation or chemotherapy alters nutrient or dietary needs.

## Common Drugs Used and Potential Side Effects

- Myelosuppressive agents may be prescribed. Anagrelide hydrochloride (Agrylin) is an oral imidazoquinazoline agent that has been shown to reduce elevated platelet counts and the risk of thrombosis. Interferon alpha may be used in younger patients; pegylated interferon alpha-2a (PEG-IFN-alpha-2a) is beneficial (Quintas-Cardama et al, 2009).
- The antimetabolite hydroxyurea may be used. Side effects include anemia and skin ulcers.
- Chemotherapeutic agents (busulfan, chlorambucil, and cyclophosphamide) may cause nausea and vomiting or weight loss.
- Low-dose aspirin is sometimes used in patients with thrombotic or ischemic conditions. It can relieve some of the burning sensations in the feet and hands. Antihistamines can help reduce itching sensation.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss need to maintain a healthy lifestyle and to eat adequate protein and calories because of the frequent phlebotomies, where completed.
- Discuss ways to make meals that are nutritious yet simple to prepare.
- Tepid oatmeal baths may help reduce pruritus.

### Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

# THROMBOCYTOPENIA

## NUTRITIONAL ACUITY RANKING: LEVEL 1

Adapted from: *Anderson's Atlas of Hematology*; Anderson, Shauna C., PhD. Copyright 2003, Wolters Kluwer Health/Lippincott Williams & Wilkins.

### DEFINITIONS AND BACKGROUND

Thrombocytopenia purpura, a myeloproliferative disorder, is a blood disease affecting the clotting factor (platelets) of the blood, with an abnormally low platelet count and shorter than normal (10 days) platelet survival time. Thrombocytopenia is the most common cause of bleeding, usually from small capillaries. Women are more affected than men.

There are many reasons for the development of decreased marrow production or platelet destruction that causes thrombocytopenia, including some hereditary causes. These can sometimes be determined by examination of bone marrow. Idiopathic thrombocytopenic purpura (ITP) is caused by platelet destruction by antibodies. Thrombotic thrombocytopenic purpura (TTP) is manifested by vascular lesions.

Plasma exchange (plasmapheresis) is used to remove the abnormal antibody from the blood and replace the

missing enzyme. Mortality of TTP has decreased from 90% to 10% (George, 2009); survival improved dramatically with plasma exchange treatments after the 1980s (Kremer-Hovinga et al, 2009). Unfortunately, adults with TTP of any etiology have a high risk for persistent minor cognitive abnormalities (George, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** Mutations in the ADAMTS13 gene cause the familial form of TPP. Alterations in the ADAMTS13 gene reduces instructions for the normal process of blood clotting.

Clinical/History	Slurred speech	H & H (decreased)
Height	Numbness and weakness of extremities	Alb, transthyretin
Weight		N balance
BMI	Fever?	PT and PTT (normal)
Diet history	Pallor	Casts in urine
I & O	Jaundice	Proteinuria
BP	Shortness of breath	CRP
Nosebleeds		Ca <sup>++</sup>
Bleeding from other sites		Na <sup>+</sup> , K <sup>+</sup>
Bruising		
Pinpoint red spots on skin	<b>Lab Work</b>	
Headache	CBC (low platelets)	

## SAMPLE NUTRITION CARE PROCESS STEPS

## Self-Feeding Difficulty

**Assessment Data:** BMI at lower end of normal, but some weight loss noted. Dx of TPP with numbness and weakness in hands and feet. Inability to feed self and remain independent; depression and easy frustration noted at mealtimes.

**Nutrition Diagnoses (PES):** Self-feeding difficulty related to numbness in hands as evidenced by inability to hold traditional utensils.

**Interventions:** Food–nutrient delivery—alter food choices to simplify options and offer more finger foods. Educate about use of adaptive feeding equipment that can be used for more independence. Counseling with tips on meal simplification.

**Monitoring and Evaluation:** Improved ability to feed self independently. No further weight loss. Less depression and frustration at mealtimes.

## INTERVENTION

## OBJECTIVES

- Avoid infections, especially upper respiratory infections and flu to prevent coughing, which increases intracranial pressure.
- Reduce bleeding tendency and complications, such as intracranial hemorrhage or GI bleeding (Goldman, 2007).
- Rest frequently.
- Prepare patient for splenectomy, if indicated. Ensure adequate nutrient stores.

## FOOD AND NUTRITION

- Maintain diet of preference. Use small, frequent feedings if patient has nausea or vomiting.
- Adequate folic acid will be needed.
- Increase fluids (e.g., 3 L/d) unless contraindicated.
- After splenectomy, patient will need adequate protein, energy, zinc, and vitamins A and C for wound healing. Vitamin K from the diet and supplements may need to be monitored.

## Common Drugs Used and Potential Side Effects

- Most drugs are stopped because nearly any drug may aggravate the condition.

- Corticosteroids such as prednisone may be used to control bleeding. Side effects are numerous and may affect nutritional status (e.g., decreased serum calcium, potassium, and nitrogen; increased serum sodium; and glucose intolerance may occur).
- Myelosuppressive agents are often prescribed. Anagrelide hydrochloride (Agrylin) is an oral imidazoquinazoline agent that has been shown to reduce elevated platelet counts and the risk of thrombosis. Interferon alpha may be used.
- Rituximab seems to be a promising drug in the treatment of refractory autoimmune thrombocytopenia.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss altering nutrients as needed, depending on medications ordered and their use over time; surgery, if required; and ability to eat adequately.

## Patient Education—Food Safety

If tube feeding or CPN is needed, careful handwashing procedures should be followed.

# Cancer

## CHIEF ASSESSMENT FACTORS

### American Cancer Society's Seven Warning Signs of Cancer

- Change in Bowel/Bladder Habits
- Indigestion or Dysphagia
- Nagging Cough or Hoarseness
- Obvious Change in Wart or Mole
- Sore That Does Not Heal
- Thickening or Lump in Breast or Elsewhere
- Unusual Bleeding or Discharge

### Other Factors

- Anorexia or Chronic Nausea
- Changes in Food Intake, Usual Functional Capacity, Energy Levels
- Depression
- Diarrhea
- Dry Mouth
- Dysphagia, Esophagitis, Mouth Sores, Mucositis
- Edema or Ascites
- Fever of Unknown Origin (Hematological, Liver, Pancreatic, Brain, Kidney Cancers)
- History of Carcinogen Exposure, Tobacco Use, Excessive Alcohol Use
- Intolerance for Nauseating Odors
- Muscle Wasting
- Nutrient Intake and Immune Function
- Pain
- Participation in Complementary and Alternative Medicine Treatments
- Side Effects of Medications
- Vomiting
- Weight Changes—Unintended Weight Loss or BMI Less Than 22

**TABLE 13-1 Cancer Definitions**

Term	Definition	Term	Definition
Adenocarcinoma	Cancer that starts in the glands.	Leukemia	Cancer where bone marrow-produced abnormal white blood cells crowd out normal white blood cells, red blood cells, and platelets.
Adenoma	Benign growth that may or may not transform into cancer.	Lymphoma	AIDS-related lymphoma; cutaneous T-cell lymphoma; Hodgkin's lymphoma; mycosis fungoides; non-Hodgkin's lymphoma; primary central nervous system lymphoma; Sézary's syndrome; and Waldenstrom's macroglobulinemia.
Antiangiogenesis	Process of stopping a tumor from growing new blood vessels.	Male reproductive cancers	Penile, testicular cancers, prostate cancers.
Antibodies	Proteins in the immune system; in cancer, antibodies are used to recognize specific cancer cell receptors and to act as smart bombs.	Meningiomas	Tumors affecting the meninges.
Basal cell carcinoma	Most common form of skin cancer, affecting 800,000 Americans each year. Chronic exposure to sunlight causes most basal cell carcinomas, which occur most frequently on exposed parts (e.g., face, ears, neck, scalp, shoulders, and back).	Mesothelioma	Rare cancer affecting the lining of the chest, heart, and abdominal cavity from exposure to asbestos.
Biotherapy	Treatment to stimulate or restore the ability of the immune system to fight infection and disease and to lessen side effects that may be caused by some cancer treatments; also known as immunotherapy, biological therapy, or biological response modifier (BRM) therapy.	Metastasis	Transfer of disease from one organ to another that is not directly connected to it; particularly the spread of carcinoma.
Cancer	Abnormal, uncontrolled growth of cells in a lump or mass that also destroys normal tissue. Oncogenes in a tumor cell may be identifying markers.	Monoclonal antibodies	Targeted therapy to locate and bind cancer cells. May be used alone or used to deliver drugs, toxins, or radioactive material directly to tumor cells.
Carcinoma	Cancer involving epithelial tissue and coverings of internal and external surfaces; lungs, colon, breast, stomach, uterus, skin, and tongue cancers. 80–90% of all cancers.	Neuroma	A tumor composed of nerve cells, which may occur along any nerve.
Chemotherapy	Use of medications to kill malignant cells.	Oat cell carcinoma	A rapidly spreading, highly fatal cancer of the bronchus.
Curative Therapy	Permanent removal of the cancer from the body.	Oncology	Scientific study of tumors.
Endocrine system cancers	Adrenocortical carcinoma; gastrointestinal carcinoid tumor; pancreatic islet cell carcinoma; parathyroid cancer; pheochromocytoma; pituitary tumor; and thyroid cancer.	Osteosarcoma	Most common bone cancer, which develops in new tissue in growing bones, affecting young people and more males.
Epithelioma	Carcinoma consisting of many epithelial cells.	Palliative therapy	Pain relief but not expected to cure the disease. Given to improve quality of life as much as possible.
Gastrointestinal (GI) cancers	Anal cancer; bile duct cancer; colon cancer; esophageal cancer; gallbladder cancer; GI carcinoid tumor; liver cancers; pancreatic cancer; rectal cancer; small intestine cancer; stomach cancer.	Radiation	Treatment with high-energy rays to kill or damage cancer cells. May be external rays or internally placed radioactive material.
Gynecological cancer	Female reproductive system: cervical cancer; endometrial cancer; gestational trophoblastic tumor; ovarian epithelial cancer; ovarian germ cell tumor; ovarian low malignant potential tumor; sarcoma; vaginal cancer; and vulvar cancer.	Sarcoma	Cancer arising from bone or connective tissue, which sometimes spreads into blood or lymphatic tissues.
Hormonal therapy	Treatment by surgery or by shrinking or killing hormone-dependent cancers.	Small cell carcinoma	Carcinoma that most commonly arises in the lung but can occur as a cancer in other body sites including the prostate, cervix, and head and neck; responsive to chemotherapy and radiation therapy.
		Vaccine	To stimulate the immune system to mount a defense against cancer cells. Example – the cervical cancer vaccine.

## CANCER PREVENTION AND RISK REDUCTION

Cancer results from dysregulated cell growth control and is caused by an interaction of dietary, genetic, and environmental risk factors. There are over 100 variations of cancer. Cancer has a strong genetic component, associated with initiation, promotion, and metastatic growth. The Human Genome Project has identified 30,000 human protein-coding genes. Individualized DNA methylation helps to control gene expression. Genotyping resources allow cancer prevention investigators to identify which genetic subsets of patients are likely to benefit most from chemoprevention and interventions. This emerging science of nutritional genomics is very promising (Kauwell, 2005).

Natural carcinogens include ultraviolet (UV) radiation, dyes, environmental chemicals from smoke or mines, viruses, nitrosamines, aflatoxins, and safrole. The most consistent carcinogen is tobacco. Approximately 30% of cancers also have a nutrition or dietary component (Williams and Hord, 2005). Functional food components greatly impact the incidence and treatment of cancer. In addition, food intake, aging, and immune function share a complex relationship; selenium, EPA, DHA, vitamin A, and sodium seem to be particularly important (Wardwell et al, 2008).

Nutritive and nonnutritive dietary constituents can either promote or hinder the development of cancer, individualized by genetic predisposition. Diets rich in carotenoids, antioxidative vitamins, phenolic compounds, terpenoids, steroids, indoles, and fibers reduce the risk of cancer and related chronic diseases (Aggarwal and Shishoridra, 2004). Studies support the role of flavonoids, carotenoids, curcumin, ascorbic acid, and citrus limonoids (Patil et al, 2009). Polyphenols are the most abundant antioxidants in the average diet and are constituents of fruits, vegetables, cereals, dry legumes, chocolate, tea, coffee, and wine.

The strongest evidence linking specific foods to a decreased risk of certain cancers is related to the consump-

tion of fruits, vegetables, and whole grains. Antioxidants protect against free radical damage, improving the resistance of cells to oxidative stress. In a study using HANES data, daily intakes of antioxidants from both diet and supplements averaged 208 milligrams of vitamin C, 20 milligrams of alpha-tocopherol, 223 retinol activity equivalents (RAE) of carotenes, 122 micrograms of selenium, and 210 milligrams of dietary flavonoids (Chun et al, 2009). Women, older adults, Caucasians, nonconsumers of alcohol, nonsmokers, and those with a higher income and exercise level than other tended to have better intakes (Chun et al, 2009). Key nutrients, chemoprotective phytochemicals, and functional food ingredients are listed in Table 13-2.

Promoting fruits, vegetables, and whole grains is the key message. Choose “better for you” foods, and make vegetables the central focus of the plate. Minimize meats, or use leaner cuts. Enhance the diet with nuts and whole grains (insoluble types to increase stool bulk and push bile out; soluble types for their cholesterol-lowering effect). A complete “anticancer” grocery list includes dark green, yellow, and orange fruits or vegetables; red grapes; cruciferous vegetables; orange juice; tomatoes; olive and canola oils; garlic; legumes; strong coffee; whole grains; soy; and other plant estrogens.

Dietary factors and physical inactivity contribute to approximately one-third of all cancers. Table 13-3 provides a list of important dietary factors. Excess body weight increases the risk of several cancers. There are five lifestyle habits to promote: maintain BMI <25, get 30 minutes of exercise, limit alcohol to—one to two drinks daily, do not smoke, and choose a healthy diet rich in phytochemicals.

Many cancer patients try CAM therapies; fish oil is the leading choice of adults. Yet the emphasis remains on food sources, not supplements or pills. The intake of whole foods and fortified, enriched, or enhanced foods has the most beneficial impact on health (American Dietetic Association, 2009).

**TABLE 13-2 Phytochemicals, Functional Food Ingredients, and Cancer**

Phytochemicals are functional foods or ingredients that occur naturally in fruits and vegetables and whole grains, often to protect against microorganisms. They are not “essential” nutrients, but some phytochemicals function as antioxidants to squelch free radicals.

Food	Functional Ingredient	Possible Roles in Reducing Cancer Risk
Apples (MALUS sp., Rosaceae)	Hydroxycinnamic acids, dihydrochalcones, catechins and oligomeric procyanidins	Also contain triterpenoids in apple peel and anthocyanins in red apples. Protect against skin, lung, breast, and colon cancer (Gerhauser, 2008).
Apples, black tea, grapefruit, onions, arugula	Quercetin, kaempferol, myricetin, isorhamnetin (flavonols)	Decreases ascorbate-dependent free radical oxidation; decreases inflammation and tumorigenesis. May be protective against colorectal cancer. Since apple skins retain pesticides, choose organic.
Beans and legumes, soybeans, whole grains, alfalfa, lentils, bean sprouts	Saponins: oleanic acid, hedagenin (terpenes)	Triterpene glycosides that neutralize enzymes in the intestine that may cause cancer; they boost immunity. Consume only moderate amounts of soy as part of a healthy plant-based diet.
Beef, lamb, yogurt, some cheeses and dairy products	Conjugated linoleic acid	Maintains immune function and normal body composition; some antitumor properties. Marinate meats in red wine or beer to cut heterocyclic amine exposure; do not burn meats.
Bell peppers, citrus fruits	Vitamin C	Protects against damage from free radicals.
Blueberries (particularly skins), blackberries, raspberries, strawberries, cherries, red grapes, red cabbage, eggplant, red onion, kidney beans, red beans, beets, black currants, elderberries, purple sweet potato skin, prunes	Anthocyanins (polyphenols/flavonols)	Bolsters cellular antioxidant defenses particularly against UV radiation; maintain brain function and motor function; neutralize free radicals; have antimicrobial action.
Brazil nuts, lean meats, tuna, salmon, seafood	Selenium and Glutathione	Increases immune cell functioning, DNA methylation, and regulation of cytokine production. Protects from damage from free radicals. SELECT study found that a 200-milligram selenium supplement actually promotes prostate cancer.
Broccoli, broccoli sprouts, horseradish, cauliflower, cabbage, bok choy, Brussels sprouts, kale	Sulforaphane; thiols	Isothiocyanates (ITCs) protect the body from cancer by inducing detoxification enzymes such as quinone reductase. They increase periods of cancer latency and are effective agents against fungi such as <i>Aspergillus</i> . Protects against stomach and skin cancers. Lightly cooked broccoli has more; use a mix of raw and cooked vegetables.
Broccoli, peas, beans, and other vegetables; soybeans, clover, alfalfa	Coumestans (phytoestrogen)	High level of estrogenic activity that may reduce the risk for lung cancer. Estimated daily intake of coumestans is 0.6 micrograms; broccoli is the main source.
Cabbage, sauerkraut	Glucosinolate	May lower the risk of hormonal cancers
Carrots, American ginseng roots	Falcarinol, falcarindiol, panaxydol (polyacetylenes)	Inhibits cell proliferation in normal and cancer cells through synergism of bioactive polyacetylenes. More effective if whole and not chopped before cooking.
Carrots, sweet potatoes, pumpkin, butternut squash, cantaloupe, mangoes, apricots, peaches, papaya, watermelon	Beta-carotene (terpenes)	Beneficial effects on human cancer prevention; increases the activity of killer cells slightly; photoprotective; neutralize free radicals; serves as antioxidants. Avoid excesses of supplements as they act as pro-oxidants. Dietary fat is needed for proper absorption. Boil or steam to protect the antioxidants.
Cereals, legumes, nuts, sesame seeds, soybeans, brown rice, corn and wheat brans	Inositol	Found as phytic acid in plants. Used by all cells to relay outside messages to the cell nucleus. Aids in the metabolism of calcium and other minerals.
Cherry juice	Chlorogenic acid (phenolic acid)	Strong antioxidant properties.
Cinnamon, cocoa, apples, strawberries, purple grapes and wines, peanuts, cranberries	Proanthocyanidins	Decreases oxidative stress; supports urinary tract health.
Citrus fruits, lemon, cantaloupe, pomegranate, potato skins, wild leafy greens, celery stalks, lettuce, chili and sweet peppers, spinach, parsley, watermelon, whole grains, tomato sauce, red wines	Apigenin, luteolin (flavones)	Tumor growth inhibition and chemoprevention; may protect against skin cancer and ultraviolet damage. May protect women against ovarian cancer.
Citrus fruits, apples, pears		
Some vegetables	Caffeic acid, ferulic acid (flavanones)	Bolsters antioxidant defenses.

(continued)

**TABLE 13-2** Phytochemicals, Functional Food Ingredients, and Cancer (*continued*)

Food	Functional Ingredient	Possible Roles in Reducing Cancer Risk
Corn, soy, wheat, wood oils	Plant stanols	Inhibits cholesterol absorption.
Cruciferous vegetables: Broccoli, cabbage, sauerkraut, Brussels sprouts, bok choy, arugula, Swiss chard, watercress, cauliflower, kale, kohlrabi, turnips, rutabaga	Indoles (indole-3-carbinol); glucosinolates (thiols)	Antimutagenics that may enhance detoxification of undesirable compounds. May contribute to a healthy immune system; downregulate estrogen and tumor formation. May yield a lower risk of breast, colon, prostate, and cervical cancers.
Cruciferous vegetables ( <i>Brassica</i> family)	Jasmonates (thiols)	Plant signaling compounds that activate the coordinated gene expression in ascorbate and glutathione metabolic pathways. Important in defense responses to oxidative stress and biosynthesis of glucosinolate, a defense compound.
Dairy products	Vitamin D <sub>3</sub> , calcium, sphingomyelin	May inhibit tumor cell growth and aid in cell death. Vitamin D <sub>3</sub> may protect against some skin cancers, but not melanoma. A level of 2000–4000 IU per day of vitamin D <sub>3</sub> is considered necessary for most adults. Sun exposure, diet, and supplements may be needed.
Flaxseed, rye, whole grains, berries, carrots, spinach, broccoli, tea, asparagus, linseeds; alcoholic beverages (red and white wines).	Lignans: matairesinol and secoisolariciresinol	Phytoestrogens attach to estrogen receptors and block real estrogen, lower cholesterol levels, and decrease cancer activity. Lignans may prevent prostate or lung cancer. Median intake of lignans is 578 micrograms (mainly from berries).
Garlic, onions	Allyl sulfides; selenium	Boosts levels of naturally occurring enzymes that may help maintain a healthy immune system. Garlic also contains arginine, oligosaccharides, sulfur and flavonoids. May be protective against cancers of the stomach, esophagus, colon, breast, and pancreas.
Ginkgo biloba	Ginkgolide A and B	Taken for 6 months or longer, may lower the risk of ovarian cancer. Involved in anti-inflammation processes.
Ginseng	Triterpene glycoside	Radioprotective capability, attributed to the ginsenosides, which are saponins with antioxidant properties. May increase lymphocyte production, stimulate natural killer cells and other immune activity; inhibit cancer cell growth; antioxidant.
Grapes, wine, raspberries, strawberries, tomatoes, citrus fruits, carrots, whole grains, nuts	Ellagic acid, Ferulic acid (phenolic acids)	May block the production of enzymes needed for cancer cells to reproduce. Protect against <i>Salmonella</i> and <i>Staphylococcus aureus</i> infections (particularly ellagitannins in raspberries).
Grape juices from green and black grapes	Gallic acid (phenolic acids)	Strong antioxidant properties
Green tea, oolong tea, black teas, dark chocolate, red wines, licorice root, cranberries and cranberry products	Catechins: epigallocatechin gallate (EGCG); glycyrrhizin; procyanidins/tannins (flavonols)	Decreases the growth of hydroquinone oxidase; decreases COX-2 gene expression and cancer cell growth; and neutralizes free radicals. Tannins in green and black tea and strong coffee inhibit the proliferation of cancer cells in prostate, ovarian, breast, lung, and possibly other sites. Avoid excesses of caffeine, which dilute the effect of the tea.
Green tea extract, watermelon, prunes, raisins, plums, eggplant, grapes, berries, cherries, apples, cantaloupe	Polyphenols	May neutralize free radicals to help block damage to DNA. Superoxide anion radical (SOR) has scavenging activity; protects against oxidation of low-density lipoprotein and protects vision.
Green vegetables: Turnip, collard, and mustard; kale, spinach, broccoli. Green peas, kiwi, cilantro, parsley, lettuce. Corn; egg yolk.	Lutein and zeaxanthin (terpenes)	Antioxidants; anti-inflammatory; DNA repair. Good for healthy vision (protects against macular degeneration). Raw spinach is higher than cooked. Lutein may improve skin health and protect against skin cancer.
Leafy greens	Folic acid	Role in DNA synthesis, mitosis, and gene expression.
Legumes, whole grains, bananas, fish, chicken	Vitamin B <sub>6</sub>	Supports a healthy immune system and increases lymphocyte numbers.
Licorice <i>Glycyrrhiza uralensis</i> and orange <i>Citrus</i> spp.	Coumarins; benzo-alpha-pyrone	Inhibits proteolysis and lipoxygenase; anti-inflammatory and antitumor effects.
Milk and dairy products, fish, liver	Vitamin A	Protects cells against free radical damage.
Nuts, nut butters, wheat germ, whole grains, oils, mayonnaise, creamy salad dressings, egg yolks, cereals, seeds	Vitamin E	Increases antibody production and B- and T-cell functioning; protects cells against free radical damage. SELECT study found that a 400 IU supplement actually promotes prostate cancer.
Oats	Avenanthramides; selenium	These polyphenols have strong antioxidant, anti-inflammatory properties (Meydani, 2009).

(continued)

**TABLE 13-2 Phytochemicals, Functional Food Ingredients, and Cancer (continued)**

Food	Functional Ingredient	Possible Roles in Reducing Cancer Risk
Oats, lima beans, navy beans, black beans, Brussels sprouts, ground psyllium seeds, peas, carrots, apples, barley, pectins, gums, mucilages	Soluble fiber	May lower cancer risk; helps lower cholesterol levels.
Olive and canola oils; tree nuts	MUFAs	Monounsaturated fats decrease tumorigenesis. Virgin olive oil phenols may reduce colorectal carcinogenesis.
Onions, garlic (particularly oil), leeks, chives, scallions, shallots	Allium and allicin (allyl sulfides, S-allylcysteine [SAC])	Organosulfurs decrease tumor cell growth; inhibit kinase activity; may protect the immune system, assist the liver in rendering carcinogens harmless, and reduce cholesterol production in the liver. Diallyl sulfide (DAS) inhibits the effects of PhIP that can cause DNA damage or transform substances into carcinogens.
Onions, garlic, leeks, shallots, inulin, Jerusalem artichokes, fructooligosaccharides (FOS); polydextrose in whole grains, some fruits, honey	Prebiotics	Support GI health and improve calcium absorption. Inulin may help protect against colon cancer.
Orange, grapefruit, lemon; cherries; citrus fruit peel	Limonoids/limonene (Terpenes); Naringenin, Hesperetin, Eriodictyol (flavanones)	Citrus glycosides decrease bacterial and fungal growth; decrease cancer cell growth by detoxifying enzymes in liver. Also cause cell apoptosis with certain types of cancers. Stimulate DNA repair with naringenin. Avoid grapefruit in estrogen+ breast cancer.
Oranges, grapefruit, lemons, tangerines, peaches, apricots, broccoli, tomatoes	Bioflavonoids, vitamin C	Minimizes damage to neutrophils; induces apoptosis; inhibits histamine
Pomegranate fruit and juice	Punicalagin (phenolic acid)	Potent antioxidant; protective against prostate cancer.
Red pepper, paprika	Capsaicin (8-methyl-N-vanillyl-6-nonenamide)	Red peppers of the genus <i>Capsicum</i> ; it contains carotenoids that may be protective against cancer.
Salmon, mackerel, sardines	Coenzyme Q10 (ubiquinone) Omega-3 fatty acids	May reduce chemotherapy-related heart damage.
Seafood, canola oil, walnuts, flaxseed, marine and other fish oils	Omega-3 PUFAs	Reduce inflammation; may reduce cancer cachexia. Genetic variations affect response of COX-2 and its inflammatory impact on cancers such as prostate.
Soybean, corn and safflower oils	Omega-6 PUFAs	Keep omega-6 to omega-3 at a ratio of 5–10:1.
Soybeans (tofu, vegetable soy milk, soy nuts); legumes such as chick peas, beans, peas; nuts; grain products, coffee, tea; raisins and currants	Isoflavones: genistein, daidzein, biochanin A	Phytoestrogens attach to estrogen receptors and block real estrogen. Red clover and soy extracts contain isoflavones, with high affinity to estrogen receptor-alpha (ER $\alpha$ ), estrogen receptor-beta (ER $\beta$ ), progesterone receptor (PR), and androgen receptor (AR). Daily dose may be 40–50 milligrams of isoflavones (biochanin A, daidzein, formononetin, and genistein). Avoid excesses.
Spices: Cumin and turmeric, ginger, mint, rosemary, garlic, thyme, oregano, sage, basil, coriander, caraway, fennel, chili powder, black pepper, mint	Myricetin	Neutralizes free radicals, supports antioxidant defense system; preserves alpha-tocopherol, decreases inflammation; decreases ATPase; protects plasma DNA from radiation damage. May protect against prostate cancer.
Supplements, herbal	Astragalus, Echinacea, Silymarin	May increase macrophage activity and enhance immunity (interferon, killer cells, Interleukin-2). Silymarin protects the liver.
Sweet potatoes, carrots, turnips, spinach, papaya, tomato, red or green bell peppers, oranges	Retinoids; beta carotene	Important for cell growth, differentiation and death. May prevent some leukemias. Sweet potatoes are high in fiber, potassium, choline, vitamin C, magnesium, iron, and calcium as well.
Tomatoes and tomato products, ketchup, peppers; pink grapefruit; watermelon	Lycopene; vitamin C	Potent antioxidant; may reduce risk of prostate cancer. Tomato products must be cooked.
Vegetable oils, soy, peanuts, rice bran	Sterols: beta-sitosterol, campesterol, stigmasterol, squalene	Can reduce the risk of lung cancer and may reduce the tumor growth of other cancers. Sterols are found in vegetable oils. Sitosterol is the most studied.
Walnuts	Phytosterols, omega-3 fatty acid (ALA)	Antioxidant, anti-inflammatory properties that reduce tumor growth.
Wheat germ, lean beef, seafood, black-eyed peas	Zinc	Increases neutrophil function and killer cell numbers; decreases cytokines.
Whole grains, beans, seeds (soybeans, oats, barley, brown rice, whole wheat, flaxseed)	Phytates; insoluble fiber; vitamin E	Decreases oxidative damage to cells. Reduces the risk for breast or colon cancer.

(continued)

**TABLE 13-2** Phytochemicals, Functional Food Ingredients, and Cancer (*continued*)

Food	Functional Ingredient	Possible Roles in Reducing Cancer Risk
Whole grains	Oligosaccharides; protease inhibitors	These increase short-chain fatty acid formation; decrease cholesterol and lower insulin levels; inhibit action of protein-splitting enzymes. May prevent cancer cell formation or decrease tumor size.
Wine, red grapes, grape juice, peanuts	Resveratrol; stilbenes (flavonoids)	Phytoalexin produced in plants in response to exposure to ultraviolet light or fungi. Decreases platelet activity, lowers cholesterol, suppresses proliferation of a variety of tumor cells.
Yogurt with <i>Lactobacilli</i> , <i>Bifidobacteria</i> ; fermented milk such as Kefir.	Probiotic bacteria	Normalizes the intestinal microflora, blocks the invasion of potential pathogens in the gut, prevents colon cancer, modulates immune function, inhibits <i>H. pylori</i> , enhances calcium absorption; synthesizes niacin, folic acid, vitamin B <sub>6</sub> , and biotin.

**TABLE 13-3** Cancer Risk Factors by Site*Factors That are Known to Increase the Risk of Cancer*

## Cigarette Smoking and Tobacco Use

- Acute myelogenous leukemia (AML).
- Bladder cancer.
- Cervical cancer.
- Esophageal cancer.
- Kidney cancer.
- Lung cancer.
- Oral cavity cancer.
- Pancreatic cancer.
- Stomach cancer.

## Infections

- Human papillomavirus (HPV) increases the risk for cancers of the cervix, penis, vagina, anus, and oropharynx.
- Hepatitis B and hepatitis C viruses increase the risk for liver cancer.
- Epstein-Barr virus increases the risk for Burkitt lymphoma.
- *Helicobacter pylori* increases the risk for gastric cancer.

Two vaccines to prevent infection by cancer-causing agents have already been developed and approved by the U.S. Food and Drug Administration (FDA). One is a vaccine to prevent infection with the hepatitis B virus. The other protects against infection with strains of human papillomavirus (HPV) that cause cervical cancer. Scientists continue to work on vaccines against infections that cause cancer.

## Radiation

- Ultraviolet radiation from sunlight: This is the main cause of nonmelanoma skin cancers.
- Ionizing radiation from medical X-rays and radon gas in our homes: Scientists believe that ionizing radiation causes leukemia, thyroid cancer, and breast cancer in women. Ionizing radiation may also be linked to myeloma and cancers of the lung, stomach, colon, esophagus, bladder, and ovary.

*Factors That May Affect the Risk of Cancer*

## Alcohol

- Oral cancer.
- Esophageal cancer.
- Breast cancer.
- Colorectal cancer (in men).
- Liver cancer
- Female colorectal cancer.

## Diet

Foods may protect against cancer and other foods may increase the risk of cancer.

- Fruits and nonstarchy vegetables may protect against cancers of the mouth, esophagus, and stomach.
- Fruits may protect against lung cancer.
- Diet high in fat, protein, calories and red meat may increase risk of colorectal cancer, but studies have not confirmed this.
- It is not known if a diet low in fat and high in fruits, vegetables and fiber lowers the risk of colorectal cancer.

## Physical Inactivity

- Colorectal cancer
- Postmenopausal breast cancer
- Endometrial cancer.

## Obesity

- Postmenopausal breast cancer.
- Colorectal cancer.
- Endometrial cancer.
- Esophageal cancer.
- Kidney cancer.
- Pancreatic cancer.
- Gallbladder cancer

## CANCER TREATMENT AND TIPS FOR LONG-TERM SURVIVAL

# CANCER: TREATMENT GUIDELINES

### DEFINITIONS AND BACKGROUND

Cancer patients can be divided into three groups: those receiving standard or experimental therapy, those who have become unresponsive to these therapies, and those in remission who are at risk for recurrence or a second new cancer.

Cancer cachexia—a wasting syndrome characterized by weight loss, anorexia, early satiety, progressive debilitation, and malnutrition—may lead to organ dysfunction and death (Mattox, 2005). Fatigue is the most common experience among cancer patients. Otherwise, each type of cancer has its own set of treatments and side effects.

**TABLE 13-4 Use of Nutrition Support in Cancer Patients**

ASPEN Cancer Guideline Updated (2009)

Nutrition support therapy should not be used **routinely** in patients undergoing major cancer operations. • Grade: A

Perioperative nutrition support therapy may be beneficial in moderately or severely malnourished patients if administered for 7–14 days preoperatively, but the potential benefits of nutrition support must be weighed against the potential risks of the nutrition support therapy itself and of delaying the operation. • Grade: A

Nutrition support therapy should not be used **routinely** as an adjunct to chemotherapy. • Grade: B

Nutrition support therapy should not be used **routinely** in patients undergoing head and neck, abdominal, or pelvic irradiation. • Grade: B

Nutrition support therapy is appropriate in patients receiving active anticancer treatment who are malnourished and who are anticipated to be unable to ingest and/or absorb adequate nutrients for a prolonged period of time. • Grade: B

The palliative use of nutrition support therapy in terminally ill cancer patients is rarely indicated. • Grade: B

Omega-3 fatty acid supplementation may help to stabilize weight in cancer patients on oral diets experiencing progressive, unintentional weight loss. • Grade: B

#### Indications for Enteral Feeding

Inability to consume 50% of estimated needs orally for 1 week or longer—estimated or actual

Functioning gastrointestinal (GI) tract with adequate capacity for nutrient absorption

Patient willingness to use tube feeding method

#### Contraindications for Enteral Feeding

Severe malabsorption that cannot be corrected with enteral nutrition

Intestinal obstruction below feeding placement site

Condition such as high-output fistula or high aspiration risk

Adapted from: ASPEN Guidelines. <http://www.nutritioncare.org/wcontent.aspx?id=4054>, accessed January 1, 2010.

Dixon SW. Nutrition care issues in the ambulatory (outpatient) head and neck cancer. *Support Line.* 27:3, 2005.

Weight loss and cachexia are common. Malnourished cancer patients commonly have high protein turnover and loss of nitrogen, significant loss of muscle mass, and impaired physical capacity. Tumor factors such as proteolysis-inducing factor (PIF), tumor necrosis factor (TNF), and lipid mobilizing factor (LMF) all tend to promote catabolism. Nutritional inadequacy mobilizes protein stores and, thus, causes a loss of lean body mass. Altered nutrient utilization causes glucose intolerance, insulin resistance, increased glucose turnover, lipolysis, hyperlipidemia, and increased protein turnover. Properly nourishing patients, particularly when malnourished, is essential therapy. The Subjective Global Assessment tool and scoring sheet is used for cancer patients. Indications for use of nutrition support are listed in Table 13-4. Parenteral nutrition (PN) should not be used to prolong life for patients at the end stages

of disease but may be appropriate for patients with responsive cancers when enteral and oral feedings are poorly tolerated.

Many cancer therapies cause unpleasant side effects. Table 13-5 defines the types of side effects and treatments in cancer therapy. Patients who are unresponsive to standard or experimental therapies have few treatment options and usually experience poor quality of life for the remainder of their lives. An active nutritional protocol including high doses of multiple dietary antioxidants (vitamin C, alpha-tocopherol, and natural beta-carotene), when administered as an adjunct to other therapies, may increase tumor response and decrease toxicity. A maintenance nutritional protocol with lower doses of antioxidants, in addition to a modified diet and lifestyle, may reduce the risk of recurrence of the original tumor and development of a second cancer among survivors.

**TABLE 13-5 Side Effects of Treatment and Common Problems of Cancer**

Side Effect	Comments
Anemias	About half of the patients coming to cancer treatment are anemic. Use a balanced diet with high-quality proteins, B-complex vitamins, and vitamin C. Eat small meals every 2–3 hours. Heme sources of iron will increase iron bioavailability. Use beef, chicken, fortified grains, dried fruits such as prunes, nuts, and seeds, and blackstrap molasses. Avoid the long-term use of iron supplementation.
Anorexia	Medications, GI distress, altered sensory experiences often leads to cachexia. Treat symptoms, such as pain, constipation, and GI symptoms. Encourage small, frequent feedings. Consider pharmacological therapy with appetite-enhancing medications. Rinse mouth with baking soda or water before eating. Ginger ale or mint can mask metallic tastes; use plastic utensils if needed. Add flavorings to food, or suck on hard candy. Try chilled, frozen, sweet, or tart foods. Avoid unpleasant odors.
Aversion to foods or flavors	A lower threshold for urea causes aversion to meat; it “smells rotten.” Substitute milk, cottage cheese, eggs, peanut butter, legumes, poultry, fish, and cheese. In addition, patient may have a decreased ability to taste salt and sugar. Add other seasonings, sauces, and more salt or sugar as desired by the patient; however, do not allow sweet foods to replace nourishing foods. Clear palate prior to meals by brushing teeth, gums, and oral cavity. Rinse with baking soda and salt water.
Cachexia	Cachexia is the clinical consequence of a chronic, systemic inflammatory response. Depletion of skeletal muscle and redistribution of the body's protein occur. Nutritional deprivation at diagnosis can lead to further depletion with treatments. Anorexia cachexia syndrome (ACS) is caused by numerous factors. Use small, frequent feedings and supplements. Teach ways to increase calories and protein. Fortify foods when possible. Relieve symptoms before meals whenever possible. Anabolic and anticatabolic agents, such as Megace and Oxandrin, may help. Use of omega-3 fatty acids (EPA and DHA) can disrupt the cachexia.
Chemotherapy	With all types (given daily, weekly, monthly for 1–2 months or even years), prompt attention to side effect management and appropriate use of supportive care (medications, nutrition, etc.) will be needed. Increase fluid intake for adequate hydration. After chemotherapy, cardiac, kidney, or pulmonary toxicity may occur. Some chemotherapy agents may cause infertility in both men and women. Nausea and vomiting can now be well controlled with Zofran (ondansetron), Kytril (granisetron), and Anzemet (dolasetron). Hemopoietic agents (e.g., Neupogen, Procrit, granulocyte colony-stimulation factor, granulocyte-macrophage colony-stimulating factor) may be needed if red blood cell production is too low; transfusions are a last resort. Avoid the risk of infection and cuts during chemotherapy. Monitor for nosebleeds, bruising, black or bloody stools, or reddish urine. Glutamine supplementation has been used with some success.
Cold food preference	Cold foods may be better accepted than hot foods. Use cold, clear fluids, carbonated beverages, ices, gelatin, watermelons, grapes and peeled cucumbers, cold meat platters, ice cream, and salted nuts. Serve supplements over ice between meals. Shakes, puddings, and custards are other alternatives.
Constipation	Establish an appropriate bowel program, including regular use of pharmacological agents. Add fiber and extra fluids to the diet. Milk is beneficial, if tolerated. Fresh or dried fruits, all vegetables, bran and a hot drink may help. Get adequate exercise, such as walking. Drink hot beverages, or use prunes or prune juice. Over-the-counter bulking agents may be useful in some cases. Avoid gas-forming foods in excess. Report any blood, vomiting, or no stool for 3+ days to the doctor.
Dental Caries	Avoid sweets and use sodium fluoride three times daily. Mouth care should be provided several times daily. Persons receiving irradiation to the head and neck area may benefit from use of fluoride trays and stannous fluoride.

(continued)

**TABLE 13-5 Side Effects of Treatment and Common Problems of Cancer (continued)**

Side Effect	Comments
Diarrhea	Evaluate all medications carefully. Assess hydration status and associated symptoms. Alter fiber in diet. Beware of lactose intolerance secondary to disease process, drug therapy, or abdominal or pelvic radiation therapy. Increase fluids that contain sodium and potassium; use of Gatorade or Pedialyte may be helpful. Use cool or room temperature foods. Avoid dairy products if lactose-intolerant. Consume small amounts of food throughout the day instead of three large meals. Decrease fatty, spicy, or acidic foods; caffeine; gas-forming vegetables; or carbonated beverages. Plain rice, potatoes, eggs, mild fish or skinless chicken may be well tolerated. Limit sorbitol and sugar substitutes. Oral glutamine may be useful.
Difficulty swallowing (dysphagia)	Modify diet consistency and follow swallowing techniques provided by speech pathologist. Use moist foods; add sauces or gravies. Semi-solid foods may be better tolerated than liquids, and pureed foods rather than regular items. Patient should sip fluids throughout meal. To prevent aspiration, try placing liquid under the tongue. Some patients find that tilting their heads back helps. Thickeners are available for liquids, if thin beverages are not tolerated well (as with choking, coughing with each swallow). Use of a straw may be beneficial. Spoons are easier to control than forks in the mouth. Avoid very hot or very cold foods. Chew sugarless gum or candy. Use artificial saliva if needed. Consider feeding tube if needed.
Dry mouth (xerostomia)	Surgical removal of salivary glands, atrophy of mucous membranes, or permanent damage from radiation to salivary glands may cause difficulty in eating and swallowing. Use salivary substitutes, lip balm, sugarless gum and candies, gravies, and sauces. Increase fluids and use softened, moist foods (custard, stews, and soups). Cut food into small pieces, or use pureed foods. Ice chips and popsicles also can help. Avoid salty foods. Tart foods, lemon drops, and lemonade may help to stimulate saliva production; avoid tart items if there are oral lesions. Sip on water or other fluids frequently throughout the day and with each bite of food. Synthetic saliva products such as Optimoist or MouthKote may help. Patients benefit from a thorough dental examination before treatment. Use fluoride trays, rinses, other measures. Avoid caffeine, alcohol and tobacco products. Salagen (pilocarpine) is approved to reduce radiation-related dry mouth.
Early Satiety	Rather than serving plain water, encourage a calorie-containing beverage. Take liquids between meals. Avoid fatty, greasy foods because they are more slowly digested and absorbed. Use small meals and frequent snacks between meals. Add protein and calories using extra butter, margarine, cheese, dry milk powder.
Edema	Fluid retention may require elevating the legs at rest, staying physically active (walking), and reducing salt intake overall. The doctor may prescribe a diuretic.
Fatigue	Fatigue is very common. Assess and treat causes such as anemia, infection, pain, neutropenia, depression, or medication side effects. Meals may be prepared in quantity when the patient is less tired. Use foods that require less chewing and provide frequent rest periods, particularly before meals. Exercise daily to build stamina. Maintain adequate sleep/nap patterns.
Graft-versus-host disease (GVHD), neutropenia	Fever, chills, sweating, coughing, shortness of breath, diarrhea. Avoid people with colds or flu. Wash hands frequently and use safe food handling procedures. Wash all produce carefully and cook thoroughly. Avoid raw eggs. Cook meats well.
Insulin resistance	Insulin resistance is common from the tumor itself, or may occur after pancreatic surgery. Control of CHO intake and oral agents may be indicated.
Loneliness, Emotional Changes	Social eating may improve food intake. Visitors should be encouraged to bring gifts of food, as appropriate. If anxiety occurs, discuss with healthcare provider.
Loss of lean body mass	Protein wasting and unintentional weight loss are common. Exercise is extremely helpful. Endurance activities can counteract loss of physical performance and improve lower and upper body strength. Patients who exercise also have less fatigue and depression. Taking hormones such as growth hormone, insulin-like growth factor (IGF-I), thyroid hormone, androgens, and cortisol makes a difference as well. Muscle protein synthesis can be increased accordingly.
Malabsorption	Elemental diets can only be used if patient has an intact duodenum and jejunum. Total parenteral nutrition should be used only in some cases, considering risk of infection. Tart beverages such as lemonade can be mixed with elemental products if they are to be taken orally.
Meal interruptions	Encourage a good breakfast and snacks to make up for interrupted meals. Keep kitchen well stocked. Meals-on-Wheels may be a useful way to serve meals to this population at home.
Mouth blindness (dysgeusia)	To alleviate disinterest and aversion to foods, emphasize the aroma and colors of foods. Foods that are served warm or hot have more flavor and aroma. Provide a variety of foods and use garnishes. Acidic foods (such as lemonade) may help stimulate patient's ability to taste foods. Use highly flavored foods and sauces. Try milk shakes that are coffee or mint flavored. Fresh vegetables, special breads, highly flavored snacks, olives and pickles may be well received.
Mouth or throat soreness or dry mouth (stomatitis, mucositis, esophagitis)	Swish mouth with lidocaine, mild saline, or sodium bicarbonate before meals. Changes in taste or enjoyment of foods may occur. Avoid acidic juices, salty foods or soups, dry toast, and coarse or grainy breads or cereals. Grind meats; use a "mechanical soft diet" as needed. Offer cold or tepid fluids frequently; use a straw if needed. Popsicles may help. Smaller meals are useful. Cut foods into small pieces; grind or puree if needed. Mix food with sauces or gravies to make it easier to swallow. Avoid smoking and use of alcohol. Oral glutamine has been used with some success. Avoid alcohol-based mouthwashes. Salagen (pilocarpine) reduces dry mouth and throat sprays or cough drops may be useful.

(continued)

**TABLE 13-5 Side Effects of Treatment and Common Problems of Cancer (continued)**

Side Effect	Comments
Muscle wasting	Muscle weakness is frequently associated with tumor growth. Include adequate amounts of protein and amino acids in the diet or in enteral feeding, particularly arginine, glutamine and leucine. Depression, altered moods, immobility, and bed rest contribute to loss of muscle mass. Structured exercise, including resistance training and aerobic exercises, can improve muscle mass and strength. Increased physical activity improves emotional stability, self-confidence, and independence. Active patients have less fatigue, nausea, and insomnia; quality of life improves.
Nausea	Treated with slow, deep breathing, ice chips, or sips of ginger ale, tea, or candied dried ginger. Try a dry diet with liquids between meals. Eat small meals; rest upright afterward. Offer toast, yogurt, sherbet, popsicles, pretzels, angel food cake, canned fruit, baked chicken, lemonade, hot cereal such as oatmeal, clear liquids, or broth. Cut down on greasy, spicy, fried, fatty foods; foods with strong odors and excessive sweetness. Sit upright for meals and snacks; avoid tight clothing. If breakfast is the best meal, it can also be the largest of the day. Keep crackers or light snacks at hand; do not skip meals. Use antiemetics as directed by physician; underusage may aggravate the nausea. Drink plenty of water/liquids the day before and after chemotherapy.
Pain	Prevention is the key. Give pain medications with the first few bites of a meal or have the patient eat when pain is lowest. Encourage trying foods again after time lapse. Try biofeedback, acupuncture, massage, muscle relaxation techniques. Keep a pain journal and report any side effects to the doctor.
Radiation therapy	Radiotherapy may involve high-energy radiation from x-rays, cobalt-60, or radium. Brachytherapy provides internal, continuous local delivery of radiation to site of malignancy (concealed). Teletherapy provides external radiation to a localized area; 7000 rads usually causes damage, particularly to small intestine (radiation enteritis). Radiation therapy (daily for 2–8 weeks) can cause nausea or vomiting if administered to the brain or abdominal/pelvic fields. A light meal is encouraged before treatment. Diarrhea may occur in radiation enteritis; glutamine may be useful in supplements or in tube feeding (TF)/CPN. Formulas containing multiple antioxidants for biological protection against radiation damage in humans are needed. Use of oral glutamine has been used with some success.  **In head and neck cancer: anorexia, dysgeusia, weight loss, odynophagia, dysphagia, difficulty chewing, xerostomia. In the thorax: nausea, esophagitis, vomiting. In abdominal, intestinal: lactose intolerance, diarrhea, distention, abdominal pain, nausea and vomiting; later—intestinal stenosis, edema, fluid and electrolyte loss, weight loss.
Radiation enteritis or colitis	About 50–80% of patients who have radiation to the pelvis end up with radiation enteritis; onset can occur up to years later. Symptoms include nausea, vomiting, mucoid diarrhea, abdominal pain, and bleeding; later, there may be colic, a decrease in stool caliber, and progressive obstipation with stricture and fibrosis. Serious injury to the intestinal epithelium and arterioles of the small or large intestines results in cell death, fibrosis, and obstruction. Radiation to the ileum is particularly devastating. If radiation must be given chronically, resection may be needed and the ability of the intestines to become hyperplastic and increase absorptive capacity is thus prevented. Of these persons, many will require home CPN.
Surgery, curative	Direct efforts at restoring nutritional health to pre-illness status. After GI surgery, effects include—Oropharynx: Difficulty with chewing and swallowing, dysgeusia, xerostomia. Esophagus: Heartburn, loss of normal swallowing, decreased motility, obstruction. Stomach: Dumping syndrome, delayed emptying, anemia, malabsorption. Small intestines: Lactose intolerance, bile acid depletion, steatorrhea, fat malabsorption, vitamin B <sub>12</sub> deficiency and anemia, short-gut syndrome. Colon: Loss of electrolytes and water; diarrhea, constipation, gas, bloating.
Thick saliva	Thick, ropy saliva can produce more caries. Use less bread, milk, gelatin, and oily foods. Puree foods such as fruits and vegetables. Encourage the intake of plenty of fluids to decrease the viscosity of oral secretions. Encourage good oral intake and regular oral rinses.
Tooth loss	Loss of teeth makes the patient's mouth more sensitive to cold, heat, and sweets. Try serving foods at room temperature. Use ground, chopped, or pureed foods as needed until dental repair is possible.
Vomiting	Sip clear liquids every 10–15 minutes after vomiting episodes cease; keep head elevated. "Flat" carbonated beverages are useful. Call doctor if abdominal pains persist. Take antiemetic medications prior to meals. Use small feedings, avoid spicy or acidic foods and those with strong odor, use liquids between meals. Use low fat, light meals.
Weight loss	Calculate 40–45 kcal/kg for repletion. Add fats to foods, dry milk to mashed potatoes and shakes, and extra sugar to coffee and cereals. Use small, frequent feedings and the patient's favorite foods. Add cream sauces, extra meat or cheeses in casseroles, and gravies. Encourage patients to be as physically active as possible, particularly using long muscles to promote lean body mass.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** HMGB1 protein—a danger signaling protein—can act as a proinflammatory and proangiogenic mediator when actively secreted by macrophages or passively released from necrotic cells; this plays an important role in the pathogenesis of cancer (Winter et al, 2009). Other genetics information for cancer can be found at <http://www.cancer.gov/cancertopics/genetics-terms-alphabet/a-e>.

<b>Sample Clinical/History</b>	X-ray Dual-energy x-ray absorptiometry (DEXA) scan Computed tomography (CT) scan or magnetic resonance imaging (MRI)	Serum folate, B <sub>12</sub> , B <sub>6</sub> Serum homocysteine Ca <sup>++</sup> , Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup> Albumin (Alb) C-reactive protein (CRP) Total lymphocyte count (TLC) (varies)

Fever, temperature		
Cough		

## INTERVENTION

### OVERALL OBJECTIVES IN CANCER TREATMENT

- Coordinate total care plan with doctor, nurse, patient, family, caregivers, and other team members.
- Review each case individually and honor patient's wishes regarding more aggressive intervention.
- Prevent or minimize weight changes. Some patients are hypometabolic; others are hypermetabolic by 10–30% above normal rates. Greatest losses occur from protein stores and body fat.
- Use indirect calorimetry to determine energy requirements; Resting Metabolic Rate (RMR) or Resting Energy Expenditure (REE) is measured after 30 minutes of recumbent rest, preferably fasting but not necessarily early in the morning, with as little physical activity as possible before the measurement (American Dietetic Association, 2010).
- Diminish toxicity of treatments and improve quality of life. Good nutritional status early on is a good prognostic indicator.
- Correct cachexia from weakness, anorexia, redistribution of host nutrients, and nutritional depletion.
- Prevent depletion of humoral and cellular immunity from malnutrition. Improved nutritional status may allow neoplastic cells to become more susceptible to medical treatment.
- An improved nutritional status reduces side effects, promotes better rehabilitation, and improves quality of life while perhaps increasing survival rates. Malnutrition can potentiate the toxicity of antineoplastic agents.
- Prevent infection or sepsis, further morbidity, or death.
- Control complications such as anemia or multiple organ dysfunction.
- Preserve body mass through structured exercise programs and specialized nutritional supplementation.
- Control gastrointestinal symptoms, which are more common with weight loss greater than 10%.
- Work with the interdisciplinary team using a sample algorithm (courtesy of RD411.com). (See Algorithm on page 743)

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Knowledge Deficit

**Assessment:** Medications, lab values, current use of herbs and botanical products.

**Nutrition Diagnosis (PES):** Knowledge deficit as evidenced by patients requesting information regarding the proper use of herbs and botanicals for cancer treatment.

**Intervention:** Education about herbs and botanical products in cancer; resources and Web sites; label reading. Counseling with responses to specific questions according to type of cancer, prevention versus treatment, side effects.

**Monitoring and Evaluation:** No reports of adverse side effects with herbs and botanicals, medications, or foods (such as allergic reactions).

### FOOD AND NUTRITION

- Determine cancer-specific energy and protein requirements (American Dietetic Association, 2010).
- If indirect calorimetry is not available, calculate energy as 30 kcal/kg body weight to maintain and 35–45 kcal/kg body weight to replete lost stores or if the patient is febrile, septic, or very active.
- In general, the intake of protein should be high (1–1.5 g/kg body weight to maintain; 1.5–2 g/kg body weight to replete lean body mass) to protect from muscle wasting, malnutrition, cachexia, and treatments.
- Provide appropriate and adequate, but not excessive, micronutrient supplementation. Avoid excesses of iron, but correct anemias when diagnosed. There is no evidence for use of vitamin E or arginine prior to radiation

## INTERDISCIPLINARY NUTRITION CARE PLAN

### Cancer

Client Name: \_\_\_\_\_ #: \_\_\_\_\_ Initiated by: \_\_\_\_\_ Date: \_\_\_\_\_

#### SCREEN

Nutrition Screen diagnosis: Cancer

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### GOALS (Check any/all):

- ☐ Maintain or improve nutritional status in \_\_\_\_\_ (goal time).
- ☐ Prevent hospitalization due to dehydration/poor nutritional intake in \_\_\_\_\_ (goal time).
- ☐ Prevent or alleviate nutrition-related complications of cancer or cancer therapy in \_\_\_\_\_ (goal time).
- ☐ Avoid delay of cancer therapy due to poor nutrition in \_\_\_\_\_ (goal time).

#### ASSESS (Check any/all)

- ☐ Receiving chemotherapy/radiation therapy
- ☐ Weight loss: \_\_\_\_\_ lb/wk
- ☐ Receiving enteral or parenteral nutrition or complex diet order
- ☐ Dehydration
- Nutrition Impact Symptoms\***
  - ☐ Problems chewing/swallowing
  - ☐ Mouth pain/dryness
  - ☐ Nausea/vomiting
  - ☐ Diarrhea/constipation
  - ☐ Fatigue
  - ☐ Anorexia
  - ☐ Altered taste perception

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### MODERATE RISK INTERVENTIONS (Check any/all)

- ☐ Build Up Your Diet provided and explained
- ☐ Food Record provided and explained
- ☐ Fluid intake encouraged
- Obtain Dr. orders as needed:**
  - ☐ RD chart consult
  - ☐ Monitor weight q: \_\_\_\_\_
  - ☐ BID/TID supplements
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### HIGH-RISK INTERVENTIONS (Check any/all)

- ☐ Build Up Your Diet provided and explained
- ☐ Food Record provided and explained
- ☐ Fluid intake stressed
- Obtain Dr. orders as needed:**
  - ☐ RD referral for home visit(s)
  - ☐ Monitor weight q: \_\_\_\_\_
  - ☐ Monitor I & O q: \_\_\_\_\_
  - ☐ BID/TID supplements
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### ASSESS RESPONSE (Check any/all)

- ☐ Further weight loss
- ☐ Exhibiting Nutrition Impact Symptoms\*
- ☐ Dehydration
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES ACHIEVED

- ☐ Weight stabilized or improved
- ☐ Hydration status maintained or improved
- ☐ Cancer therapy initiated without delay
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Risk Screen in \_\_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### ASSESS RESPONSE (Check any/all)

- ☐ Further weight loss
- ☐ Continued dehydration
- ☐ Exhibiting Nutrition Impact Symptoms\*
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES ACHIEVED

- ☐ Weight stabilized or improved
- ☐ Hydration status maintained or improved
- ☐ Cancer therapy initiated without delay
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Risk Screen in \_\_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES NOT ACHIEVED

Reassess/evaluate need for EN/PN (refer to Tube Feeding Nutrition Care Plan). Document on Nutrition Variance Tracking form.

or chemotherapy (American Dietetic Association, 2010). Use foods that are high in phytochemicals and antioxidants.

- Use adequate fluid for hydration.
- Schedule larger meals earlier in the day. If needed, schedule five to six small meals daily, with tube feeding or intravenous feeding. If the gut works, use it.
- Parenteral nutrition (PN) is not likely to benefit advanced cancer patients who are unresponsive to treatment and should be used with caution in current or potentially septic patients because of the risks (American Dietetic Association, 2010). Use CPN if enteral nutrition is contraindicated and if the patient is at low risk for infection.
- After surgery or abdominal radiation, glutamine may be useful to protect from enteropathy, lower morbidity, augment tumor cell kill, and boost natural killer (NK) cell activity.

## Common Drugs Used and Potential Side Effects

- Drugs used will be matched to the specific type of cancer. Tables 13-6 and 13-7 list drugs and some common side effects.
- See the NCI list available at <http://www.cancer.gov/drugdictionary/>.

## Herbs, Botanicals, and Supplements

- Answer questions about the use of herbs and botanicals in cancer treatment plans. Use of complementary and alternative medicine (CAM) therapy is common in the cancer population.
- Some products are harmless, but some may lead to serious problems. Table 13-8 describes herbs that are commonly used and some general comments.

**TABLE 13-6 Cancer Drugs and Chemotherapy Agents**

There are many chemotherapy drugs available. With chemotherapy, patients may suffer severe side effects such as nausea, hair loss, infection, and injury to the GI tract. Serotonin antagonists such as Anzemet (dolasetron), if administered at the same time as chemotherapy, can prevent nausea and vomiting, but abdominal pain, headache, and constipation may occur. Biologic therapies such as interferon and interleukin may cause flu-like symptoms and myalgias, shortness of breath, or edema. Monoclonal antibodies such as Herceptin and Rituxan are also used to treat cancer and may cause chills, fever, lethargy and muscle aches. With antineoplastic agents, side effects include nausea, anorexia, stomatitis, diarrhea, taste alterations, some vomiting, and possibly sloughing of colonic mucosa (see Table 13-7 also).

Drug	Description
Alkylating agents: cyclophosphamide, fluorouracil	These drugs kill cancer cells by stopping their growth or by making it hard for cancer cells to repair damage. Nausea, vomiting, hyperuricemia.
Antiangiogenic agent: humanized monoclonal antibody bevacizumab (Avastin)	Tumors require nutrients and oxygen in order to grow; angiogenesis provides access to these nutrients.
Antimetabolites: flucytosine	This is a DNA substrate analog that leads to incorrect DNA synthesis affecting the cancer cells. Nausea, vomiting, diarrhea, and stomatitis can occur.
Antiemetics: granisetron or ondansetron; medical cannabis, Marinol; domperidone, promethazine (Phenergan); metoclopramide (Reglan)	May be useful for anorexia/cachexia syndrome. Also used to relieve nausea and vomiting after chemotherapy. Headache may result. Other side effects include nausea, diarrhea, increased gastric emptying, or drowsiness.
Aspirin and anti-inflammatory agents	May prevent some types of cancer, including colon cancer. The use of herbal nonsteroidal anti-inflammatory drugs (NSAIDs) may be recommended with these medications to enhance effectiveness.
Irinotecan (Camptosar)	For the treatment of stage 1–4 breast, lung, prostate, colon, skin, and most other metastatic or nonmetastatic forms of cancer.
Corticosteroids: prednisone	Hyperglycemia, sodium and fluid retention, weight gain, and calcium losses can occur.
Folate antagonist: methotrexate	Use of folate preparations can alter drug response. Folate, lactose, vitamin B <sub>12</sub> , and fat are less well absorbed. Mouth sores are common.
Immunotherapy: interleukin-2 and interferon	Lymphokine is administered to decrease tumor growth. Nausea, vomiting, abdominal pain, fatigue, and anorexia can result. In addition, low levels of folate and vitamins A and B <sub>6</sub> may result.
Monoclonal antibodies (MAbs): cetuximab, Campath-1 H, rituximab (Rituxan), and Bexsar	These drugs correct the abnormal enzyme that causes cancerous cells to grow out of control. These attack only abnormal elements of cells (“kinder and gentler” cancer therapies). Cetuximab specifically binds to the epidermal growth factor receptor with high affinity.
Vinca alkaloids: vincristine, vinblastine	Nausea and vomiting can occur.

**TABLE 13-7 Antineoplastic Agents: Generic and Brand Names**

Generic	Brand	Generic	Brand
Altretamine	Hexalen	Interferon- $\alpha$ 2 a	Roferon-A
Asparaginase	Elspar	Interferon- $\alpha$ 2b	Intron-A
Bevacizumab	Avastin	Interferon- $\alpha$ n3	Alferon-N
BCG	TheraCys, TICE BCG	Irinotecan	Camptosar
Bleomycin sulfate	Blenoxane	Leucovorin calcium	Wellcovorin
Busulfan	Myleran	Leuprolide	Lupron, Lupron-Depot
Carboplatin	Paraplatin	Levamisole	Ergamisol
Carmustine	BiCNU	Lomustine	CeeNU
Chlorambucil	Leukeran	Megestrol	Megace
Cisplatin ( <i>cis</i> -platinum, <i>cis</i> -diammine-dichloroplatinum)	Platinol, Platinol-AQ	Melphalan, L-phenylalanine mustard, L-sarcosylsin	Alkeran (R)
Cladribine, 2-chlorodeoxyadenosine	Leustatin	Melphalan hydrochloride	IV Alkeran
Cyclophosphamide	Cytosan, Neosar	Mercaptopurine	Purinethol Tablets
Cytarabine, cytosine arabinoside	Cytosar-U	Mesna	Mesnex
Dacarbazine, imidazole carboxamide	DTIC-DME	Mechlorethamine, nitrogen mustard	Mustargen
Dactinomycin	Cosmegen	Methylprednisolone	Solumedrol, Medrol
Daunorubicin, daunomycin	Cerubidine	Methotrexate, amethopterin	Trexall
Dexamethasone	Decadron, Tobradex	Mitomycin	Mutamycin
Doxorubicin	Adriamycin	Mitoxantrone	Novantrone
Erlotinib	Tarceva	Paclitaxel	Taxol
Etoposide (epipodophyllotoxin)	VePesid	Plicamycin, mithramycin	Mithracin
Floxuridine	FUDR	Prednisone	Deltasone
Fludarabine	Fludara	Procarbazine	Matulane
Fluorouracil	Fluorouracil Injection	Streptozocin, streptozotocin	Zanosar
Fluoxymesterone	Halotestin	Tamoxifen	Nolvadex
Flutamide	Eulexin	6-Thioguanine	Tabloid
Goserelin	Zoladex	Thiotepa, triethylene thiophosphoramide	Thiotepa
Hydroxyurea	Hydrea	Vinblastine	Velban
Idarubicin HCL	Idamycin	Vincristine	Oncovin
Ifosfamide	IFEX	Vinorelbine tartrate	Navelbine Injection
Interferon-alfa	Roferon-A, Intron-A		

Source: Medicine Online. Antineoplastic agents generic abbreviations, [http://www.medicineonline.com/reference/Health/Conditions\\_and\\_Diseases/Cancer](http://www.medicineonline.com/reference/Health/Conditions_and_Diseases/Cancer), accessed January 3, 2010.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Educate family about special patient needs (Dixon, 2005).
- There is evidence that cancer survivors who adopt a healthy lifestyle reap physical and emotional benefits. See Table 13-9 for more guidance and patient education tips.

#### Patient Education—Food Safety for Cancer Patients

- Clean: Wash hands and surfaces often.
- Separate: Don't cross-contaminate. Keep raw meat and poultry apart from cooked foods.
- Cook: Use a food thermometer to be sure meat and poultry are safely cooked.
- Chill: Refrigerate or freeze food promptly.
- Avoid:
  - Hot dogs, luncheon, and deli meats unless they are reheated until steaming hot.
  - Refrigerated plate, meat spreads from a meat counter, smoked seafood, and raw or undercooked seafood.
  - Raw (unpasteurized) milk and foods that contain unpasteurized milk.
  - Soft cheeses such as Feta, queso blanco, queso fresco, Brie, Camembert cheeses, blue-veined cheeses, and Panela unless it is labeled as made with pasteurized milk.
  - Salads made in the store such as ham salad, chicken salad, egg salad, tuna salad, or seafood salad.
  - Soft-boiled or "over-easy" eggs, as the yolks are not fully cooked.

**TABLE 13-8 Herbs, Dietary Supplements, and Cancer**

Most patients diagnosed with cancer explore complementary and alternative medicine (CAM), particularly herbal medicine. Dietetics professionals must evaluate the risks and benefits of the use of herbs and botanical products in various cancers; indicate whether **"guidance"** or **"promotion"** is being offered. Alternative therapies should be reviewed in the light of potential harm. Herbs should be appropriately labeled to alert consumers to potential interactions when used with drugs, and consultation with a general practitioner is recommended.

Ashwagandha ( <i>Withania somnifera</i> )	Used for cancer treatment, diabetes, epilepsy, fatigue, gastrointestinal (GI) disorders, pain, rheumatoid arthritis (RA), skin infections, and stress.	Should not be used in pregnant women because it is an abortifacient.
Astragalus	Stimulates interferon and positively impacts the immune system. Possibly reduces the effectiveness of chemotherapy. Strong immune booster.	A type of legume used for years in Chinese medicine. No convincing evidence in cancer.
Black cohosh ( <i>Remifemin</i> )	May relieve the symptoms of menopause. No known side effects with chemotherapy. Source of vitamin A and pantothenic acid. Drug interactions: may increase the toxicity of doxorubicin and docetaxel.	Used to lower hot flashes, which can be a challenge for breast cancer patients.
Bromelain	Bromelain (from pineapple extract) positively impacts the immune system. Improved tumor boundaries.	Studies have not demonstrated evidence in cancer therapy.
Cat's claw	May have some effect on the immune system, but more comprehensive studies are needed. Antioxidant.	Contains alkaloids.
Chamomile	No proven efficacy in cancer. May promote sedation or allergic reactions.	
Chili powder	Capsaicin may actually have tumor-promoting effects; chili powder has been implicated in several GI cancers, but the results are conflicting.	In Mexico, higher use of chili powder is related to more stomach cancer.
Chinese herbal medicine	Chinese herbal medicine uses a variety of herbs, in different combinations, to restore balance to the body.	See Astragalus, Ginkgo, Ginseng, Green tea, and Siberian ginseng.
Chinese PC-SPES	Contains chrysanthemum, isatis, licorice, Panax ginseng, saw palmetto, skullcap; <i>Rabdosia rubescens</i> is the most potent ingredient. PC-SPES contains flavonoids, alkaloids, polysaccharides, amino acids, and trace minerals such as selenium, calcium, magnesium, zinc, and copper.	Antiestrogenic effects.
Cloves	Contains eugenol, which reduces lipid peroxidation and reduces cancer cell proliferation.	
Dehydroepiandrosterone (DHEA)	DHEA is a steroid hormone produced by the adrenal gland and converted into estrogen and testosterone.	It is normally found in humans, plants, and animals. DHEA extracted from a wild yam plant is available as a dietary supplement.
Echinacea	No evidence of usefulness in reducing incidence or symptoms of cancer.	May reduce colds or flu for some people.
Eleuthero (Siberian ginseng)	May boost energy. More studies are needed.	
Essiac	Mixture of four herbs: burdock root ( <i>Arctium lappa</i> ), sheep sorrel ( <i>Rumex acetosella</i> ), slippery elm bark ( <i>Ulmus rubra</i> ), and Indian rhubarb root ( <i>Rheum officinale</i> ) to make a tea.  Watercress ( <i>Nasturtium officinale</i> R. Br.), blessed thistle ( <i>Cnicus benedictus</i> L.), red clover ( <i>Trifolium pratense</i> L.), and kelp ( <i>Laminaria digitata</i> [Hudson] Lamx.) have been added to a product sold as Flor Essence.	Potent antioxidant and DNA-protective activity. Possibly estrogenic, antioxidant, anti-inflammatory, antimicrobial, and anticarcinogenic.
Evening primrose oil or gamma linolenic acid (GLA)	Proposed to reduce the effects of cancer treatments. GLA is an omega-6 unsaturated fatty acid made in the human body from other essential fatty acids. The main supplemental sources of GLA are oils of the seeds of evening primrose, borage, and black currant plants.	GLA is found in human breast milk. Claimed to slow cancer cell growth. Increases effectiveness of chemotherapy; boosts efficiency of tamoxifen; antioxidant; boosts immune system.
Falcarinol	A cancer-fighting substance found only in carrots.	Human studies are needed.
Flaxseed	Flaxseed supplements along with low-fat diets may be useful in men with early-stage prostate cancer.	Controlled clinical studies are needed.

(continued)

**TABLE 13-8 Herbs, Dietary Supplements, and Cancer (continued)**

Garlic	Seems to have reduced gastric and prostate cancers. Sulfur compounds tend to be the most chemoprotective. Useful in treatment as well as prevention. Garlic appears to induce cytochrome P-450 3A4 and may enhance metabolism of many medications such as cyclosporine and saquinavir. Antimicrobial properties are helpful.	Supplements are not as effective as real garlic for allicin and S-allylcysteine activity. Garlic poultices may cause burns in infants. Used as spice and to treat hyperlipidemia, hypertension, atherosclerosis, cancer, and infections, but sustained response has not been found. Mixed effects regarding reduction of blood glucose levels, blood pressure, or cardiovascular diseases. Garlic should not be used in patients on anticoagulants and patients with platelet dysfunction.
Ginger (6-gingerol)	May help to reduce the side effects of cancer treatments as an antiemetic, anti-inflammatory agent. Effective in preventing nausea and vomiting in some patients. It is a relatively safe herb, but patients taking blood thinners or about to undergo surgery should avoid ginger supplements. Interaction with many drugs including antacids, anticoagulants and antiplatelets, antidiabetics, antihypertensives, H <sub>2</sub> blockers, proton pump inhibitors (PPI), and barbiturates.	Ginger may be effective in treating chemotherapy-induced nausea and vomiting.
Ginkgo biloba (maidenhair tree)	Antioxidant and anti-inflammatory effects; role in cancer is being studied (see Table 13-2). Stimulates blood circulation and helps improve memory.	Ginkgo causes bleeding when combined with warfarin or aspirin (acetylsalicylic acid), raises blood pressure when combined with a thiazide diuretic, and causes coma when combined with trazodone. Lowers the threshold for seizures in seizure-prone individuals.
Ginseng, Asian (Panax ginseng)	The dried roots of the plants are used in some traditional medicines to treat a variety of conditions, including cancer. Rh2 is a ginsenoside extracted from ginseng that has effects on cell proliferation, induction of apoptosis, and stimulation of natural killer cells and other immune activity.	Asian ginseng may prevent some cancers. Proposed to give strength and stamina. Interactions with monoamine oxidase (MAO) inhibitors.
Ginseng, American (Panax quinquefolius)	A plant with similar (but not exactly the same) properties, is grown mainly in the United States.	Used for health maintenance, strength, stamina, and immunostimulation. Contraindicated in patients with hypertension and in premenopausal women.
Glucarate (calcium glucarate)	Proponents claim that glucarate may reduce the risk of colon, lung, liver, skin, prostate, and other cancers by increasing the body's ability to eliminate cancer-causing toxins that come from diet and the environment. May help the body remove excess estrogen and other hormones that promote these diseases.	Glucarate is found in many fruits and vegetables including apples, grapefruit, broccoli, Brussels sprouts, and bean sprouts. It also occurs naturally in the body in very small amounts.
Green tea (Camellia sinensis)	Contains polyphenols and may slow the delivery of nutrients to cancer cells by inhibiting the formation of new blood vessels (angiogenesis). Recent research has focused on green tea for the prevention of breast, prostate, skin, esophagus, stomach, colon, pancreas, lung, and bladder cancers.	The use of skin products that contain green tea may be somewhat protective against skin cancers. Epigallocatechin gallate (EGCG). EGCG may cause cancer cells to die and may stop new blood vessels from forming, thereby cutting off the supply of blood to cancer cells. Do not use with pregnant or lactating mothers. Use with caution with many drugs particularly anticoagulants.
Isatis root (Ban lan gen, Radix isatidis baphicacanthi, Isatis tinctoria, Isatis indigotica)	Used for common cold, sore throat, mumps, respiratory ailments, and malignant tumors. Leaves are used in one of the herbal formulas to treat prostate cancer. No adverse reactions known.	This herb is also used to treat chronic myelogenous leukemia. Studies also indicate that this plant has antiviral and immunostimulatory effects.
Licorice	Licorice root is an ingredient in many traditional Chinese herbal remedies. More research is needed to find out whether licorice extract has any role in cancer prevention or treatment.	May cause serious side effects, including hypertension or muscle weakness or paralysis.

(continued)

**TABLE 13-8 Herbs, Dietary Supplements, and Cancer (continued)**

Lipoic acid (alpha lipoic acid)	Lipoic acid plays an important role in metabolism. Recent research has shown that it is beneficial in treating nerve damage in diabetics. It may be helpful for other conditions as well. There is currently no evidence that lipoic acid prevents the development or spread of cancer.	Lipoic acid is an antioxidant found in certain foods including red meat, spinach, broccoli, potatoes, yams, carrots, beets, and yeast. It is also made in small amounts in the human body. Its possible role as a form of complementary therapy to reduce the side effects of radiation therapy or chemotherapy is still unclear.
Lyprinol (green-lipped mussel)	This is a fatty acid complex extracted from <i>Perna canaliculus</i> —a green-lipped mussel (shellfish) native to New Zealand. It contains omega-3 fatty acids. Lyprinol is promoted as a dietary supplement with anti-inflammatory properties to work against leukotrienes.	It is available in capsule form as a dietary supplement.
Macrobiotic diet	The standard macrobiotic diet today consists of 50–60% organically grown whole grains, 20–25% locally and organically grown fruits and vegetables, and 5–10% soups made with vegetables, seaweed, grains, beans, and miso (a fermented soy product). Early versions of the diet included no animal products at all.	Potatoes, tomatoes, eggplant, peppers, asparagus, spinach, beets, zucchini, and avocados are excluded. The diet also advises against eating bananas, pineapples, and other tropical fruits. The use of dairy products, eggs, coffee, sugar, stimulant and aromatic herbs, red meat, poultry, and processed foods is discouraged.
Melatonin	May aid in the effectiveness of chemotherapy and in improving survival in numerous types of cancer. Melatonin inhibits tumorigenesis with the suppression of tumor linoleic acid (LA) uptake and its metabolism. Melatonin may also stimulate natural killer cells, which attack tumors. Inhibits cachexia.	Circadian rhythm may be enhanced with use of melatonin; this may help to alleviate fatigue associated with cancer.
Milk thistle (Silymarin)	Antioxidant for treating liver diseases such as cirrhosis or chronic hepatitis. May help with cancer prevention; human studies are needed.	It contains flavonolignans; perhaps has a role in decreasing skin or prostate cancer.
Mistletoe (Iscador)	Lectin-rich mistletoe extract should be further evaluated.	There may be toxic side effects.
Mulberry	Anthocyanins in mulberry have an anticancer effect.	More research is needed.
Mustard seed ( <i>Brassica campestris</i> )	Mustard seeds enhance the antioxidant defense system and provide protection against the toxic effects of carcinogens.	May protect against stomach and uterine cancers.
Oleandrin, odoroside ( <i>Nerium odorum</i> )	Raw leaves are toxic. May cause apoptosis in various cancer cell lines.	Side effects include nausea, vomiting and diarrhea, tachycardia, and arrhythmia.
Noni juice ( <i>Morinda citrifolia</i> )	An immunomodulatory polysaccharide-rich substance from the fruit juice is rich in potassium.	Common in Polynesian diets. High sugar content.
Pokeweed (Poke salad)	Pokeweed antiviral protein has anti-tumor effects in mice and laboratory studies. Clinical trials have not yet been done.	All parts of the mature plant contain chemically active substances such as phytolaccine, formic acid, tannin, and resin acid; all are mildly poisonous when eaten.
Probiotics	Evidence suggests the following beneficial effects: normalization of the intestinal microflora, the ability to block the invasion of potential pathogens in the gut, prevention of colon cancer, modulation of immune function, inhibition of <i>H. pylori</i> .	Regular use of yogurt and other natural functional foods may be useful for cancer patients. Daily intake of <i>Bifidobacterium lactis</i> enhances natural immune function.
Pycnogenol; pine bark extract ( <i>Pinus pinaster</i> )	Pycnogenol is the name of a group of bioflavonoids with proanthocyanidins taken from a number of natural sources, such as grape seeds.	The maritime pine tree contains naturally occurring proanthocyanidins.
Quercetin	Quercetin is promoted to help prevent or treat different types of cancer.	See Table 13-2.
Reishi mushroom ( <i>Ganoderma lucidum</i> )	The medicinal mushroom Reishi has been widely used to treat cancer, diabetes, and neurasthenia in many Asian countries. Used for fatigue, high cholesterol, HIV and AIDS, hypertension, immunostimulation, inflammation, strength and stamina, and viral infections.	Can interfere with immunosuppressants and chemotherapeutic drugs. Adverse reactions may include dry throat and nose, GI upset, itchiness, nausea, and vomiting.
Rosemary and marjoram (ursolic acid)	Terpenoids in these spices provide anticancer effects.	Triterpenoid compound that occurs naturally in a large variety of vegetarian foods, medicinal herbs, and plants.

(continued)

**TABLE 13-8 Herbs, Dietary Supplements, and Cancer (continued)**

Saffron ( <i>Crocus sativus</i> )	This spice contains glutathione and crocetin, which decreases tumor growth and protects platelets from aggregation.	Being studied for effects on depression and Parkinson's disease also.
Saw palmetto ( <i>Serenoa repens</i> )	Permixon, a phytotherapeutic agent derived from the saw palmetto plant, is a lipid/sterol extract; mixed research results.	Often used to prevent prostate cancer; no side effects noted.
Shark cartilage	It seems to have a role in inhibiting angiogenesis. Frequently recommended to cancer patients by family members.	No evidence that it plays a role in cancer. Prolonged use can have adverse side effects.
Shark oil	Alkylglycerols, found in shark liver oil, may fight cancer by killing tumor cells indirectly and activating the immune system by stimulating macrophages.	Depending on the supplement, it may be rich in omega-3 fatty acids and vitamin A.
Shiitake mushrooms	Contains lentin, which stimulates T-cell and natural killer cell production; antitumor, cholesterol-lowering, and virus-inhibiting effects.	Additional research is needed.
Skullcap ( <i>Scutellaria barbata</i> )	It seems to play a role in the reduction of aflatoxin toxicity. Contains flavanone compounds such as scutellarein, scutellarin, carthamidin, and isocarthamidin.	Do not take orally.
Soy isoflavones	Role in cancer prevention is not clear. Exact dosage and effects on specific genes are not currently known. The best advice is to encourage usual dietary use and not to change drastically. Reduces menopausal symptoms.	Soy should not be used in estrogen-dependent breast cancer or with endometrial cancer. Avoid with use of tamoxifen.
Spirulina; blue-green algae ( <i>Spirulina spp</i> )	Adverse effects are uncommon unless contaminated. Used to treat cancers, viral infections, weight loss, oral leukoplakia, increased cholesterol.	If contaminated, it is hepato-, nephro-, and neurotoxic.
St. John's wort ( <i>Hypericum perforatum</i> )	Not effective against acute depression. Avoid with all types of chemotherapy; cyclosporine, midazolam, tacrolimus, amitriptyline, digoxin, indinavir, warfarin, and theophylline.	It accelerates the effects of tamoxifen and must be used cautiously. May cause breakthrough bleeding and unplanned pregnancy when used with oral contraceptives. Avoid with selective serotonin reuptake inhibitors and in pregnancy or lactation.
Turkey tail mushroom ( <i>Coriolus versicolor</i> ; Yunzhi)	A mushroom used in traditional Asian herbal remedies. Polysaccharide K (PSK) and polysaccharide peptide (PSP), are being studied as possible complementary cancer treatments.	
Turmeric ( <i>Curcuma longa</i> )	Turmeric and other phenols have an anticancer effect. Additional research is needed about the efficacy of turmeric as a cancer treatment).	Warn breast cancer patients on cyclophosphamide to restrict the intake because it inhibits the antitumor action of these chemotherapeutic agents.
Valerian	Used to promote natural sleep; 2–4 weeks of use is needed. People who are going to have surgery should not use valerian or should taper down slowly, starting several weeks before surgery.	Avoid taking with alcohol, certain antihistamines, muscle relaxants, mental health drugs, sedatives, antiseizure drugs, or narcotics. Talk with their doctors or pharmacists about possible drug interactions before taking valerian.
Wheatgrass	Few scientific studies in humans to support claims made for wheatgrass.	Proponents suggest that wheatgrass strengthens the immune system.
White Birch (betulinic acid)	Potential role in treating melanoma and certain brain cancers; clinical trials are needed.	Birch bark, buds, and leaves are used as folk medicines but have not been studied to find out if they are safe or effective.
<b>HARMFUL</b>	<b>Avoid oral use:</b> Aconite (bushi, monkshood) aloe vera arnica (wolfbane, mountain tobacco) aveloz (pencil cactus) belladonna (deadly nightshade) blue cohosh (squaw root) boragebroom (broom tops, Irish broom) calamus (sweet root/flag) cesium chloride chaparral (creosote bush; <i>Larrea tridentate</i> )	May have serious side effects.

(continued)

**TABLE 13-8 Herbs, Dietary Supplements, and Cancer (*continued*)**

<b>HARMFUL</b>	<b>Avoid oral use:</b>
	coltsfoot
	comfrey (bruise wort; <i>Symphytum officinale</i> )
	Convallaria (lily of the valley)
	DiBella (DMB)
	ephedra (ma huang)
	germander
	germanium
	horse chestnut
	Hoxsey herbal treatment
	jimson weed
	jin bu huan
	Kava ( <i>Piper methysticum</i> )
	Kombucha tea
	krebiozin (creatine)
	laetrile (amygdalin)–cyanide toxicity
	licorice ( <i>Glycyrrhiza glabra</i> )
	liferoot (golden senecio, ragwort)
	lobelia (Indian or wild tobacco)
	mandrake
	oleander
	Pau d'Arco ( <i>Taebuia</i> )
	pennyroyal
	periwinkle
	poke root
	sassafras
	sea cucumber
	tea tree oil
	wormwood (madder, mug or Ming wort, <i>Artemisia</i> )
	yohimbe

**TABLE 13-9 General Patient Education Tips**

For **cancer treatment**, start “where the patient is.” Instruct patient to use unscientific treatments with caution. Discuss these issues with compassion and an understanding of patient’s perspective. Patients want *faith* in their health provider, *hope* for coping and for strength, and *respect* for their wishes.

For **cancer survivors**, optimal attention to physical activity and nutrition should continue. Because there are different phases of cancer survivorship, from active treatment to advanced disease, existing evidence must be reviewed and informed decisions made regarding dietary choices. Obese and overweight patients can pursue modest weight loss provided that close monitoring occurs. Healthy food intake, low in energy density but high in nutrient and phytochemical content, is the goal. This translates into 5–9 fruits and vegetables, more fish, and plenty of whole grains. Teach good sources of folate, vitamin A, calcium and iron; highlight antioxidant foods rich in selenium, vitamins C and E, and beta-carotene. Excellent resources are available from the cancer survivor Web site at <http://www.cancerrd.com/> and from the American Institute for Cancer Research Web site [http://www.aicr.org/site/PageServer?pagename=reduce\\_diet\\_recipes\\_test\\_kitchen](http://www.aicr.org/site/PageServer?pagename=reduce_diet_recipes_test_kitchen).

For **family member counseling**, teach that nutrition is fundamental in the molecular basis of cancer. Tailor interventions according to nutritional status, genotype, current health status, and nutritional requirements of the individual. Changes in diet, lifestyle and behaviors may be required.

For **terminal, palliative care**, emotional support and comfort may be the best treatment. The counselor should be aware of the stages of death and dying to identify where the patient is: (a) denial, (b) anger, (c) bargaining, (d) depression and loss, or (e) acceptance.

The patient must be included in all decisions. If not competent, follow the living will or advanced medical directives to follow. A court-appointed legal guardian may be needed. Evaluate the benefits and burdens of the illness on the patient, as well as any court or family decisions. Forego heroic measures, including tube feeding and CPN, if so chosen. Otherwise, maintain measures and re-evaluate at a later date. Hydration is the priority when “palliative care” orders are written.

## BONE CANCER AND OSTEOSARCOMA

### NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Yochum TR and Rowe LJ. *Yochum and Rowe's Essentials of Skeletal Radiology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 2004.

### DEFINITIONS AND BACKGROUND

Bone is a fertile ground for cancer cells to flourish (Clines and Guise, 2005). Bone cancers include osteosarcomas, chondrosarcomas, and the Ewing family of tumors. The correct diagnosis depends on an evaluation of clinical, radiologic, pathologic, and genetic features (Li and Siegel, 2010).

Osteosarcoma involves a rapidly growing malignant bone tumor of unknown origin, occurring most often in the long bones of young people. It is most common in males between 10 and 25 years of age.

People who have had previous high doses of radiotherapy to a bone or Paget's disease have an increased risk of developing bone cancer. This type of cancer often spreads to the lung. When metastases from other organs occur, it is considered a secondary bone cancer. Patients with metastasis to the spine may present with pain, neurological deficit, or both. Optimal treatment should include consideration of the patient's neurological status, general health, age, quality of life, and the anatomical extent of the disease (Ecker et al, 2005).

Staging on bone cancer is as follows: stage 1 – low grade, no spread; stage 2 – high grade but not spread; stage 3 – bone cancer of any grade that has spread beyond the bone in which it started to other organs in the body, such as the lungs. In recurrent bone cancer, the cancer has returned after initial treatment.

The most common treatment for bone cancer pain is radiation. Radiation decreases bone cancer pain by direct effects on tumor cells (Goblirsch et al, 2005). Chemotherapy may also be needed; sore mouth or anemia may result. Surgery is reserved for neurological compromise, radiation failure, or spinal instability (Ecker et al, 2005). When possible, limb-sparing surgery is effective. Occasionally, amputation is necessary when the cancer has spread from the bone into the surrounding blood vessels.

Quality of life in this population is affected by depression, socialization problems, and physical limitations (Rustoen et al, 2005). Bisphosphonates are the standard of care for preventing skeletal morbidity and treating hypercalcemia of malignancy in patients with bone metastases; zoledronic acid may be given intravenously at the rate of 4 milligrams monthly (Gnant, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Bone morphogenetic proteins (BMPs) may impact tumorigenesis and promote tumor spread (Thawani et al, 2009).

<b>Specific Clinical/ History</b>	Fever and cough	Na <sup>+</sup> , K <sup>+</sup>
	Bone scan	Albumin (Alb)
Height	CT scan	C-reactive protein (CRP)
Weight		Total lymphocyte count (TLC) (varies)
BMI	<b>Lab Work</b>	Alanine amino-transferase (ALT) (increased)
Weight loss	H&H	
Leg, shin, shoulder pain?	Alkaline phosphatase (Alk phos) (increased)	
Limited use of the extremity	Glucose (Gluc)	
Fatigue	Ca <sup>++</sup>	
Warmth in a local area	Mg <sup>++</sup>	

## INTERVENTION

### OBJECTIVES

- Prevent dehydration; correct fever.
- Relieve pain; prolong and improve quality of life.
- Correct side effects, such as sore mouth or anemia.
- Counteract effects of surgery (perhaps limb amputation), radiation therapy, or chemotherapy.
- Meet needs related to growth or elevated metabolic rate in children.

### FOOD AND NUTRITION

- A balanced diet (high in energy and protein) will be needed.
- Extra fluids are used, unless contraindicated.
- Supplement with nutrients that are low in the patient's dietary intake. A diet rich in zinc, vitamins A and C, and other key nutrients will help with wound healing after surgery. A multivitamin–mineral supplement may be suggested.
- Small, frequent feedings may be better tolerated than large meals.

### Common Drugs Used and Potential Side Effects

- Bisphosphonates may be used to restrict the action of the osteoclasts, help reduce the breakdown of the bone, reduce the risk of fracture and hypercalcemia, and reduce bone pain.

- Cisplatin, carboplatin (Paraplatin), cyclophosphamide (Cytoxan), doxorubicin (Adriamycin), high-dose methotrexate with leucovorin, ifosfamide (Ifex) may be used.
- Dry mouth, anemia, stomatitis, nausea, esophagitis, or vomiting may occur.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss ways to make meals more attractive and appetizing.
- Discuss with the patient and family how to adjust diet for therapies given.
- Encourage the patient to address depression or other issues that affect quality of life.
- Offer suggestions according to side effects such as sore mouth or dry mouth.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

# BONE MARROW OR HEMATOPOIETIC STEM-CELL TRANSPLANTATION

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

Hematopoietic stem cells are cells from which all blood cells evolve. Since bone marrow contains the greatest concentration of blood stem cells, most transplantations, historically, have been bone marrow transplantations. However, with the administration of an artificial growth factor called granulocyte colony-stimulating factor (G-CSF), stem cells are stimulated to grow and leave marrow and can be collected from the bloodstream by apheresis.

The terms “hematopoietic stem-cell transplantation” and “peripheral-blood stem-cell transplantation” are used when referring to bone marrow transplantation. Peripheral-blood stem-cell transplantations are being used with increased frequency because it is much less invasive. Traditional bone marrow harvest requires the use of general anesthesia.

Treatment consists of a preparative regimen that includes high-dose chemotherapy and may also include total-body irradiation. An infusion of autologous (the patient’s own), syngeneic (from an identical twin), or allogeneic (from a histocompatible related or unrelated donor) marrow follows.

Hematological malignancies, including leukemias, lymphomas, multiple myeloma, and aplastic anemia, are the main indications for stem-cell transplantation. Nonhematological malignancies, such as testicular cancer and some autoimmune conditions, are also indications for stem-cell transplantation. Stem-cell transplantations are performed in both adult and pediatric populations. Stem-cell transplantations in patients with matched siblings versus unrelated donors have been associated with significantly better long-term survival (Talano et al, 2006).

After transplantation, the patient is often neutropenic, and nutritional status may decline rapidly. Children undergoing bone marrow transplantation may have suboptimal nutritional status; body mass index (BMI) is not an accurate indicator in these cases (White et al, 2005). Hospitalized transplantation patients resume oral intake sooner than ambulatory patients.

Treatment is aggressive and has many side effects. Early side effects are basically the same as those of any other type of high-dose chemotherapy and are caused by damage to bone marrow and other rapidly reproducing tissues of the body. Hepatic veno-occlusive disease (VOD) occurs after high doses of chemotherapy in preparation for bone marrow transplantation. Rapid weight gain, elevated bilirubin, right upper quadrant (RUQ) pain, ascites, jaundice, and hepatomegaly can occur.

Long-term side effects could include radiation damage to the lungs with shortness of breath, graft-versus-host disease (GVHD), damage to the ovaries causing infertility and loss of menstrual periods, damage to the thyroid gland causing problems with metabolism, cataracts, bone damage, and growth changes in children. GVHD causes erythroderma, jaundice, abdominal pain, emaciation, pneumonitis, infec-

tions, and gastrointestinal tract problems. Hemolytic uremic syndrome (HUS) is an uncommon but potentially life-threatening complication of stem-cell transplantation.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Umbilical cord blood may be used in children born after a genetic diagnosis for human leucocyte antigen (HLA) matching for donation to a sick sibling.

<b>Specific Clinical/History</b>	Gluc Mg <sup>++</sup> , Ca <sup>++</sup>	Cholesterol (Chol)
Height	Complete blood count (CBC)	Triglycerides (Trig)
Weight	Absolute neutrophil count (ANC)	TLC (varied reliability)
BMI	to evaluate engrafting	Ferritin
Weight changes	Na <sup>+</sup> , K <sup>+</sup>	Transferrin
Diet history	Alb,	Blood urea nitrogen (BUN)
I & O	frequent infections	Creatinine (Creat)
Temperature	Viral hepatitis screening	
Ascites, jaundice	CRP	
Frequent infections	Serum phosphorus (low from cyclosporine A)	
Hepatomegaly?		
RUQ pain?		
Rectal biopsy for GVHD <sup>a</sup>		
<b>Lab Work</b>		
H & H	Uric acid	
Bilirubin		

<sup>a</sup>Severe colonic crypt loss predicts severe clinical GI-GVHD that is more likely to be refractory to steroid treatment and have high mortality (Melson et al, 2007).

### INTERVENTION

### OBJECTIVES

#### Pretransplantation

- Replace the malignant or defective hematopoietic system for the production and development of blood cells.
- Provide adequate nutrient stores (glucose, calories, vitamins, minerals, and protein). Supplementation with EPA

## SAMPLE NUTRITION CARE PROCESS STEPS

**Decreased Oral Food–Beverages Intake**

**Assessment Data:** Analysis of oral intake compared to requirements from nursing flow sheet; patient states pain while eating; physical examination of the oral cavity.

**Nutrition Diagnosis (PES):** NI-2.1 oral intake related to pain and mucositis as evidenced by the refusal of food at mealtimes.

**Intervention:** Diet modification for consistency. Education about foods that may be better tolerated. Counseling about taking pain medicines ahead of meals.

**Monitoring and Evaluation:** Follow-up in 24 hours to evaluate improvement and changes in oral intake.

fish oil improves energy intake and may reduce complications and inflammatory markers when compared with usual care (Elia et al, 2006).

- Assure adequate hydration.

**Posttransplantation**

- Restore normal hematopoiesis and immunological function.
- Individualize needs; promote engraftment of marrow.
- Prevent or manage gastrointestinal Graft-Versus-Host Disease (GI-GvHD). Rejection occurs less often in well-nourished patients.
- Prevent infections, viral hepatitis, mucositis, gastroenteritis, and pneumocystosis.
- Reduce nausea, vomiting, diarrhea, appetite loss and fatigue, which can seriously affect nutritional status (Iversen et al, 2009).
- Improve weight status; promote anabolism. Most patients are in the hospital for 4–6 weeks.
- Correct early satiety, anorexia, stomatitis, xerostomia, and depression—all of which reduce total intake.
- Provide nutrition support due to hypermetabolism and side effects of treatments. Promote positive nitrogen balance when possible.
- Correct hyperglycemia from metabolic stress, insulin resistance, and medication side effects.
- Monitor closely for renal insufficiency and necessary changes for diet.
- Prevent or prepare for long-term complications such as hyperphagia and obesity, insulin resistance and diabetes, hyperlipidemia, hypertension, and osteoporosis.
- Maximize quality of life. Health-related quality of life (HRQoL) is reduced before, during, and after intensive therapy (Iversen et al, 2009).

**FOOD AND NUTRITION**

- Protective isolation may be needed. A low-bacteria (neutropenic) diet may be useful for several months before and after transplantation. A neutropenic diet guide is found in Table 13-10.
- CPN may be needed to initiate recovery after transplantation or with severe intestinal GVHD. Where possible,

**TABLE 13-10 Neutropenic Diet Guidelines**

To reduce the introduction of pathogenic organisms into the gastrointestinal tract of immunocompromised patients, food safety practices and dietary changes are in order. The following are practices that may be helpful to patients after bone marrow transplantation (for 3 months or until immunosuppressive therapies are complete):

- Ensure careful hand washing.
- Keep foods at a safe temperature to prevent food infection.
- Microwave hot foods immediately before service.
- Avoid foods that fall into the following categories:
  - All moldy or outdated food products
  - Deli cheeses and foods
  - Hot dogs, bacon, sausage, luncheon meats
  - Miso and tempeh products
  - Pickled fish, cold smoked salmon, and lox
  - Powdered infant formula
  - Raw and unpasteurized milk and dairy products
  - Raw brewer's yeast
  - Raw honey
  - Raw or undercooked meats, fish, shellfish, poultry, eggs, game meats
  - Raw vegetable sprouts
  - Salad dressings made with raw eggs
  - Soft or mold-containing cheese (Brie, feta, blue)
  - Stir fried vegetables or fruits
  - Tofu
  - Unboiled well water (it should be boiled at least one minute)
  - Unpasteurized beer or fruit juices
  - Unrefrigerated cheese-based salad dressings
  - Unwashed fruits or vegetables
  - Yogurt and other dairy products with active cultures

Adapted from: Oncology Nutrition Practice Group. *The clinical guide to oncology nutrition*. 2nd ed. Chicago, IL: American Dietetic Association, 2006.

the use of intravenous fluids and oral diet should be considered as a preference to parenteral nutrition; however, with severe gastrointestinal failure, even with a trial of enteral feeding, use PN (Murray and Pindoria, 2009). A naso-jejunal (NJ) feeding is associated with less vomiting and aspiration. The use of glutamine to decrease oral mucositis or diarrhea among patients receiving autologous or allogeneic HCT is not necessary (American Dietetic Association, 2010).

- Use indirect calorimetry to determine energy requirements where possible (American Dietetic Association, 2010). Provide 30–35 kcal/kg for the first month; increase for weight gain, infection, GVHD, or neutropenia.
- Protein intake should be 1.5–2 g/kg of weight; increase during corticosteroid therapy.
- Fat intake should be 25–30% of total kilocalories to prevent fatty acid deficiency and to support blood glucose control (American Dietetic Association, 2010). Monitor for hyperlipidemia. An olive oil-based lipid emulsion compared with a MCT/LCT emulsion can be well tolerated; maintain essential fatty acids, and support a favorable plasma lipid profile (Hartman et al, 2009).

- If there is hyperglycemia, keep carbohydrate intake at a steady amount each day.
- Sterile water may be used for hydration and renal health. Maintain 1 mL/Kg intake.
- A multivitamin–mineral supplement may be useful. Assure adequate intake of vitamin D and calcium with long-term steroid use. Potassium and magnesium can be depleted by some medications; monitor carefully. Avoid iron in supplements if transfusions have been frequent; iron overload may occur.
- Patient may need a low-lactose, low-fiber, low-fat diet. Progress, as tolerated, to normal diet.
- As patient recovers and no longer requires a protective setting, the use of live-culture pasteurized yogurt may be beneficial to increase bowel flora. *Lactobacillus acidophilus* therapy can also be helpful.

### Common Drugs Used and Potential Side Effects

- See Table 13-11.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.
- St. John's wort and echinacea should not be taken with cyclosporine, because they alter drug functioning.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The neutropenic, low-bacteria diet protocol should be made available, as appropriate.
- Help the patient and family to manage signs of gastrointestinal GVHD; this usually includes anorexia, nausea, vomiting, watery diarrhea, abdominal pain, and GI bleeding (Xu et al, 2008).
- Small, frequent meals of bland, cold consistency may be well-tolerated.
- Discuss any necessary nutritional support methods and procedures to be used at home or in discharge planning.

**TABLE 13-11** Drugs Commonly Used in Bone Marrow or Stem-Cell Transplantation

Conditioning chemotherapy or irradiation is given immediately before the transplant to suppress immune reactions.

Drug	Comments
Analgesics, antihistamines, and antidepressants	Monitor for specific side effects.
Antibiotics	Amphotericin may be used to fight infections. Nausea, stomach pain, or vomiting may occur.
Antivirals	Acyclovir may be given prophylactically to resolve oral ulcers. Headaches, gastrointestinal (GI) distress, or diarrhea may occur.
Bisphosphonates	These may be needed if there is osteopenia or osteoporosis.
Chemotherapy	Busulfan (to destroy marrow stem cells) and cyclophosphamide (Cytoxan) are given to prevent rejection of the transplant. They can cause nausea, vomiting, diarrhea, and anorexia. Methotrexate, fludarabine, carmustine, and cyclophosphamide may cause anorexia, mucositis, and esophagitis; some also cause diarrhea. Gleevec interferes with an abnormal enzyme that sends signals to the nucleus of a cancer cell. Nausea, extensive diarrhea, and vomiting are potential side effects. Useful for leukemia or advanced stomach cancer.
Immunosuppressive therapy (graft-versus-host disease [GVHD] prophylaxis)	GVHD prophylaxis consists of T-cell depletion (antibody T10B9 or OKT3 and complement) with posttransplantation cyclosporine (Talano et al, 2006). Antithymocyte globulin may cause vomiting, nausea, diarrhea, and stomatitis. Azathioprine may cause vomiting, nausea, diarrhea, mucosal ulceration, esophagitis, and steatorrhea. Beclomethasone can lead to thrush, nausea, and xerostomia. Corticosteroids cause sodium and fluid retention, weight gain, hyperglycemia, skeletal muscle wasting, growth retardation in children, peptic ulceration, and elevated triglycerides. Cyclosporine (Sandimmune) may cause nausea and vomiting, skin rashes, hemorrhagic cystitis, and altered potassium metabolism. Methotrexate causes nausea and vomiting, mucositis, esophagitis, diarrhea, renal and liver changes, decreased absorption of vitamin B <sub>12</sub> , fat, and D-xylose, and taste changes. Monoclonal antibodies cause nausea and vomiting. Sirolimus elevates triglycerides. Tacrolimus can be nephrotoxic or cause hyperglycemia, hyperkalemia, or hypomagnesemia. Ursodeoxycholic acid can cause nausea and vomiting, diarrhea, and GI distress.
Filgrastim (Neupogen)	Neutropenia secondary to immune suppression may be managed with Neupogen and a low-bacteria diet.
Insulin	May be needed if there is hyperglycemia.
Oral hygiene	Clotrimazole (Mycexel) may cause nausea or vomiting; it is used for oral hygiene and prevention of oral candidiasis.
Total-body irradiation (TBI)	Side effects vary for each individual, but anorexia, diarrhea, and mucositis or esophagitis are common.

Transition from CPN and PN to enteral nutrition or oral diet will be helpful.

- Physical therapy may be helpful to maintain strength and to regain mobility.

### Patient Education—Food Safety

- Educate about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.
- The neutropenic, low-bacteria diet includes the careful use of raw fruits and vegetables, milk, and shellfish—all of which may be contaminated easily with bacteria. These diets are often used in bone marrow transplantation units.

## BRAIN TUMOR

### NUTRITIONAL ACUITY RANKING: LEVEL 3

## DEFINITIONS AND BACKGROUND

Tumors are either primary or secondary when they are found in the brain. Primary brain tumors start their growth in the brain and can be benign or malignant. They can occur in children, particularly girls between the ages of 5 and 9. Approximately 17,000 Americans each year are diagnosed with a primary brain tumor. Secondary brain tumors are more common, with about 90,000 cases diagnosed each year. These tumors result from cancer that has metastasized to the brain from the lung, breast, melanoma, kidney, or other part of the body.

Brain tumors destroy or damage brain cells by producing inflammation, compressing other parts of the brain as the tumor grows, and causing swelling and pressure inside the skull. Headache is the most common symptom. Brain tumor headaches are usually worse upon awakening and do not respond to the usual headache medicines. Depression, fatigue, and memory and personality changes may complicate care (Stewart-Amidei, 2005). Table 13-12 describes types of brain tumors and cells of origin.

The nerve cells (neurons) carry signals, and the cells that support them are called glial cells. There are a number of different types of glial cells, all with different names and functions, and they outnumber the neurons by a ratio of 10:1. A glioma is a tumor of neurological origin; it constitutes over 50% of all brain tumors.

**Glioblastoma multiforme** (GBM) is the most frequent and devastating primary malignant brain tumor in adults. Surgery followed by standard radiotherapy with temozolomide chemotherapy is the standard of care, but the prognosis remains poor with survival in the range of 12–15 months

(Minniti et al, 2009). While fruit, vegetables, and carotenoids do not increase the risk of glioma (Holick et al, 2007), adequate GLA and DHA fatty acids, lycopene, beta carotene, and other antioxidants are under study. There is also no evidence that the intake of meat, nitrate, nitrite, or nitrosamines is related to the risk of glioma (Michaud et al, 2009).

**Meningiomas** are also common and may be classified as benign, atypical, or malignant. While surgical excision is curative for most patients, up to 20% recur (Lee et al, 2009).

Because malignant brain tumors are largely dependent on glycolysis for energy, normal neurons and glia readily transition to ketone bodies (beta-hydroxybutyrate) for energy when glucose levels are reduced (Seyfried and Mukherjee, 2005). Increased melanocortin activity and reduced neuropeptide Y function lead to catabolism with reduced energy intake, increased energy expenditure, increased muscle proteolysis, and adipose tissue loss (Laviano et al, 2008).

Nutritional status and weight decline early in treatment (Ward et al, 2009). Anorexia, early satiety, changes in taste/smell, and nausea are frequently reported. Ghrelin has anti-inflammatory properties that may help to alleviate cachexia and improve weight gain; ghrelin receptor agonists show promise (DeBoer 2008).

Some brain tumors can be treated successfully with surgery, radiation therapy, and chemotherapy. Emerging technologies allow physicians to target and treat brain tumors more precisely. Antiangiogenesis approaches have the potential to be particularly effective in the treatment of glioblastoma tumors (Anderson et al, 2008). Convection-enhanced delivery (CED) has emerged as a leading investigational delivery technique for the treatment of brain tumors (Bidros et al, 2010).

**TABLE 13-12** Types of Brain Tumors

Type of Tumor	Location, Cell Origin, or Function
CNS Lymphoma	Affects the body's immune system, which defends against infection and foreign substances.
Craniopharyngiomas	Located around the pituitary gland.
Germinomas	Germ cell tumors.
Gliomas	Originate in the glial supporting tissues. Types include astrocytoma; brain stem glioma; oligodendroglioma that affects myelin production; ependymoma affects the ventricles that aid in the circulation of cerebrospinal fluid.
Meningioma	The meninges cover and protect the brain and spinal cord.
Medulloblastoma	These cells normally do not remain in the body after birth; primitive neuroectodermal tumors (PNET).
Neuroblastoma	Originate in the brain.
Pineal gland tumors	Pineocytoma or pineoblastoma are around the pineal gland.
Schwannoma	Affects the myelin that protects the acoustic nerve for hearing; acoustic neuromas are in this category.

Source: National Cancer Institute, <http://www.cancer.gov/cancertopics/alphalist/a-d>, accessed January 5, 2010.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Five “classes” of meningiomas have been detected by gene expression analysis where chromosomes 22q, 6q, and 14q are involved (Lee et al, 2009). Genomic deletion of chromosomes 6, 21, and 22 represents new targets for further research (Lassman et al, 2005).

Specific Clinical/History	Aphasia	Hemianopsia,
	Cerebral edema,	blurred or
	headaches	decreased
Height	Vertigo	vision
Weight	Altered	Ptosis
BMI	consciousness	Altered gait or
Weight changes	or convulsions	immobility
Diet history	Mental or	Dysphagia
BP (hypertension?)	personality	Vomiting (with
Inability to	changes	or without
follow	Unequal pupil	nausea)
commands	response	Tinnitus

Loss of sense of smell	<b>Lab Work</b>	TLC, white blood cell count (WBC) (altered)
CT scan	Gluc (elevated)	WBC in CSF (normal or increased)
Diffusion MRI	Cerebrospinal fluid (CSF)—elevated protein levels	Transferrin
Skull x-ray	Alb, transthyretin	ALT (elevated)
Electroencephalogram (EEG)	CRP	NA <sup>+</sup> , K <sup>+</sup>
Lumbar puncture		Serum folate

## INTERVENTION

### OBJECTIVES

- Provide adequate energy (30 kcal/kg or more if needed).
- Provide adequate protein for surgery: 1.2–1.5 g/kg body weight; for radiation: 1.0–1.2 g/kg body weight. Adjust for renal/hepatic dysfunction; obesity; skin breakdown or wound healing.
- Avoid constipation and straining.
- Prevent lower respiratory infections; coughing can increase intracranial pressure.
- Counteract side effects of therapy (e.g., radiation, surgery).
- Monitor carefully for elevated blood glucose levels, which may occur with corticosteroids that are used to control brain edema.
- Prevent complications such as the loss of ability to interact, care for self, or permanent neurological losses.

### FOOD AND NUTRITION

- Maintain diet, as ordered. Include extra fluid, unless contraindicated.
- If oral diet is possible, include fish, fruits, vegetables, and adequate fiber. Include green tea, food sources of beta carotene, and fish oil to enhance neuroprotection.
- Alter texture and liquids, if necessary, for dysphagia. If necessary, tube feed or offer CPN.
- Limit sodium to 4–6 g/d to correct cerebral edema.

#### SAMPLE NUTRITION CARE PROCESS STEPS

##### Swallowing Difficulty

**Assessment Data:** Weight loss of 10# in 6 weeks; cognitive changes; brain tumor. Mealtime observation shows choking on thin liquids and inability to swallow solids.

**Nutrition Diagnosis (PES):** NC-1.1 Swallowing difficulty related to neurological changes as evidenced by inability to consume solids, choking on thin liquids, and 10# weight loss in 6 weeks.

**Intervention:** Enteral nutrition support with gastrostomy. Educate the patient and family about the benefits of tube feeding.

**Monitoring and Evaluation:** Recovery of lost weight; tolerance for chemotherapy and radiation treatments.

- Offer meal setup and assistance with eating, altered liquid/food textures, and/or enteral tube feedings for patients with cognitive deficits, swallowing difficulties, or limited function of upper extremity.

## Common Drugs Used and Potential Side Effects

- Seizures are best managed with antiepileptic drug therapy (Stewart-Amidei, 2005). Levetiracetam (Keppra), an anti-convulsant, reduces seizures in malignant brain tumors and may help improve chemotherapy outcomes. Monitor for decreased serum folic acid levels and other nutrients.
- The use of procarbazine (an antineoplastic) may warrant the restriction of tyramine-containing foods that are secondary to its monoamine oxidase (MAO) inhibitor–like action.
- Nonsteroidal anti-inflammatory agents may help to reduce inflammation (Byrne, 2005).
- Steroid therapy may be used. Decrease sodium and increase potassium if appropriate. Negative nitrogen balance or hyperglycemia may result. Maintain near-normal blood glucose levels if possible.
- Osmotic diuretics may be needed for edema. Antacids or antihistamines may be needed for stress ulcers.
- Temozolomide (Temodar) was approved for brain cancer and GBM in particular.

## Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The importance of regular and attractive meals should be stressed to help appetite if fair or poor. Keep in mind that sense of smell may have declined recently.
- Discuss the importance of a balanced diet with good sources of protein at meals.
- Early discussion about end-of-life issues is necessary because the disease can impair the patient's decision-making ability (Stewart-Amidei, 2005).
- A multidisciplinary approach using physical, occupational, and speech therapies is essential to maximize neurological function and activities of daily living.

## Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

# COLORECTAL CANCER

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### The Stages of Cancer

The earlier cancer is found and treated, the better the chances of getting well. The diagnosis of cancer is done by a microscopic test (biopsy) of a piece of tissue. Measuring the amount the cancer has spread (grown), called staging, can be done using medical imaging techniques.

The stage of a cancer tells the doctor how far it has spread. It is important because treatment is often decided according to the stage of a cancer. Doctors use different systems to stage cancers.

## DEFINITIONS AND BACKGROUND

Colorectal cancer (CRC) is the third most common type of cancer in the United States, but the second leading cause of cancer deaths. Family history of colorectal cancer is a risk factor in 25% of cases. Hereditary nonpolyposis colorectal cancer (HNPCC, or Lynch syndrome) is one inherited form.

High risk for CRC exists among patients with ulcerative colitis and Crohn's disease after 8 or more years of duration. The incidence of colorectal cancer rises significantly after age 50 and doubles with each successive decade. Cyclooxygenase-2 (COX-2) and its proinflammatory metabolite, prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), enhance colon cancer progression (Castellone et al, 2005).

Obesity is a risk factor (Fuemmeller et al, 2009). Bile acid deoxycholic acid (DCA) promotes the hyperproliferation of colonic epithelial cells and the risk of colon cancer (Zeng et al, 2009). Table 13-13 lists other factors that either promote or prevent CRC.

The adenomatous polyp is the precursor of most colorectal cancers. In Stage 0 CRC, early cancer is on the innermost layer of the intestine; in Stage 1, it is in the inner layers of the colon; in Stage 2, cancer has spread through the muscle wall of the colon. In Stage 3, the cancer has spread to the lymph nodes and in Stage 4, it has spread to other organs and is usually incurable.

Biomarkers may become a way to find or treat CRC. The 8-OH-dG in colorectal crypts is a biomarker of risk from oxidative DNA damage (Fedirko et al, 2010). Ibuprofen-type drugs, IL6 polymorphisms (rs1800796), and dietary alpha-tocopherol and lycopene significantly decrease the effects of TP53 mutations; beta-carotene and ibuprofen lower the risk of KRAS2 tumors (Slattery et al 2009). The interactions between genes, inflammation, and diet have been elucidated.

Fecal occult blood test and flexible sigmoidoscopy are used for diagnosis. Either standard colonoscopy (optical) or computed tomography (CT) colonoscopy may be used, but the CT (virtual) colonoscopy is not available at all facilities. In **cancer of the small intestine**, malignancy generally is found in the lower duodenum and lower ileum, with a high rate of mortality and few early symptoms; it presents in only 5% of cases. **Rectal cancer** is more common in men than in women and often occurs after middle age, with bleeding, pain, and irregular bowel habits.

In the **colon**, slow-growing malignancies are usually found in the cecum, lower ascending colon, and sigmoid colon. Few early symptoms are found, but the prognosis is optimistic. The right side of the colon (ascending) absorbs fluids and salts; cancer spreads upward here and obstruction is rare. The left side of the colon (the descending colon) stores feces; cancer here tends to encircle the bowel and cause obstructions. If surgery is required, maintaining the ileocecal valve is crucial.

**TABLE 13-13 Risks and Protective Factors for Colorectal Cancer**

Protective Factors	Risk Factors
Alpha-tocopherol and beta carotene (Slattery et al, 2009)	
Aspirin or nonsteroidal anti-inflammatory drugs (Kaur Saini et al, 2009; Slattery et al, 2009)	Age >50
Calcium and vitamin D <sub>3</sub> (Fedirko et al, 2010; Jenab et al, 2009)	Alcohol intake, excessive (Emmons et al, 2005)
Folic acid (Ulrich, 2005)	Chronic inflammatory and inflammatory cytokines (Bowen et al, 2009)
Lutein and lycopene (Slattery et al, 2009)	Family history of familial adenomatous polyposis (FAP) or hereditary non-polyposis colon cancer (HNPCC)
Green tea	Medical history of colon polyps, inflammatory bowel disease, other types of cancer
Omega-3 fatty acids	Overweight and obesity
Selenium; methylselenolol is a critical metabolite (Zeng et al, 2009)	Smoking, particularly at an early age (Botteri et al, 2008; McCleary et al, 2010)
Sulforaphane (broccoli, cruciferous vegetables)	Western-style diet, high in red meat and fat; low in vegetables, folic acid, calcium and vitamin D (Emmons et al, 2005)

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Both cellular factors and genetic changes enhance tumor invasion. Vitamin D receptor (VDR) genes regulate the epithelial changes that initiate tumor cells; the BB genotype of the VDR polymorphism is associated with a reduced risk of colon cancer (Jenab et al, 2009). Chemokine receptor CCR5 expression and increased CD8(+) T-cell infiltration may be found (Zimmermann et al, 2010). While folate status may be linked with CRC because of its role in DNA synthesis, the C>T MTHFR polymorphism decreases risk by 15–18% (Levine et al, 2010). Finally, phosphatase and tensin homolog deleted on chromosome 10 (PTEN) is associated with late stage CRC (Bowen et al, 2009).

<b>Specific Clinical/History</b>	Dehydration, electrolyte imbalances	MTHFR genotyping
Height	Intestinal obstruction,	Fecal occult blood test
Weight	bowel abscess	(FOBT)
BMI	Fistula	H & H (decreased)
Obesity?	Proctoscopy	Serum Fe
Unintentional weight loss?	Colonoscopy	Transferrin
Diet history	Digital rectal examination	Na <sup>+</sup>
Rectal bleeding, pain		K <sup>+</sup> (often decreased)
Irregular bowel habits	<b>Lab Work</b>	Chol, Trig
Alternating diarrhea and constipation	CEA level (CEA 125)	TLC (varies)
Abdominal distention, bloating	8-OH-dG in colorectal crypts	WBC, ESR (increased)
Thin, pencil stools	Colon lavage cytology	Alb, transthyretin
Weakness	Serum folate, B <sub>12</sub>	CRP
Anorexia	Serum homocysteine	Mg <sup>++</sup> , Ca <sup>++</sup>
		Serum zinc

## INTERVENTION

### OBJECTIVES

- Decrease residue, particularly with obstruction, until fiber is better tolerated.
- Prevent rapid weight loss; correct anemia. Maintain hydration.
- Counteract side effects of therapies: chemotherapy, resection, or radiation. Nutrition counseling improves patient outcomes in radiotherapy (Ravasko et al, 2005).
- Provide nutrients in a tolerable form—oral, parenteral, or enteral.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Abnormal Gi Function

**Assessment Data:** Recent weight loss (10# in 2 months). Diarrhea and constipation; hx of dark, thin stools and blood. Dx of colon cancer.

**Nutrition Diagnosis (PES):** Abnormal GI function related to alternating diarrhea and constipation as evidenced by dark stools, and constipation 3× weekly on average followed by bloody diarrhea.

**Intervention:** Food-nutrient delivery—oral nutritional supplement between meals; mild fiber supplement as tolerated. Educate the patient about dietary changes that can be beneficial. Provide counseling about possible nutritional procedures (i.e., colostomy) after surgical resection.

**Monitoring and Evaluation:** No further weight loss before surgery. Tolerance for fiber in diet and from supplement. Adequate preparation for surgery, followed with appropriate changes in feeding method and counseling after colostomy.

- Include sufficient total amounts of folate and vitamin B<sub>6</sub> since disrupted DNA synthesis affects carcinogenesis (Sharp et al, 2008).
- Provide sufficient vitamin D<sub>3</sub> (Grant, 2009).
- Prevent or ameliorate starvation diarrhea.
- Protect against recurrence by dietary changes indicated in Table 13-13.

## FOOD AND NUTRITION

- CPN or TF may be needed for an extended period of time; include glutamine.
- Administer parenteral fluids with adequate electrolytes, vitamins C and K, and selenium (if used over a long time). Monitor vitamin D, calcium, iron, zinc, and fat intakes for adequacy.
- With ileal resection, vitamin B<sub>12</sub> deficiency can occur, and bile salts may be lost in diarrhea. Hyperoxaluria and renal oxalate stones can be a problem. With massive bowel resection, malabsorption, malnutrition, metabolic acidosis, and gastric hypersecretion may result.
- With ileostomy and colostomy, salt and sodium/water balance are problems. Ostomy diets may be needed (see ileostomy and colostomy entries in Section 7). Increase energy and ensure adequate protein.
- Decrease fiber until tolerated. Eventually, increase whole grains including rye bread, cereals, fruits, and vegetables.
- Consume less alcohol and more folic acid from spinach, broccoli, asparagus, avocado, orange juice, dried beans, and fortified cereals (Kim, 2007).
- Eat less red meat; use more poultry, fish, tofu, and beans as protein sources.
- Discuss the inclusion of other protective foods, such as calcium-rich foods; lutein and lycopene (tomato products, watermelon, spinach, kale, greens, broccoli, romaine lettuce, and pink grapefruit); cumin; cereal, bean, vegetable, and fruit fiber; flavonoids (apples, onions, green tea, and chamomile tea); cruciferous vegetables; coffee; omega-3

fatty acids from fish and walnuts; selenium foods such as Brazil nuts; and unsaturated fats such as flaxseed, salmon, and canola and olive oils.

- A multivitamin supplement is beneficial, particularly for folic acid and vitamins B<sub>6</sub> and D<sub>3</sub>.
- Monitor carefully for lactose intolerance. Use lactase enzyme products when indicated.
- Physical activity should be encouraged as much as possible.

### Common Drugs Used and Potential Side Effects

- Chemotherapy may be used for 6–8 months, particularly with stage 3 colon cancer. Monitor for side effects because these agents may further impact bowel function.
- The multidrug combination of oxaliplatin, fluorouracil, and leucovorin is standard treatment for metastatic colorectal carcinoma (Caraglia et al, 2005). Fluorouracil plus levamisole, methotrexate, mitomycin, lomustine, and vincristine may lead to diarrhea, nausea, vomiting, low WBC, and mouth sores.
- Bevacizumab (Avastin) use leads to a significant decrease in colon cancer deaths. Cetuximab (Erbix), when added to chemotherapy, will shrink tumors and delay progression.
- COX-2 inhibitors may be helpful because 50% of polyps and 85% of colonic tumors in humans overexpress COX-2 (Samoha and Arber, 2005). The nonsteroidal anti-inflammatory drug, Diclofenac, is a preferential COX-2 inhibitor, which can be an effective chemopreventive agent in colon cancer (Kaur et al, 2009).
- Regular low doses of aspirin may reduce prostaglandin production; GI bleeding can result.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.
- Folate vitamers (tetrahydrofolate, 5,10-methylenetetrahydrofolate) should be studied further for their roles in CRC (Sharp et al, 2008).
- With methotrexate (Rheumatrex), avoid echinacea; it may damage the liver.
- A vitamin D<sub>3</sub> supplement, such as 1100 IU daily, seems to be of benefit (Grant, 2009).
- Low-dose fish oil supplementation may be useful to reduce inflammation.
- Sea cucumber extract contains Frondanol A5—a glycolipid extract with potential chemopreventive properties (Janakiram et al, 2009).
- Sour orange (cirtus aurantium) has protective liminoid properties (Perez et al, 2009).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- At first, limit foods that may cause gas, such as corn, broccoli, cauliflower, beans, cabbage, melon, and carbonated beverages. Provide instruction on hydration and the use

of fiber to help with bowel management, particularly for rectal cancer patients.

- Family members (offspring and other first-degree relatives) should have a digital examination annually at 40 years of age, stool tests for blood after 50 years of age, and sigmoidoscopy or colonoscopy after age 50 every 3–5 years.
- Medical advice may include regular use of aspirin or non-steroidal anti-inflammatory drugs (NSAIDs).
- Discuss an appropriate dietary regimen for any specific problems. Weekly Medical Nutrition Therapy (MNT) that includes an individualized nutrition prescription and counseling improves calorie and protein intake, nutrition status, quality of life (QOL), and reduces symptoms of anorexia, nausea, vomiting and diarrhea (American Dietetic Association, 2010).
- Encourage family participation in all levels of care.
- Discuss how to prevent future polyps. High compliance with a low-fat, high-fiber diet is associated with a reduced risk of adenoma recurrence (Sansbury et al, 2009). Omit trans-fatty acids as much as possible (Vinikoor et al, 2009). A high intake of flavonols, which are at greater concentrations in beans, onions, apples, and tea, is also associated with decreased risk (Bobe et al, 2008).
- Suggest an intake of berries, chocolate, coffee, soy foods, folate from foods and supplements, lutein and carotenoids from fruits or vegetables, and whole grains such as rye.
- Encourage dairy products for calcium, vitamin D, and lactose content. If necessary, use lactase enzymes.
- Encourage physical activity when feasible.
- Surveillance following curative treatment generally includes history and physical exams every 6 months for 5 years, then every 3 months for 2 years, and then every 6 months for 3–5 years (Sunga et al, 2005).

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

## ESOPHAGEAL, HEAD AND NECK, AND THYROID CANCERS

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

#### Mouth and Throat Cancer

Cancer-causing chemicals from tobacco products increase the risk of cancer of the lip, cheek, tongue, and larynx (voice box). The removal of these cancers can be disfiguring and can result in loss of the larynx.

Asset provided by Anatomical Chart Co.

Asset provided by Anatomical Chart Co.

#### DEFINITIONS AND BACKGROUND

**Head and neck cancers** affect esophageal, hypopharyngeal, laryngeal, lip and oral cavity, nasopharyngeal, oropharyngeal, paranasal sinus and nasal cavity, parathyroid, or salivary glands. Annually, approximately 38,000 people in the United States are diagnosed with a head or neck cancer; the highest overall incidence rate is in black males. Tobacco is linked with 85% of these cancers; alcohol is another risk.

Obesity is a factor in many cases (Steffen et al, 2009). See Table 13-14 for more details.

Damage from acid reflux may contribute to esophageal cancer. Folate and homocysteine derangements are common. A diet rich in fruits, vegetables, selenium, zinc, and folate is associated with a reduced risk of head and neck cancer (Falciglia et al, 2005; Kane, 2005; Steevens et al, 2010).

Head and neck squamous cell carcinoma (HNSCC) is an aggressive cancer with low survival rates in advanced stages.

**TABLE 13-14 Key Factors in Types of Head and Neck Cancer**

Site	Comments
Oral cavity	Caused by sun exposure (lip); possibly <u>human papillomavirus (HPV) infection</u> ; paan (betel quid) used by Southeast Asians; intake of mate, a tea-like beverage habitually consumed by South Americans. May present with gingival swelling, pain, bleeding, and loosening teeth. The disorder is rare in persons younger than age 40. Risk of metastasis is great; only about half of these individuals will live longer than 5 years.
Nasopharynx	More common in Chinese ancestry. Caused by <u>Epstein-Barr virus</u> infection; occupational exposure to wood dust; and consumption of certain preservatives or salted foods. Signs include unilateral obstruction, epistaxis, pain, otological changes, and nasal obstruction.
Oropharynx	Caused by poor oral hygiene; HPV infection and the use of mouthwash that has a high alcohol content are possible, but not proven, risk factors. There may be a dull ache, dysphagia, referred otalgia, and trismus.
Paranasal sinuses and nasal cavity	Caused by industrial exposures, such as wood or nickel dust inhalation. Tobacco and alcohol use play less of a role in this type of cancer.
Hypopharynx	Plummer-Vinson syndrome is a rare disorder that results from iron and other nutritional deficiencies with severe anemia. Dysphagia results as webs of tissue grow across the upper part of the esophagus.
Larynx	Caused by exposure to airborne particles of <u>asbestos</u> , particularly in the workplace. Voice changes, dysphagia, odynophagia, and dyspnea occur.
Parotid and salivary glands	Caused by radiation to the head and neck. This exposure can come from diagnostic X-rays or from radiation therapy for noncancerous conditions or cancer. Unilateral symptoms and impaired jaw mobility can occur. The parotid gland is the largest salivary gland. Cancer here is rare. Surgery is often curative.
Esophageal cancer	Develops in the middle or lower third of the esophagus. It is one of the more common types of head and neck cancer. It presents as adenocarcinoma or squamous cell cases that require surgical resection. This condition is more common in persons older than 50 years of age, particularly males. Barrett's esophagus (BE) is a premalignant condition associated with esophageal cancer; cyclooxygenase-2 (COX-2) is overexpressed. Aspirin and other nonsteroidal anti-inflammatory drugs may help prevent esophageal cancer. Stage 0 is very early and affects only the first layer of cells; in Stage V, the cancer has metastasized.
Thyroid cancer	A lump on the side of the neck, hoarseness, and dysphagia can be signs. Thyroidectomy may be used, or radioactive iodine (RDI) can be used to destroy cancerous cells that remain after surgery. A low-iodine diet may be needed about 2 weeks before the RDI treatment.

Derived from: National Cancer Institute, <http://www.cancer.gov/cancertopics/factsheet/sites-types/head-and-neck>, accessed January 9, 2010.

The prognosis for cure worsens as the depth of tumor invasion increases. Surgery is possible for some cases. Cervicofacial and cervicothoracic rotation flaps provide a reliable means to reconstruct complex defects of the face, lateral skull base, and neck (Moore et al, 2005). Many head and neck cancer patients are malnourished before treatment begins, and those who are treated with radiotherapy are at an increased risk of malnutrition due to the severe side effects (Moore et al, 2005; Wood, 2005). Radiation therapy side effects may include odynophagia, dysphagia, mucositis, esophagitis, xerostomia (with occasional osteoradionecrosis), dental caries, weight loss, taste changes, and decreased appetite. Prophylactic placement of a gastrostomy feeding tube is useful.

**Thyroid cancer** affects approximately 26,000 people in the United States. Thyroid-stimulating hormone (TSH) from the pituitary causes the thyroid gland to produce thyroid hormones and to release thyroglobulin. Papillary tumors are the most common type; they arise as an irregular, solid, or cystic mass from otherwise normal thyroid tissue. Distant metastasis is uncommon, but lung and bone are the most common sites. Tumors that invade or extend beyond the thyroid capsule have a worse prognosis. Often, the thyroid gland is surgically removed as a cure. Thyroxine medicine (Synthroid, Levoxyl, and Unithroid) is needed to keep TSH levels low.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** An epigenome-wide screen has revealed a set of genes that are commonly methylated and downregulated in head and neck cancers (SEPT9, SLC5A8, FUSSEL18, EBF3, and IRX1). All five interact with components of the TGF-beta pathway; their silencing results in a coordinated decrease in apoptosis, increased proliferation, and decreased differentiation (Bennett et al, 2009).

#### Specific Clinical/History

Diet history	Substernal pain or feeling of fullness
BP	Regurgitation of undigested food
I & O	Malaise
Dehydration?	Malnutrition
Temperature	Anemia
Dysphagia, painful swallowing	
Obesity?	
Unplanned weight loss	

Regurgitation after eating	Taste changes, decreased appetite	CRP
Hiccups, foul breath	Loosening teeth	Transferrin
Aspiration	Oral biopsy	H & H
Increased salivation	Esophageal webs with achalasia?	ALT (increased)
Hoarseness and coughing	Palpable mass	Gluc
Gingival swelling, pain, bleeding, or hyperplasia	Barium swallow	Serum zinc (low?)
Nonhealing ulcerative oral lesions	Endoscopy	Triiodothyronine (T3)
Mucositis, esophagitis	Nasopharyngoscopy	Thyroxine (T4)
Xerostomia	Direct laryngoscopy, esophagoscopy	Thyroid-stimulating hormone (TSH)
Dental caries	Biopsy	Ca <sup>++</sup> , Mg <sup>++</sup> , Na <sup>+</sup> , K <sup>+</sup>
		Alb,
		transferrin
		Chol
		Bicarbonate
	<b>Lab Work</b>	
	Alb,	
	transferrin	

## INTERVENTION

### OBJECTIVES

- Prepare for treatments such as surgery, radiation, or chemotherapy. The dietitian should provide a pre-treatment evaluation and weekly visits for 6 weeks during chemoradiation treatment to reduce weight loss,

unplanned hospitalization, length of stay, and tolerance for full treatment (American Dietetic Association, 2010).

- Prevent malnutrition, further weight loss, cachexia, and aspiration. Weight loss, caused by acute mucositis and dysphagia, is common during concurrent chemotherapy and irradiation (chemoradiotherapy) of head and neck cancer (Lin et al, 2005).
- Because nutrition support for patients with head and neck cancer is associated with a significant increase in total energy ingestion, placing gastrostomy tubes prophylactically prevents disruption to treatment plans (Moore et al, 2005; Wood, 2005).
- Meet nutritional needs with tube feeding, as needed. Progress to goal with minimal signs and symptoms of intolerance (nausea, fullness). Transition to full or partial oral intake when feasible.
- If resection is needed, fat malabsorption, reflux, dumping syndrome, increased mediastinal pressure, and increased food transit time may be side effects.
- Hydrate adequately; encourage fluids between meals and limit fluid intake at meals to improve intake of other foods.
- Promote adequate wound healing, positive nitrogen balance, and retention of lean body mass.
- Prevent or correct anemia, sepsis, abscesses.
- Monitor for dysphagia, difficulty chewing, mucositis, xerostomia, fibrosis, and dental caries after treatments. Assure adequate mouth care.
- Omit alcoholic beverages and abstain from tobacco, including chewing snuff.
- In patients with advanced cancer: reduce symptoms, preserve organ function, and improve quality of life as much as possible. Provide palliative care if needed.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Involuntary Weight Loss

**Assessment:** Recurrent squamous cell carcinoma of the larynx; s/p emergency tracheostomy, radiation and chemotherapy. NPO due to swallowing difficulty; on GT bolus feeding. Elevated BUN & creatinine levels. On oxycodone for pain.

**Nutrition Diagnosis (PES):** Involuntary weight loss (NC-3.2) related to decreased oral intake and dysphagia as evidenced by weight loss of 21% in 17 months.

**Interventions:** Nutrient delivery—ND 2.41 enteral feeding tube; ND 3.21 multivitamin supplement.

**Education:** Discuss home tube feeding that is appropriate for the patient's condition.

**Counseling:** C-2.2 goal setting: minimize weight loss, maintain adequate hydration, prevent aspiration, and improve quality of life.

**Coordination of Nutrition Care:** RC-1.1 Interdisciplinary team meeting with nursing, speech therapy, social worker, and recreational therapy.

**Monitor and Evaluation:** Monitor for weight improvement. No GI problems or enteral nutrition intolerance. Improvement in renal lab values. Reassess nutritional needs via GT. Reassess with speech evaluation for possible transition to full or partial oral intake when feasible.

## FOOD AND NUTRITION

- Adjust diet individually to meet the patient's needs. Nutrition support enhances desirable outcomes (Odelli et al, 2005). After radiation: xerostomia, ulceration, bleeding, and pain may result; after chemotherapy, nausea, vomiting, weakness, and fatigue may occur (Dixon, 2005).
- Be careful not to create refeeding syndrome, which is potentially fatal. Progress slowly in patients who have been malnourished for a week or longer. Begin with 10 kcal/kg per day and increase slowly; use thiamin and other B-complex vitamins in a supplement (Mehanna et al, 2009).
- Eventually, provide a diet high in energy and protein with bland or pureed foods as required: 30–35 kcal/kg; 1.0–1.5 g protein/kg.
- A dysphagia diet (thick pureed foods, decrease in thin liquids) may be needed. Tolerance will vary for hot and cold foods and drinks; monitor and alter intake accordingly.
- Patients are often fed with gastrostomy or jejunostomy feedings. Cellular and morphological changes follow a period of malnutrition; enteral feeding is an important strategy for maintaining gut integrity and function (Sica et al, 2005). Use enteral feeding formulas that are high in omega-3 fatty acids (Aiko et al, 2005) and arginine (De Luis et al, 2009).
- Increase fluid intake as tolerated; dehydration is common.

- Increase intake of vitamins D<sub>3</sub>, A and C; zinc; and other nutrients that may be low. Otherwise, a multivitamin–mineral supplement is indicated if oral intake is not possible.
- If esophagectomy has been performed, gastric stasis or dumping syndrome may occur. The use of needle catheter jejunostomy (NCJ) is safe, with an extremely low rate of complications over a prolonged period at low costs (Sica et al, 2005).
- If an oral diet is possible, omit irritants such as black pepper and chili powder and dilute acidic fruits or juices such as orange, grapefruit, and tomato.
- Use protective foods to prevent recurrence; use beans, vegetables, fish, foods rich in zinc and lycopene, whole grains, citrus fruits, and vitamin C–rich foods.
- Polyphenols show great promise; EGCG in green tea is particularly beneficial (Baumeister et al, 2009).
- With thyroid cancer, a low-iodine diet may be needed prior to surgery or treatment.
- In advanced cases, offer palliative care. Hydration and comfort are the focus.

### Common Drugs Used and Potential Side Effects

- Aspirin can lower esophageal cancer risk by 90% by reducing prostaglandin production. Some doctors will prescribe a low daily dose to prevent recurrence.
- Chemotherapy with cisplatin may be used, along with radiation therapy. Cisplatin can cause nausea, vomiting, altered taste, changes in renal function, and diarrhea. Weight loss during cisplatin-containing chemoradiotherapy is associated with reduced kidney function; findings highlight the importance of intensive supportive measures of nutrition and hydration beyond standard measures, and these steps should be started before 10% weight loss occurs (Lin et al, 2005).
- Bleomycin and methotrexate can lead to nausea, vomiting, anorexia, or stomatitis.
- Steroids may be used to reduce inflammation; hyperglycemia, sodium retention, potassium depletion, and negative nitrogen balance can result.
- Pilocarpine may be used as a saliva substitute for xerostomia.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.
- Avoid the use of echinacea with cyclosporine or methotrexate (Rheumatrex) because of potential damage to the liver. Avoid St. John's wort also.
- Curcumin is a powerful inhibitor of COX-2 expression (Khafif et al, 2009).
- L-carnitine is sometimes used to decrease toxicity from agents such as bleomycin.
- Zinc supplementation helps in managing mucositis after radiation.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss a diet rationale that is appropriate for the patient's condition. If the patient can eat orally, encourage him or her to chew slowly.
- If jejunostomy feeding is required after esophagogastric surgery, teach the patient/family/caretaker how to prepare feedings and how to produce the item in a clean environment.
- During radiation therapy/surgical recovery, patients with gastrostomy tubes should be encouraged to practice swallowing exercises, as prescribed by the speech pathologist, to maintain swallowing function and reduce the risk of fibrosis. Encourage help from speech therapy.
- Hypothyroid status can cause dysphagia; counsel accordingly.
- If oral diet is possible, discuss the use of protective foods.
- Relaxation therapy or biofeedback can be beneficial.
- Radiation-induced fibrosis (RIF) is caused by reduced blood supply months or years later. Rinse with vitamin E solutions and use 1000 IU tocopherol with pentoxifylline to decrease mucositis (Chiao and Lee, 2005; Haddad et al, 2005). Use small frequent feedings and oral supplements.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.
- For home tube feeding or CPN, teach the principles of safe handling and administration. Discuss the signs of infection or intolerance and when to contact the health team.

## GASTRIC CANCER

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

#### DEFINITIONS AND BACKGROUND

Gastric cancer (GC) is a carcinoma that most commonly occurs in the pyloric segment and along the lesser curvature. Cancer that begins in the glandular cells is an adenoma; this type is over 90% of gastric cancers. If the cancer starts in the immune system, it is a lymphoma; if it starts in the hormonal system, it is called carcinoid syndrome. Another very rare form starts in the nervous system and is called a gastrointestinal stromal tumor (GIST). Diffuse forms have a poor prognosis.

In GC, early definitive signs are rare. GC may follow long-term pernicious anemia, Ménétrier's disease, or chronic gastritis. It is generally found in males aged 50–70 years and among smokers. While frequency is low in the United States, it is high in Japan and China. Gastric carcinoma is the second leading cause of cancer-related deaths in the world, accounting for more than 700,000 deaths each year (Hatakeyama, 2009).

*Helicobacter pylori* infection plays a role. Chemokine production and antiapoptosis are mediated by *H. pylori* and may drive lymphocytes to malignancy. Infection with cagA-positive *H. pylori* plays an essential role; this protein is delivered into gastric epithelial cells via the bacterial secretion system where it contributes to the transformation of gastric epithelial cells (Hatakeyama, 2009). See Table 13-15 for other risk factors.

A recent study shows a protective role for riboflavin and vitamin B<sub>6</sub> (Eussen et al, 2010). Physical activity and eating a diet high in fruits, vegetables, beta-carotene, and vitamin C may also decrease the risk for GC (Kim et al, 2005; Vigen et al, 2006). Greater adherence to a Mediterranean dietary pattern is associated with a significant reduction in the risk of incident GC (Buckland et al, 2009).

Surgery is the most common treatment. Very small, stage 1 cancers that are limited to the inside lining of the stomach may be removed using endoscopy. In a subtotal gastrectomy, only the affected stomach portion is removed. In stages 3 or 4, it may be necessary to remove the entire stomach and connect the esophagus to the small intestine. Laparoscopic surgery is less invasive and recovery is faster.

Neoadjuvant radiation may be used before surgery to shrink a stomach tumor, or it can also be used after surgery to kill any remaining cancer cells. Radiation therapy may cause diarrhea, nausea, or vomiting. Chemotherapy may also be used along with radiation therapy or for advanced cancers that cannot be treated through surgery.

**TABLE 13-15 Risks for Gastric Cancer**

Advanced age
Chronic atrophic gastritis, pernicious anemia, gastric polyps
Diet high in red meat
Diet high in salt, salted foods, smoked and preserved foods
Diet low in vitamin E or selenium
Eating foods contaminated with aflatoxin fungus
Ethnicity—young white and Hispanic males; African-Americans from poor socioeconomic backgrounds
Family history of gastric cancer, Ménétrier's disease, intestinal metaplasia
<i>H. pylori</i> gastric infection
Low use of fruits and vegetables
Male gender
Smoking

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Genetic predisposition is a risk factor in gastric cancer. Aberrant methylation of several genes is noted; some have a poor prognosis. E-cadherin is involved with diffuse forms; and SNP analysis (including IL1B) may elucidate the role of inflammation and stem cells in premalignant lesions (Milne et al, 2009).

<b>Specific Clinical/History</b>	Anorexia Anemia, pallor Vertigo Nausea or vomiting Melena MRI or CT scan Barium swallow Endoscopy	Alb, transthyretin CRP Ca <sup>++</sup> , Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup> Gluc H & H Transferrin ALT (increased) Melena, occult blood Serum folic acid, B <sub>12</sub>

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Mineral Intake

**Assessment Data:** Diagnosis of gastric cancer, stage 1; several small polyps found on endoscopy. BMI normal, no sign of *H. pylori*. Lives in region known to have low levels of selenium in the soil (coastal Carolinas). Diet history indicates no intake of selenium-rich foods or multivitamin–mineral supplementation. Some nausea and melena noted.

**Nutrition Diagnosis (PES):** Inadequate selenium intake related to poor diet and supplementation as evidenced by diet history and residence in area known to have selenium-poor soil.

**Intervention:** Food-Nutrient Delivery—Provide foods high in selenium; encourage the use of a daily multivitamin supplement that contains the daily value for selenium. Educate—teach the patient and family about food sources of selenium. Counseling—provide tips on other cancer preventive factors. Coordinate care with the medical team after the surgical removal of the gastric polyps.

**Monitoring and Evaluation:** Successful minor surgery. Improvement in intake of selenium from food and daily supplement; better intake of other protective factors. Able to maintain BMI within desirable range. No further melena or nausea.

## INTERVENTION

### OBJECTIVES

- Prevent or reverse weight loss and further malnutrition.
- Encourage fluids.
- Counteract side effects of chemotherapy, radiation, or gastrectomy. If gastrectomy is performed, dumping syndrome or hypochlorhydria may result.
- Promote wound healing. Replete visceral proteins as stress level decreases.
- Correct protein-losing enteropathy.
- Prevent cancer recurrence by including protective foods.
- Improve quality of life.

### FOOD AND NUTRITION

- Parenteral therapy may be used, particularly before surgery.
- If oral diet is possible, include protective foods such as *Allium* in garlic (raw or lightly cooked), carotenoids and lycopene (Ito et al, 2005), fish, fruits, nonherbal tea, indoles and sulforaphane from cruciferous vegetables, and quercetin from apples and yellow onions. Vitamin B<sub>6</sub> and riboflavin should be included (Eussenn et al, 2010) as should selenium and vitamin E (Qiao et al, 2009).
- After resection, patients are often volume-sensitive and need small meals and snacks with fluids between meals. When oral intake is allowed, try light meals that are nutrient-dense, high-protein/high-energy. Drink 35 mL/kg of fluid or more, unless contraindicated.
- After gastrectomy, manage dumping syndrome, where undigested food enters the small intestine too quickly. Small, frequent feedings may be better tolerated. Concentrated carbohydrates, alcohol, and carbonated beverages should be severely limited or omitted. See entry in Section 7 also.
- Jejunostomy feeding may be needed at the time of a resection. Monitor tolerance carefully.
- Be sure that dietary intake and supplementation includes selenium, zinc, vitamin C, and other key nutrients for wound healing and correction of anemia. Take supplements with food.

### Common Drugs Used and Potential Side Effects

- Antibiotic therapy is needed to eradicate *H. pylori* bacteria where present.
- Cytotoxic drugs such as mitomycin C may cause fever, nausea, vomiting, anorexia, and stomatitis.
- With fluorouracil (FU), anorexia and nausea are common. Sore mouth, taste changes, and vomiting also may result. Added thiamin is recommended, and leucovorin is often used with FU.
- In a rare form of gastrointestinal stromal tumor (GIST), imatinib (Gleevec) is useful; it interferes with an abnormal enzyme that sends signals to the nucleus of a cancer cell. Nausea and vomiting are potential side effects. Imatinib shrinks tumors by more than half with minimal side effects (Heinrich and Corless, 2005).

- Sunitinib (Sutent) is useful in stomach cancer when imatinib is not effective.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.
- Treatment with a combination of 50 micrograms of selenium, 30 milligrams of vitamin E, and 15 milligrams of beta-carotene leads to decreased mortality from gastric cancer (Qiao et al, 2009).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Feeding tubes such as jejunostomy may be useful in the home setting.
- If eating orally, instruct patient on postgastrectomy diet. Encourage patient to chew slowly and well.
- Discuss protective foods and phytochemicals.
- If the stomach was resected, vitamin B<sub>12</sub> anemia is likely to occur within several years; monitor carefully. Injections will likely be needed for life.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

- With tube feeding, discuss the safe handling of formula and tubing.

## LIVER CANCER

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

Adapted from: Rubin E MD and Farber JL MD. *Pathology*, 3rd ed. Philadelphia: Lippincott Williams & Wilkins, 1999.

### DEFINITIONS AND BACKGROUND

Liver cancer (hepatocellular carcinoma, HCC) is the fifth most common cancer and is one of the leading causes of cancer death worldwide (Yam et al, 2010). Primary hepatic tumors are common with alcohol abuse, aflatoxin ingestion, chronic hepatitis, or low weight at birth (see Table 13-16). HCC may develop after years of chronic inflammation and persistent mucosal or epithelial cell colonization by hepatitis B or C viruses. Malignant hepatic tumors are common due to metastatic lesions from other organs. HCC accounts for almost half a million cancer deaths a year, and the incidence is escalating in the Western world and in developing countries. HCC progresses in a stepwise manner, mostly regulated by gene expression; untreated liver cancer may rapidly lead to death within a year.

Early identification of malnutrition status is required for proper intervention. In one study, over 60% of hospitalized patients were malnourished; the prevalence was higher in

**TABLE 13-16 Risk Factors for Liver Cancer**

Aflatoxins (Voight, 2005)
Anabolic steroids
Arsenic in drinking water
Cirrhosis from alcohol abuse or hemochromatosis (Kuper et al, 2001)
Male gender
Liver disease: hepatitis B virus (HBV) and hepatitis C virus (HCV)
Obesity
Oral contraceptive use (higher dose estrogen)
Tobacco use
Vinyl chloride and thorium dioxide (Voight, 2005)

male patients with long hospital stays, readmitted patients, and patients who had liver cancer (Wie et al, 2009).

Surgical resection is sometimes possible in some cases; laparoscopic procedures are becoming more common. Laser-induced thermotherapy for the treatment of liver metastases may be an option. In some cases, liver transplantation may be possible.

Chemotherapy may be administered. Where radiation is used, radioactive substances are sent into the artery that leads directly to the liver. Computed tomography-guided focal liver irradiation combined with chemotherapy delivered via the hepatic artery may extend the lives of patients with unresectable cancer.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** HCC is strongly linked to increases in allelic losses, chromosomal changes, gene mutations, epigenetic alterations, and alterations in molecular cellular pathways (Yam et al, 2010).

<b>Specific Clinical/History</b>	Stearrhea, diarrhea	Alcohol abuse?
	Abdominal fullness	Pesticide exposure?
Height		CT or MRI
Weight	Low-grade fever	
BMI	Anemia, malnutrition	<b>Lab Work</b>
Progressive weight loss	Portal hypertension	Alpha-fetoprotein (AFP)
I & O, dehydration	Dyspnea	Prothrombin time (PT) (prolonged)
Anorexia, weakness	Jaundice, ascites	H & H
Nausea and/or vomiting	Hepatic coma?	Transferrin
Increased flatulence	Melena	
	Hepatomegaly	
	Temperature (fever?)	

Aspartate aminotransferase (AST) – altered?	Sedimentation rate (ESR), increased? Ca <sup>++</sup> , Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup>	Alb (decreased), transthyretin CRP
ALT (abnormal)	Ammonia	Gluc (decreased) Alk phos TLC (varies)

## INTERVENTION

### OBJECTIVES

- Reduce fluid retention and ascites.
- Correct serum protein levels and improve hepatic production capacity.
- Prevent further nausea and vomiting, weight loss, anorexia, and malnutrition.
- Counteract side effects of therapy (e.g., surgery, chemotherapy, radiation).
- Improve overall nutritional and hematologic status.
- Maintain adequate hydration.
- Improve prognosis and prolong life as long as possible. Improve quality of life.

### FOOD AND NUTRITION

- Tube feed if oral diet is not feasible; patients with hepatic cancer usually have significant fluid balance/overload/retention problems. Avoid CPN.
- Progress, if and when tolerated, to high-protein diet with sufficient carbohydrate intake. Managing weight will be important to prolong life; a carefully planned weight loss diet is needed in those patients who are obese.
- If hepatic coma occurs, decrease protein and supplement with amino acids (see hepatic encephalopathy in Section 8). Branched-chain amino acids may be beneficial (Togo et al, 2005).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Poor Nutritional Quality of Life

**Assessment Data:** Liver cancer patient, weight loss of 5# in the past 2 weeks. Anorexia, nausea, and vomiting while on chemotherapy. Very fatigued.

**Nutrition Diagnosis (PES):** Poor nutritional quality of life related to chemotherapy treatments as evidenced by fatigue, anorexia, nausea, and vomiting.

**Intervention:** Food and nutrient delivery—offer preferred foods and beverages. Educate the patient about ways to enhance nutrient and energy density in smaller, more frequent meals. Counsel about ways to manage nausea and vomiting during chemotherapy weeks.

**Monitoring and Evaluation:** Improvement in intake. Tolerance of chemotherapy. No further weight loss. Improved nutritional quality of life.

- Reduce sodium if ascites and edema are significant; extra protein may be needed if albumin is also low. Monitor serum levels of other electrolytes to determine if other restrictions are needed.
- Supplemental vitamins may be beneficial. Monitor serum levels of vitamins A, D, and K because of poor hepatic clearance.
- With surgery, monitor nutritional intake for adequate wound healing and recovery.
- Encourage small meals and snacks as tolerated throughout the day.
- Decreased calcium absorption may occur after surgery. Calcium supplementation is needed, particularly in postmenopausal women.
- Discuss signs of hepatic coma that require dietary alterations.
- Encourage hepatitis B virus vaccination and offer information.
- Provide education related to diet (regular, six small feedings) or jejunostomy tube feeding.
- Community-based programs to discourage and deal with excessive alcohol intake, to promote tobacco smoking awareness, and to avoid exposure to aflatoxin and other food toxins and measures taken to reduce the pandemic of obesity and diabetes are vital for lowering the incidence of HCC from nonviral liver disease (Fan et al, 2009).

### Common Drugs Used and Potential Side Effects

- Antiemetics may be used for vomiting.
- Diuretics are used commonly; monitor side effects carefully.
- Chemotherapy may include cisplatin, interferon, doxorubicin, and fluorouracil.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.
- Use of prebiotics (inulin and oligosaccharides) and silymarin may be protective.
- Polyphenols, mainly flavonoids and tannins, prevent oxidative stress-induced injury (Soory, 2009). Resveratrol has anti-inflammatory action through hepatic cyclooxygenase (COX-2) inhibition (Luther et al, 2009).
- Vitamin D<sub>3</sub> can be used to treat HCC, but hypercalcemia limits its use; a lower dose is possible if fish oil is given at the same time (Chiang et al, 2009).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Hepatic cancer from hepatitis C virus infection warrants maintaining a lean weight to prolong life.
- Teach the patient about the signs of deficiency of vitamins K and C, such as bleeding gums and easy bruising.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.
- Offer tips for managing jejunostomy tube feeding safely at home under sanitary preparation and storage methods.

# KIDNEY, BLADDER, AND URINARY TRACT CANCERS

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Asset provided by Anatomical Chart Co.

### DEFINITIONS AND BACKGROUND

**Urinary tract cancers** affect more than 50,000 Americans each year. Men are more prone to this type of cancer than women. Surgery is usually required; prognosis with early intervention is good. Survival has improved. Fruit, extra fluids, vitamin C, retinol, daily multivitamin supplements, and green and nonherbal tea tend to be protective. It is likely that vitamin D<sub>3</sub> plays a role as well (Grant, 2009).

**Renal cell cancer (RCC)** accounts for approximately 2% of cancers worldwide. It is most common in persons over 45 years of age, particularly among blacks. Blood in the urine and an increased frequency of urination are the most common symptoms. Smoking, long-term dialysis, occupational exposure to dyes, rubber, and leather products are risk factors. Hypertension increases the risk of RCC in both sexes, while effective blood pressure control may lower the risk (Weikert et al, 2008). Finally, obesity contributes to morbidity and mortality in renal cancer (Anderson and Caswell, 2009). Total consumption of fruits, vegetables, fat, red meat, processed meat, poultry, and seafood are not associated with the risk of RCC (Lee et al, 2008; Weikert et al, 2006). RCC can often be cured if it is diagnosed and treated when still localized to the kidney. Fortunately, the majority of patients are diagnosed at that time. Surgical resection or nephrectomy may be needed.

**Wilms' tumor** (nephroblastoma or embryoma of the kidney) is a highly malignant tumor occurring almost exclusively in children younger than 6 years of age. It is more common in girls than in boys, and in African-American children. Symptoms and signs include weight loss, anorexia, enlarged kidney,

hypertension, fever, anemia, and abdominal pain. A cure may be possible if metastasis has not occurred before nephrectomy. There is now an overall survival rate of 85%, and treatment-related morbidity has been reduced by chemotherapy (Gommersall et al, 2005). Metastasis to lungs, liver, and brain can occur.

**Bladder cancer** can be caused by factors such as smoking, exposure to chemicals at work (such as hair dyes, textiles, and paint), old age, chronic bladder infections, and infectious parasites. Well water should be tested for arsenic. Bladder cancer is more common in Caucasians. It can often be cured in the early stages using surgery, radiation, chemotherapy, or immunotherapy. If dual nephrectomy is needed, as in a stage 5 tumor, permanent dialysis may be required until a transplant is possible.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutation of the VHL gene is associated with the development of RCC and the overexpression of the angiogenesis pathway (George and Bukowski, 2009). Some cases of Wilms' tumor are related to defects in either Wilms' tumor 1 (WT1) or Wilms' tumor 2 (WT2) or to several other genes.

<b>Specific Clinical/History</b>	Smoking history	Alb, transthyretin
	Painful urination	CRP
Height	Frequent urinary tract infections	BUN
Weight	Incontinence	Creat
Weight changes	Abdominal CT scan	Gluc
BMI (obesity?)	Cystoscopy	H & H (low?)
Growth percentile in child	X-ray (intravenous pyelogram)	Serum Fe, ferritin
Diet history	Bone scan for metastasis	Transferrin
BP (increased)	Urine cytology	Liver function tests
I & O; dehydration?		ALT
Hematuria		
Anorexia		
Enlarged kidney?		
Fever?		
Abdominal or lower back pain		
	<b>Lab Work</b>	
	Urinalysis	
	Ca <sup>++</sup> , Mg <sup>++</sup>	
	Na <sup>+</sup> , K <sup>+</sup>	

## SAMPLE NUTRITION CARE PROCESS STEPS

## Unintentional Weight Loss

**Assessment Data:** BMI 20, down from the usual BMI of 24. Poor appetite, stomatitis. Taking temsirolimus for renal cancer.

**Nutrition Diagnosis (PES):** Unintentional weight loss related to anorexia and stomatitis as evidenced by a BMI of 20 when the usual is 24.

**Intervention:** Food-Nutrient Delivery—Suggest small, frequent meals of low-acid, mild foods and beverages. Educate the patient about foods that are more easily tolerated with stomatitis. Counsel about the long-term efforts to regain lost weight to tolerate cancer therapies; surgery is a possibility.

**Monitoring and Evaluation:** No further weight loss; tolerating medication and treatments while managing side effects.

## INTERVENTION

## OBJECTIVES

- If needed, prepare patient for surgery and for postsurgical wound healing.
- Control the side effects of radiotherapy and chemotherapy.
- Promote normal growth and development, as far as possible, in children and teens.
- Control hypertension; correct anemia, which is common.
- Maintain adequate hydration.
- Minimize unplanned weight loss.
- Promote adequate bowel function.

## FOOD AND NUTRITION

- Provide adequate energy and protein according to age and to compensate for weight loss. In obese adults, weight loss regimens are not recommended until several months after surgery.
- Restrict excessive sodium with hypertension. Provide sufficient potassium, calcium, and magnesium; supplement if necessary.
- Monitor protein tolerance and adjust according to lab values, blood pressure, edema, and other signs of renal failure.
- Ensure adequate fluid intake, particularly water.
- Follow the Mediterranean or DASH diets, which encourage plenty of fruits and vegetables that are rich in antioxidants. Include fish that contains omega-3 fatty acids.

## Common Drugs Used and Potential Side Effects

- Rapamycin (mTOR) controls translation of key proteins during cancer cell proliferation; temsirolimus is the first mTOR inhibitor approved for the treatment of advanced RCC (Hudes et al, 2009). Side effects may include hyperglycemia, hyperlipidemia, stomatitis, rash, or even pneumonitis.

- Interferon and interleukin-2 may also be used in advanced kidney cancer. Interferon often causes patients to have flu-like symptoms, and nausea and vomiting are common; interleukin-2 can cause nausea and vomiting or fluid retention. Sunitinib (Sutent) is useful in advanced kidney cancer where chemotherapy has not been effective.
- Zoledronic acid is a bisphosphonate that is approved for preventing fractures after bone metastasis from renal cancer.
- For **bladder cancer**, chemotherapy often involves carboplatin, fluorouracil, cisplatin, cyclophosphamide, methotrexate, or vinblastine. Many side effects are common, including nausea, anorexia, diarrhea, or vomiting. The use of gemcitabine and cisplatin is as useful as older treatments.
- **Wilms' tumor** requires perioperative vincristine and dactinomycin, with or without doxorubicin or radiotherapy (Gommersall et al, 2005).

Herbs, Botanicals, and Supplements  
(see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician. Herbal preparations are subject to contamination with metals such as mercury or may contain potassium—all of which can be harmful to the kidney.
- Some studies promote the use of green tea for prevention, but others have not identified its efficacy.

NUTRITION EDUCATION, COUNSELING,  
CARE MANAGEMENT

- Discuss the side effects that the patient is experiencing in light of the therapies used (e.g., radiation therapy, chemotherapy, or surgery).
- Discuss normal growth and/or desirable weight for the patient. Obesity is a concern.
- Highlight meals that are attractive so that the patient eats as well as possible. Cut down on fried meats and fats.
- Discuss how to manage anemia through appropriate medications or dietary measures.
- There is no risk for bladder or renal cancers from the use of artificial sweeteners.

## Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.
- In some countries, schistosomiasis infestation is a risk. Monitor for water and food safety.

# LUNG CANCER

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

**Bronchiolar carcinoma  
infiltrating growth**

Adapted from: Moore KL, PhD, FRSM, FIAC & Dalley AF II, PhD. *Clinical Oriented Anatomy*, 4th ed. Baltimore, Lippincott Williams & Wilkins 1999.

## DEFINITIONS AND BACKGROUND

Lung (bronchial) cancer begins in the lungs and is the most common type of cancer in the Western world. There are two main types of lung cancer: non-small-cell lung cancer and small-cell lung cancer. **Non-small-cell lung cancer (NSCLC)** has three major subtypes: adenocarcinoma (40% of cases), squamous carcinoma (30–35% of cases, slow growing, and

formerly called epidermoid carcinoma), and large-cell carcinoma (affecting 5–15% of cases). NSCLC is the leading cause of cancer-related death in the United States (Budde and Hanna, 2005).

**Small-cell lung cancer (SCLC)** is a more aggressive type of lung cancer that comprises 15% of all lung cancer diagnoses. It is highly correlated to smoking. SCLCs grow quickly but tend to respond to specific chemotherapy protocols. Oat cell cancer is a highly fatal form of SCLC; aggressive chemotherapy is needed.

In 85% of cases, smoking causes lung cancer. Heavy tobacco or marijuana smokers are 25 times more susceptible to lung cancer. Other causes include exposure to industrial chemicals, radon, and passive smoke. Smoking is associated with lower levels of vitamin C. The best protection against lung cancer is the avoidance of airborne carcinogens and increased consumption of fruits and vegetables (Cranganu and Camporeale, 2009).

Foods rich in flavonoids may protect against certain types of lung cancer. Onions and apples have quercetin. Vitamin E food sources (gamma-tocopherol) are protective; supplemental alpha-tocopherol is not. Resveratrol may be beneficial, but excess alcohol is not (Barnardi et al, 2010). Antioxidant sources seems to be an important issue.

The focus should be on food; supplemental beta-carotene is a concern (Roswall et al, 2010) whereas dietary beta-carotene is protective against lung cancer. Cryptoxanthin, alpha-carotene, and ascorbic acid need to be investigated further as potentially protective factors (Comstock et al, 2008). Isothiocyanates from cruciferous vegetables are anti-carcinogenic. Because the glutathione S transferase M1 (GSTM1) gene promotes urinary isothiocyanate excretion, the reduced lung cancer risk with higher isothiocyanate intake may be slightly stronger among individuals with a deletion of GSTM1 and GSTT1 (Carpenter et al, 2009; Lam et al, 2009). Novel interventions to prevent lung cancer should be developed based on the ability of diet and dietary supplements to affect reprogramming of the epigenome (Stidley et al, 2010).

Lung cancer's 5-year survival rate is only 15%, which is worse than many other types of cancer. Cancer cells of the lung often spread to the brain, bone, liver, and skin. Radiation and chemotherapy are needed, but surgery after standard chemotherapy and radiation can be an option for some patients. Medical nutrition therapy is often required for the nutrition-related side effects of cancer treatment, which include anorexia, nausea and vomiting, and esophagitis (Cranganu and Camporeale, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Eight genes are commonly silenced in lung cancer and are associated with risk. Smoke-induced methylation may reduce HtrA3 expression, which is one concern (Beleford et al, 2010). Promoter methylation factors are controlled with the use of leafy green vegetables, folate, and the use of multivitamins (Stidley et al, 2010). Epidermal growth factor receptor (EGFR) mutations in tumors are prognostic markers in patients with early stage lung cancer. Tumor microRNAs may help to predict SCLC patients who are resistant to chemotherapy.

Specific Clinical/History	Recurring	Lab Work
Height	pneumonia or bronchitis	Partial pressure of carbon dioxide (pCO <sub>2</sub> )
Weight	Fatigue	Partial pressure of oxygen (pO <sub>2</sub> )
BMI	Hoarseness	CEA
Diet history	Shortness of breath	Alb,
I & O	Swelling of neck or face	transferrin
Weight loss?	Bronchoscopy	Gluc
Fever of unknown cause	Biopsy	CRP
Persistent cough	MRI, CT scan	Ca <sup>++</sup> , Mg <sup>++</sup>
Bloody sputum	Thoracentesis	Na <sup>+</sup> , K <sup>+</sup>
Chest pain	Chest x-ray	ALT (increased)
	Sputum cytology	

## INTERVENTION

### OBJECTIVES

- Patient must stop smoking, avoid passive smoke, or discontinue exposure to radon or other contributors.
- Prepare patient for therapy (e.g., surgery, radiation, or chemotherapy).
- Meet energy needs, which are often elevated as much as 30% above normal. The use of indirect calorimetry to measure REE is more accurate than estimation (American Dietetic Association, 2010).

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Intake From Parenteral Infusion

**Assessment Data:** Inability to eat due to esophagitis over the past 1–2 days. Patient has been receiving chemotherapy treatment for lung cancer. Patient is only on PPN. Patient's weight has been stable at home; lung cancer is a recent diagnosis yet quite advanced. Labs: WBC 1.8, slightly below normal for Na, phosphorus, magnesium, Hgb and Hct.

#### Nutrition Diagnosis (PES):

- 1- Inadequate intake from parenteral infusion (NI 2.3) related to limitations of peripheral access as evidenced by the inability to meet energy requirements through PPN.
- 2- Inadequate oral food intake (NI 2.1) related to esophagitis as evidenced by the inability to swallow and decreased food intake over the past 2–3 days.

**Interventions:** Food and Nutrient Delivery: ND 4.2 Insert enteral nutrition feeding tube; NPO until PEG is surgically placed. ND 2.2 Modify rate, concentration, composition, or schedule. Once the PEG was placed, Jevity 1.5 was started 8 hours later at a rate of 35 ml/h. This was increased as tolerated by 10 milliliters every 8 hours until the goal rate of 65 ml/hr was reached.

**Education:** Discuss appropriate feeding using a PEG tube; safe handling; signs of intolerance.

**Counseling:** Adequate intake of tube feeding and how to adjust when oral intake is possible.

**Coordination of Care:** RC 1.3 Collaboration/referral to other providers; patient to have home health; instruct patient on tube feeding at home.

**Monitoring and Evaluation:** Patient tolerating goal rate of 65 ml/hr; discharged from hospital. Follow patient weight, tolerance, and intake status in 1 week. Evaluate for progress back to oral diet if esophagitis subsides.

- Maximize intake through side-effects management. Cachexia, infections, atelectasis, syndrome of inappropriate antidiuretic hormone (SIADH), esophagitis, weight loss, and anorexia may occur.
- Minimum weight loss.
- Maximize pulmonary health and improve quality of life. Increase disease-free time.

## FOOD AND NUTRITION

- Increase the intake of protein, CHO, energy, and fluids.
- Tube feedings are highly recommended if weight loss, decreased appetite, dehydration, or electrolyte imbalance occurs.
- Alter diet as appropriate for side effects (see general cancer entry). Adequate vitamin-mineral intake should come from diet as much as possible. Providing medical nutrition therapy may help to improve protein and calorie intake, which may prevent weight loss and improve quality of life (American Dietetic Association).
- Small, frequent meals may be beneficial.

- If oral diet is possible, promote a protective diet. Include citrus fruits, vegetables, sesame seeds and pecans (for gamma-tocopherol), quercetin (apples and onions) and other flavonoids, selenium, lycopene, carotenoids, and natural estrogens (such as soy foods). Use curcumin as seasoning if tolerated.
- Include phytosterols from sunflower seeds, pistachio nuts, sesame seeds, and wheat germ (Phillips et al, 2005).
- Include more omega-3 fatty acids from fish, shellfish, flaxseed, and walnuts.
- Include resveratrol from red grapes and juice, berries, peanuts, or red wine if tolerated.

### Common Drugs Used and Potential Side Effects

- Cytotoxic drugs are often used. Vincristine can cause severe constipation.
- With methotrexate, nausea and vomiting are common; doxorubicin (Adriamycin) causes stomatitis, anorexia, hair loss, and diarrhea. Coadministration of methotrexate with intravenous glucose may alleviate some of the toxic gastrointestinal (GI) effects.
- Cyclophosphamide (Cytoxan) and other combinations of therapy may cause anorexia, stomatitis, nausea, or vomiting.
- Toxicity is far less than with docetaxel if vitamin B<sub>12</sub> and folate supplements are used (Budde and Hanna, 2005).
- Tarceva modestly improves survival in NSCLC patients.
- With immunotherapy, bacillus Calmette-Guérin (BCG) vaccine is often used.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- The use of complementary and alternative medicine by lung cancer patients is prevalent. Clinicians should investigate to avoid any potential side effects and interactions with conventional therapies (Cranganu and Camporeale, 2009). Herbs and botanical supplements should not be used without discussing with the physician.
- Five promising herbs have been identified in Chinese herbal medicine (CHM) that, when used in conjunction with chemotherapy, may improve quality of life in NSCLC (Chen et al, 2009).
- Luteolin, 3',4',5,7-tetrahydroxyflavone, exists in many types of plants and in Chinese medicinal herbs; it functions as an antioxidant with anticancer properties (Lin et al, 2009). Luteolin is found in carrots, celery, olive oil, oregano, peppers, peppermint, rosemary, and thyme.
- Avoid beta-carotene supplements. Diet is more protective.
- Clinical trials using dietary garlic, selenium, N-acetylcysteine, vitamins B<sub>6</sub> and C are needed.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss alternate methods of intake if oral is not feasible.
- A diet high in antioxidant-rich foods such as fruits, vegetables, and spices is protective and a prudent preventive strategy (Roswall et al, 2010).
- Discuss the side effects of drugs being used.
- Dietary acrylamide affects carcinogenesis but not through genetic alterations (Hogervorst et al, 2009). Researchers are reviewing its role from heat-treated foods.
- Self-reported smoking consistently explains approximately 50% of the inequalities in lung cancer risk due to differences in education (Menvielle et al, 2009). Smokers who quit will allow their lung tissues to repair much of the damage.
- Smokers who cannot quit should use a brand of cigarettes with lower nicotine and low tar. Avoid smoking prior to or with meals; smoking may decrease appetite.
- Chewing tobacco or snuff is also carcinogenic and should be stopped.
- Offer tube feeding or nutritional build-up education as appropriate.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.
- If tube feeding is needed, safe preparation, handling, storage, and administration will be important.

## PANCREATIC CANCER

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### DEFINITIONS AND BACKGROUND

Pancreatic cancer is the fourth most common cause of death from cancer in men and the fifth for women, primarily occurring between 65 and 79 years of age. Development of pancreas cancer progresses over many years before symptoms appear, and many people with pancreatic cancer die within 6 months of diagnosis. Nearly all pancreatic cancers are primary pancreatic adenocarcinomas.

About 50–70% of patients have cancer in the head of the pancreas, and 50% have cancer in the body and tail. Patients who have cancer in the head of the pancreas often present with cholangitis, nausea, anorexia, weight loss, new-onset diabetes, light-colored stools, dark urine, steatorrhea, jaundice, and pruritus. Those who have cancer in the body or tail of the pancreas present with vague abdominal pain, dyspepsia, nausea, intermittent diarrhea, unexpected diabetes, and constant back pain. When there are spontaneous blood clots in the portal blood vessels, this may be associated with pancreatic cancer; this thrombophlebitis is called Trousseau sign.

Risks for pancreatic cancer increase with age. It is slightly more common in men, in smokers, in African-Americans, and in people who are obese. Almost a third of the cases of pancreatic cancer are due to cigarette smoking. Persons with a history of pancreatitis are also at risk; type 2 diabetes is not a true risk factor. Diets high in red meat or low in fruits

and vegetables may also be linked to pancreatic cancer. Doses of alcohol greater than 30 grams per day contribute to only a modest increase for this type of cancer.

Exercise, such as walking 4 hours or more weekly, may protect against this cancer. Good folate, B<sub>12</sub>, and pyridoxine status also helps (Schernhammer et al, 2007), as does an increased intake of citrus fruits (Bae et al, 2009). Lifestyle choices are the most preventive steps; cut down on smoking, alcohol and poor food choices (Whitcomb and Greer, 2009).

Nutrition intervention together with chemotherapy improves outcomes in these patients. An increased risk has been found for dietary intakes of saturated and polyunsaturated fat (Thiebault et al, 2009; Zhang et al, 2009). A diet high in omega-3 fatty acids may mitigate pancreatic precancer by inhibition of cellular proliferation through induction of cell cycle arrest and apoptosis (Strouch et al, 2009). DHA may be the primary fatty acid that is beneficial. However, the use of supplemental omega-3 fatty acids is not recommended (American Dietetic Association, 2010).

Malignancy in the pancreas has a high mortality rate from a lack of early symptoms, symptoms that mimic other conditions, and rapid metastasis to other organs. Medical treatment consists of radiation, chemotherapy, immunotherapy, or vaccine therapy. When the tumor has spread (metastasized) to other organs such as the liver, chemotherapy alone is usually used. The standard chemotherapy drug is gemcitabine, which can help some patients.

Unfortunately, only about 20% of patients with pancreatic cancer have a form that can be resected. **Whipple's procedure** (pancreaticoduodenectomy) involves many operations. The entire duodenum is usually removed, and the pancreas, gallbladder, and spleen may also be removed. It has many nutritional implications (Petzel, 2005; Tang et al, 2005). After surgery, the diet can be liberalized after 10–14 days, adding one new food at a time and using supplements when appetite is poor.

Survival rates have improved; approximately 30% will live for 3 years after diagnosis and treatment. But the 5-year survival rate is low; 95% of the people diagnosed with it will not be alive 5 years later.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Five to ten percent of cases are related to family history, such as mutations in BRCA2 or PALB2 genes, Lynch syndrome, Peutz-Jeghers syndrome, familial atypical mole-malignant melanoma (FAMMM), familial adenomatous polyposis, or mutations in the CDKN2A tumor suppressor gene. Much research is going toward understanding the genes in pancreatic cancer (Hruban et al, 2008). Folate genes may be involved, but more studies are needed.

<b>Specific Clinical/ History</b>	Throm- bophlebitis (Trousseau sign).	Bilirubin (increased) PT (increased) Gluc (increased)
Height	Fatigue	Serum lipase
Weight	Ascites	(increased)
BMI	Angiography	Secretin
Rapid weight loss	Abdominal CT scan or MRI	PSCA levels
Midepigastic pain	Endoscopic ultrasound	Serum amylase (increased)
Temperature	Fine-needle biopsy	ALT, AST (increased)
BP	Endoscopic retrograde cholangiopan- creatography (ERCP)	Transferrin Serum insulin TLC (varies) Serum B <sub>12</sub> , folic acid Homocysteine levels Cholecystokinin
Jaundice, pruritus	<b>Lab Work</b>	Alb
Dark urine?	Ca 19–9 (>37 U/mL)	CRP
Biliary obstruction?	Elevated microRNAs (miR-155, miR196a)	Chol, Trig H & H Ca <sup>++</sup> , Mg <sup>++</sup> Na <sup>+</sup> , K <sup>+</sup>
Pancreatic insufficiency (indigestion, cramping, bloating)	Alk phos (increased)	
Belching		
Steatorrhea or loose stools		
Anorexia		
Nausea and vomiting		

## SAMPLE NUTRITION CARE PROCESS STEPS

### Undesirable Food Choices

**Assessment Data:** BMI 20, recent weight loss of 2#. Diet history reveals high red meat and saturated intake, low use of fruits and vegetables. Dx pancreatic cancer in past month.

**Nutrition Diagnosis (PES):** Undesirable food choices related to nutrient density and cancer diagnosis as evidenced by diet history showing high intake of red meats and low intake of fruits and vegetables.

**Intervention:** Food-nutrient delivery—offer acceptable fruit and vegetable choices and juices. Educate the patient and family about the role of diet in cancer. Counsel about tips for managing symptoms, weight changes, and anorexia while including protective food choices. Coordinate care with the medical team for home care and potential hospice care.

**Monitoring and Evaluation:** No further weight loss; good tolerance for small meals that are nutrient-dense but not high in fat.

## INTERVENTION

## OBJECTIVES

- Reduce or control nausea and vomiting.
- Prevent or correct weight loss, which is associated with poor outcomes, and restore lean body mass.
- Control side effects of therapies and the disease such as diabetes, anemia, pancreatic fistula, wound infection, bile leak, cholangitis, dumping syndrome, weight loss, and lactose intolerance (Petzel, 2005).
- Provide foods or supplements that include all necessary nutrients to prolong health. Augment nutritional intake; correct anemia. Include protective foods.
- Monitor for depression; encourage the use of antidepressants if needed to help with appetite.
- Manage problems such as pancreatic cancer–related diabetes and vitamin B<sub>12</sub> malabsorption.
- Parenteral nutrition (PN) is indicated mainly for perioperative use in patients with known malnutrition preoperatively. Postoperatively, tube feeding is the nutrition support method of choice.
- Wean off tube feeding with increasing oral intake and resolving gastroparesis, usually 4–6 weeks postoperatively.

## FOOD AND NUTRITION

- **For pancreatic insufficiency:** Medium-chain triglycerides (MCT), fat-soluble vitamins (water-miscible form), and essential fatty acids (EFAs) should be included. Calcium, selenium, zinc, and iron may become deficient unless supplemented.
- After Whipple's procedure, if pain is severe, tube feeding should be attempted before CPN. If possible, feed after bowel sounds return. Pancreatic enzyme replacement will be needed. Use a low-lactose, low-fat diet (40–60 g) and omit fried foods, nuts, and seeds.

- Small meals are best tolerated—six to eight feedings may be better tolerated than three large meals. Delayed gastric emptying is common, so avoidance of simple sugars and hot liquids may also be needed.
- Increased energy and protein intake should be provided to restore lost weight, unless the patient is hyperglycemic or has extensive liver impairment. Carbohydrate control may be needed to manage diabetes.
- Include protective foods, particularly tomato products for lycopene, other vegetables, and citrus fruits (Bae et al, 2009; Nkondjock et al, 2005). Onions, garlic, beans, orange and yellow vegetables, spinach, broccoli, kale, and raw vegetables are particularly protective.

### Common Drugs Used and Potential Side Effects

- Chemotherapy may include gemcitabine.
- Pancreatic enzymes (pancrelipase and pancreatin) are given. Enteric coating aids in maintaining the integrity of enzymes until they reach the small intestine. If a pork allergy is present, there may be a reaction to these enzymes; a pork-free product is PAN-2400. As much as 20,000–30,000 units of lipase may be needed per meal; 10,000 units may be needed with snacks. They must be swallowed whole and not chewed.
- Insulin may be needed if the patient is hyperglycemic. In islet cell tumors, hypoglycemia may occur instead. Monitor with meal timing.
- Acid-reducing medications (such as proton-pump inhibitors or H<sub>2</sub> blockers) are usually needed.
- Vitamin B<sub>12</sub> supplements may be required with total pancreatectomy, particularly with steatorrhea.
- Water-miscible fat-soluble vitamins A, D, E, and K will be needed until intake of pancreatic enzymes is sufficient. Brands may include Vitamax, Source CF, and ADEKs.
- Antiemetics, diuretics, and analgesics may be needed. Monitor side effects according to medications prescribed.
- Calcium carbonate twice daily may be useful to help bulk stools that are loose. Antidiarrheal medications (e.g., Lomotil, opiates, or Imodium) may be needed if loose stools are persistent. Guar gum and psyllium can be used to add soluble fiber.
- Targeted drug therapy blocks chemicals that signal cancer cells to grow and divide. Erlotinib (Tarceva) is usually combined with chemotherapy for advanced pancreatic cancer.
- A pancreatic cancer vaccine is under study.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.
- There are potential drug-nutrient interactions (e.g., anti-coagulant and anti-hypertensive medications/herbal supplements) with the use of EPA fish oil supplements; they are not recommended for pancreatic cancer (American Dietetic Association, 2010).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss specific dietary recommendations appropriate for the patient's condition and therapies.
- Discuss the use of pancreatic enzymes.
- Provide education for diet and jejunostomy feeding.
- With pancreatectomy, a diabetic diet may be absolutely essential. Discuss the rationale with the patient.
- Explain how diet affects malabsorption in regard to fat, protein, vitamins, and minerals.
- Research does not support the theory that high intakes of sugar or sugar-sweetened beverages cause this cancer.
- Lactase enzymes may be helpful if lactose intolerance persists.
- Family members may need genetic counseling. The fundamental problem underlying pancreatic cancer is altered genetics (Whitcomb and Greer, 2009).

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

# SKIN CANCERS

## NUTRITIONAL ACUITY RANKING: 1–2

### DEFINITIONS AND BACKGROUND

Skin cancer is the most common cancer in the United States, and the incidence is increasing. Vitamin D is made in the skin upon exposure to solar radiation; regular use of a tanning bed that emits vitamin D–producing ultraviolet (UV) radiation is associated with higher 25-hydroxyvitamin D concentrations, which may benefit the skeleton but not necessarily the skin. UVB-induced skin damage places individuals more at risk for basal cell and squamous cell carcinomas than for malignant melanoma.

Risk factors for skin cancer include certain types or a large number of moles; excessive exposure to sun and ultraviolet light with susceptible vitamin D receptor genes; family or personal history of skin cancer; freckles; light skin color, hair color, or eye color; and sunburns early in life. Since carcinogenesis and photoaging are multistep processes, tumor development may be halted at several points. The intake of flavonols may be protective (McNaughton et al, 2005).

Deficiency of the prohormone calcidiol (25OH vitamin D<sub>3</sub>) seems to be associated with cancer, but not calcitriol (Tuohimaa, 2008). Daily brief exposure of a substantial area of the skin to ultraviolet light, climate allowing, provides adults with a safe, physiologic amount of vitamin D, equivalent to an oral intake of approximately 10,000 IU vitamin D<sub>3</sub> per day; the plasma 25-hydroxyvitamin D (25(OH)D) concentration potentially reaches 88 ng/mL (Vieth, 2009). The occupational sun exposure rate is positively correlated with a lower risk of overall organ mortality. Adequate vitamin D<sub>3</sub> is protective; benefits of sunlight may outweigh some risks (Krause et al, 2006).

Skin cancer and photoaging are the result of excessive ultraviolet radiation exposure. UVB (280–315 nm) in natural

sunlight is associated with skin cancer through keratinocyte proliferation and cell cycle progression (Han and He, 2009). Excessive UVB light exposure in childhood promotes the development of melanomas (Wolpowitz and Gilchrest, 2006).

**Basal cell cancer (BCC)** starts as small, shiny, firm nodules that enlarge slowly, bleed and scab, then heal, and finally repeat the cycle. These are the most common type of skin cancer. Basal cell tumors should be removed to avoid destruction to other tissues. Most basal cell carcinomas occur on parts of the body that are excessively exposed to the sun—particularly the face, ears, neck, scalp, shoulders, or back. Rarely, these tumors come from exposure to arsenic or radiation, open sores that will not heal, chronic inflammatory skin conditions, and complications of burns, scars, infections, vaccinations, or tattoos.

**Squamous cell carcinoma (SCC)** originates in the middle layer of the epidermis and may develop on sun-damaged skin or even in the mouth lining or tongue. This type begins as a reddened area with a scaly, crusted surface that does not heal. A precursor is often an actinic keratosis (solar keratosis) that appears on the bald scalp, face, ears, lips, backs of the hands and forearms, shoulders, neck, or any other areas of the body that are frequently exposed to the sun. SCC may have the appearance of a wart and eventually becomes an open sore. Removal is important before it can spread. Leukoplakia anywhere in the mouth may be an early sign. SCC is more common in men than in women and is most likely to occur after age 50. In addition, people who use tanning beds are twice as likely to get SCC.

**Melanoma**, the deadliest type of skin cancer, originates in the melanocytes and tends to spread rapidly. Biopsy is essential. It is the most common cancer for women aged 25–29 years and the second most common cancer for women aged 30–34 years. Most melanomas are black or brown, but some may even be skin-colored, pink, red, blue, or white. Early warning signs of melanoma have been identified by the acronym “ABCDE” (A stands for Asymmetry, B stands for Border, C for Color, D for Diameter, and E for Evolving or changing was recently added). Individuals who have had breast cancer are at risk for melanoma and vice versa. Disfiguring surgery is no longer necessary to remove a melanoma. Mohs micrographic surgery is available.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The melanocortin 1 receptor (MC1R) is a highly polymorphic G protein-coupled receptor; MC1R alleles have been associated with a red hair/fair skin phenotype, increased incidence of skin cancer, and altered sensitivity to ultraviolet (UV)

radiation (Smith et al, 2007). Specific alleles of the gene that codes for the melanocortin 1 receptor are also predictive of skin cancer risk, independent of skin type and hair color (Lynde and Sapra, 2010).

<b>Specific Clinical/History</b>	Changes in skin or mole	H & H
Height	Itching, bleeding of mole	Serum ferritin
Weight	Nausea and vomiting	Transferrin
Weight changes	Anorexia	Ca <sup>++</sup> , Mg <sup>++</sup>
BMI		Na <sup>+</sup> , K <sup>+</sup>
Diet history		Serum
Light-colored hair, skin, eyes		25(OH)D
	<b>Lab Work</b>	
	Alb	
	CRP	

## INTERVENTION

### OBJECTIVES

- Maintain appropriate weight for height.
- General healthy dietary guidelines should be followed.
- Prevent or correct nutritional deficiencies and improve patient tolerance of treatment.
- Minimize potential treatment side effects.
- Optimize immune function to increase effectiveness of therapy.
- Enhance quality of life.
- Ensure appropriate healing of surgical sites, if applicable.

### FOOD AND NUTRITION

- Eat a variety of foods, particularly fruits and vegetables and whole grains such as oats. Use flavonols such as apples, tea, and coffee.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Bioactive Substance Intake

**Assessment Data:** Diagnosis of skin cancer. Hx of tanning bed use for psoriasis. Diet history indicates low intake of fruits and vegetables. Patient has been following a macrobiotic diet to lose weight for 6 months, eating mostly rice.

**Nutrition Diagnosis (PES):** Inadequate bioactive substance intake related to low consumption of fruits and vegetables as evidenced by diet history.

**Intervention:** Food-nutrient delivery—Provide a nutrient-dense diet that includes flavonols and anti-inflammatory foods. Educate the patient about the role of bioactive substances in reducing future skin cancer risks. Counsel about returning to a balanced diet with plenty of phytochemicals.

**Monitoring and Evaluation:** Improved diet with balanced intake of nutrients and phytochemicals.

- A high-fat diet may influence the UV-induced inflammatory responses in the skin (Meeran et al, 2009). Choose a diet that is moderate in fat while controlled in saturated fat and cholesterol. Include good sources of omega-3 fatty acids regularly (i.e., salmon, tuna, mackerel, herring, and sardines).
- Use sugars, salt, and alcoholic beverages in moderation.
- If anemic, a diet that meets at least DRI requirements for blood-forming nutrients will be needed.
- Weight gain caused by fluid retention is commonly seen in patients receiving biological therapy (immunotherapy). Use a diet with 2–4 grams of sodium or fluid restriction if needed.
- Provide adequate amounts of vitamin D<sub>3</sub> and dietary beta carotene. Consumption of 40 IU/d of vitamin D(3) raises plasma 25(OH)D by approximately 0.4 ng/mL (Vieth, 2009).

## Common Drugs Used and Potential Side Effects

- Aldara skin cream reduces basal cell lesions without surgery.
- Interferon-α2b (Intron-A) is used in adult patients who have surgically treated melanoma considered at high risk of recurrence. This immunotherapy (biologic therapy) makes use of chemicals that occur naturally in the body.
- Immunomodulating agent histamine dihydrochloride (Maxamine), when used in combination with interleukin-2 (IL-2), improves survival for stage 4 malignant melanoma patients.

## Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.
- Evidence from clinical trials shows that a prolonged intake of 10,000 IU/d of vitamin D(3) poses no risk of adverse effects for adults (Vieth, 2009).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the rationale for spacing meals throughout the day to avoid fatigue.
- Offer recipes and meal plans that provide the nutrients required to improve status and immunological competence.
- Patients undergoing treatment should be allowed flexibility in their food selections, while focusing on high-energy, high-quality protein, and phytochemical-rich choices whenever possible.
- Offer recipes and menu options for individual planning.
- Use sunscreen with sun protective factor (SPF) 15 or higher and both UVA and UVB protection; apply sunscreen after about 10–15 minutes in the sun.
- Biofeedback and stress management techniques may be useful.
- Dietary protection is provided by carotenoids, tocopherols, ascorbate, flavonoids, or omega-3 fatty acids.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

## HORMONAL CANCERS

# BREAST CANCER

### NUTRITIONAL ACUITY RANKING: LEVEL 2–3

### DEFINITIONS AND BACKGROUND

Breast (mammary) carcinoma is the second most common cancer in women, with over 200,000 cases diagnosed annually in the United States. It affects one in eight women. Having routine breast screenings for cancer is important. When a woman has specific family history patterns that put her at risk for gene mutations, her primary care physician should suggest DNA testing, but only about 2% of women have this level of risk. Age >30, health history related to fertility, ovar-

ian function, and estrogen exposure play a role in the onset of breast cancer. Exposure to diets that produce high levels of estrogen seems to be most important in utero and after menopause; high estrogen levels during reproductive years seems to be protective. A longer duration of breastfeeding may be associated with a reduced risk. Breast cancer in men is less common and is generally preceded by gynecomastia.

Some breast cancer cells have a high proportion of estrogen and/or progesterone receptors in the nucleus. Those women who are ER/PR positive might benefit from hormonal therapy with tamoxifen or aromatase inhibitors; these drugs block hormone receptors in the cancer cell. Protein phosphatase 2A (PP2A) is a major cellular phosphatase that plays key regulatory roles in growth, differentiation, and apoptosis; its role in the suppression of breast cancer is being studied (Dupont et al, 2009).

Breast cancer may be related to oxidative stress. Receptor CXCR1 (IL-8) is a protein produced during chronic inflammation and tissue injury; it may play a role in breast cancer. Recent studies show that the intake of anthocyanins and ellagic acid can prevent cancer cells from developing (Stoner et al, 2009). Berries and pomegranates are particularly protective.

Being physically active is also protective, whereas obesity and Western dietary patterns increase cancer risk. Weight gain in the years preceding the onset of puberty is a promoter; increased fat cell adiposity increases estrogen availability at this time (Michels et al, 2006). Overweight breast cancer survivors commonly have metabolic syndrome (MetS) and elevated CRP (Thomson et al, 2009). Weight reduction is a reasonable goal.

**TABLE 13-17 Staging of Breast Cancer**

Stage 0	In situ—Cancer cells are present in either the lining of a breast lobule or a duct, but they have not spread to the surrounding fatty tissue.
Stage 1	Rarely metastasizing/noninvasive (<2 cm or 1 inch in diameter)—Cancer has spread from the lobules or ducts to nearby tissue in the breast; cancer has not spread to the lymph nodes.
Stage 2	Rarely metastasizing/invasive—The tumor can range from 2 cm to <5 cm in diameter (approximately 1–2 inches); sometimes, cancer may have spread to the lymph nodes.
Stage 3	Moderately metastasizing/invasive (≥2 inches)—Cancer cells have grown extensively into axillary (underarm) lymph nodes.
Stage 4	Highly metastasizing/invasive into other parts of the body, such as bone, liver, lung, or brain.

Eating soy foods yields greater benefits than taking isoflavone supplements (Li et al, 2005). Early exposure in childhood or early adolescence to phytoestrogens may be protective (Duffy et al, 2007).

Alcohol intake is a problem if folic acid intake is low; 600 micrograms of folic acid is protective. High intake of well-done meat and high exposure to meat carcinogens, particularly HCAs, may increase the risk of breast cancer (Zheng and Lee, 2009).

Breast cancer can be treated very effectively, particularly when it is diagnosed in the early stages. Staging of breast cancer is described in Table 13-17. Tumors are frequently found in the upper/outer quadrant of the breast (45%) and nipple area (25%), with 30% identified in other breast areas. In the early stages, a single nontender, firm, or hard mass with poorly defined margins may exist. Later, skin or nipple retraction, axillary lymphadenopathy, breast enlargement, redness, mild edema, and pain may occur. In the late stages, ulceration, moderate edema, and metastases to bone, liver, or brain are common.

Four standard types of therapy are used to treat breast cancer: surgery for the removal of cancerous tissue and, sometimes, other tissue; radiation therapy; chemotherapy; and hormonal therapy. New therapies are being researched through clinical trials.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Mutations in the *BRCA1* gene (on chromosome 17) result in an elevated risk of breast cancer and ovarian cancer (Kroiss et al, 2005). The *HER2* (Her2/neu, c-erb-2 or erb-2) gene produces a protein that acts as a receptor on the surface of all cells; some cancer cells have more receptors than normal, and they receive more messages to grow and

divide. The C677 T polymorphism of the folic acid (*MTHFR*) genotype increases the risk of postmenopausal breast cancer, particularly with low intakes of folate and vitamin B<sub>6</sub> (Maruti et al, 2009).

### Specific Clinical/History

Height  
Weight  
BMI  
Weight changes  
Diet history  
Anorexia, nausea  
Breast self-examination—masses  
Calcifications  
Biopsy  
Skin or nipple retraction  
Axillary lymphadenopathy

Breast enlargement  
Redness, mild edema, pain  
Ulceration, moderate edema  
I & O  
Temperature

### Lab Work

Estrogen receptors (positive or negative)  
Serum estrogen  
Carcinoembryonic antigen (CEA)  
Prolactin

Serum carotenoid levels  
Mg<sup>++</sup>, Ca<sup>++</sup>  
H & H  
Gluc  
Alk phos  
Erythrocyte sedimentation rate (ESR) to evaluate metastasis  
Complete blood cell count (CBC)  
Chol, Trig  
Alb, transthyretin  
CRP  
Mammography

## INTERVENTION

### OBJECTIVES

- Control side effects of therapy and treatments (e.g., local or extensive mastectomy, chemotherapy, external-beam radiation therapy, brachytherapy).
- Promote intake of phytochemicals and protective foods to reduce inflammation.
- Promote good nutritional status to reduce future incidents and recurrence. Encourage regular breast self-examinations, physical activity, and other healthy behavior changes.
- Maintain or attain appropriate weight for height. Obese patients should lose weight before treatment; be careful not to lose lean body mass (LBM).
- Increase the likelihood of survival, wellness, and improved quality of life.
- For mastectomy patients, promote wound healing and prevent infection.

### FOOD AND NUTRITION

- Because most studies have found that exercise, weight reduction, low-fat diet, and reduced alcohol intake are associated with a decreased risk of breast cancer, a diet with controlled total energy and fat is helpful (Cummings et al, 2009). While the Western style of diet should be discouraged (Adebamowo et al, 2005), meat, eggs and low-fat dairy foods can be used in moderation (Pala et al, 2009). Use fewer processed meats and less red meat, particularly if well-done (Zheng and Lee, 2009).

## SAMPLE NUTRITION CARE PROCESS STEPS

**Poor Nutrition Quality of Life**

**Assessment Data:** Status post partial mastectomy; dysphagia and cachexia noted. Poor appetite and BMI dropped to 18.5 from 24 over the past 6 months.

**Nutrition Diagnosis (PES):** Poor nutrition, quality of life (NB-2.5) related to dysphagia, depression, and cachexia as evidenced by appetite <50% and BMI of 18.5.

**Nutrition Intervention:**

**Food and Nutrient Delivery:** ND 1.3 specific food/beverage: Puree, nectar, thick liquids and thinned soft foods. ND 3.1.1 commercial beverage supplement: 1 can 2× daily. ND 3.2.1: MVI.

**Counseling:**

**C-2.2 Goal setting:** Minimize weight loss, maintain adequate weight loss, monitor for signs and symptoms of aspiration, improve quality of life with exercise, and improve intake of phytochemical and nutrient-dense foods and tea.

**Coordination of Nutrition Care:**

RC 1.1 Interdisciplinary team meeting with nursing, social worker, recreational therapy, physical therapy, speech therapy.

**Monitoring and Evaluation:** No signs of aspiration, nausea, vomiting, speech evaluation follow-up, promote wound healing and prevent infection; reassess nutrition and quality of life.

- Promote use of the Mediterranean diet (Cottet et al, 2009; Masala et al, 2006). Olive/sunflower/canola oils, grape juice, red wine, and cheese are beneficial. Calorie restriction and use of omega-3 fatty acids decrease inflammation (Jolly, 2005).
- High fiber diets reduce hormone production and decrease cancer risk (Gaskins et al, 2009). At least 5–9 fruits and vegetables (Ahn et al, 2005; Rock et al, 2005) and 6 grain foods daily should be encouraged. The fruits and vegetables should include sources of alpha- and beta-carotene, zeaxanthin, and lycopene. Berries, pomegranate, garlic, and spices such as curcumin should be used often. Use cruciferous vegetables often (Warin et al, 2009).
- Sources of choline and betaine should be included (Xu et al, 2009). Choline is found in beef liver, wheat germ, and eggs. Betaine is found in beets.
- Alcohol may promote estrogen receptor-positive tumors (Suzuki et al, 2005). Red wine and resveratrol may be acceptable; limit to one drink per day.
- While some women are estrogen-sensitive (Fang et al, 2005; Li et al, 2005), overall, soy-enhanced diets are significantly associated with a decreased risk of death and recurrence (Shu et al, 2009; Steiner et al, 2008). This may be due to a new phytochemical found in soy called glyceollin I (Zimmermann et al, 2010). An isoflavone-rich diet might include wild leafy greens (as in the Greek diet), celery stalks, shredded lettuce, sweet peppers, raw spinach, fresh lemon, and sprigs of fresh parsley.
- A general supplement also may be safely recommended for folic acid (Zhang et al, 2005), calcium, vitamin D, vitamin A, vitamin C, and vitamin E as alpha-tocopherol.

## Common Drugs Used and Potential Side Effects

- For patients who are **estrogen receptor positive**, hormonal therapy may be a breast cancer promoter; oral contraceptive use should be monitored or discontinued. Estrogen replacement (to prevent osteoporosis) increases risk levels.
- Antiestrogen therapy with tamoxifen (NoralDEX) may be prescribed to treat estrogen-dependent breast cancer or be used in women at high risk. Nausea, vomiting, and hot flashes are common side effects. Avoid high doses of soy when using tamoxifen.
- For patients who are **estrogen receptor negative**, hormonal therapy actually may be recommended (e.g., progesterone and androgen therapy). Megestrol acetate (a hormonal antineoplastic drug and a synthetic derivative of progesterone) may reverse anorexia and weight loss.
- Chemotherapy may be used. Cyclophosphamide (Cytosan) requires extra fluid intake. Doxorubicin, fluorouracil, and methotrexate are also commonly used; many gastrointestinal (GI) side effects are noted. Taste alterations are common for beef, chicken, and coffee. Anastrozole (Arimidex) can cause anorexia, weight changes, nausea, vomiting, dry mouth, constipation, and diarrhea. Gemcitabine (Gemzar) in combination with paclitaxel is used with metastatic breast cancer after failure of other chemotherapy.
- Trastuzumab (Herceptin) helps with early-stage HER2 breast cancer as an adjunct to chemotherapy to decrease recurrence.
- Repertaxin, originally developed to prevent organ transplant rejection, blocks receptor CXCR1 and kills breast cancer stem cells. It is under study in humans.

## Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician. Women with a history of breast cancer may seek out “natural” phytoestrogens in the belief that they are safe or perhaps even protective against recurrence, but studies do not support a protective role (Duffy et al, 2007). The following herbal/botanical supplements should be avoided by patients with breast cancer because of their phytoestrogen content: Ginseng, Ginkgo biloba, Licorice root, Black cohosh, Wild yam root, DHEA.
- Grape seed extract, berry powder, and pomegranate products are beneficial (Kim, 2005; Stoner, 2009). Dietary sources of omega-3 fatty acids, vitamin C, vitamin E, beta-carotene, selenium, and coenzyme Q10 may be of particular value.
- With the use of methotrexate (Rheumatrex), avoid echinacea because of potential damage to the liver.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Breast cancer detection projects are available throughout the United States; check with local chapters of the National Cancer Institute (NCI) and the American Cancer Society (ACS). Early detection of new tumors is crucial because lower stage tumors are much easier to control.

- Attain or maintain healthy body weight. Low total energy or lower fat dietary patterns may also be helpful (Elias et al, 2005). Reduce intake of sweets and high-glycemic index foods (Tavani et al, 2006). Eat a diet high in whole grains, fruits, and vegetables (Ahn et al, 2005).
- Discuss ways to make meals more appetizing, particularly if appetite is poor.
- Use of moderate amounts of soy may be encouraged. Increase use of cruciferous vegetables (Warin et al, 2009).
- Exercise and consumption of tea are important preventive factors to reduce depression among breast cancer survivors (Chen et al, 2010). Yoga and hypnosis may also be beneficial.
- Daughters of women with breast cancer should have a first mammogram before 40 years of age as a baseline and annually every 1–2 years thereafter. Lumps and changes should be reported immediately to a physician.
- Limit alcoholic beverages to one drink per day (Suzuki et al, 2005) and avoid high intakes of well-done meats and processed meats (Zheng and Lee, 2009).
- Calcium and vitamin D<sub>3</sub> supplementation may be indicated for patients who are menopausal or postmenopausal as they are at increased risk for developing osteoporosis.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

# CHORIOCARCINOMA

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Michael S. Baggish, Rafael F. Valle, Hubert Guedj, *Hysteroscopy: Visual Perspectives of Uterine Anatomy, Physiology and Pathology*. Philadelphia: Lippincott Williams & Wilkins, 2007.

### DEFINITIONS AND BACKGROUND

Choriocarcinoma involves a highly malignant neoplasm of the placenta with a secretion of human chorionic gonadotropin (hCG). It may develop in women after a molar pregnancy (where the fetus does not develop but a tumor develops instead), a miscarriage, or a full-term delivery.

Gestational choriocarcinoma occurs in approximately 1 in 20,000–40,000 pregnancies (Alvarez et al, 2005). It is more common among Asian women. Alternative names include chorioblastoma, trophoblastic tumor, chorioepithelioma, gestational trophoblastic disease, and gestational trophoblastic neoplasia. Rarely, a hydatidiform mole grows as a mass inside the uterus at the beginning of a pregnancy. When choriocarcinoma occurs in males, it presents as a testicular neoplasm, with skin hyperpigmentation (from excess beta hCG cross-reacting with the alpha MSH receptor), gynecomastia, and weight loss.

Diet affects the development of this type of cancer, because the placenta has such a large role in nutrient availability (Briese et al, 2005). Placental trophoblasts and immunomodulatory molecules are under investigation (Petroff et al, 2005). Phytoestrogens (PEs) induce biologic responses by mimicking or modulating the action or production of endogenous hormones; isoflavonoids and coumestrol increase progesterone receptor protein expression and decrease ERalpha expression (Taxvig et al, 2010).

Fatty acid synthase (FASN) is a tumor-associated marker found in all choriocarcinomas (Ueda et al, 2009). After the initial diagnosis, a careful examination is done to rule out metastasis. It can be fatal if there is metastasis to the kidney.

Gestational choriocarcinoma is responsive to chemotherapy; surgical excision or D & C is reserved for acute emergencies

(Alvarez et al, 2005). A hysterectomy is rarely indicated but may be used for some women under age 40.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Trophoblast factors are activated by hypoxia; interleukin (IL)-6, CD126, CD130, vascular endothelial growth factor (VEGF), and hypoxia inducible factor-1alpha (HIF-1alpha) are silenced in JEG-3 choriocarcinoma cells (Dubinsky et al, 2010).

<b>Specific Clinical/History</b>	Cough, hemoptysis	Alb, transthyretin
Height	Chest pain	CRP
Weight	Headache	Transferrin
BMI	Chest X-ray	Gluc
Weight loss?		H & H
Diet history	<b>Lab Work</b>	Serum Fe, ferritin
Nausea, vomiting	Human chorionic gonadotropin	Mg <sup>++</sup> , Ca <sup>++</sup>
I & O	β-hCG levels	Na <sup>+</sup> , K <sup>+</sup>
BP;		ALT (increased)
hypertension?	Elevated TSH	Kidney function tests
Vaginal bleeding		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Bioactive Substance Intake

**Assessment Data:** Pregnancy 6 months ago; still breastfeeding but showing high levels of β-hCG. Diagnosis of choriocarcinoma. BMI 25. No other unusual medical history. Diet history completed.

**Nutrition Diagnosis (PES):** Inadequate bioactive substance intake related to phytoestrogens as evidenced by food frequency records showing no intake of soy or other isoflavonoids.

**Intervention:** Food-nutrient delivery—Offer recipes and tips for ways to increase the intake of isoflavonoids from soy, legumes, spinach, and Brussels sprouts. Educate the patient about the role of bioactive substances in isoflavonoids in the prevention of relevant forms of cancer. Coordinate care with the medical team for the methotrexate treatment.

**Monitoring and Evaluation:** No undesirable outcomes (e.g., no renal metastasis); methotrexate treatment successful.

## INTERVENTION

### OBJECTIVES

- Maintain appropriate weight for height. Correct weight loss and cachexia.
- Increase intake of isoflavonoids and other bioactive substances.
- Correct side effects of chemotherapy if used.
- Treat and correct all other side effects of therapy and disease state.
- Prepare patient for surgery, if necessary.

### FOOD AND NUTRITION

- Modify diet to patient preferences. Include isoflavonoids and coumestrol from soy products, legumes, spinach, and Brussels sprouts.
- Increase liquids as needed.
- Provide adequate protein, B-complex vitamins, iron, calories, and other nutrients for wound healing, as appropriate. Use RDA and DRI levels as a guide.
- Alter the texture of the diet if the patient is fatigued at mealtimes or if stomatitis occurs after chemotherapy.

### Common Drugs Used and Potential Side Effects

- Methotrexate or actinomycin D may be used; nausea and vomiting are common side effects. Administer with glucose to reduce toxicity.
- Combined EMACO therapy (etoposide, methotrexate, actinomycin D, cyclophosphamide, and oncovin) may be used with high-risk disease; thinning hair or GI distress can occur.
- A new FASN inhibitor, C93, is being developed to initiate apoptosis in these cells (Ueda et al, 2009).

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.

- Phytoestrogens from isoflavonoids may prove to be quite effective in the treatment of this cancer.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Nausea or vomiting may require small, frequent feedings and control of fluid intake at mealtimes.
- With the high hCG levels, menstrual periods stop; periods start again when the levels are normal again. Delay pregnancy for 6 months or longer after treatment. With chemotherapy, periods will stop temporarily, and there may be early menopause.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

# PROSTATE CANCER

## NUTRITIONAL ACUITY RANKING: LEVEL 2

### DEFINITIONS AND BACKGROUND

Prostate cancer is third to lung and colon cancer as the cause of cancer-related deaths in American men (Colli and Amling, 2009). Prevalence is high in northwestern Europe and the United States, highest among African-American males worldwide. Men also at great risk are those with abdominal obesity, those with family history of the disease, and those whose diets are low in fiber and high in saturated fats or red meats. High serum cholesterol levels may be linked with the progression of prostate cancer (Freedman and Aronson, 2009).

An effective chemoprevention strategy for prostate cancer serves as a model for chemoprevention of other adult malignancies (Canby-Hagino and Thompson, 2005). Diets rich in specific vitamins, grains, fish, fruits, and vegetables may be associated with lower cancer rates (Chan et al, 2005; Lamb and Zhang, 2005). Chemoprotective factors are listed in Table 13-18.

Surgical intervention, radiation, and hormonal therapy are used. Radiation therapy may cause temporary changes in bowel habits (such as increased frequency, increased flatulence, and bowel cramping). Brachytherapy is internal radiation therapy in which small radioactive pellets are inserted or implanted into the prostate gland.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Overexpression of the *AMACR* gene is associated with prostate cancer risk (Xu et al, 2005). Strict nutritional interventions can change gene expression (Ornish et al, 2008). Secondary analyses of two randomized, controlled phase III trials have demonstrated that selenium and vitamin E could reduce prostate cancer incidence through cell type- and zone-specific tissue effects (Tsavachidou et al, 2009).

#### Clinical/History

------------------------------	--	--

## INTERVENTION

### OBJECTIVES

- Prepare patient for surgery, radiation, medications, chemotherapy, or hormone therapy.
- Prevent or correct side effects such as nausea, vomiting, and diarrhea.
- Prevent or correct weight loss.

**TABLE 13-18 Preventive Dietary Factors for Prostate Cancer**

Allium vegetables (garlic, scallions, onions, chives, and leeks)
Apigenin
Cruciferous vegetables (Chan et al, 2005)
Curcumin
Epigallocatechin gallate (EGCG)
Grains, nuts, cereals
Grape seed extract
Green tea (Trottier et al, 2010)
Herbs and herbal supplements (saw palmetto)
Lignans
Lower fat diet
Lycopene, other carotenoids (Trottier et al, 2010)
Omega-3 fatty acids, EPA and DHA (Chan et al, 2005)
Physical activity and exercise (Jian et al, 2005; Zeegers et al, 2005)
Polyphenols (Chan et al, 2005)
Pomegranate (Trottier et al, 2010)
Quercetin
Resveratrol
Selenium (Chan et al, 2005; Trottier et al, 2010)
Soy genistein and isoflavones (Chan et al, 2005; Trottier et al, 2010)
Statins, 5-alpha-reductase inhibitors, and NSAIDs
Vegan diet
Vitamin D <sub>3</sub> (Schwartz, 2005; Tokar and Webber, 2005; Trottier et al, 2010)
Vitamin E as gamma-tocopherol in walnuts, pecans, sesame seed, corn and sesame oils (Chan et al, 2005; Trottier et al, 2010)

## SAMPLE NUTRITION CARE PROCESS STEPS

### Increased Energy Needs

**Assessment Data:** 90-year-old male resident in a long-term care facility; diagnosed with prostate cancer 1 year ago. Gradual weight loss, recently 5# in past month. Intake records show 25–50% at mealtime in the past month; previously 50–75% at all meals and taking oral supplements between meals.

**Nutrition Diagnosis (PES):** NC-3.2 Increased energy needs related to the inflammatory process and diagnosis of prostate cancer as evidenced by the insidious weight loss over six months.

### Intervention:

**Food and Nutrient Delivery—**Provide fortified foods such as super oatmeal and potatoes because of increased energy needs; MVI with minerals to ensure adequate nutrients are available. **Coordinate care—**Continue high calorie supplements between meals and with medication passes by nursing.

**Monitoring and Evaluation:** No further weight loss. Improved intake of kilocalories as noted on 3-day calorie count.

- Promote intake of protective foods and phytochemicals. Support intensive nutrition and lifestyle intervention to change gene expression, where appropriate (Ornish et al, 2008).
- Maintain or achieve a healthy body weight.

## FOOD AND NUTRITION

- Provide adequate calories and protein; avoid excesses.
- It may be beneficial to have some weight loss prior to surgery using a low-fat, low glycemic index diet (Schenk et al 2009).
- After surgery, a multiple vitamin—mineral supplement may be indicated to promote wound healing.
- Monitor the need for lower sodium if corticosteroids are prescribed.
- Increase the use of fruits and vegetables, particularly green and yellow-orange, and sources of folic acid. Tomato products, pizza sauce, strawberries, and salsa provide lycopene. Pomegranate juice may reduce the likelihood of recurrence (Malik et al, 2005).
- Increase the use of isoflavonoids (Haddad et al, 2006; Steiner et al, 2008). Choose beans, soybeans, lentils, tofu, tempeh, soy nuts, soymilk, and dried fruit often.
- Low-fat, vegan, and high-fiber diets may be indicated (Dewell et al, 2008; Van Patten et al, 2008).
- Increased use of omega-3 fatty acids has been shown to be useful; include salmon, sardines, tuna, mackerel, and herring in the diet.
- Vitamin D<sub>3</sub> is needed; drink fortified milk, get a modest exposure to the sun, and take a vitamin pill that contains cholecalciferol.

## Common Drugs Used and Potential Side Effects

- Aspirin improves survival after prostate cancer. NSAIDs and statins may also be beneficial.

**TABLE 13-19 Antioxidant Color Link**

Colors	Examples of Fruits-Vegetables	Antioxidants
Red	Grapes, red wine	Resveratrol
Red/Pink	Tomatoes, pink grapefruits, watermelon	lycopene
Red/Purple	Pomegranates, grapes, plums, berries	Anthocyanins
Orange	Carrots, mangoes, apricots, cantaloupes, pumpkin, sweet potato	Alpha and beta carotenes
Orange/Yellow	Oranges, peaches, papaya, nectarines	Beta-cryptoxanthin
Yellow/Green	Spinach, collard, yellow corn, green peas, avocado, honeydew melon	Lutein and zeaxanthin
Green	Broccoli, Brussels sprouts, cabbage, bok choy, kale	Sulforaphane, isothiocyanates, indoles
Whit/Green	Garlic, onions, asparagus, leeks, shallots, chives	Allyl sulfides

Source: Prostate Cancer Foundation, [http://www.prostatecancerfoundation.org/atf/cf/%7B705B3273-F2EF-4EF6-A653-E15C5D8BB6B1%7D/Nutrition\\_Guide.pdf](http://www.prostatecancerfoundation.org/atf/cf/%7B705B3273-F2EF-4EF6-A653-E15C5D8BB6B1%7D/Nutrition_Guide.pdf), accessed January 15, 2010.

- Chemotherapy drugs have varying side effects; monitor closely. Fatigue, nausea and vomiting, mouth sores, hair loss, and a low white blood cell count are common.
- The Prostate Cancer Prevention Trial (PCPT) identified the benefits of reducing prostate cancer risk with the use of 5 $\alpha$ -reductase inhibitors (Crawford et al, 2009). Finasteride lowers prostate cancer risk and can be available to men who are at high risk (Kaplan et al, 2009).
- Hormonal therapy may be used as the treatment of choice (Bracarda et al, 2005). Luteinizing hormone-releasing hormone (LH-RH) agonists can decrease the amount of testosterone produced by a man's testicles as effectively as surgical removal. Lupron Depot (leuprolide acetate for depot suspension), an LH-RH agonist, is used in the palliative treatment of advanced prostate cancer.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Complementary and alternative medicine (CAM) includes the use of vitamin and mineral supplements, herbs, antioxidants, saw palmetto, selenium, vitamin E, and lycopene (Chan, Elkin et al, 2005). Herbs and botanical supplements should not be used without discussing it with the physician.
- Saw palmetto has some efficacy. Avoid taking it with estrogens, testosterone, anabolic steroids, oral contraceptives, or finasteride because the herb and drugs function in similar ways and additive effects are possible.
- Phytoestrogens found in common herbal products are effective inhibitors of prostate tumor cell growth through different mechanisms; these include quercetin, genistein, epigallocatechin gallate (EGCG), curcumin, apigenin, resveratrol, and isoflavones in soy and red clover.
- Pygeum and nettle are being studied at this time.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the side effects of therapy and the long-term plans for recovery.
- Maintain adequate hydration.

- Discuss lifestyle and dietary changes. This may include lowering the intake of red meats and saturated fats, increasing fruits and vegetables and tomato products, increasing fiber and whole grains, and consuming vitamin D-fortified milk.
- Chemopreventive agents include 5 $\alpha$ -reductase inhibitors; statins; NSAIDs; selenium; vitamins E and D; lycopene; allium vegetables (garlic, scallions, onions, chives, and leeks); soy/isoflavones; pomegranate and green tea polyphenols (Colli and Amling, 2009; Trottier et al, 2010; Van Patten et al, 2008). Table 13-19 provides a color chart to remember the antioxidant foods.
- Lifestyle changes tend to correlate with quality of life after prostate cancer treatments (Sheriff et al, 2005). Diet and exercise changes are important.
- Offer menu plans for sufficient intake of protective nutrients. Lycopene can be found in foods such as tomatoes, watermelon, guava, and red grapefruit. Include pomegranates, soy, fish, and more vegan or plant-based choices.
- Help to maintain a positive, optimistic outlook to yield favorable results (Kronenwetter et al, 2005).

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

## HEMATOLOGICAL CANCERS

# LEUKEMIAS

### NUTRITIONAL ACUITY RANKING: LEVEL 3–4

Adapted from: McClatchey KD M.D., D.D.S. *Clinical Laboratory Medicine*, 2nd ed. Philadelphia: Lippincott Williams & Wilkins, 2002.

## DEFINITIONS AND BACKGROUND

Leukemia involves the uncontrolled proliferation of leukocytes and their precursors in blood-forming organs, with infiltration into other organs (Table 13-20). The blood has a grayish-white appearance. Leukemia incidence is highest among whites and lowest among American Indians/Alaskan natives and Asian and Pacific Islander populations. Acute leukemia progresses rapidly, with an accumulation of immature, functionless cells in the marrow and blood. Then, the marrow stops producing enough normal red cells, white cells and platelets and anemia develops. Chronic leukemias progress more slowly.

Leukemia is the most common childhood cancer. Because chromosomal abnormalities are present at birth in children who later develop leukemia, nutrition during pregnancy affects their risk. Insulin-like growth factor I (IGF-I) is associated with high birth weight and an increased risk of childhood leukemia (Tower and Spector, 2007). Both insulin and IGF-I act to promote cell proliferation and to inhibit apoptosis (Fair and Montgomery, 2009). Obesity is a well-known problem in children with ALL; it may be the result of an excess in energy intake, reduced energy expenditure, or both (Jansen et al, 2009).

Dietary exposures to cured/smoked meat or fish, nitrites, and nitrosamines are associated with leukemia in children and adolescents (Liu et al, 2009). It may be prudent for women to consume a diet rich in vegetables, fruit, iron, soybean curd, and protein (particularly fish and seafood) prior to and during pregnancy to reduce the ALL risk in their children (Kwan et al, 2009; Liu et al, 2009; Petridou et al, 2005).

Phytochemicals, such as grape extract, apigenin, quercetin, kaempferol, and myricetin, are protective against cancer cell survival (Chen et al, 2005). Red wine polyphenolic extract may inhibit leukemia cell growth (Sharif et al, 2010). In adults with AML, individuals who smoke, do not drink coffee, and eat more meat have a higher risk (Ma et al, 2009).

The primary treatment of leukemias currently involves chemotherapy to kill attacking abnormal blood cells. Bone marrow transplantation may be feasible in some cases. Table 13-21 lists various types of leukemias, relevant signs and symptoms, and treatments.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** FLT3 is a receptor tyrosine kinase that plays an important role in hematopoietic stem cell proliferation, differentiation and survival; alterations have a role in leukemia. BCR-ABL cancer gene is another gene of importance in leukemias. Persons with Down syndrome, Fanconi's anemia, and other genetic disorders have a high risk of leukemia. Lack of maternal folate causes DNA hypomethylation and increased DNA strand breaks; *MTHFR* gene polymorphisms have been associated with adult and childhood ALL (Smith et al, 2005; Tower and Spector, 2007). Chronic lymphocytic leukemia (CLL) is a malignancy of B cells of unknown etiology; deletions of the chromosomal region 13q14 are commonly associated with CLL (Klein et al, 2010).

<b>Specific Clinical/History</b>	Cough, sternal tenderness	Zinc (decreased)
Height	Splenomegaly, hepatomegaly	Uric acid (increased)
Weight	Hemorrhages, nosebleeds	Immunocytochemistry
BMI	Headache	Cytogenetics (FISH test)
Weight changes (slight weight loss?)	Anorexia	Molecular genetic studies
Diet history	Nausea and vomiting	Alb, transthyretin
BP	Mouth ulcers	CRP
Fever (over 101°F?)	Bleeding	Serum copper (increased)
Frequent infections	Enlarged lymph nodes?	Gluc
Malaise, irritability	Night sweats?	H & H, Serum Fe, Ferritin
Pallor	Lumbar puncture	Transferrin
Hemorrhage		PT or
Petechiae, ecchymosis, purpura	<b>Lab Work<sup>a</sup></b>	International Normalized Ratio (INR)
Palpitations	WBC (increased)	Na <sup>+</sup> , K <sup>+</sup>
Shortness of breath	Ferritin (increased)	Ca <sup>++</sup> , Mg <sup>++</sup>
Bone or joint pain	Platelets	
	Lactate dehydrogenase (LDH) (elevated)	

<sup>a</sup>A useful Web site describing lab tests is available at [http://www.leukemia-lymphoma.org/attachments/National\\_br\\_1216925469.pdf](http://www.leukemia-lymphoma.org/attachments/National_br_1216925469.pdf).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Intake of Unsafe Foods

**Assessment Data:** Status post bone marrow transplant for ALL in a 14-year old male. Now at the emergency room, complaining of gastric pain and vomiting after eating items at a restaurant salad bar. BMI normal for age. Labs all within normal limits.

**Nutrition Diagnosis (PES):** Intake of unsafe foods related to raw vegetables and salad items at public restaurant following BMT procedure, as evidenced by gastric pain and vomiting.

**Intervention:** Education about the benefits of the low bacteria (neutropenic) diet for a few months longer until the immune system and tolerance improves. Counseling about the use of cooked fruits and vegetables and avoidance of salad bars until tolerance is better.

**Monitoring and Evaluation:** No further episodes of vomiting and GI pain with the use of the neutropenic diet. Good acceptance of the restrictions until immunity improves.

- Correct anorexia and nausea or vomiting.
- Prevent complications and further morbidity, such as veno-occlusive disease (VOD).
- Alter diet according to medications and therapies such as chemotherapy. A low-bacteria (neutropenic) diet may be useful, particularly if bone marrow transplant is used.
- Maintain weight that is appropriate for height. Correct weight loss and cachexia.
- Maintain adequate hydration.

### FOOD AND NUTRITION

- Serve attractive meals at temperatures that are tolerated.
- Choose soft foods or foods that can be cooked until tender. Cut foods into bite-sized pieces; grind or blend them so that less chewing is needed.
- Follow neutropenic diet guidelines for BMT. Avoid all uncooked vegetables, most uncooked fruits, raw or rare-cooked meat, fish. All eggs should be thoroughly cooked. Avoid salad bars and deli counters. Buy vacuum-packed luncheon meats rather than freshly sliced meats. Eat or drink only pasteurized milk, yogurt, cheese, or other dairy products. Avoid soft mold-ripened and blue-veined cheeses including Brie, Camembert, Roquefort, Stilton, Gorgonzola, and Blue. At home, use tap water or bottled water; avoid well water or boil it for one minute before using.
- Small meals may be better tolerated than large ones. In some cases, cold or iced foods may be preferred.
- A high-protein, high-energy, high-vitamin/mineral intake should be offered. Tube feeding in these patients is often useful, but intolerance due to treatment side effects may be an obstacle.
- Extra fluids will be important during febrile states or with the use of interferon, but avoid overload. Sip water and

## INTERVENTION

### OBJECTIVES

- Prevent hemorrhage and infections.
- Promote recovery and stabilization before bone marrow transplantation, if performed.

**TABLE 13-20 Various Forms of Leukemia**

Form	Description
Acute Leukemias	Sx: easy fatigue, malaise, irritability, fever, pallor, petechiae, bruising, purpura, hemorrhage, palpitations, shortness of breath, slight weight loss, bone or joint pain, painless lumps in underarm or stomach, cough, sternal tenderness, splenomegaly, hepatomegaly, anemia, hemorrhages or nosebleeds, headache, nausea, vomiting, and mouth ulcers.
Acute lymphocytic leukemia (ALL)	ALL affects bone marrow and lymph nodes. It progresses rapidly and mainly affects children; it accounts for 50% of all childhood leukemias. Control of bone marrow and systemic disease is the goal. Treatment may include monthly lumbar punctures. ALL often spreads to the coverings of the brain and spinal cord; patients may receive chemotherapy into spinal fluid, or radiation therapy to the head. Bone marrow transplantation (BMT) treatment or peripheral-blood stem-cell transplant (PBSCT) may lead to bloody diarrhea, fever, and other symptoms of graft-versus-host disease (GVHD).
Acute myelogenous leukemia (AML)	AML starts in the bone marrow but moves into the blood and to the lymph nodes, liver, spleen, central nervous system, and testes. AML consists of proliferation of myeloblasts, which are immature polynuclear leukocytes. AML is more common in adult males but also accounts for just under half of cases of childhood leukemia. Average onset of AML is the sixth decade. Smoking, obesity, chronic workplace exposure to benzene, large doses of irradiation have been established as causes. Treatments vary according to the age of the patient and according to the specific subtype. The goal is to control bone marrow, CNS, and systemic disease.
<b>Chronic Leukemias</b>	Sx: anemia, increased infections, bleeding, enlarged lymph nodes (in lymphatic form), night sweats, fever, weight loss, and anorexia.
Chronic lymphocytic leukemia (CLL)	CLL involves a crowding out of normal leukocytes in lymph glands, interfering with the body's ability to produce other blood cells. CLL is more common in people older than 50 years of age and in males. It is twice as common as CML. Treatment depends upon the stage and symptoms of the individual patient. Low-grade disease does not benefit from treatment. With complications or more advanced disease, treatment may be needed. Hairy cell leukemia is a subtype of CLL.
Chronic myelogenous leukemia (CML)	CML affects mostly adults and is very rare in children. The standard of care for newly diagnosed patients is oral administration of imatinib (Gleevec), which has few side effects and makes CML a chronic, manageable condition.
T-cell prolymphocytic leukemia	Has similar overproduction of white blood cells in the bone marrow; less common than the other types. Difficult to treat and does not respond well to chemotherapy drugs. Alemtuzumab (Campath) is a monoclonal antibody that attacks white blood cells with some success.

other clear liquids such as broth, ginger ale, or lemonade frequently.

- Vitamins A and D may be beneficial (Trump et al, 2005) but avoid excesses above the UL levels.
- Include protective foods such as isoflavones in soy and flavonoids in grapes, coffee, tea, nuts, seeds, fruits, and vegetables.

### Common Drugs Used and Potential Side Effects

- See Tables 13-22.
- Methadone kills leukemia cells while not affecting the normal ones; it activates the mitochondrial pathway, which activated specific enzymes within the cancer cell, causing pre-programmed death. This is a great breakthrough in leukemia research.

**TABLE 13-21 Medications for Acute Leukemias**

**Induction:** The first phase destroys as many cancer cells as quickly as possible to bring about a remission.

**Consolidation:** The goal is to get rid of leukemia cells where they reside.

**Maintenance:** After the number of leukemia cells has been reduced by the first two phases of treatment, lower doses of chemotherapy drugs are given over 2 years.

CEP-701 (lestaurtinib) inhibits the receptor tyrosine kinase FLT3 in AML patients

Chemotherapy often includes methotrexate, 5-azacitidine, cytarabine, thioguanine, and daunorubicin, which may cause stomatitis, nausea, or vomiting.

Coadministration of these agents with glucose and adequate fluid is needed. When methotrexate is used, neurotoxicity is a concern; use low-dose folinic acid rescue (Leucovorin).

Gemtuzumab ozogamicin (Mylotarg) may be added. Granulocyte colony-stimulating factors (Neupogen, Leukine) may improve response to chemotherapy. This intensive therapy, which usually takes place in the hospital, typically lasts 1 week.

L-asparaginase (Elspar) may be used; hepatitis or pancreatitis may result; watch carefully.

Pegaspargase (Oncaspar) can cause nausea, vomiting, anorexia, and glucose changes.

Interferon may be used.

Prednisone may be used, with side effects related to steroids with chronic use. Alter diet and intake accordingly to manage hyperglycemia, hypokalemia, and nitrogen losses.

**TABLE 13-22 Medications for Chronic Leukemias**

Chemotherapeutic agents may be used with varying side effects. Chlorambucil (Leukeran) and busulfan are common; nausea, severe fatigue, flu-like symptoms, low-grade temperature, vomiting, glossitis, and cheilosis may occur. Avoid hot, spicy, or acidic foods, if not tolerated.

Pegaspargase (Oncaspar) can cause nausea, vomiting, anorexia, and glucose changes.

Imatinib (Gleevec), for CML, interferes with an abnormal enzyme that sends signals to the nucleus of a cancer cell. Nausea and vomiting are potential side effects. Dasatinib (Sprycel) and nilotinib (Tasigna) block the BCR-ABL cancer gene, but each works in a different way than Gleevec. Sprycel and Tasigna are approved for certain CML patients who are resistant or intolerant to prior therapy including Gleevec. All three drugs are given orally.

For CLL: Multiple treatments include purine analogs, monoclonal antibodies, and stem-cell transplantation.

Antifungals, antivirals, or antibiotic drugs may be used; side effects vary.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.
- For CML, bioflavonoids, vitamin A, Retin-A, vitamin D<sub>3</sub>, vitamin E, vitamin B<sub>12</sub>, indirubin (found in herbs including *Indigofera tinctoria* and *Isatis tinctoria*), and *Curcuma longa* have shown promise (Matsui, 2005).
- Omega-3 fatty acid supplements may increase the blood-thinning effects of aspirin or warfarin.
- St. John's wort reduces the effectiveness of imatinib, which is used to treat CML and Philadelphia-positive ALL.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- A well-balanced diet is essential; discuss ways to improve or increase intake.
- Tumor lysis syndrome is a side effect caused by the rapid breakdown of leukemia cells. When these cells die, they release substances into the bloodstream that can affect the kidneys, heart, and nervous system. Giving patient extra fluids or certain drugs that help rid the body of these toxins can prevent this problem.
- Offer guidelines to transition from CPN or PN to enteral nutrition and oral intake.
- Discuss guidance for graft-versus-host disease (acute vs. chronic symptoms).
- Discuss alternative ways to make meals more attractive and appealing.
- Instruct patient on nutrition repletion if appropriate. For extra calories, blend cooked foods or soups with high-

calorie liquids such as gravy, milk, cream or broth instead of water.

### Patient Education—Food Safety

- People who are being treated for leukemia have weakened immune systems and increased risk for food-borne illness.
- Keep hands, counters, dishes, cutting boards, and utensils clean. Change sponges and dishtowels often.
- Keep foods at proper temperatures, reheating foods properly.
- Wash fruits and vegetables thoroughly.
- Use separate dishes, cutting boards, and utensils for preparing raw meat, fish, or poultry.
- Thaw frozen items in the microwave or refrigerator, not on the kitchen counter.
- Use a food thermometer to make sure that meat is fully cooked.
- Read the expiration dates on food products. Look for signs of food spoilage; if in doubt, throw it out.

# LYMPHOMAS

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

Chronic antigenic stimulation leads to lymphoid malignancy (Anderson et al, 2009). There are two types: **Hodgkin's lymphoma (HL)** and non-Hodgkin's lymphoma (NHL), which is far more common. In HL, patients present with enlarged lymph nodes that are firm and rubbery, severe pruritus, jaundice, night sweats, fatigue and malaise, weight loss, slight fever, alcohol-induced pain, cough, dyspnea, and chest pain. It presents most commonly in males between the ages of 15 and 34 or after age 60 in persons who have lupus, Epstein-Barr virus (mononucleosis) or HIV infection. Abnormal B cells, called Reed-Sternberg cells, develop and enlarge. The treatment of HL involves radiation and chemotherapy. Stage 1 is limited to one body part; stage 2 involves two or more areas on the same side of the diaphragm; stage 3 involves lymph nodes above and below the diaphragm; and stage 4 involves lymph nodes and other areas such as the lungs, marrow, and liver. Patients who present with weight loss initially have a worse prognosis than those without weight loss. The 5-year survival rate for Hodgkin's disease is 84%; it is one of the more curable forms of cancer. Unfortunately, survivors may have a stroke later in life, and young women who receive high-dose radiation for Hodgkin's disease are more at risk for breast cancer. **Non-Hodgkin's lymphoma (NHL)** is a malignant tumor of lymphoid tissue, resulting from an invasion of the lymph nodes and other tissues by lymphocytes. NHL is relatively common among individuals whose immune system is suppressed. Rheumatoid arthritis, Sjögren syndrome, T-cell lymphoma with hemolytic anemia, psoriasis, discoid lupus erythematosus, and celiac disease are associated with an increased risk of NHL (Anderson et al, 2009). *H. pylori* is associated with the development of lymphoma in the stomach wall. Burkitt's lymphoma is most common in children, young adult males, and patients with AIDS; it originates from a B lymphocyte and requires chemotherapy. This lymphoma is associated with a prior infection with the Epstein-Barr virus.

Exposure to certain chemicals (such as nitrates) in herbicides and pesticides promotes risk. Enteropathy-associated T-cell lymphoma (EATL) is a rare form of high-grade, T-cell NHL of the upper small intestine that is specifically associated with celiac disease (Catassi et al, 2005). Capsule endoscopy is used to evaluate this celiac disease-associated enteropathy (Joyce et al, 2005). Strict adherence to the gluten-free diet protects against NHL, particularly if started early (Hervonen et al, 2005).

Symptoms and signs of NHL include difficulty breathing, swelling of face, thickened or dark, itchy skin areas, increased incidence of bacterial infections, night sweats, weight loss, fever, anemia, and pleural effusion. It is possible, as well, to develop chylous ascites or chyloperitoneum. By the time of NHL diagnosis, it is often widely spread. It may spread to the cervix, uterus, and vagina in women. Radiation is a common treatment for the early stages. A cure is less likely for those over age 60.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** HL and NHL have several gene mutations. The presence of the Reed-Sternberg cell in HL is an expression of the CD30 antigen. In NHL, t(14;18)(q32;q21) chromosomal translocations occur in the BCL2 gene.

Specific Clinical/History	Alcohol-induced pain	ESR
Height	Cough, dyspnea, and chest pain	Uric acid (increased)
Weight	Diarrhea	PT (increased)
BMI	I & O	Gluc
Weight loss?	Lymphangiogram	CRP
Diet history	X-ray or CT scan	Serum Cu (increased)
Enlarged, rubbery lymph nodes	Bone marrow biopsy	H & H
Painless adenopathy		Bilirubin (increased)
Pruritus, severe	<b>Lab Work</b>	Alk phos (often increased)
Jaundice	Ceruloplasmin (increased)	Ferritin (increased)
Night sweats	Reed-Sternberg cells (more than one nucleus)	ALT (increased)
Fatigue and malaise		Serum lipids—Chol, Trig
Slight fever, temperature		Ca <sup>++</sup> , Mg <sup>++</sup> , Na <sup>+</sup> , K <sup>+</sup>

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Obesity

**Assessment Data:** BMI 42, new diagnosis of NHL. Diet hx indicates low intake of whole grains and vegetables and high intake of sugary, refined foods and beverages.

**Nutrition Diagnosis (PES):** Obesity related to poor food choices as evidenced by BMI 42 and preference for sugary, refined foods.

**Intervention:** Food-Nutrient Delivery—Promote the use of low energy foods and beverages. Educate the patient about the risks of obesity in cancer promotion. Counsel about ways to safely lose weight, with the focus on a healthy body weight and nutrient density.

**Monitoring and Evaluation:** Reasonable amount of weight lost, slowly and without loss of lean body mass but with tolerance for chemotherapy treatments. Improved BMI.

## INTERVENTION

### OBJECTIVES

- Prevent or correct weight loss, fever, malaise, and infections such as candidiasis.
- Correct dysphagia, nausea and vomiting, and anorexia.
- Control protein-losing enteropathy, chylous ascites, and other side effects.
- Control enteropathy in patients who also have celiac disease.
- Modify diet according to the side effects of therapy (e.g., radiation or chemotherapy).
- If obese, a gradual weight loss plan may be indicated.

### FOOD AND NUTRITION

- Increase protein and fluids. Balance energy intake to meet the needs of treatments without causing weight gain.
- Six small feedings are generally better tolerated than three large meals. Alter diet according to symptoms.
- Bland, low acidic foods may be better accepted for a while.
- With celiac disease, the gluten-free diet is required.
- With hyperglycemia, control carbohydrates and overall energy intake.
- Support the use of a protective diet with folate and B vitamins, vegetables, and legumes. Include vitamin D<sub>3</sub>, particularly from sunlight (Grant, 2009; Kelly et al, 2009).

## Common Drugs Used and Potential Side Effects

### HL

- Chemotherapy is often given in combination. The regimen MOPP, which includes mechlorethamine (nitrogen mustard), vincristine (Oncovin), procarbazine, and prednisone may cause nausea, vomiting, diarrhea, weakness, constipation, and mouth sores. The regimen ChlVPP, which includes chlorambucil, vinblastine, procarbazine, and prednisone, may cause similar side effects. After chemotherapy, young women may have amenorrhea.
- Corticosteroids can aggravate the electrolyte status and will decrease the calcium, potassium, and nitrogen balance over time. Hyperglycemia may also occur; monitor blood glucose levels.

### NHL

- Chemotherapy is often given as a regimen called CHOP, which includes cyclophosphamide, doxorubicin, vincristine (Oncovin), and prednisone. CHOP may cause nausea, vomiting, anorexia, diarrhea, and other gastrointestinal (GI) side effects. Single agents may also be used. Methotrexate causes GI pain, mouth ulcers, nausea, and folic acid depletion.

## Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.

- Lymphoma survivors tend to use CAM therapies more than the general population (Habermann et al, 2009). Chiropractic, massage, and use of St. John's wort and shark cartilage have been noted.
- Acupuncture, coenzyme Q10, and polysaccharide K are under study.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss methods of improving appetite by the use of attractive meals.
- Encourage rest periods before and after meals to reduce fatigue.
- Encourage a diet that is protective with plenty of vegetables and legumes.
- Vitamin D<sub>3</sub> may protect against both types of lymphomas (Grant, 2009; Kelly et al, 2009).

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

# MYELOMA

## NUTRITIONAL ACUITY RANKING: LEVEL 3

Adapted from: Raphael Rubin, David S. Strayer, *Rubin's Pathology: Clinicopathologic Foundations of Medicine*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 2008.

### DEFINITIONS AND BACKGROUND

Myeloma is the second most common blood cancer. Multiple myeloma (MM) is a malignant cancer in which plasma cells proliferate, invade bone marrow, and produce abnormal immunoglobulin. Different types of myeloma are classified by the type of immunoglobulin produced by the abnormal cells. The condition is rare, affecting only 4/100,000 persons and representing only 1% of all cancers. Males are affected more often than females, and the disorder usually strikes after age 50. African-Americans are twice as likely to acquire MM as Caucasians, Hispanics, or Asians.

Obesity promotes this type of cancer. MM affects several areas of bone marrow. If significant bone lesions, renal failure, or hypercalcemia occur, chemotherapy or transplantation is recommended. Stem-cell transplantation or radiation therapy may be administered (Iversen, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** The premalignant condition of monoclonal gammopathy of undetermined significance (MGUS) precedes all cases of MM (Jagannath, 2010).

Specific Clinical/History	BP	Fatigue, weakness, apathy
Height	Bone pain	Sudden confusion
Weight	Pathological fractures	Renal disorders
BMI	Nausea and vomiting	Bleeding tendency
Weight loss?	Anorexia	(particularly gums)
Shortened stature?	History of bleeding	
I & O		

Frequent urinary tract infections	Total protein	Proteinuria (Bence Jones proteins)
Pneumonia?	Parathormone (PTH) (increased)	Sedimentation rate (increased)
Skeletal survey	TLC (varies)	Uric acid (increased)
<b>Lab Work</b>	Hypercalciuria	RBP
Ca <sup>++</sup> (increased)	Alb (often increased)	ALT (increased)
Mg <sup>++</sup>	CRP	
Na <sup>+</sup> , K <sup>+</sup>	Transferrin	
	H & H	

### INTERVENTION

#### OBJECTIVES

- Avoid fasting. Space meals and snacks adequately.
- Counteract episodes of fatigue and weakness.
- Manage pain effectively.
- Counteract side effects of antineoplastic therapy, steroid therapy, and radiotherapy.
- Avoid infections and febrile states.
- Prevent spontaneous fractures, as far as possible.
- Correct anorexia, nausea and vomiting, and weight loss.

#### FOOD AND NUTRITION

- Provide diet as usual, with six small feedings rather than large meals.
- A higher protein intake may be useful to counteract losses.
- Provide adequate energy to meet requirements of weight control, preventing unnecessary losses.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Oral Food and Beverage Intake

**Assessment Data:** Mucositis following chemotherapy for the treatment of multiple myeloma. Unable to chew and swallow comfortably because of inflamed oral tissues.

**Nutrition Diagnosis (PES):** Inadequate oral food and beverage intake (NI-2.1) related to sore mouth as evidenced by mucositis after chemotherapy and difficulty finding tolerated foods and beverages.

**Intervention:** Food-nutrient delivery—offer soft, ground, or pureed foods that are low in acid and spices. Educate the patient about the use of a soft, easily tolerated diet that has nutrient-density. Counsel with tips for gradually increasing the oral diet as mucositis subsides.

**Monitoring and Evaluation:** Resolution of mucositis with an improvement in oral intake.

- Avoid dehydration by including adequate fluid intake (e.g., 3 L daily). This is important.
- Ensure sufficient intake of omega-3 fatty acids, vitamins, minerals, and phytochemicals, particularly from fruits and vegetables.

### Common Drugs Used and Potential Side Effects

- Arsenic trioxide (Trisenox), carmustine (BiCU, BCNU), cyclophosphamide (Cytoxan), doxorubicin (Adriamycin, Rubex), idarubicin (Idamycin), interferon-alpha (Roferon-A, Intron-A), lenalidomide (Revlimid), pamidronate (Aredia), vincristine (Oncovin), or zoledronic acid (Zometa) may be given as chemotherapy, often with several in a mixture. Melphalan (Alkeran) or nitrosoureas may also be used; monitor for anorexia, anemia, nausea, vomiting, and stomatitis.
- Bisphosphonates may be used to prevent bone fractures.
- Pamidronate may be used. Ensure adequate fluid intake but not excess. Avoid use with calcium and vitamin D supplements. Extra phosphorus may be needed. Nausea, vomiting, gastrointestinal bleeding or distress, and constipation can occur.
- Prednisone, if used chronically, can increase nitrogen losses and potassium and magnesium depletion and can cause hyperglycemia and sodium retention.
- Lenalidomide delays disease progression in late-stage multiple myeloma. It also helps to reduce the need for blood transfusions.
- The immunomodulatory agents thalidomide and lenalidomide and the proteasome inhibitor bortezomib are now routine components of MM therapy (Jagannath, 2010). However, all patients with MM eventually relapse; efforts to identify novel synergistic combinations and agents are ongoing (Jagannath, 2010).
- Bortezomib (Velcade), a proteasome inhibitor, delays disease progression and extends survival.

### Herbs, Botanicals, and Supplements (see Table 13-8)

- Herbs and botanical supplements should not be used without discussing it with the physician.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the rationale for spacing meals throughout the day to avoid fatigue.
- Offer recipes and meal plans that provide the nutrients required to improve status and immunological competence.

### Patient Education—Food Safety

- Educate the patient about food safety issues. Discuss safe food handling and preparation, keeping foods at proper temperatures, the use of sterile water, and reheating foods properly.

# Surgical Disorders

## CHIEF ASSESSMENT FACTORS

### Presurgical Status

- Anemia, Blood Loss
- Appetite Changes
- Blood Pressure, Abnormal
- Electrolyte Status
- History of Illness—Acute or Chronic (Such as Diabetes, Cerebrovascular Disease, Coronary Heart Disease)
- Hydration Status
- Infections
- Nausea, Vomiting
- Obesity and Anesthesia Risk
- Recent Starvation or Prolonged Malnutrition
- Recent Weight Changes, Especially Unintentional Loss
- Respiratory Function, Oxygen Saturation
- Serum Albumin, Transferrin, Retinol-Binding Protein, and C-Reactive Protein (CRP) (Inflammation)
- Surgical Procedure with Gastrointestinal (GI) Impact

### Postsurgical Status

- Abnormal GI Function (diarrhea, constipation, obstruction)
- Altered Labs Such as Glucose, CRP, Electrolytes
- Breathing Rate
- Fever
- Impaired Skin Integrity, Wound Dehiscence
- Infection or Sepsis
- Nausea, Vomiting
- Pain, Sleep Disturbance
- Paralytic Ileus, Abdominal Distention
- Pneumonia or Lung Collapse
- Respiratory Function, Oxygen Saturation
- Urinary Tract Infection

## GENERAL SURGICAL GUIDELINES

## SURGERY

## NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Smeltzer SC, Bare BG. *Textbook of Medical-Surgical Nursing*, 9th ed. Philadelphia: Lippincott Williams & Wilkins, 2000.

## DEFINITIONS AND BACKGROUND

Nutritional risk from surgery is related to the extent of surgery, prior nutritional state of the patient, and the effect of surgery on the patient's ability to digest and absorb nutrients. Weight loss is one of the most important assessment tools to predict surgical risk as related to nutritional status. Techniques to assess body composition help to quantify weight loss and clarify the impact of malnutrition on postsurgical status.

Surgery is the term used for treatments that involve cutting or stitching tissue, laser surgery, and robotic surgical procedures. Major surgery involves opening a major body cavity, such as the abdomen (laparotomy) or the skull in a craniotomy. "General anesthesia," a surgical team, and a hospital stay are required. Minor surgery may be done in an outpatient or emergency room setting, often with minimal anesthetic treatment. Surgeries with high risk include hip replacement, open heart surgery, and prostatectomy. Patients who are at high surgical risk include those with heart or renal failure, those who have had a recent heart attack, those who are severely malnourished, and those with chronic lung or liver diseases.

After surgery or injury with extensive tissue damage, plasma cortisol generally increases rapidly and fat breaks down rapidly to fatty acids and glycerol. The metabolic

response to surgical or accidental injury leads to breakdown of skeletal muscle protein and the transfer of amino acids to visceral organs and the wound. At the wound site, substrate serves to enhance host defenses and support vital organ function and wound repair. Increased excretion of nitrogen and sodium retention occur, but these are reversed in approximately 5–7 days or as late as 12–14 days in elderly individuals and after severe burns. Increased excretion of potassium occurs but begins to reverse itself 1–2 days after surgery.

Malnutrition is prevalent among surgical patients and is associated with higher surgical complication rates and mortality (Figure 14-1). Some causes of poor nutritional status are related to the underlying disease, socioeconomic factors, age, and length of hospitalization. If medical teams overlook malnutrition, patients are at risk for malnutrition and complications. Use of tools such as the Subjective Global Assessment identifies malnutrition in many patients.

Elective surgery involves minimal increases in nitrogen loss and a 10–15% increase in energy requirements. Major surgery involves greater intensity and duration that will increase catabolic effects. Prevention of hypoxia in surgical wounds is especially important and preventable; fluid and temperature management are key factors. Table 14-1 defines the average length of time and stages of catabolic response after surgery, followed by anabolism.

The presence of cancer, infection, age more than 60 years, upper gastrointestinal (GI) disease, and longer length of hospital stay all negatively influence nutritional status. Nutritional status plays an important role in determining outcome after many types of operations. Enteral immunonutrition is an important consideration preoperatively as well, if time permits. Early postoperative enteral nutrition with a formula supplemented with arginine, omega-3 fatty acids, and RNA increases hydroxyproline synthesis and improves surgical wound healing in patients undergoing gastric surgery (Farreras et al, 2005).

Fever causes increased nutritional needs; for every 1°F increase, there is an increased energy requirement of 7–8% and the need for extra fluid. Optimal wound healing requires integration of responses to inflammatory mediators, growth factors, cytokines, and mechanical forces (Falanga, 2005). Extra protein is needed for wounds, burns, and hemorrhage; major wounds and burns can cause a loss of greater than 50 g of protein per day. With hemorrhage

**TABLE 14-1 Postsurgical Phases in Nutrition**

3–7 days	Marked catabolic response
2–5 weeks	Turning point and anabolic phase at which spontaneous improvement begins
>6 weeks	Fat gain phase; vigorous nutritional support could promote excessive fat stores

or major blood loss, or even when much blood is drawn for laboratory tests, loss of iron and plasma protein may be significant; loss of 1 L of blood equals a loss of 500 mg of iron and 50 g of plasma protein.

C-reactive protein (CRP) is a risk factor for cardiovascular outcomes and mortality in the general population; it predicts all-cause mortality (Winklmayer et al, 2005). Preoperative serum albumin concentration may predict surgical outcomes such as sepsis, renal failure, and major infections. Early identification of high-risk patients undergoing major surgery allows aggressive management. After surgery, the presence of systemic inflammatory response syndrome is a predictor of later sepsis (Mokart et al, 2005). Other patient risk factors predictive of postoperative morbidity include anesthesia and complexity of the operation.

A complete, balanced diet is recommended after surgery. A clear liquid diet has about 600 kcal/d and D5W solutions have only 170 kcal/L. Early postoperative oral feeding has been demonstrated to be safe (Lucha et al, 2005). Enhanced rate of recovery can be achieved by enhancing the metabolic status of the patient before (e.g., carbohydrate and fluid loading), during (e.g., epidural anesthesia), and after (e.g., early oral feeding) surgery (Fearon and Luff, 2003).

Healing of wounds involves blood cells, tissues, cytokines, growth factors, and metabolic demand for nutrients. Vitamin A is required for epithelial and bone formation, cellular differentiation, and immune function. Vitamin C is necessary for collagen formation, for proper immune function, and as a tissue antioxidant. Adequate protein is absolutely essential for proper wound healing.

Tissue levels of the amino acids arginine and glutamine (GLN) influence wound repair and immune function. GLN depletion in skeletal muscle is an outstanding metabolic marker related to acute skeletal muscle wasting (Roth and Oehler, 2010.) Energy-saving signals may be switched on to protect organs in a mode similar to hibernation; this may explain the low energy expenditure in septic patients (Roth and Oehler, 2010.) Its use in various enteral or parenteral products is accepted in many facilities.

Patients who receive enteral immunonutrition with multiple nutrients before and after major GI surgery often have lower treatment costs. Arginine is helpful in wound healing after trauma (Wilmore, 2004; Wittman et al, 2005). Major surgery, skeletal trauma, prolonged immobilization, and soft tissue damage are followed by increased calcium loss. Vitamin C may be destroyed by extensive inflammation in postoperative conditions. Table 14-2 indicates the extent of body reserves of nutrients. Higher nutrient reserves are advantageous in most surgeries.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Surgery may be needed to repair a genetic condition, such as a congenital heart disorder.

Clinical/History	History of dehydration or slow wound healing	Ca <sup>++</sup> Mg <sup>++</sup> Phosphorus (P) Urinary electrolytes Serum osmolality (Osm) N balance Transferrin Prothrombin time (PT) or international normalized ratio (INR) Hemoglobin and hematocrit (H & H) Serum Fe Vitamin B <sub>12</sub>
Height Weight Body mass index (BMI) Weight changes Diet history Blood pressure (BP) Intake and output (I & O) Nausea, vomiting Constipation Anorexia Urinary tract infection Skin integrity; pressure ulcers	Transfusions  <b>Lab Work</b> Glucose (Gluc) C-reactive protein (CRP) Platelet count Albumin (Alb), transthyretin Blood urea nitrogen (BUN) Creatinine (Creat) Na <sup>+</sup> K <sup>+</sup>	

## INTERVENTION

## OBJECTIVES

### Preoperative

- Maintain or enhance reserves. Many patients admitted to hospitals are malnourished; therefore, proper presurgical assessment and nourishment should be emphasized.

**TABLE 14-2 Time Required to Deplete Body Nutrient Reserves in Well-Nourished Individuals**

Nutrient	Time
Amino acids	Several hours
Carbohydrate	13 hours
Sodium	2–3 days
Water	4 days
Zinc	5 days
Fat	20–40 days
Thiamin	30–60 days
Vitamin C	60–120 days
Niacin	60–180 days
Riboflavin	60–180 days
Vitamin A	90–365 days
Iron	125 days (women); 750 days (men)
Iodine	1000 days
Calcium	2500 days

From: Guthrie H. *Introductory nutrition*. 7th ed. St Louis: Times Mirror/Mosby College Publishers, 1989.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Involuntary Weight Loss**

**Assessment Data (sources of info):** Food records, input and output reports, medication history, assessment of depression.

**Nutrition Diagnosis (PES):** NC-3.2 Involuntary weight loss related to depression and poor intake after above-knee (AK) amputation as evidenced by weight loss of >6% in past 2 weeks and statement that "I just don't feel like eating any more."

**Intervention:** Food-Nutrient Delivery—Offer nutrient and energy-dense foods until appetite improves. Counsel about desired food and beverage intake for wound healing. Coordinate care—Discuss status of depression and medications or counseling with health care team.

**Monitoring and Evaluation:** Improved food intake as per I & O records. Better weight status and rate of wound healing. Improvement in symptoms of depression with medication.

Some facilities use glucose and potassium intravenous loading in nondiabetic, nonrespiratory patients for surgical preparation.

- Identify risks for cardiac events after surgery, which are common and costly (Maddox, 2005).
- Prepare patients who are morbidly obese. Fatty tissues are not resistant to infections, hard to suture, and prone to dehiscence. A large amount of anesthesia is needed in the morbidly obese patients, and it is difficult to awaken them. Controlled weight loss should be instituted before surgery whenever possible.
- Elevated serum glucose on admission is an accurate predictor of postoperative infection, length of stay, and mortality (Bochicchio et al, 2005). Reducing hyperglycemia is important.

**Postoperative**

- Replete nutrient stores, such as protein and iron from hemorrhage or other blood losses. Replace important vitamins and minerals (vitamin C, 100–200% recommended amounts; vitamin K, zinc, and vitamin A).
- Correct imbalances in fluid, sodium, potassium, and other electrolytes.
- Promote wound healing. The surgical wound has priority only for the first 5–10 days. Wound tensile strength peaks at 40–50 days.
- Use enhanced immunonutrition where needed to provide sufficient amounts of protein and energy to preserve muscle function; stimulate and protect enterocytes while limiting bacterial translocation; keep liver function as normal as possible; and prevent or compensate for disturbances in the immune response. Arginine triggers anabolic hormones (e.g., insulin, growth hormone) and speeds wound healing (Zaloga et al, 2004). Arginine is important for growth, wound healing, cardiovascular function, immune function, inflammatory responses, energy metabolism, urea cycle function, and other metabolic processes (Zaloga et al, 2004). While

**TABLE 14-3 Measuring Energy Expenditure in Critical Illness**

Measuring energy expenditure via indirect calorimetry (IC) is the most accurate method of determining needs. For short-term use, predictive equations such as the Ireton-Jones calculation for nutrition support are recommended.

Ireton-Jones Equations for Estimated Energy Expenditure (EEE)  
(Ireton-Jones and Jones, 1998)

1. Spontaneously Breathing Patient:  $EEE = 629 - 11(A) + 25(W) - 609(O)$
2. Ventilator-Dependent Patient:  $EEE = 1784 - 11(A) + 5(W) + 244(G) + 239(T) + 804(B)$

Key: A = age in years; W = weight in kg; O = obesity (>130% ideal body weight); G = gender (female = 0, male = 1); T = diagnosis of trauma (absent = 0, present = 1); B = diagnosis of burn (absent = 0, present = 1).

somewhat controversial, it may be helpful to select an immune-enhanced tube feeding (TF) product for GI surgeries.

- Attend to special needs such as fever, trauma, pregnancy, and growth in infants and children.
- Prevent infection and sepsis, which can occur in more than 10% of surgical cases.
- Prevent aspiration, a leading cause of pneumonia and the most serious complication of enteral TF. Traditional clinical monitors of glucose oxidase strips and blue food coloring (BFC) should never be used; evaluation of gastric residual volumes is recommended.
- Minimize weight loss, which is not obligatory.
- Prevent or correct sarcopenia and protein—energy malnutrition (PEM). Table 14-3 describes the use of estimated energy requirement calculations when indirect calorimetry is not available. With complete bed rest, young adults lose about 1% of their muscle per day; seniors lose up to 5% per day because of lower levels of growth hormone, which maintains muscle tissue. Sitting up in bed, moving, standing, and exercising as soon as possible and safe is good for surgical patients.
- Manage pain, blood clots, and other complications. Constipation or difficulty urinating may also occur, especially with opioids and anticholinergic drugs, inactivity, and not eating.

**FOOD AND NUTRITION****Preoperative**

- Because malnutrition is a recognized risk factor for perioperative morbidity, the Nutrition Risk Screening 2002 score should be used to identify patients at nutritional risk who may benefit from nutritional support therapy; it has been officially adopted by the European Society of Parenteral and Enteral Nutrition (Schiesser et al, 2008.)

- Use a high-protein/high-energy diet, a TF, or parenteral nutrition, if needed. Enteral nutrition is effective, poses lower risks than parenteral nutrition, reduces infection rates, and shortens hospital length of stay of critically ill patients (Grimble, 2005).
- If patient is obese, use a low-energy diet that includes carbohydrates adequate for glycogen stores and protein to protect lean body mass. Elevated serum glucose on admission is an accurate predictor of postoperative infection, length of stay, and mortality (Bochicchio et al, 2005).
- Ensure that intakes of zinc and vitamins C and K are adequate.
- Bowel cleansing regimens commonly require adherence to liquid diets for 24–48 hours before examination, which often leads to poor compliance. Offering patients a regular breakfast and a low-residue lunch before bowel cleansing with sodium phosphate oral solution may be better tolerated.
- Gradually restrict diet to clear liquids and then nothing by mouth (NPO).

### Postoperative

- Immediately after surgery, use intravenous glucose, insulin, or electrolytes as needed (Bossingham et al, 2005). As treatment progresses, advance diet as tolerated to a combination of liquid and solid items.
- A complete, balanced mix of nutrients is best. Excessive vitamin and mineral supplements do not increase rate of healing. In fact, because zinc and iron are bacterial nutrients, excesses may be detrimental.
- If oral feeding is not possible, use enteral nutrition. Initiate TF within 12–18 hours for less sepsis and fewer complications. The gut can generally tolerate early feedings, even in patients with pancreatitis (Gabor et al, 2005; Lucha et al, 2005; Marek and Zaloga, 2004). Early postoperative feeding is generally safe, effective, and cost-effective (Braga and Gianotti, 2005).
- When necessary, because of prolonged GI compromise or short bowel syndrome, use central parenteral nutrition (CPN). Use caution with intravenous lipids due to proinflammatory omega-6 fatty acids. Omega-3 fatty acids are acceptable and not inflammatory. The adaptive role of the small intestine after surgery is described in Table 14-4.
- For elective GI surgery, specialized immunonutrition does not have to be routine (Klek et al, 2008.) Enteral nutrition is preferred over parenteral nutrition when the GI tract is functional (Zaloga, 2006). GLN-enhanced products are useful, especially in malnourished patients; they improve antioxidant levels (Grimble, 2005; Luo et al, 2008). If PN is needed, glutamine-supplemented parenteral nutrition (GLN-PN) significantly decreases infections in surgical intensive care patients after cardiac, vascular, and colonic surgery (Estivarez et al, 2008.)
- With oral diet, offer increased fluid and include sources of protein, zinc, and vitamins C and A for wound healing. Use 25–45 kcal/kg and 1–1.5 g protein/kg; this varies depending on extent of surgical intervention and degree of catabolism. Losses of 5–15 g of nitrogen daily may occur.
- An analysis of clinical studies using enteral formulas with supplemental arginine suggests overall benefits (Zaloga

**TABLE 14-4 The Small Intestine After Surgery**

- The small intestine has a large adaptive capacity, with resection of small segments generally not causing nutritional problems.
- If the terminal ileum is removed, vitamin B<sub>12</sub> and bile salts will not be reabsorbed.
- Diarrhea can be massive if the ileocecal valve is removed with the terminal ileum, with great electrolyte losses and hypovolemia.
- Cholestyramine may be needed to bind bile salts.
- Fat malabsorption with steatorrhea and inadequate vitamin A, D, E, and K absorption may also occur. Medium-chain triglycerides (MCT) and water-miscible supplements may be necessary.
- Hyperoxaluria and renal stones may occur. Calcium supplements, altered polyunsaturated fatty acid (PUFA) intake, and aluminum hydroxide binders may be needed.

et al, 2004). Arginine is found in shrimp, lean ground beef, pumpkin seeds, garbanzo beans, cottage cheese, peanuts, and soy milk.

- Hyperglycemia is associated with poor wound healing, increased susceptibility to infection, and other complications. While perioperative hyperglycemia has been associated with increased surgical site infections, there is insufficient evidence to support strict versus conventional glycemic control (Kao et al, 2009.)
- Electrolyte imbalances are common after surgery; see Table 14-5.
- Fluid imbalances are also common. Monitor for changes in urine output or concentration. Check labs such as BUN, albumin, sodium, and glucose. Check for

Adapted from: Nettina, Sandra M., MSN, RN, CS, ANP, *The Lippincott Manual of Nursing Practice*, 7th ed. Lippincott Williams & Wilkins, 2001.

fever. Calculate fluid needs; evaluate using I & O records. Be sure that medications are given with 4 oz of fluid and that sufficient fluid is served with and between meals.

- Intravenous therapy will likely be used to give fluids directly into a vein. IVs can be intermittent or continu-

ous. Risks of IV therapy may include infiltration, fluid overload, electrolyte imbalances, phlebitis, or infection. It is important to calculate the content of IV fluids when they contain glucose, as indicated in this example:

Solution	Name	Na <sup>+</sup> (mmol/L)	Cl <sup>-</sup> (mmol/L)	K <sup>+</sup> (mmol/L)	Ca <sup>2+</sup> (mmol/L)	Glucose (mg/dL)
D5W	5% dextrose	0	0	0	0	5000
2/3D & 1/3 S	3.3% dextrose/0.3% saline	51	51	0	0	3333
Normal saline	0.9% NaCl	154	154	0	0	0
Ringer's lactate	Lactated Ringer	130	109	4	3	0

Follow an interdisciplinary protocol for managing dehydration, as shown on the following page.

### Common Drugs and Anesthesia Used with Surgery and Potential Side Effects

- Anesthesia delays peristalsis; eat ice chips or sip carbonated beverages until nausea subsides.
- Analgesics should provide effective pain relief. Epidural analgesia in GI surgery yields shorter duration of postoperative ileus, attenuation of the stress response, fewer pulmonary complications, and improved postoperative pain control and recovery (Fotiadis et al, 2004). Pain medications should be taken sufficiently in advance of meals to allow a pleasant, pain-free mealtime.
- Antibiotics may be needed; monitor specific side effects for selected medication.
- Insulin may be needed if hyperglycemia persists.
- Laxatives may deplete electrolytes. When able to progress, use a higher fiber intake and plenty of liquids.
- Metoclopramide (Reglan) may help with postoperative ileus (Chan et al, 2005). Dry mouth or nausea can result after prolonged use.
- Vitamin K can help with clotting. There are generally no side effects with this injection. Warfarin (Coumadin), a blood thinner used to prevent emboli, requires that patients maintain steady intake of vitamin K foods (cabbage, kale, and spinach) to control levels. Heparin has no dietary consequences.

### Herbs, Botanicals, and Supplements

- Interactions between herbs, anesthesia, and surgery must be noted. For surgical patients, herbs can affect sedation, pain control, bleeding, heart function, metabolism, immunity, and recovery. As many as one third of presurgical patients take herbal medications, and many of those patients fail to disclose herbal use during preoperative

assessment, even when prompted. Table 14-6 describes these potential interactions.

- Antioxidant foods are protective. Consume plenty of tea and foods listed in Table 13-2. Coenzyme Q10 may help to lower angiogenesis markers and lipid levels; studies are ongoing.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Immobilization of the patient can produce unwanted side effects. Have patient drink plenty of fluids and ambulate as soon as possible.
- Patients tend to lose 0.5 lb daily early in postoperative period. Weight gain during this time suggests fluid excess.
- Eat and drink slowly to prevent gas formation from swallowed air.
- Discuss the role of surgery as “planned trauma,” allowing adequate time for return to homeostasis. Discuss wound healing priority, tensile strength, and role of nutrients (zinc, vitamin C, vitamin A, and amino acids). Note that poor nutrient intake can decrease anabolism, delaying scar formation. B-complex vitamins are also beneficial. While zinc deficiency impairs wound healing, supplementation in people who are not deficient does not accelerate wound healing and an excess can interfere with immune system function and copper absorption.
- During the rehabilitative anabolic stage (3 months to 1 year postoperatively), energy intake should be adequate but not excessive.
- With amputation, determine the percentage of body mass lost and decrease estimated energy needs accordingly; see Table 14-7.
- Table 14-8 lists other types of surgeries and their specific nutritional impact.

### Patient Education—Food Safety

Surgical patients may be vulnerable to foodborne illness; safe food handling and handwashing are essential.

## INTERDISCIPLINARY NUTRITION CARE PLAN

### Dehydration

Client Name: \_\_\_\_\_ #: \_\_\_\_\_ Initiated by: \_\_\_\_\_ Date: \_\_\_\_\_

#### SCREEN

Nutrition Screen diagnosis: Dehydration

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### GOALS (Check any/all):

- ☐ Assure intake of minimum daily water need of \_\_\_\_\_ mL in \_\_\_\_\_ (goal time).  
(Calculate using **Daily Water Need for Adults.**)
- ☐ Maintain or improve hydration status as indicated by weight gain, fluid intake greater than or equal to output and normalization of biochemistries in \_\_\_\_\_ (goal time).
- ☐ Prevent dehydration-related adverse events in \_\_\_\_\_ (goal time).
- ☐ Reduce or eliminate dehydration risk factors in \_\_\_\_\_ (goal time).

#### ASSESS (Check any/all)

##### Hydration status

- ☐ Fluid intake  $\leq$  fluid output
- ☐ Diuretics\* multiple medications
- ☐ Ostomy\*
- ☐ Increased environmental temperature/  
no air conditioning/low humidity

##### Biochemistries

- ☐  $\uparrow$  BUN ☐  $\uparrow$  Serum sodium

##### Complex diet order

- ☐ High-protein, high-calorie diet
- ☐ Fluid restriction

##### Infection/Wounds

- ☐ Fever ☐ Pneumonia, UTI, URI
- ☐ Pressure ulcers, wounds

##### Poor Oral Intake Symptoms

- ☐ Anorexia ☐ Nausea/vomiting\*
- ☐ Poor appetite ☐ Diarrhea\*

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### MODERATE RISK INTERVENTIONS (Check any/all)

**Getting the Fluid You Need** provided and explained

**Food Record** provided and explained

**Obtain Dr. orders as needed:**

- ☐ RD chart consult
- ☐ Monitor weight q: \_\_\_\_\_
- ☐ **Other:** \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### HIGH-RISK INTERVENTIONS (Check any/all)

- ☐ **Getting the Fluid You Need** provided and explained
- ☐ **Food Record** provided and explained
  - ☐ Assure intake of a 2qt (2L) of appropriate fluids/day

**Obtain Dr. orders as needed:**

- ☐ RD referral for home visit(s)
- ☐ Monitor weight q: \_\_\_\_\_
- ☐ Monitor I & O q: \_\_\_\_\_
- ☐ Oral rehydration fluid if diarrhea, vomiting, ostomy are present

☐ **Other:** \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### ASSESS RESPONSE (Check any/all)

- ☐ Weight loss
- ☐ Fluid intake less than fluid output
- ☐ Onset of new infection
- ☐ Dehydration
- ☐ Exhibiting Poor Oral Intake symptoms
- ☐ **Other:** \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES ACHIEVED

- ☐ Hydration status maintained or improved
- ☐ Weight maintained or improved
- ☐ Nutrition status maintained or improved
- ☐ **Other:** \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Risk Screen in \_\_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### ASSESS RESPONSE (Check any/all)

- ☐ Further weight loss
- ☐ Fluid intake less than fluid output
- ☐ Onset of new infection
- ☐ Dehydration
- ☐ Exhibiting Fewer Oral Intake symptoms
- ☐ **Other:** \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES ACHIEVED

- ☐ Hydration status maintained or improved
- ☐ Weight maintained or improved
- ☐ Nutrition status maintained or improved
- ☐ **Other:** \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Risk Screen in \_\_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES NOT ACHIEVED

Notify physician. Reassess/evaluate need for EN/PN (refer to Tube Feeding Nutrition Care Plan). Document on Nutrition Variance Tracking form.

\* Requires replacement of water and electrolytes.

**TABLE 14-5 Managing Electrolyte Imbalances**

Three variables regulate pH in blood plasma: carbon dioxide, electrolyte concentrations, and total weak acid concentrations.

Acid–base balance is when blood pH is out of the normal range (7.35–7.45). An excess of acid leads to acidosis (pH < 7.35) and an excess of base leads to alkalosis (pH > 7.45). Imbalance is classified according to the source: respiratory or metabolic.

There are four basic conditions: metabolic acidosis, respiratory acidosis, metabolic alkalosis, and respiratory alkalosis.

Dietitians typically address electrolyte imbalances, which involve calcium, potassium, magnesium, and sodium and are discussed here.

Normal Range	Causes of Elevation	Causes of Decline
<b>Sodium (Na):</b> 135–145 mEq/L	<b>Hypernatremia:</b> Excessive loss of water through GI system, lungs, or skin; fluid restriction, certain diuretics, hypertonic IV solutions, tube feeding; hypothalamic lesions, hyperaldosteronism, corticosteroid use, Cushing's syndrome, diabetes insipidus	<b>Hyponatremia:</b> Congestive heart failure, cirrhosis, nephrosis, excess fluid intake, syndrome of inappropriate anti-diuretic hormone secretion (dilutional hyponatremia); sodium depletion, loss of body fluids without replacement, diuretic therapy, laxatives, nasogastric suctioning, hypoaldosteronism, cerebral salt-wasting disease
<b>Potassium (K):</b> 3.5–5.0 mEq/L	<b>Hyperkalemia:</b> Aldosterone deficiency, sodium depletion, acidosis, trauma, hemolysis of red blood cells, potassium-sparing diuretics	<b>Hypokalemia:</b> Lack of dietary intake of potassium, vomiting, nasogastric suctioning, potassium-depleting diuretics, aldosteronism, salt-wasting kidney disease, major GI surgery, diuretic therapy with inadequate potassium replacement
<b>Calcium (Ca):</b> 8.5–10.5 mg/dL	<b>Hypercalcemia:</b> Excessive vitamin D, immobility, hyperparathyroidism, potassium-sparing diuretics, ACE inhibitors, malignancy of bone or blood	<b>Hypocalcemia:</b> Hypoparathyroidism, malabsorption, insufficient or inactivated vitamin D or inadequate intake of calcium, hypoalbuminemia, diuretic therapy, diarrhea, acute pancreatitis, bone cancer, gastric surgery
<b>Magnesium (Mg):</b> 1.5–2.5 mg/dL	<b>Hypermagnesemia:</b> Excessive use of magnesium-containing antacids and laxatives, untreated diabetic ketoacidosis, excessive magnesium infusions	<b>Hypomagnesemia:</b> Malabsorption related to GI disease, excessive loss of GI fluids, acute alcoholism/cirrhosis, diuretic therapy, hyper- or hypothyroidism, pancreatitis, preeclampsia, nasogastric suctioning, fistula drainage

Kee J, et al. *Fluids and electrolytes with clinical applications: a programmed approach*. 7th ed. Clifton Park, NY: Delmar Learning, 2004.

Signs and Symptoms	Comments and Nutritional Concerns
<b>HYPONATREMIA</b> Lethargy, anorexia, nausea, vomiting, cramping, muscular twitching, confusion, fingerprinting over the breastbone, seizures, and coma. Hyponatremia is associated with increased morbidity and mortality.	Distinguish between the different types of hyponatremia and their treatments. Contracted extracellular fluid volume may occur; a hypertonic or isotonic saline solution is given (perhaps salty broth). Avoid giving large water flushes with isotonic tube feeding. Fluid restriction and low-sodium diet with diuretics may cause hyponatremia. D5W used in excess can cause hyponatremia with water intoxication.
<b>HYPERNATREMIA</b> Thirst, dry and sticky mucous membranes, fever, dry and swollen tongue, disorientation, and seizures. Flushing, fever, loss of sweating, dry tongue and mucous membranes, tachycardia, hallucinations, or coma.	High-protein tube feedings without adequate water flushes, excessive diaphoresis, diabetes insipidus, or watery diarrhea may cause problems. Correct dehydration. Monitor thirst, the first sign of water loss. High doses of steroids, solutions that contain NaCl, other sodium additives, and sodium-containing analgesics should be managed or omitted. Determine patient's fluid needs (generally 30 mL/kg or 1 mL/kcal given in enteral or total parenteral infusions. Adjust according to the renal or cardiovascular status, especially in seniors. Patients with dysphagia may have difficulty obtaining enough fluid; monitor closely.
<b>HYPOKALEMIA</b> Severe muscle weakness, electrocardiogram (ECG) changes and arrhythmias, lethargy, hypotension, shallow breathing, fatigue, anorexia, constipation, confusion, and impaired carbohydrate (CHO) tolerance. Chloride depletion usually accompanies hypokalemia; alkalosis is also common.	Replace potassium (generally done with intravenous or oral KCl, except in renal tubular acidosis). Kaochlor, Kay-Ciel, K-Lor, K-Lyte, K Tab, Klotrix, Micro-K, K-Dur, Klor-Con, Ten-K, and Slow-K are all sources of potassium. Some products are slow release. Diarrhea, nausea, or vomiting may occur; take with meals. A potassium-rich diet may also be needed. Monitor serum levels and adjust accordingly. Be sure fluid intake is adequate.

(continued)

**TABLE 14-5 Managing Electrolyte Imbalances (continued)**

Signs and Symptoms	Comments and Nutritional Concerns
<b>HYPERKALEMIA</b> Weakness, anxiety, altered ECGs (with $>7$ mEq/L, a fatal arrhythmia can occur), flaccid muscle paralysis, or even respiratory arrest, if severe.	Immediate treatment is needed to prevent arrhythmias, bradycardia, heart block, and respiratory arrest. If all else fails, dialysis may be needed. Intravenous feedings are likely to be used (glucose, insulin, bicarbonate) to shift potassium intracellularly. Sodium or calcium may also be needed as physical antagonists; infusions will be given until serum potassium is corrected. Monitor closely. Avoid high-potassium foods and $K^+$ in salt substitutes. Kayexalate may be needed and should be given with sorbitol to prevent constipation; take separately from calcium or antacids. Read labels of oral supplements to be sure total $K^+$ is calculated.
<b>HYPOCALCEMIA</b> Tetany, seizures, and cardiac arrest. In the long term, bone demineralization with bone pain and compression fractures may result.	Correct symptomatic condition (usually calcium gluconate intravenously). Supplement with vitamin $D_3$ as needed. When able to eat orally, provide a high-calcium intake; dry milk can be added to foods. Avoid excesses of caffeine, oxalate, fiber, and aluminum-containing antacids. Calcium carbonate (as in Tums) provides 40% elemental calcium. Drink extra water. Avoid use of iron supplements at the same time. Beware of bone meal and dolomite because of their toxic metal content.
<b>HYPERCALCEMIA</b> Drowsiness, lethargy, stupor, muscle weakness, decreased reflexes, nausea and vomiting, anorexia, constipation, ileus, polyuria, renal stones, azotemia, nocturia, hypertension, bradycardia, pruritus, and eye abnormalities.	Correct underlying condition with rehydration (usually with normal saline) and hemodilution. Correct nausea, vomiting, constipation, and other side effects. Avoid excesses of milk, vitamins A or D, calcium supplements and antacids, and lactose. Potassium and magnesium may also be depleted; monitor carefully. Extra caffeine, oxalates, fiber, and phytates can help to decrease calcium absorption and can help excretion. Sometimes furosemide or prednisone is used to excrete calcium also. Intravenous etidronate (Didronel) may be used; nausea and vomiting could occur.
<b>HYPOMAGNESEMIA</b> Anxiety, hyperirritability, confusion, hallucinations, seizures, tremor, hyperreflexia, tetany, tachycardia, hypertension, arrhythmias, vasomotor changes, profuse sweating, muscle weakness, grimaces of facial muscles, and refractory hypocalcemia.	Correct low serum magnesium levels to prevent sudden death. Discuss long-term measures to prevent further episodes. Long-term use of magnesium-free CPN can be one aggravating source of the problem. Monitor intake from all sources (oral, TF, CPN.) Milk of magnesia (MOM) can be used for liquid form of magnesium hydroxide; nausea, cramps, or diarrhea may result. Normal renal function is needed for use of magnesium sulfate; diarrhea can occur. Chocolate, nuts, fruits and green vegetables, beans, potatoes, wheat, and corn are considered good sources.
<b>HYPERMAGNESEMIA</b> Lethargy, hyporeflexia, and respiratory depression. Bradycardia, myocardial infarction, and respiratory failure may be fatal.	Reduce or eliminate sources of exogenous magnesium from diet, supplements, CPN solutions, and medications until resolved. Calcium-containing medications may be given to help with excretion of excessive magnesium. Avoid megadoses of multivitamin-mineral supplements.
<b>HYPOPHOSPHATEMIA</b> Anorexia, weakness, bone pain, dizziness, and waddling gait may be observed. In severe cases, elevated creatine phosphokinase (CPK) levels are seen, with rhabdomyolysis superimposed on myopathy. Hypophosphatemia may result in sudden death, rhabdomyolysis, red cell dysfunction, and respiratory insufficiency. Heart failure can result if phosphorus is not administered. Low serum phosphorus levels will result in lowered 2,3-diphosphoglyceric acid (2,3-DPG), which facilitates oxyhemoglobin dissociation and leads to tissue hypoxia and low partial pressure of oxygen.	Phosphorus is a major component of bone and is one of the most abundant constituents of all metabolic processes and tissues; 85% is found in the skeleton. Only about 12% is bound to proteins; a typical laboratory assessment is of elemental phosphorus, with some values for $HPO_4$ and $NaHPO_4$ as well. Prevent further complications. Use appropriate measures according to the cause; for example, low-phosphorus diet with high calcium and adequate vitamin D will be needed in renal osteodystrophy. Note that 50–60% of dietary phosphorus is absorbed, and more is absorbed in depleted persons. If potassium phosphate (K-Phos) is used as an acidifier, it may cause nausea, vomiting, or diarrhea.
<b>HYPERPHOSPHATEMIA</b> Phosphorus levels tend to be higher in children and to rise in women after menopause.	Provide appropriate levels of phosphorus according to age and serum status. Monitor glucose and phosphorus intake, especially from enteral or parenteral nutrition. Monitor dietary intake of milk, meat, and other foods high in phosphorus. Observe serum levels regularly, especially in renal patients. Antacids containing aluminum will prevent phosphorus absorption in intestinal lumen. Calcium acetate is useful in dialysis patients.

**TABLE 14-6 Herbal Medications and Recommendations for Discontinued Use before Surgery**

Most commonly used herbs and antidepressant medications have potentially deleterious effects on the patient during surgery, ranging from increased risk of bleeding to fatal interactions (Chin et al, 2009.) The top four used by the general public are Echinacea, garlic, ginseng, and ginger (Heller et al, 2006.)

Herb	Relevant Effects	Perioperative Concerns	Recommendations
Echinacea	Boosts immunity	Allergic reactions, impairs immune system, especially for transplantation patients	Discontinue as far in advance as possible.
Ephedra (ma huang)	Increases heart rate and increases blood pressure	Risk of heart attack, arrhythmias, stroke, kidney stones, interaction with other drugs	Discontinue 24 hours before surgery.
Garlic	Prevents clotting	Risk of bleeding, especially when combined with other drugs that inhibit clotting	Discontinue at least 7 days before surgery.
Ginkgo	Prevents clotting	Risk of bleeding, especially when combined with other drugs that inhibit clotting	Discontinue at least 36 hours before surgery.
Ginseng	Lowers blood glucose, inhibits clotting	Increases risk of bleeding; interferes with warfarin (an anticlotting drug)	Discontinue at least 7 days before surgery.
Kava	Sedates, decreases anxiety	May increase sedative effects of anesthesia	Discontinue 24 hours before surgery.
St. John's wort	Inhibits reuptake of neurotransmitters	Alters metabolisms of other drugs	Discontinue at least 5 days before surgery.
Valerian	Sedates	Could increase effects of sedatives. Long-term use could increase amount of anesthesia needed.	If possible, taper dose weeks before surgery. Withdrawal symptoms resemble diazepam (Valium) addiction.

**TABLE 14-7 Percentage of Body Weight in Amputees**

Body weight is a good indicator of a person's size and is widely used in assessments. Body mass index (BMI) values in subjects with limb amputation are not useful unless lost weight of the limbs is not considered in the calculation. To reduce the underestimation of nutritional status in persons with limb amputation, estimation of body weight is necessary so that BMI can be reliably estimated for persons with limb amputation. Estimated body weight after amputation uses the following formula:

$$\text{Estimated Ideal Body Weight (IBW)} = (100 - \% \text{ amputation})/100 \times \text{IBW for original height.}$$

**Body Part and % Loss from Amputation**

Below knee	6.5%
Bilateral below knee (BK)	13%
Bilateral above knee (AK)	16%
BK + AK	14.5%
Foot	1.5%
Both feet	3%
Hand	0.7%
Both hands	1.4%
Forearm and hand	3%
Both forearms/hands	6%
Entire arm	5%
Both entire arms	10%
Entire leg	16%
Both entire legs	32%

Adapted from: Osterkamp LK. Current perspective on assessment of human body proportions of relevance to amputees. *J Am Diet Assoc*. 95:215, 1995.

Amputee BMI calculator, [http://touchcalc.com/calculators/bmi\\_amputation](http://touchcalc.com/calculators/bmi_amputation), accessed January 20, 2010.

**TABLE 14-8** Surgeries, Level of Nutritional Acuity, and Nutritional Recommendations

Background	Specific Objectives	Food and Nutrition Recommendations
<b>Amputation, Level 2</b> Amputations may result from poorly controlled diabetes, trauma, peripheral artery disease, congenital deformity, chronic infections, gangrene, or tumors such as osteosarcoma.	<p><u>Postoperative:</u> Determine percentage of body weight of amputated area and calculate changes from preoperative to postoperative status in height, weight, and body mass index (BMI). Provide adequate protein, calories, zinc, vitamins C, K, and A for healing. Low albumin levels, serum carotene, zinc, and vitamin C are commonly found.</p> <p><u>Long Term:</u> Provide a low-calorie diet, if needed. For patients who lose too much weight, a higher energy diet should be used. Otherwise, immobilized patients tend to gain weight and will need weight control measures.</p>	<p><u>Postoperative:</u> Use a high-protein/high-energy diet for healing. Supplement diet with vitamins and minerals, especially zinc, vitamins A, C, and K, and arginine. Use tube feeding (TF) if necessary; consider use of an immune-enhanced product. For hand or arm amputations, consider adaptive feeding equipment with Occupational therapy (OT) specialists.</p> <p><u>Long Term:</u> Discuss how to control or increase calories in diet for energy use. Patients with an AK amputation who walk with or without prosthesis use 25% more energy than a nondisabled person who walks at the same speed; these patients have difficulty maintaining weight.</p>
<b>Appendectomy, Level 1</b> Appendectomy generally is an uncomplicated procedure with minimal recovery time. A low-fiber diet may contribute to appendicitis.	<p><u>Preoperative:</u> White blood cell count and erythrocyte sedimentation rate may be increased.</p> <p><u>Postoperative:</u> Reduce fever. Lower risks of infection or sepsis, peritonitis, or abscess formation.</p>	<p><u>Postoperative:</u> Use a balanced diet with adequate amounts of zinc and vitamins C, K, and A.</p> <p><u>Long-Term:</u> After recovery, include more fruits, vegetables, and whole grain for fiber.</p>
<b>Cesarean delivery (C-section), Level 1</b> C-section is performed for numerous reasons, including HIV infection, maternal diabetes, or edema-proteinuria-hypertensive (EPH) gestosis.	<p><u>Postoperative:</u> Manage nausea, which is common after anesthesia. Replenish stores of nutrients from blood and fluid losses. Reduce likelihood of complications such as hemorrhage, infection, fever, drainage, cystitis, anemia, or pneumonia after the operation.</p>	<p><u>Postoperative:</u> Nothing by mouth (NPO) with intravenous or clear liquids and ice chips will be given until nausea subsides. Progress to usual diet, with increased fiber and fluid to soften stools. Promote wound healing with protein and energy; include iron, vitamins C and A, and zinc in diet or supplemental form.</p>
<b>Coronary Artery Bypass Graft (CABG), Level 3</b> Open heart procedures require use of a cardiopulmonary machine for extracorporeal circulation. Narrowed or blocked arteries are bypassed; the vein usually comes from the leg. Blood can then flow directly into the heart muscle. CABG usually takes 4–5 hours.	<p><u>Preoperative:</u> Monitor serum levels of electrolytes, albumin, and glucose. Provide the diet as prescribed (may be sodium, energy, or fluid restricted). Provide ample amounts of glycogen for stores. Use nutrition support, if needed, for malnourished cardiac patients.</p>	<p><u>Postoperative:</u> Control fluid intake by measuring previous day's output plus 500 mL for insensible losses. Provide adequate protein, kilocalories, and micronutrients for wound healing. Use TF or CPN if severely malnourished. Replete slowly and keep head of bed elevated 30° to prevent worsening of heart failure. Low-sodium, high-calorie, low-volume TF products may be useful.</p>
Heart valve replacement involves replacing the damaged valve with a mechanical prosthesis (St. Jude valve) or biological tissue valve. This may be done with robotic techniques, which are less invasive than open heart procedures.	<p><u>Postoperative:</u> Promote wound healing and restore normal fluid and electrolyte balance. Promote weight control. Wean from ventilator support when possible. Prevent hyperglycemia, coma, sepsis, renal failure, cardiac tamponade, wound dehiscence, and atelectasis. Maintain comfort and educate regarding follow-up.</p> <p><u>Long Term:</u> Avoid excessive weight gain, which can further aggravate heart condition. Teach appropriate measures for changes in daily diet to prevent further problems while wound is healing. Discuss need to alter lifestyle (diet, exercise, and stress) to prevent additional problems; many patients have atherogenic effects even after heart surgery. Control carbohydrates in patients with diabetes or hypertriglyceridemia.</p>	<p><u>Long-Term:</u> Modify diet to control sodium and potassium intake, lessen edema, and improve blood pressure. Diuretics and digoxin may deplete potassium; anorexia, nausea, and diarrhea may occur. Beta-blockers, ace inhibitors, and other cardiac drugs may require use of low-sodium, low-calorie diets. Hypoalbuminemia can cause digoxin toxicity. National Cholesterol Education Program guidelines may be used if serum cholesterol remains high.</p>

(continued)

**TABLE 14-8** Surgeries, Level of Nutritional Acuity, and Nutritional Recommendations (*continued*)

Background	Specific Objectives	Food and Nutrition Recommendations
<b>Craniotomy, Level 2</b> Craniotomy involves removing and replacing the bone of the skull to provide access to intracranial structures, usually for a brain tumor.	<b>Postoperative:</b> Prevent aspiration. Prevent or correct dysphagia, constipation, urinary tract infection (UTI), nausea and vomiting, and diabetes insipidus. Normalize electrolyte levels. Prevent blood clots using anticoagulant therapy. If anticonvulsants are used, prevent folic acid depletion. Prevent or manage nausea, vomiting, facial or extremity paralysis, wound drainage, hyperthermia, dysphagia, diabetes insipidus, and syndrome of inappropriate antidiuretic hormone (SIADH). Monitor consciousness, gag reflex, results of examinations such as ECG and cerebrospinal fluid (CSF) levels.	<b>Postoperative:</b> NPO is needed until nausea and vomiting subside. Progress from liquids to soft diet as tolerated. Patient should be fed while lying on his/her side or with his/her head elevated 30° to prevent aspiration. Check swallowing reflex. Assist with feeding if needed, and TF may be required. Adequate fiber may be beneficial. If steroids are used, reduce sodium intake to 4–6 g/d (or less).  <b>Long-Term:</b> Discuss importance of diet in correcting any malnutrition or anemia. As needed, teach family about a diet for dysphagia (e.g., thick, pureed foods with reduced thin liquids). When oral intake is possible, suggest slow chewing and eating. Aphasia occurs in some patients, making it hard to communicate their needs.
<b>Hip Replacement, Level 2</b> A total hip replacement (arthroplasty) is the formation of an artificial hip joint. Prostheses are either cemented in place or uncemented. The procedure is performed for severe degenerative joint disease, rheumatoid arthritis, or congenital deformities.	<b>Preoperative:</b> Enhance nutritional intake in preparation for surgery.  <b>Postoperative:</b> Replenish stores. Prevent side effects of immobilization (renal calculi, pressure ulcers, and UTIs). Promote adequate wound healing. Regain maximum mobility. Use small, frequent meals if nausea is a problem.  <b>Long-Term:</b> Promote early ambulation, when possible, to promote healing and increase strength.	<b>Preoperative:</b> Nutritional status before arthroplasty is a good predictor of surgical outcomes after surgery; albumin levels >3.4 often predict a better outcome.  <b>Postoperative:</b> Use a high-protein/high-energy diet. Supplement diet with zinc and vitamins A, C, and K. Determine whether blood loss can cause anemia; provide sufficient iron and protein in cooperation with medical team.  <b>Long-Term:</b> If weight loss is needed, provide a balanced, low-energy diet after wound healing is completed. Include calcium and phosphorus.
<b>Hysterectomy, abdominal, Level 1</b> Abdominal hysterectomy is the surgical removal of the uterus through an abdominal incision. This approach is used if the uterus is enlarged or if an oophorectomy (ovary removal) and salpingectomy (removal of the fallopian tubes) are also performed.	<b>Postoperative:</b> Promote wound healing and rapid recovery. Replete nutrient reserves and glycogen stores. Replace protein, iron, and vitamin K if blood loss was extensive. Prevent complications such as UTIs, incisional infections, fever, nausea, vomiting, or diverticular colovaginal fistula.  <b>Long-Term:</b> Support gradual return to normal activity; exercise improves nutrient repletion and tissue repair.	<b>Postoperative:</b> Use a high-protein/high-calorie diet. Ensure that adequate fiber and fluid are provided to alleviate constipation. Provide a diet with adequate iron, zinc, and vitamins K, C, and A.  <b>Long-Term:</b> Emphasize the importance of a good diet for wound healing.
<b>Pancreatic Surgery, Level 3</b> This may include total pancreatectomy with or without islet cell autotransplantation for chronic pancreatitis and cancer; subtotal or pancreaticoduodenectomy (Whipple's procedure) for islet cell tumors.	<b>Preoperative:</b> Monitor for history of ethanol (ETOH) abuse with resulting malnutrition and malabsorption; replete if possible.  <b>Postoperative:</b> Prevent or correct sepsis, which is a common complication. Encourage nourishing and well-balanced meals; control CHO if diabetes occurs or is present. Determine pancreatic function according to type and extent of resection and underlying disorder. Whipple's procedure results in dumping syndrome, diarrhea, dyspepsia, ulceration at gastroenterostomy site, and extensive weight loss unless a pylorus-saving technique is used.  <b>Long-Term:</b> Monitor impact of medications and replacement enzymes or hormones that are ordered. Alter fat source with malabsorption or steatorrhea. Offer resources for control of diabetes or for alcohol addiction, as needed.	<b>Preoperative:</b> Use enteral nutrition or CPN to prepare patient for a major operation.  <b>Postoperative:</b> Enteral nutrition, CPN, or oral intake may progress as tolerated. Enteral nutrition has better outcomes if the tube is placed in the jejunum. Standard treatment following major pancreatic surgery includes the administration of pancreatic enzymes and inhibition of acid secretion by proton pump inhibitors; monitor effects on vitamin B <sub>12</sub> status.  <b>Long-Term:</b> A carbohydrate-controlled diet may be needed, along with small, frequent feedings. Most patients develop diabetes that may require insulin; hypoglycemia is the most difficult problem to manage.

(continued)

**TABLE 14-8** Surgeries, Level of Nutritional Acuity, and Nutritional Recommendations (*continued*)

Background	Specific Objectives	Food and Nutrition Recommendations
<b>Parathyroidectomy, Level 1</b> Surgical removal of the parathyroid glands	<p><u>Preoperative:</u> Prepare patient for surgery.</p> <p><u>Postoperative:</u> Manage hypoparathyroidism (with tingling, tetany, hoarseness, and seizures.)</p> <p><u>Long-Term:</u> Vitamin D, calcium, and chemotherapy are often required. A low-phosphorus diet with aluminum hydroxide (Amphojel) may be needed; constipation is one side effect.</p>	<p><u>Postoperative:</u> IV or TF may be needed. Avoid CPN because of high risk for sepsis in the neck area. Provide extra fluids.</p> <p><u>Long-Term:</u> A high-calcium/low-phosphorus diet may be necessary. Monitor carefully. Counsel about follow-up measures and potential medication interactions.</p>
<b>Pelvic Exenteration, Level 1</b> This surgery involves removal of all female reproductive organs and adjacent tissues (i.e., radical hysterectomy, pelvic node dissection, cystectomy and formation of an ileal conduit, vaginectomy, and rectal resection with colostomy). Cancer is usually the reason.	<p><u>Preoperative:</u> A low-residue or elemental diet may be needed, regressing to clear liquids, NPO. Vitamin K may be needed 24–48 hours before the procedure.</p> <p><u>Postoperative:</u> Colonic stasis occurs after major abdominal surgery and persists for approximately 3 days. Prevent hemorrhage, infection, urinary or GI problems, shock, fever, anemia, and sepsis.</p> <p><u>Long-Term:</u> Promote wound healing and recovery. Provide colostomy teaching if needed.</p>	<p><u>Postoperative:</u> Parenteral fluids with electrolytes may be needed (3–4 L/d unless contraindicated).</p> <p>CPN or TF may also be appropriate. If nausea is an extensive problem, give fluids between meals.</p> <p><u>Long-Term:</u> Progress, as tolerated, to a high-protein/high-calorie intake with snacks (eggnog, custard, oral supplements). Adequate iron, zinc, and vitamins A and C help with wound-healing process.</p>
<b>Spinal Surgery, Level 2</b> This surgery generally is performed to relieve pressure on spinal nerves or cord due to herniated discs, trauma, displaced fractures, osteoporosis, or incomplete vertebral dislocation from rheumatoid arthritis. Laminectomy, discectomy, or spinal fusion may be performed.	<p><u>Preoperative:</u> Nutrients may be needed for adequate stores (e.g., glucose, protein, vitamins A, C, and K, and zinc).</p> <p><u>Postoperative:</u> Correct nausea and vomiting if a problem.</p> <p>Prevent calculi, UTIs, and pressure ulcers. Fluid and fiber will be important, but prevent over-hydration.</p> <p><u>Long-Term:</u> Avoid weight gain.</p>	<p><u>Postoperative:</u> Parenteral fluids may be given as ordered. A balanced diet, when patient is ready, with control of total energy intake to prevent excessive weight gain, may be used. If patient has been malnourished, a gradual increase in calories may be beneficial. Adequate hydration will be necessary unless contraindicated.</p> <p><u>Long-Term:</u> Increase fiber intake if constipation is a problem; prune juice, crushed bran, and other items may be used. If tolerated, extra fruits and raw vegetables may be used.</p>
<b>Tonsillectomy/Adenoidectomy, Level 1</b> These tissues are considered to be part of the protective immune system; removal is for severe and chronic ear, throat, and sinus infections.	<p><u>Preoperative:</u> Supply adequate nourishment for glycogen stores.</p> <p><u>Long-Term:</u> Help patient select nonirritating foods for use at home. Avoid hot, spicy foods, raw vegetables, toast and crackers, citrus juices, and other related foods until full recovery.</p>	<p><u>Postoperative:</u> Give cold liquids (sherbet, ginger ale, nectars, and gelatin). Do not use red gelatin as it may mask blood if there is any vomiting. Use extra fluid intake; large swallows are less painful than many small ones. Avoid milk products only if patient cannot tolerate them. On day 2 or 3, use soft, smooth foods (pudding, strained cereals, soft-cooked eggs). Progress to regular diet when tolerated.</p> <p><u>Long-Term:</u> Use supplements of vitamin C if patient cannot tolerate juices. Evaluate zinc intake and encourage dietary sources when possible.</p>

## GASTROINTESTINAL SURGERIES

# BARIATRIC SURGERY AND GASTRIC BYPASS

## NUTRITIONAL ACUITY RANKING: LEVEL 3

The gastric bypass procedure has replaced the jejunal bypass, which had many undesirable nutritional consequences. Adapted from: Neil O. Hardy. Westport, CT. *Stedman's Medical Dictionary*, 27th ed. Baltimore: Lippincott Williams & Wilkins, 2000, p. 1249.

## DEFINITIONS AND BACKGROUND

More than 10 million Americans are severely obese. Bariatric surgery is a viable option for the treatment, resulting in long-term weight loss and improved health risk factors. Bariatric surgery is expensive, \$20,000 and \$25,000, but is an effective weapon against the consequences of morbid obesity. Candidates should be 100 lb or more over ideal weight range, have a BMI greater than 40, or a BMI greater than 35 in addition to serious medical comorbidities. Obesity surgery is superior to medical intervention in this population (Leslie et al, 2007.) Results show lower incidence rates of diabetes, hypertriglyceridemia, and hyperuricemia. In fact, bariatric surgery should be considered for adults who have type 2 diabetes and a BMI greater than 35 kg/m<sup>2</sup>, especially if the diabetes is difficult to control with lifestyle and pharmacologic therapy (American Diabetes Association, 2009.)

Bariatric surgery may be implemented in carefully selected, older, severely obese adolescents (Jen et al, 2010). However, surgical treatment should be considered only when adolescents have tried for at least 6 months to lose weight and have not been successful, have a BMI greater than 40, have reached their adult height (usually 13 or older for girls and 15 or older for boys), and have serious weight-related health problems such as T2DM, heart disease, or sleep apnea (NIDDK, 2010). Teens should be referred only to specialized adolescent bariatric centers.

**Gastric bypass (GBP)** achieves permanent and significant weight loss. The **Roux-en-Y gastric bypass (RYGB)** induces long-term remission of type 2DM, returning impaired glucose tolerance to euglycemia in a matter of days (Pories and Albrecht, 2001). Exclusion of food and alteration in signals from the antrum, duodenum, and proximal jejunum to the pancreatic islet cells improve glucose tolerance. While altered gut and pancreatic hormone secretion may resolve insulin resistance after RYGB, the independent effects of weight loss and hormonal secretion on peripheral glucose disposal are observed only after substantial weight loss (Campos et al, 2010.)

GBP procedures reduce capacity to 40–60 mL and induce physiological and neuroendocrine changes that affect the weight regulatory centers in the brain. Major adverse events include anastomosis leakage, pneumonia, pulmonary embolism, band slippage, and band erosion (Picot et al, 2009.) **Laparoscopic Roux-en-Y gastric bypass (LRYGB)** has fewer side effects, but anastomotic leak is one of them.

**Biliopancreatic diversion with duodenal switch** reduces the stomach to 20%, like a thin sleeve. The duodenal switch (valve) remains along with a limited portion of the duodenum; the intestine is connected to the duodenum near the stomach (biliopancreatic diversion). This weight loss leads to more malnutrition and vitamin deficiencies and requires close monitoring.

**Lap-band adjustable gastric banding** uses an inflatable band to divide the stomach into two parts by wrapping a band around the upper part and tightening it like a belt. Lap-band adjustable gastric banding is simple, has a lower complication rate, and can be adjusted or removed if necessary.

Most patients lose more than 60% of their excess weight after bariatric surgery. GBP and laparoscopic isolated sleeve gastrectomy are more effective for weight loss than vertical banded gastroplasty and adjustable gastric banding; more

research is needed (Picot et al, 2009.) Because gallstones are common after the surgery, cholecystectomy may be done at the same time as the bariatric procedure.

Bariatric surgery appears to be a clinically effective and cost-effective intervention for moderately to severely obese people compared with nonsurgical interventions (Picot et al, 2009.) Expected long-term outcomes include improvement or resolution of diabetes, metabolic syndrome, coronary artery disease, dyslipidemia, gastroesophageal reflux disease, sleep apnea, hypertension, osteoarthritis, and cardiovascular mortality (Jhaveri et al, 2009; Madan et al, 2006; Torquati et al, 2005.)

Deficiencies in protein, iron, vitamin B<sub>12</sub>, folate, calcium, fat-soluble vitamins (A, D, E, and K), and other micronutrients are common and become clinically significant if not recognized and treated with supplements (Carlin et al, 2006.) Copper deficiency, for example, has been noted in this population with cardiovascular and neurological changes (Tan et al, 2006.)

Rhabdomyolysis is a risk from extended immobilization. It is accompanied by pain in the region of the referred muscle group, increase in creatine phosphokinase levels, myoglobinuria, severe renal failure, multiorgan system failure, and death if not treated in time (Filis et al, 2005). Another rare complication is hyperfunction of the pancreatic beta cells (nesidioblastosis) which can lead to life-threatening hypoglycemia (Service et al, 2005). Weight regain after RYGB occurs in approximately 20% of patients and constitutes another serious complication; failure to sustain elevated plasma PYY concentrations occurs (Meguid et al, 2008.)

Quality assurance produces better outcomes (Rendon and Pories, 2005). A multidisciplinary clinical pathway, preprinted orders, discharge home instruction sheet, and daily guidelines are important aspects of treatment. As long as obesity and the popularity of bariatric surgery continue, medical practitioners must be aware of preexisting nutritional deficiencies and treat any nutritional deficiencies that may arise or worsen following surgery (Xanthakos, 2009.) Monitoring and follow-up with a dietitian should be standard procedure. Tips are available in Table 14-9.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The usual reason for GBP is morbid obesity, some of which may be genetically related, but it is believed that environment plays a greater role.

#### Clinical/History

Height  
Weight  
Postoperative weight  
BMI (pre-/post-surgery)

Diet history  
Waist-hip ratio (WHR)  
Waist circumference  
Vomiting  
I & O  
BP

Sleep apnea  
Endoscopy

#### Lab Work

Gluc  
Hemoglobin A1c  
CRP

**TABLE 14-9** Tips for Diet after Gastric Bypass

Diet Order	Timing	Beverage and Food Choices
Clear Liquids ( <i>no more than 1/2 cup total</i> )	1–2 days after surgery	Water, unsweetened drinks, sugar-free gelatin or popsicles, and clear broths. Diluted (pulp-free) juices (1 part juice to 10 parts water.) Decaffeinated tea. NO CARBONATED BEVERAGES. Sip at least 48–64 oz of liquid (especially water) each day. Take a prescribed multivitamin every day.
Full Liquids ( <i>gradually increase to no more than 3/4 cup total</i> )	Days 3–21	<i>Items listed above, plus:</i> Use nonfat acidophilus milk, sugar-free Carnation Instant Breakfast drink, plain soymilk, low-fat cream soups made with skim milk for protein in this stage. May also add cream of wheat or rice cereal; sugar-free yogurt or pudding; unsweetened applesauce or strained infant fruits; sugar-free powdered drinks or iced tea. Sip at least 48–64 oz of liquid (especially water) each day. Take a prescribed multivitamin every day.
Pureed ( <i>gradually increase to no more than 1 cup total</i> )	3–6 weeks after surgery	<i>Items listed above, plus:</i> Low-fat cottage cheese, eggs, tofu, baby food chicken or turkey for protein in this stage. May also add hummus, regular unflavored oatmeal, baby food or toddler fruits and vegetables, blended fruit smoothies, chicken or vegetable broth. Sip at least 48–64 oz of liquid (especially water) each day. Take a prescribed multivitamin every day.
Regular ( <i>small meals and snacks with no more than 1 cup total; 2 oz total meat</i> )	6 weeks on	<i>Items listed above, plus:</i> Low-fat foods (<5 g fat per serving) such as plain rice, well-cooked pasta. Avoid concentrated sweets and sugar (>10 g sugar per serving). For protein, use lean chicken or deboned fish and most tender meats except for tough meats like beef or pork. Allow 30–45 minutes for each meal. Take small bites, and chew food until fairly liquefied before swallowing. Sip at least 48–64 oz of liquid (especially water) each day. Take a prescribed multivitamin every day.

Interleukin-6	Serum Fe	Alkaline
Na <sup>+</sup> , K <sup>+</sup>	Serum B <sub>12</sub>	phosphatase
Ca <sup>++</sup> , Mg <sup>++</sup>	Serum folic acid	Cholesterol
Alb, transthyretin	Serum vitamin D	Triglycerides
H & H	Serum copper	

## INTERVENTION

### OBJECTIVES

#### Preoperative

- Provide adequate glycogen stores and vitamins C and K for surgical procedure. Consider enteral immunonutrition.
- Patients with diabetes should be under fairly good glucose control or at least stable.

#### Postoperative

- Promote wound healing and restoration of depleted glycogen in the liver.
- Prevent side effects during weight loss. The weight loss results of GBP surgery average 10 lb per month and stabilize between 18 and 24 months after surgery. Most patients will never achieve an ideal body weight, but they will be closer to a healthy body weight.
- Prevent complications such as alkaline reflux gastritis, esophagitis, perforation, gastric dilation, stomal obstruction, peptic ulcer, staple line disruption, and excessive vomiting.
- Monitor and manage rare conditions such as rhabdomyolysis, nesidioblastosis, bowel obstruction, and acute renal failure (Capella et al, 2006; Sharma et al, 2006.)
- At 4–6 weeks postoperatively, patients often report that foods taste sweet and will modify intake accordingly. Aversions to meat may occur. Pica may be found in some patients who also have iron deficiency anemia (Kushner and Shanta Retelny, 2005).
- Have patient eat and sip liquids slowly to prevent vomiting; take meat and toast in small bites.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Vitamin Intake

**Assessment Data:** Medication history. Intake records after GBP surgery indicating no animal protein sources. Not taking prescribed vitamin–mineral supplement. BMI >50 before surgery; 6-month postoperation, BMI 48. Low serum B<sub>12</sub> level. Recent complaints of tingling and numbness in extremities.

**Nutrition Diagnosis (PES):** NI-5.9.11 Inadequate vitamin B<sub>12</sub> intake related to inadequate intake and not taking vitamin supplement as evidenced by diet history, low serum B<sub>12</sub> level, and symptoms of neurological changes (tingling in hands and feet.)

**Intervention:** Food–nutrient delivery—Encourage use of milk products as tolerated throughout the day. Educate—Discuss the importance of vitamin B<sub>12</sub> from supplemental intake when dietary intake is poor. Counsel about acceptable sources of B<sub>12</sub> while on the highly restricted GBP diet. Coordinate care with medical team and family members to emphasize improving the diet.

**Monitoring and Evaluation:** Pill count for prescribed vitamin supplements. Improvement in neurological symptoms; normalized vitamin B<sub>12</sub> lab values within 1–2 months of therapy.

- Prevent neurological, hematological, and cardiovascular side effects of thiamin, vitamin B<sub>12</sub> deficiency, and other nutrients that may be inadequate (Bloomberg et al, 2005).

## FOOD AND NUTRITION

### Preoperative

- Use a balanced diet with adequate energy, protein, vitamins, and minerals. Enteral immunonutrition may be useful.
- Diet should regress from liquids to NPO.

### Postoperative

- Over several days, progress from clear to full liquids. Enteral feeding with a high-protein intake may be useful to promote healing. Provide at least 1000 kcal/d with 1.5–2.0 g protein/kg.
- Until weight loss is achieved, add semisolid or pureed foods in small amounts. Initial gastric capacity is 30–60 mL; progression is up to 250 mL. Three meals and two snacks are better tolerated than three meals.
- Include 60–80 g of protein per day when possible. High-protein, low-fat foods such as milk, eggs, yogurt, boneless fish, and skinless poultry are important for maintaining adequate lean body mass while losing weight.
- Carbohydrate should be less than 30 g total per meal. A minimum of 130 g of carbohydrate per day should be included to meet Dietary Reference Intakes (DRIs).
- Patients will vomit if they eat too rapidly, drink fluids right after eating, lie down after eating, or overeat. Recommend chewing slowly and consuming liquids 30 minutes before or after meals.
- Dumping syndrome may also occur. Avoid alcoholic beverages, soft drinks, high-fat food such as fried foods and pastries, and high-carbohydrate foods such as cookies, cake, and candies.
- Ensure adequate fluid intake to prevent dehydration. Use at least 40 mL/Kg of noncaffeinated/noncaloric fluid daily, especially water.
- Meet micronutrient requirements, such as a daily liquid multivitamin–mineral supplement and a monthly vitamin B<sub>12</sub> injection (Johnson et al, 2005). Monitor for iron and calcium deficiencies. Progress to a chewable supplement that meets 100% of the DRIs.
- Avoid obstructive foods, such as popcorn, celery, nuts, seeds, and membranes of citrus fruits.

### Common Drugs Used and Potential Side Effects

- Drugs used will be for the specific condition and side effects of surgery.
- Combining RYGB with pharmacologic stimulation of PYY secretion may increase long-term success of surgical weight reduction in morbidly obese adults (Meguid et al, 2008).

### Herbs, Botanicals, and Supplements

- Answer questions about the use of herbs and botanicals; stop them before surgery.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- **Preoperative evaluations** include: all weight loss attempts and outcomes; usual eating patterns and nutritional intake evaluations; frequency of eating away from home; cooking and shopping habits; reasons and motives for surgery; knowledge about protein, vitamins, and minerals; awareness of signs of dehydration; and food allergies and intolerances. Keeping a food diary and sharing it with the dietitian is important. Continuous nutrition monitoring can prevent poor outcomes if the patient and the dietitian work together.
- **Postoperative education** includes: use of high-protein supplemental beverages, especially for wound healing. Thinned baby food, low-fat and sugar-free milk shakes, thinned hot cereals, blenderized soups, vegetable juices, and sugar-free instant breakfast drinks are useful.
- Patients require close monitoring, with special regard to the rapidity of weight loss and vigilant screening for signs and symptoms of subclinical and clinical nutritional deficiencies (Bloomberg et al, 2005.)
- Discuss appropriate quantities and qualities of foods that will be consumed; overeating may stretch the stoma or cause dumping syndrome. Have patient take small bites and sip liquids slowly to prevent vomiting.
- Help patient progress to normalized diet with 120–200 mL per meal. Increase awareness of the eating and satiety process.
- A multivitamin–mineral preparation is definitely needed. Vitamin B<sub>12</sub>, folacin, iron, potassium, copper, and vitamins A and D are special risks for deficiency. Nutritional deficiencies may become apparent, including PEM (Shuster and Vasquez, 2005).
- Discuss methods for blenderizing foods and recipes.
- Avoid fasting, as it may cause hypoglycemia.
- Promote adequate sleep, exercise, and other lifestyle measures that support a sense of well-being.
- Discuss how to manage dumping syndrome by avoiding simple sugars.
- Most patients lose a significant amount of weight and maintain their weight loss for long term, thereby having an improved quality of life. Unfortunately, between 5% and 30% of patients lose little weight or are unable to maintain their weight loss postoperatively (Puzziferri, 2005). Encourage exercise to help with weight loss and self-esteem.

### Patient Education—Food Safety

Surgical patients may be vulnerable to foodborne illness; safe food handling and handwashing are essential.

# BOWEL SURGERY

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

**Small bowel surgery** may be needed for inflammatory bowel disease, intestinal blockage, precancerous polyps, cancer, necrotizing enterocolitis, and other problems. Emergency surgical procedures in patients with inflammatory bowel disease are rare but can have a high morbidity unless carefully managed. Patients with short bowel syndrome (SBS) may have a higher than average prevalence of small intestinal bacterial overgrowth and may be at risk for septicemia due to bacterial translocation while on PN (Walzer and Buchman, 2010.) Failure to provide enteral nutrients creates a physiologic profile that exacerbates oxidative stress and increases the systemic inflammatory response syndrome (McClave and Heyland, 2009.)

After small bowel surgery, SBS occurs. Earlier feeding may reduce the risk of postsurgical complications after gastrointestinal (GI) surgery (Andersen et al, 2006.) When possible, early enteral feeding should be attempted (Lewis et al, 2009.). Residual small bowel length remains an important predictor of duration of the need for PN.

Most people with SBS experience spontaneous small bowel adaptation over time, when they can be weaned from PN. There are some individuals who cannot be weaned and are potential candidates for techniques to promote intestinal adaptation. Small bowel transplantation has become the treatment of choice for patients with chronic intestinal failure, whose illness cannot be managed with medications or who cannot be maintained on home parenteral nutrition. Rejection, bacterial translocation, and sepsis rates are high.

**Colectomy** removes part or all of the colon. A colostomy or ileostomy creates an opening on the abdomen (stoma) for the drainage of feces; it may be permanent or temporary. Patients who have an ileostomy lose a considerable amount of fluid that contains sodium and potassium. Fat and vitamin B<sub>12</sub> absorption is reduced. See section 7 for more details on nutritional management.

Patients who have had a **hemorrhoidectomy** usually tolerate a low-residue diet to delay defecation and allow healing at operative site. After patient is healed, it is important to have patient return to a high-fiber diet to prevent constipation.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

<b>Clinical/History</b>	Nausea, vomiting, anorexia	Alb, trans- thyretin
Height	Constipation	BUN, Creat
Weight	Infection or pressure ulcers	Na <sup>+</sup> , K <sup>+</sup>
Body mass index (BMI)	History of dehydration?	Ca <sup>++</sup> , Mg <sup>++</sup>
Weight changes		Serum Osm
Diet history	<b>Lab Work</b>	N balance
Blood pressure (BP)	Gluc	PT, INR
Intake and output (I & O)	CRP	H & H
	Platelet count	Serum Fe, ferritin
		Vitamin B <sub>12</sub>

## INTERVENTION

### OBJECTIVES

#### Preoperative

- Replenish depleted reserves by using special immune-enhanced formulas. Uninterrupted enteral nutrition (before, during, and after surgery) is popular in practice to achieve energy intake goals.
- Mechanical bowel preparation before surgery offers no major benefits.

#### Postoperative

- Restore enteral autonomy (Weseman and Gilroy, 2005).
- Early enteral feeding is generally recommended; this down-regulates systemic immune responses, reduces oxidative

stress, and improves patient outcome (McClave and Heyland, 2009.)

- Slowly progress back to a normal diet. Progress from clear liquids to soft—solid diet and avoid dairy products if there is lactose intolerance. Modify diet, as needed, for part of bowel that was affected.
- Correct inadequate digestion or absorption of fluid, electrolytes, and nutrients (Matarese et al, 2005).
- Prevent complications, such as peritonitis or ileus. Chewing gum can prevent ileus in some patients.
- Coordinate efforts with a transplantation team to restore nutritional autonomy to transplantation recipients (Weseman and Gilroy, 2005). Successful transplantation recipients can resume unrestricted oral diet eventually.
- Fight surgical infections by adding probiotics to enteral nutrition (EN) improve the immune status of the colon.

## FOOD AND NUTRITION

#### Preoperative

- Regress from soft diet to full liquids and then clear liquids.
- If needed, use a hydrolyzed formula or jejunostomy.

#### Postoperative

- Enteral nutrition is a primary therapy. Growth hormone, GLN, short-chain fatty acids, and fermentable fiber sources are useful. Intestinal rehabilitation regimens provide specialized oral diets, soluble fiber, oral rehydration solutions, and tropic factors to enhance absorption (Matarese et al, 2005).
- Probiotics may be beneficial (Floch et al, 2006).
- Slowly progress from a low-residue diet to a normal diet. Suggest that patient eat slowly and chew foods well. Excesses of fiber should be avoided. Probiotics may be included (Jenkins et al, 2005).
- Focus on adequate fluids; needs are usually greater than normal.
- Long-term nutritional support may be needed; CPN may be required for a short time.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Fluid Intake

**Assessment Data:** Food records, input and output reports showing poor fluid intake, medication history, assessment of depression following bowel surgery for cancer. Showing signs of dehydration.

**Nutrition Diagnosis (PES):** Inadequate fluid intake related to semiconscious state after bowel surgery and decreased oral intake as evidenced by I & O records showing only 800 mL intake for the past 3 days. Poor skin turgor, sunken eyeballs.

**Intervention:** Food-Nutrient Delivery—Add extra fluids to meal trays; encourage nursing to provide at least 4–5 oz with each medication given. Educate family and nursing staff about desired fluid intake; ensure that I & O records are kept accurately. Counsel about the dangers of dehydration. Coordinate care with medical team to increase fluid intake.

**Monitoring and Evaluation:** Improved fluid intake as per I & O records; achieving 35 mL/Kg fluid goal.

### Common Drugs Used and Potential Side Effects

- Drugs used will be for the specific condition and side effects of surgery. New medications to reduce rejection in transplant patients are under study.

### Herbs, Botanicals, and Supplements

- Answer questions about the use of herbs and botanicals; stop them before surgery.
- Patients may benefit from prebiotics and probiotics to decrease sepsis. Use with caution.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Evaluate and discuss preoperative weight loss, eating problems and fears, nutritional intake evaluations, frequency

of eating away from home, and cooking and shopping habits. Discuss changes that will be needed after the specific bowel surgery. See section 7 for ileostomy and colostomy guidance.

### Patient Education—Food Safety

Surgical patients may be vulnerable to foodborne illness; safe food handling and handwashing are essential.

# AIDS and Immunology, Burns, Sepsis and Trauma

## CHIEF ASSESSMENT FACTORS

- Accidents or Trauma
- Altered Breathing
- Altered White Blood Cell (WBC) Count and Differential
- Anemia
- Anorexia, Malnutrition
- Culture Results, Specimens
- Environmental Sanitation and Level of Personal Hygiene
- Fever, Chills
- Fluid Status, Edema
- Infection, Sepsis (Heat, Pain, Redness, Swelling, or Drainage in Any Area)
- Indicators of Immunity (T Cells, Other Lymphocytes)
- Medications, Prescription and Over-the-Counter
- Metabolic Rate (Indirect Calorimetry or Estimated)
- Multiple Organ Dysfunction Syndrome (MODS)
- Nutritional Status for Zinc, Iron, Selenium; Vitamins A, C, E; Albumin, CRP
- Presence of Chronic Diseases
- Pulse Rate
- Recent Illness or Surgery
- Urinary Changes (Frequency, Urgency, Burning)

## OVERVIEW OF NUTRITION AND IMMUNOCOMPETENCE

The interdependency between the disciplines of nutrition and immunology has been recognized for many decades. Fetal and early infant programming of thymic function suggests that early environments have long-term implications for immunocompetence and adult disease risk. Nutrition and physical growth affect immunocompetence and morbidity from infections.

Common diseases such as atopy and allergy, autoimmunity, chronic infections, and sepsis are characterized by a dysregulation of the pro- versus anti-inflammatory and T helper (Th) 1 versus Th2 cytokine balance. Proinflammatory cytokines promote atherosclerosis, major depression, visceral-type obesity, metabolic syndrome, and sleep disturbances (Elenkov et al, 2005).

Studies regarding the role of nutrients on gene expression and cytokine production have established the importance of maintaining a balanced immune system throughout life. Lack of adequate macronutrients or selected micronutrients, especially zinc, selenium, iron, and the antioxidant vitamins, can lead to clinically significant immune deficiency and infections, especially in children (Cunningham-Rundles et al, 2005). Reduced number of lymphocytes causes loss of host defense in zinc deficiency. In turn, infections aggravate micronutrient deficiencies by reducing nutrient intake, increasing losses, and altering metabolic pathways (Wintergerst et al, 2007). See Table 15-1 and Table 15-2.

Large variations in immunity relate to genetics, age, gender, smoking habits, exercise habits, alcohol consumption,

diet, stage in the female menstrual cycle, stress, history of infections, vaccinations and early life exposures. Sound nutritional practices, stress management, good hygiene and sanitation, adequate rest and sleep, and maintaining healthy physical activity can enhance immunocompetence and reduce risks of infection in any population. Even in older adults, improved nutrition can decrease risks for infection. Nutritional supplementation may reduce this risk and reverse some of the immune dysfunction associated with advanced age. The role of calorie restriction and zinc on immunity, aging, autoimmunity, and malignancy has been studied extensively; adding omega-3 fatty acids (fish oil) is also beneficial (Fernandes, 2008).

Hospital admission screening that best identifies patients who are at risk for malnutrition-related complications include presence of a wound, poor oral intake or evident malnutrition, low serum albumin or hemoglobin values, and low total lymphocyte count (TLC) (Brugler et al, 2005). The ability of admission information to accurately reflect malnutrition-related complication risk is crucial to early initiation of restorative medical nutritional therapy (Brugler et al, 2005). New approaches exploring the link through nutrigenomics, proteomics, and metabolomics may provide insight into controlling age-related diseases by following a balanced diet intake (Fernandes, 2008). Table 15-3 provides a list of key nutrients for immunocompetence. Table 15-4 provides important factors to consider in critical illness. Table 15-5 lists nutritional implications in some specific conditions, and Table 15-6 lists virulence increased by iron supplementation.

### TABLE 15-1 How the Immune System Works

The immune system is designed to provide protection from invading organisms, including bacteria and viruses, tumor cells, dirt, pollen, and other foreign material. Normally, barriers from the skin and linings of the lungs and gastrointestinal (GI) and reproductive tracts protect the underlying tissues from the outside environment. Whenever there is a breakdown in the protective lining, germs and other irritants can enter the body. The immune system is designed to conquer these foreign molecules by engulfing them or by destroying them with enzymes or other detoxifying means. In addition to fighting off these foreign invaders, the immune system has evolved to destroy abnormal cells (such as tumor cells) but occasionally reacts against the body's own normal tissues (autoimmunity).

#### *Innate and Acquired Immunity*

The two principal types of immune response, innate and adaptive (acquired) immunity, are distinguished from one another by both their speed and specificity. The innate immune system, present from birth, involves nonspecific responses that are the first line of defense against common infectious agents, including bacteria and viruses. This system is generally able to recognize foreign organisms but is unable to distinguish between particular invaders. Thus, an innate response does not require stimulation by sophisticated cell-to-cell interactions to remove bacteria or other foreign material and degrade it.

The more specific adaptive (acquired) immune system must be triggered by a specific virus, bacterium, or other foreign material, which stimulates lymphocytes to produce antibodies that can combat the foreign substance. At the next exposure, the preformed antibodies will allow the person to respond with an even stronger, more specific response known as *immunological memory*.

#### *Cells of the Immune System*

The immune system consists of white blood cells (WBCs, leukocytes), which are produced in the bone marrow and mature there or in the thymus and other lymphoid organs. Leukocytes circulate in the blood along with oxygen-carrying red blood cells. Under normal conditions, leukocytes leave the circulation and migrate into organs where germs can appear, including the skin, lungs, intestine, and reproductive tract. There, they can wait for infectious agents, or they can migrate back through the circulation to other organs.

(continued)

**TABLE 15-1** How the Immune System Works (*continued*)

There are three major types of leukocytes. *Neutrophils* are the most plentiful and are the first line of defense; they contain an arsenal of preformed enzymes that are capable of destroying bacteria. In addition, they are phagocytic, and they engulf viruses, bacteria, or other foreign material, protecting the host from further damage. Neutrophils are very short-lived, often destroyed during the fight. *Monocytes* are leukocytes that migrate to tissues and mature into macrophages. Macrophages are phagocytic and can remove foreign material and parts of dead cells from the tissues. They contain enzymes that can destroy infectious material but live longer than neutrophils and do not tend to self-destruct as easily. The tissue macrophage in the liver is called the Kupffer cell. *Lymphocytes* are selective, specialized WBCs that combat specific infectious agents.

The two types of lymphocytes are B cells and T cells. *B cells* are responsible for humoral immunity in the body fluids (classically known as the humors); they release specialized, soluble protein antibodies into the blood and other body fluids. The antibodies recognize and bind to the surface of foreign substances (i.e., pathogens), immobilizing them and further labeling them as foreign so that they can be more readily taken up by phagocytic cells. *T cells*, in contrast, act directly on other cells rather than manufacturing antibodies. Because of this direct interaction with other cells, T cells are responsible for cellular immunity. They can be further divided into *helper T cells*, which recognize foreign invaders and stimulate immune responses from other cells, and *cytotoxic T cells*, which destroy infected cells. Some of these cells are extremely long-lived “memory cells,” capable of remembering certain features on the foreign molecules so that, if the organism encounters that foreign molecule in the future, it can quickly stimulate a response.

#### *Communication Between Immune Cells: Cytokines*

One form of communication between immune cells is *direct cell-to-cell contact*, which can occur either as a loose, transient association or as a tighter, long-lasting encounter. Either way, cells must make physical contact with one another. In the second form of contact, cells release small proteins called *cytokines*, which bind to specific receptors on the surface of target cells.

Cytokines interact only with the appropriate target cell and not with surrounding cells. Although many of the effects of cytokines are local, they have been called the hormones of the immune system because they are transported by the circulating blood. Cytokines can affect the same cell that produced them, a neighboring cell, or a cell far away. They stimulate or dampen cell proliferation (replication), production of other cytokines, killing of damaged cells or tumor cells (cytotoxicity), and cell migration (chemotaxis). The latter response is controlled by a subset, chemokines. Just as there are cells that can stimulate or inhibit immune response, cytokines can regulate a variety of cell functions either positively or negatively. *Interleukin-6* is an important cytokine. Excessive production of proinflammatory cytokines or their production in the wrong biological context may lead to chronic inflammation and negative health consequences.

#### *Gut Immunity*

An extremely important function of the GI tract is its ability to regulate the flow of macromolecules between the environment and the host through a barrier mechanism. The GI immune response maintains critical pathways in the body. Gut-associated lymphoid tissue (GALT) is the dominant location for initiation of mucosal immune response and is dependent on fats, amino acids, and micronutrients. A healthy GI mucosal immune system provides barriers against systemic access for food antigens and microbes. Changes in the GALT immune response may contribute to intestinal dysfunction and susceptibility to postinjury gut-derived sepsis. Together with GALT and the neuroendocrine network, the intestinal epithelial barrier controls the equilibrium between tolerance and immunity to non-self-antigens (Fasano and Shea-Donohue, 2005). Because genetic and mucosal immunity strongly influence the composition and function of enteric bacteria, strategies are needed to correct dysfunctional microbiota in genetically susceptible individuals and to correct dysbiosis in many inflammatory disorders (Hansen et al, 2010).

**TABLE 15-2** Immunocompetence and Immunity Concerns

Almost all nutrients in the diet play a crucial role in maintaining an optimal immune response. Thus, deficient and excessive intakes can have negative consequences on immune status and susceptibility to a variety of pathogens. In addition, botanical and herbal products can be a concern. While Echinacea is used to reduce symptoms of the “common cold” or flu, there is a risk of hepatotoxicity, exacerbation of allergies or asthma, and even anaphylactic reactions. Garlic is also used to relieve cough, colds, and rhinitis but gastrointestinal disturbances, allergic reactions, or hypoglycemia can occur. Other agents, including angelica, German chamomile flower, ephedra, ginkgo, grape seed extract, licorice root, St. John’s wort, kava-kava rhizome, peppermint, stinging nettle, and ginseng, may also have undesirable side effects (see Section 2).

Nutrition and dietary patterns have been shown to have direct impact on health of the population and of selected patient groups, related to a reduction of oxidative damage from free radical production (Berger, 2005). Insufficient intake of micronutrients occurs in people with eating disorders, in smokers (both active and passive), in individuals with chronic alcohol abuse, in patients who are immunocompromised or malnourished, during pregnancy and lactation, and in the elderly (Wintergerst et al, 2007; Happel and Nelson, 2005). Concerns are listed here.

Infants	Undernutrition in critical periods of gestation and neonatal maturation and during weaning impairs the development of a normal immune system. There is a high prevalence of micronutrient deficiencies and infectious diseases in infants in developing countries. Breastfed infants have lower morbidity and mortality due to diarrhea than those fed formula; human milk oligosaccharides protect against pathogens (Newburg et al, 2005).
---------	--

(*continued*)

**TABLE 15-2 Immunocompetence and Immunity Concerns (continued)**

Young children	Risks and adverse functional and health outcomes may be associated with deficient and excessive intakes and nutrition status of iron, iodine, zinc, vitamins A and D, folate, vitamin B <sub>12</sub> , and riboflavin in children. Altered growth and development, mental and neuromotor performance, immunocompetence, physical working capacity, and morbidity can result. Vitamin C and zinc may reduce the incidence and improve the outcome of pneumonia, malaria, and diarrhea infections, especially in developing countries (Wintergerst et al, 2005).
Older adults	Adults 65 years and older comprise the fastest-growing segment of the U.S. population. Older adults experience greater morbidity and mortality due to infection than do young adults (High et al, 2005). Nutritional factors can modify susceptibility to disease and promote healthy aging. Interleukin-6 (IL-6), a cytokine, is tightly controlled by hormonal feedback (estrogen, testosterone) that is lost in the aging process. Elevated IL-6 levels progressively increase and may promote tumorigenesis, osteoporosis, neurodegenerative diseases, and sarcopenia. Zinc is important for immune efficiency (innate and adaptive), antioxidant activity (superoxide dismutase), and cell differentiation (Mocchegiani et al, 2007).  Use of a daily multivitamin/mineral supplement that contains 100% of the Dietary Reference Intakes (DRIs) may be encouraged.
Upper respiratory infections	The role of large doses of vitamin C to reduce duration or severity of cold symptoms has been inconclusive. Vitamin E supplementation may reduce the incidence of respiratory infections among the elderly. Echinacea or ginseng may also be modestly protective (Predy et al, 2005).
Immunocompromised persons (cancer, AIDS, tuberculosis)	Supplementation of vitamin C improves antimicrobial and natural killer cell activities, lymphocyte proliferation, chemotaxis, and delayed-type hypersensitivity (Wintergerst et al, 2005). Glutamine, arginine, fatty acids, and vitamin E provide some additional benefits for immunocompromised persons or patients who suffer from various infections but avoid excesses of arginine in septic patients. Chronic undernutrition and infection further weaken the immune response. Assessment of immunocompetence by available methods can identify individuals who are most in need of appropriate nutritional support to enhance host defense to infectious pathogens
Undernutrition	Iron and vitamin A deficiencies and protein–energy malnutrition are highly prevalent worldwide. Vitamin A and zinc play important roles in protecting individuals from severity in illnesses such as diarrhea and HIV infection. Zinc undernutrition or deficiency impairs cellular phagocytosis, natural killer cell activity, and the generation of oxidative burst (Wintergerst et al, 2005).
Overnutrition	Obesity caused by excess nutrition or excess storage of fats relative to energy expenditure is a form of malnutrition. Leptin is a cytokine-like immune regulator that has complex effects in both overnutrition and in the inflammatory response in malnutrition.
Surgical patients	Preoperative oral intake of immunonutrition containing omega-3 fatty acids, arginine, and nucleotides at home may prevent the risks of hospitalization and may lead to immunomodulating effects, which can improve nutritional status (see Section 14). Postsurgical or septic patients given branched-chain amino acids intravenously show improved immunity and improved outcomes (Calder, 2006).
Trauma	Sepsis and multiple organ failure have mortality rates of up to 80%. Vitamin C concentrations in the plasma and leukocytes rapidly decline during infections and stress (Wintergerst et al, 2005).

**TABLE 15-3 Nutritional and Host Factors in Immunity**

Nutrient status is an important factor contributing to immune competence; undernutrition impairs the immune system, suppressing immune functions that are fundamental to host protection. Both macronutrients and micronutrients are essential. Protein is very important. Branched-chain amino acids (BCAAs) and other essential amino acids support synthesis of protein, RNA, and DNA in lymphocytes to respond to pathogens. Arginine and glutamine support a healthy gut and healing processes, but excesses are to be avoided. To prevent protein use for energy, sufficient carbohydrate intake is needed. Fats, especially omega-3 fatty acids, provide needed calories and support the immune system.

Vitamin A deficiency impairs both innate and adaptive immune responses to infection. Carotenoids such as beta-carotene, lycopene, and zeaxanthin protect the immune system. As a precursor of NAD<sup>+</sup>, the substrate for DNA repair, niacin contributes to genomic stability (Moccegiani et al, 2008). Antioxidant vitamins C and E counteract damage caused by reactive oxygen species and modulate immune cell function (Wintergerst et al, 2007). Excesses of vitamin E must be avoided as they can also be immunosuppressive. Vitamin D<sub>3</sub> regulates the differentiation, growth, and function of monocytes, dendritic cells, and T and B lymphocytes (Equils et al, 2006). Vitamins B<sub>6</sub>, folate, B<sub>12</sub>, C, and E support the Th1 cytokine-mediated immune response with sufficient production of proinflammatory cytokines (Wintergerst et al, 2007). Protection against macular degeneration has been noted with prescriptions that contain omega-3 fatty acids, lutein and zeaxanthin, vitamins C, E, beta-carotene, zinc and copper (Krishnadev et al, 2010).

Minerals and other substances also play an important role. Chromium can enhance the ability of white blood cells to respond to infection. Iron, as lactoferrin, deprives invading cells of their defense systems. Manganese can enhance natural killer cells and macrophage activity; CoQ10 is thought to do the same. Selenium deficiency may allow viruses to mutate into more dangerous pathogens. Selenium, copper, and zinc modulate immune cell function; they, along with iron, help to produce proinflammatory cytokines (Wintergerst et al, 2007). A summary of important factors is listed here.

#### *Infectious Disease Determinants*

- |                             |   |
|-----------------------------|---|
| • Environmental sanitation  | • Host immunity, including nutritional status |
| • Microorganismic virulence | • Personal hygiene                            |

#### *Host-Resistance Factors*

- |  |  |
|--|--|
| • Cell-mediated T cells                  | • Oligosaccharides and other prebiotics      |
| • Complement system                      | • Phagocytes (leukocytes, macrophages)       |
| • Immunoglobulins, antibodies (B cells)  | • Physical barriers (skin, mucous membranes) |
| • Monocytes and dendritic cells          | • Probiotic bacteria                         |
| • Mucus and cilia on epithelial surfaces |  |

#### *Immune System*

- |                                 |                          |
|---------------------------------|--------------------------|
| • Bone marrow (B cells)         | • Peyer patches in gut   |
| • GALT                          | • Spleen                 |
| • Luster patches in bronchioles | • Thymus gland (T cells) |
| • Lymph nodes                   | • Tonsils                |

#### *Nutrients of Immunocompetence*

- |  |  |
|--|--|
| • <b>Macronutrients</b>                    | • Folic acid, vitamin B <sub>6</sub> , vitamin B <sub>12</sub> |
| • Arginine and glutamine                   | • Niacin   |
| • Dietary nucleotides (RNA)                | • Vitamin C  |
| • Essential amino acids (especially BCAAs) | • Vitamin D  |
| • Linoleic acid (essential fatty acid)     | • Vitamin E  |
| • Omega-3 fatty acids                      | • <b>Micronutrient Minerals</b>                                |
| • <b>Micronutrient Vitamins</b>            | • Chromium   |
| • Vitamin A; carotenoids                   | • Copper   |
| • Iron                                     | • Selenium   |
| • Magnesium and CoQ10                      | • Zinc   |
| • Manganese                                |  |

#### *Immunonutrition*

- To provide immunonutrition, enteral feeding can be supplemented with arginine, glutamine, omega-3 polyunsaturated fatty acids (PUFAs), and nucleotides.
- Immunonutrition is a less invasive alternative to immunotherapy to lessen chronic inflammation.
- Excessive intravenous lipid can be deleterious due to the proinflammatory effects of omega-6 fatty acids. Omega-3 fatty acids are anti-inflammatory and, combined with medium-chain triglycerides and olive oil, they are more desirable (Grimble, 2005).
- Antioxidants, plant fibers, and live lactic acid bacteria are also important to boost the immune system and reduce inflammation (Bengmark, 2005).

(continued)

**TABLE 15-3 Nutritional and Host Factors in Immunity (continued)***Nutrient–Nutrient Interactions, Excesses, and Immunocompetence*

- Under most circumstances the systemic inflammatory response is beneficial to the host, improving the eventual outcome of injury or infection.
- Chronic, excessive inflammation may lead to cardiac, hepatic, and mitochondrial dysfunction.
- Excessive counterinflammation leads to immune depression; excesses of iron, zinc, vitamin E, and PUFA interfere with immunity, especially if given intravenously or intramuscularly.
- Excess calcium interferes with leukocyte function by displacing magnesium.
- Long-term parenteral nutrition reduces immune functions (Bengmark, 2005). Parenteral iron and zinc are to be used with great caution; central parenteral nutrition is contraindicated in septic patients.
- Associations for “zinc plus selenium and niacin” have a role in healthy immunity, especially in the aging process (Moccegiani et al, 2008).

**TABLE 15-4 Factors of Importance in Critical Care**

Metabolic complications can occur from overfeeding critically ill patients. In general, current practice is to underfeed slightly rather than to overfeed: 20–25 kcal/kg actual body weight ABW is recommended; use 30% fat.

**Indirect calorimetry (IC) remains the best method of determining a patient's energy needs.** IC decreases complications from overfeeding and saves costs by reducing length of stay. Use a combination of prediction equations, clinical judgment, and monitoring of the appropriateness of the nutrition prescription.

- Harris–Benedict equation: using ABW or IBW in the calculation tends to underestimate energy needs (Campbell et al, 2005).
- Ireton–Jones formula: tends to overestimate the energy needs of mechanically ventilated patients (Campbell et al, 2005).

Maintain protein at approximately 1.5 g/kg. In critical illness, glutamine levels are much higher in the duodenal mucosa than during starvation; glutamine supplementation may be beneficial (De-Souza and Greene, 2005).

Arginine is a conditionally essential amino acid. It is a substrate for protein synthesis but can also be metabolized to various compounds, including nitric oxide, ornithine, and creatine phosphate, that are important for growth, wound healing, cardiovascular function, immune function, inflammatory responses, energy metabolism, urea cycle function, and other metabolic processes. Arginine supplementation improves outcomes with sepsis, wounds, ischemia-reperfusion injury, and burns.

The use of specific nutrients to modify immune, inflammatory, and metabolic processes offers the possibility for reducing morbidity following major surgery (Heys et al, 2005). Trace elements and antioxidant nutrients, especially selenium, are important for use in critical care and may reduce mortality (Heyland et al, 2005). Vitamin E levels tend to be low and may be supplemented accordingly. Use of omega-3 fatty acids is also important.

In general, enteral nutrition poses fewer risks than parenteral nutrition. Calories and protein that are delivered early by the enteral route have a significant effect on outcome in patients in critical care units; specific nutrients may also be needed to replace acute deficiencies brought on by specific injury or disease states (Wischmeyer and Heyland, 2010).

Control of hyperglycemia is very important to lessen infection and sepsis (Butler et al, 2005).

**TABLE 15-5 Infections and Febrile Conditions and Nutritional Implications**

Emergence of new infectious diseases and old diseases with new properties may affect the whole world; severe acute respiratory syndrome and avian flu are examples.

**Condition, Nutritional Acuity, Background****Nutritional Implications****Bacterial endocarditis, Level 3**

Bacterial endocarditis is an infection (often *Streptococcus*) of the membrane lining the heart chambers, often occurring after rheumatic fever. It accounts for 2% of all cases of organic heart disease. Symptoms and signs include fever, chills, joint pain, lassitude, anorexia, weight loss, and malaise.

Restore patient's nutritional status to normal. Replenish electrolytes and fluids. Reduce edema, if present. Prevent heart failure, infections, anemia, embolism, and nephritis. Penicillin, erythromycin, and other antibiotics may be used; monitor for timing of meals and drugs. Use a high-energy and high-protein diet. If patient's appetite is poor, encourage intake of favorite foods. Ensure adequate intake of fluids, vitamins, and minerals, especially vitamins A and C. Antibiotic prophylaxis is generally needed before dental work.

**Candidiasis, Level 2**

*Candida albicans* is normally found in the mouth, feces, and vagina. Greater colonization occurs in debilitated persons in whom thrush or vaginitis or cutaneous lesions are common. Susceptible individuals are those with leukemias, those who are immunosuppressed or on long-term central parenteral nutrition, and those who are obese or have diabetes.

Prevent or treat systemic infections. Prevent endocarditis, emboli, splenomegaly, and other complications. Correct underlying conditions when possible. Ensure a diet high in quality proteins, fluid, and calories. Use regular meals and small, frequent snacks; avoid skipping meals or fasting. Increase vitamin and mineral intake from tolerated fruits and vegetables, especially for vitamins A and C. Nystatin or amphotericin B may be used; diarrhea, nausea, and stomach pain may occur. Synthetic antimicrobial peptides are under development for use in oral candidiasis.

**Clostridium difficile–infection, Level 3**

The common name is *Clostridium difficile*–associated disease (CDAD); it is hard to treat. Suppression of gastric acid with proton pump inhibitor drugs such as Prilosec (omeprazole) or Nexium (esomeprazole) is associated with a 2–3 times increase in community-acquired CDAD.

Repeat antibiotics are indicated, either metronidazole or vancomycin. Tapering the dose after a 10-day course decreases the incidence of recurrences compared with abruptly stopping antibiotics.

*C. difficile* causes one fourth of nosocomial antibiotic-associated diarrheas. The incidence is rising, with more colectomy and mortality.

Long-term use of metronidazole may cause neurotoxicity. Vancomycin followed by rifaximin or immune therapy are treatments under study. Probiotics such as *Saccharomyces boulardii* may decrease recurrences when combined with high-dose vancomycin.

**Chronic fatigue and immune dysfunction syndrome (CFIDS), Level 1**

CFIDS is a serious health concern affecting more than 800,000 Americans of all ages, races, socioeconomic groups, and genders. CFIDS involves severe exhaustion, weakness, headaches, sore throat, tender lymph nodes, unrefreshing sleep, fever, muscle aches, inability to concentrate, and depression. Symptoms tend to mimic lupus or even cancer. Testing for viral load is helpful. There may be a link to Hodgkin disease or multiple sclerosis; patients may have neurally mediated hypotension.

Improve immunological status and prevent malnutrition. Lessen severity of symptoms. Avoid infections and stress to prevent recurrent attacks, where possible. Discourage use of high fat diets. Provide adequate protein (0.8–1 g/kg) and 35 kcal/kg. Include adequate vitamins, minerals, and antioxidant foods. Extra salt or fluids may be needed for hypotension. Fludrocortisone promotes sodium retention. Use analgesics for aches and pain. A multidisciplinary approach is beneficial. Traditional Chinese medicine has shown some merit in reducing sleeplessness and fatigue.

**Encephalitis and Reye syndrome, Level 2**

Encephalitis involves an inflammation of brain cells, usually by a virus such as measles, mumps, mononucleosis, or herpes simplex. If caused by the tsetse fly, it is known as *African sleeping sickness*. **Reye syndrome** is a disease of the brain and liver, affecting mostly children and teenagers after viral illness. Symptoms include headache, lethargy, nightmares, heavy vomiting; stupor and fatty liver; coma, double vision; hypoglycemia; multiple organ failure, or even death.

Ease symptoms. Allow natural defense system to work. Assist breathing with respirator if necessary. Control any pernicious vomiting. Tube feed if patient is comatose. A ketogenic diet may help when there are seizures. Otherwise, use a high-protein, high-calorie diet with a multivitamin–mineral supplement and extra fluids. If steroid therapy is used, monitor glucose, potassium, and nitrogen levels carefully; reduce sodium in foods if there is edema. Aspirin should be avoided.

**Fever, Level 2**

Fever is considered to be elevated body temperature  $>37.5$ – $38.3^{\circ}\text{C}$  ( $100$ – $101^{\circ}\text{F}$ ). Fever (pyrexia) may be caused by acute (pneumonia, measles, flu, or chicken pox) or chronic causes (tuberculosis, hepatitis, or malaria). Disturbed thermoregulation is controlled by the hypothalamus. Prostaglandin E<sub>2</sub> (PE<sub>2</sub>) is released from the arachidonic acid pathway and can help increase leukocyte, phagocyte, T cell and interferon activity. **Hyperpyrexia** is considered to be  $41.5^{\circ}\text{C}$  ( $106.7^{\circ}\text{F}$ ). **Fever of unknown origin (FUO)** involves illness for more than 3 weeks with a temperature higher than  $101^{\circ}\text{F}$ . Approximately 40% of FUO is from infections, 20% from cancer, 15% from connective tissue disease, and 25% from undetermined causes.

Meet increased nutrient needs caused by patient's hypermetabolic state, especially energy requirements. Each  $1^{\circ}\text{F}$  elevation causes a 7% increase in metabolic rate. Replace nitrogen losses. Replenish carbohydrate since liver stores last only 18–24 hours. Normalize electrolyte status, replace losses from perspiration, and facilitate toxin elimination through increased urine output. Prevent dehydration but avoid water intoxication. Treat anorexia, nausea, or vomiting. Adults need 30–40 kcal/kg/day; infants and children need additional calories as well. Monitor weight changes closely. Adults need 1.5–2 g protein/kg if temperature is high and chronic. If fever is acute, patient may prefer liquids. With longer duration, thiamin and vitamins A and C may be depleted, and a supplement may be used. Parenteral zinc or iron supplementation may significantly increase temperature in patients with recent injury or infection; avoid until fever improves. As treatment progresses, a diet with small, frequent feedings can be used. Offer preferred foods according to appetite, such as puddings, shakes, and soups.

(continued)

**TABLE 15-5 Infections and Febrile Conditions and Nutritional Implications (continued)**

Condition, Nutritional Acuity, Background	Nutritional Implications
<p><b>Herpes simplex, Level 1</b></p> <p>Herpes simplex involves a viral infection of skin or mucous membranes (herpes simplex I for oral lesions, whereas herpes simplex II usually involves genital/anal area) with vesicular eruptions of repeated frequency. Oral lesions ("cold sores" or "fever blisters") are latent in the nerve cell ganglia of the trigeminal nerve and are triggered by stress. This virus is similar to the chicken pox virus. Testing includes polymerase chain reaction, herpes simplex virus test, and swollen lymph nodes. Herpetic outbreaks are common in HIV-positive and other immunocompromised patients.</p>	<p>Take antipyretics/aspirin with food or milk and avoid alcoholic beverages. Take erythromycin with a full glass of water on an empty stomach to avoid sore mouth, nausea, or diarrhea. Penicillins should not be taken with acidic food or fluids such as fruit juice; so use adequate protein. Take tetracycline on an empty stomach with a full glass of water; avoid milk and dairy products for 2 hours before or after taking tetracycline. Avoid use in pregnancy and in children.</p> <p>Reduce inflammation and duration. Lessen recurrences and virulence. Reduce stress, febrile states, or further complications such as encephalitis or aseptic meningitis. Highlight relaxation and stress reduction techniques. Use high-quality protein and adequate calories. Increase intakes of vitamins A and C. Discuss relationship of nutrition to immune status. Take prescribed medication at first sign of an outbreak. Acyclovir (Zovirax), famciclovir (Famvir), and antiviral agents such as Valtrex are available; nausea, vomiting, or headaches may occur. If interferon is used, gastrointestinal (GI) distress, stomatitis, nausea and vomiting, abdominal pain, and diarrhea may be side effects. A herpes vaccine is being tested.</p>
<p><b>Herpes zoster (shingles), Level 1</b></p> <p>Herpes zoster is an acute viral infection with vesicles, usually confined to a specific nerve tract, and neuralgic pain in the area of the affected nerve. It is a reactivation of the <i>Varicella</i> virus (chicken pox); severity correlates with age. Symptoms include pain along the affected nerve tract, fever, malaise, anorexia, and enlarged lymph nodes. Bacterial infection of the lesions, poor nutritional status, and risk of dehydration may occur if rehabilitation requires a long period. There is a comprehensive, sensitive assay that detects simultaneous HSV-1, HSV-2, varicella-zoster virus, human cytomegalovirus, and Epstein-Barr virus (EBV). The Zostavax vaccine is effective.</p>	<p>Facial nerves may be affected; alter diet as needed. Prevent further systemic infection; reduce fever. Correct or prevent malnutrition, constipation, and encephalitis. Hydrate adequately. Prevent or correct unplanned weight loss. Prevent or reduce severity of postherpetic neuralgia, which is a very painful complication. A balanced diet with frequent, small feedings may be needed. Increased fiber may be useful to correct constipation. Adequate vitamins E and B<sub>12</sub> have been suggested for postherpetic neuralgia. Use adequate vitamins A and C. Acyclovir or famciclovir may shorten the duration and decrease pain. Monitor for GI distress, nausea and vomiting, or diarrhea. Valacyclovir is effective at facilitating healing lesions, reducing pain and postherpetic neuralgia. Narcotics and analgesics are needed to reduce pain. Capsaicin cream from hot peppers has proven to be useful for pain relief. Injecting lidocaine and prednisone directly into spinal column for pain relief of postshingles neuralgia has been tested. Oral prednisone may be used; alter sodium intake and monitor for glucose intolerance.</p>
<p><b>Infection, Levels 1–2</b></p> <p>Infection results from successful invasion, establishment, and growth of microorganisms in a host. Responses involve general and antigen-specific immunological defense systems. In infectious processes, vitamin A is excreted in large amounts from the urine. Correct iron-deficiency anemia, but do not use excesses as microbes depend on iron for growth and proliferation. Iron is mostly protein bound as transferrin. Avoid parenteral or intravenous iron and zinc until fever is resolved.</p>	<p>Provide adequate nourishment to counteract hypermetabolic state. Support body's host defense system. Prevent or correct dehydration, hypoglycemia, complications, and anorexia. Replace nutrient losses (potassium, nitrogen, magnesium, phosphorus, and sulfur). Discuss role of nutrients in maintaining skin and mucous membrane integrity and preventing bacterial invasion and subsequent infections. Use a high-protein, high-calorie diet, rich in vitamins, minerals, and fluids. Needs increase up to 20% in mild infection, 20–40% in moderate, or 40–60% in septic conditions. Administration of antibiotics with or without food is specific to the type of drug used. Avoid caffeine, sodas, and fruit juices when taking penicillins. For tetracycline, avoid milk and dairy products 2 hours before and after taking drug. With amoxicillin (Augmentin), diarrhea, nausea, and vomiting may occur. Cephalosporins (e.g., Ceclor, Cephalexin, Duricef) may cause diarrhea, nausea and vomiting, sore mouth, hypokalemia, and vitamin K deficiency. Griseofulvin for fungal infections should be taken with a high-fat meal; dry mouth, nausea, and diarrhea are common effects. Ketoconazole (Nizoral) is used in fungal infections and should be taken with an acidic liquid such as orange juice; avoid taking ketoconazole within 2 hours of use of calcium or magnesium. Metronidazole (Flagyl) may cause nausea and vomiting, diarrhea, and anorexia; avoid alcoholic beverages.</p>
<p><b>Influenza (flu) and the common cold, Level 1</b></p> <p>The common cold and influenza are the most common syndromes of infection in human beings. Influenza virus is transmitted by respiratory route, generally in the fall and winter months. Incubation is 1–4 days, with abrupt onset. Signs and symptoms include chills, fever for 3–5 days, malaise lasting 2–3 weeks, muscular aching, substernal soreness, nasal stuffiness, sore throat, some nausea, nonproductive cough, and headache. Annual vaccinations are suggested for high-risk populations, including elderly individuals and those individuals with pulmonary diseases. Low humidity, cold weather, or psychological stress may increase susceptibility. Adequate rest and hydration are essential. Discuss infection control.</p>	<p>Reduce fever and relieve symptoms. Chicken soup is actually useful by providing potassium and sodium, as well as fluid; it increases mucus flow. Prevent complications such as Reye syndrome, secondary bacterial infections (especially pneumonia), otitis media, and bronchitis. Promote bed rest, adequate hydration, and calorie intake. Replace fluid and electrolyte losses. Increase fluids from salty broths, juices, and other fluids. A high-energy and protein intake should be encouraged. Small meals and snacks may be better tolerated than three large meals. Adequate vitamins A and C, sodium, and potassium should be considered. Adequate zinc and low zinc status may be a risk factor for pneumonia in the elderly (Barnett et al, 2010). Antibiotics may be needed if secondary bacterial infections occur; monitor for proper timing of administration with food and beverages. Amantadine or rimantadine may be helpful, especially in type A flu. Nausea, dry mouth, and constipation may occur. Avoid use of aspirin in children.</p>

(continued)

**TABLE 15-5 Infections and Febrile Conditions and Nutritional Implications (continued)**

Condition, Nutritional Acuity, Background	Nutritional Implications
<p><b>Meningitis, Level 1</b></p> <p>Infection of the meninges causes inflammatory reactions, usually in the pia mater or arachnoid membranes. The condition may be viral or bacterial. Bacterial forms are more likely to be fatal if left untreated. Bacterial forms include <i>Listeria monocytogenes</i>, <i>Neisseria meningitidis</i>, <i>Haemophilus influenzae</i>, or <i>Streptococcus pneumoniae</i>. Meningitis can be caused by lung or ear infections or by a skull fracture. Symptoms and signs include headache, neck rigidity, fever, tachycardia, tachypnea, nausea and/or vomiting, disorientation, diplopia, altered consciousness, photophobia, petechial rash, irritability, malaise, seizure activity, and dehydration. Spinal tap or lumbar puncture is needed to assess cerebrospinal fluid. Meningitis could lead to septic shock, respiratory failure, or death. It most commonly affects children aged 1 month–2 years. Chronic meningitis can affect people with cancer or HIV/AIDS.</p>	<p>Prevent or correct weight loss. Force fluids but do not overhydrate, especially if there is cerebral edema. Prevent or correct constipation, fever, and other symptoms. Maintain intravenous feedings as appropriate; prevent overhydration. Progress diet, as possible, to high-calorie, high-protein intake. Unless contraindicated, provide 2–3 L of fluid. Adequate fiber will be beneficial to correct or prevent constipation. Gradually return to normal caloric intake for age. Ensure adequate intake of vitamins A and C from fruits, juices, and vegetables. In the long term, control obesity. Antibiotics (penicillin, ampicillin, and cephalosporin) may be used in bacterial forms or to prevent complications in viral forms; nausea, vomiting, and diarrhea can result. If corticosteroids are used, side effects may include nitrogen and calcium losses and sodium retention.</p>
<p><b>Mononucleosis, Level 1</b></p> <p>Infectious mononucleosis is an acute disease caused by EBV; it causes gland swellings in the neck and elsewhere (“glandular fever”). It causes fatigue, malaise, headache, chills, and other symptoms such as sore throat, fever, abdominal pain, jaundice, stiff neck, chest pain, breathing difficulty, cough, and hepatitis. Incubation is 5–15 days. It is most common in those between ages 10 and 35 years. Lab work may include evaluation of increased cerebrospinal fluid pressure, EBV titer, uric acid, and liver enzymes. It is also useful to evaluate a serum agglutination test.</p>	<p>Use a high-protein, high-calorie diet. Use liquids when swallowing solid foods is difficult. Use small, frequent feedings to improve overall nutritional quality and quantity. Ensure adequate intakes of vitamins A and C, especially from fruits and vegetables. Modify food textures when swallowing is difficult. Emphasize importance of exercise in restoring lean body mass. Restore fluid balance. Replenish glucose stores. Spare protein. Restore lost weight. Reduce fever. Prevent complications such as myocarditis, hepatitis, and encephalitis. Acyclovir (Zovirax) may be useful in initial infection, preventing typical persistence; nausea, anorexia, and vomiting may occur. Other antibiotics may be needed for related infections.</p>
<p><b>Pelvic inflammatory disease (PID), Level 1</b></p> <p>PID involves inflammation of the pelvic cavity, affecting the fallopian tubes (salpingitis) and ovaries (oophoritis) with acute pelvic and abdominal pain, low back pain, fever, purulent vaginal discharge, nausea and vomiting, urinary tract infection (UTI), diarrhea, maceration of the vulva, and leukocytosis. Long-term sequelae may include tubal infertility or chronic pelvic pain.</p>	<p>Promote good nutritional status to maintain weight and immunity. Increase hydration as tolerated. Lessen diarrhea, nausea, and vomiting. If nausea or vomiting is extensive, discuss need for small meals and consumption of fluids separately from meals. Provide diet as tolerated with small, frequent feedings until nausea and vomiting subside. Alter fiber and fluid, as needed. Increase energy and protein if needed to improve patient’s nutritional status. Ensure adequate intake of all vitamins and minerals, especially vitamins A and C. Antibiotics may be used; quinolones, cephalosporins, metronidazole, and doxycycline may be prescribed. Analgesics are generally used to reduce pain; chronic use may cause GI distress.</p>
<p><b>Poliomyelitis, Level 1</b></p> <p>A highly contagious enterovirus, poliomyelitis attacks the motor neurons of the brain stem and spinal cord; it may or may not cause paralysis. Polio is transmitted by personal contact, by eating contaminated food, or by drinking contaminated fluids. Polio is rare in areas where the vaccine is available, but there are risks in areas where the vaccine is not administered to all members of the population. Extra immunization may be needed for persons traveling to tropical areas. Symptoms and signs include headache, sore throat, fever, and neck and back pain. For breathing problems, a ventilator may be needed. Postpolio syndrome produces neuromuscular symptoms 25–30 years after attack; serious swallowing difficulties can ensue. Beware of possible choking or aspiration in the bulbar type of paralysis; patient may be unable to swallow. Provide adequate nourishment. Correct electrolyte imbalances.</p>	<p>For patient with acute paralysis, use a high-protein, high-calorie diet in liquid form. Use intravenous feeding and tube feeding when needed. Use vitamin supplements with 1–2 times the DRI; extra calcium and potassium may be needed to replace losses. As the treatment progresses, diet may be changed from a liquid to a solid diet as tolerated. A dysphagia diet may be useful, with varying levels of thickened liquids to enhance swallowing. Wean to oral diet as intake increases. Frequent high nutrient-density snacks are recommended. Instruct patient regarding how to puree or blend foods as needed, including how to add thickeners to liquids. Discuss appropriate recipes for high-energy and high-protein foods. Prevent complications of prolonged immobilization: renal stones, pressure ulcers, and negative N balance. Current antiviral drugs do not work; polio has no cure.</p>

(continued)

**TABLE 15-5 Infections and Febrile Conditions and Nutritional Implications (continued)**

Condition, Nutritional Acuity, Background	Nutritional Implications
<p><b>Rheumatic fever, Level 1</b></p> <p>Rheumatic fever is an inflammatory condition affecting the connective tissues that causes joint pain, swelling, fever, rash, jerky movements (Sydenham chorea), facial grimacing, and carditis. It usually ensues 3 weeks after streptococcal infection. Lab work includes testing for serum antibodies to streptococci; albumin, transthyretin, and cholesterol may be decreased; erythrocyte sedimentation rate and white blood cell (WBC) level may be increased. Heart inflammation usually disappears but may cause permanent damage to the valves (especially the mitral valve), with a resulting heart murmur. Long-term effects are called rheumatic heart disease.</p>	<p>Use a full-liquid diet for acute rheumatic fever. As treatment progresses, gradually change diet, first to a soft diet, then to a regular diet. Restrict sodium intake if edema is present or if steroids are used. Increase intake of vitamin C, protein, and calories. Include adequate vitamin A as well. Reduce inflammation in joints and heart. Decrease physical activity and encourage rest while heart is inflamed. Recover lost weight. Reduce fluid retention, if present. Cure the infection and prevent its recurrence. Prevent complications such as bacterial endocarditis, atrial fibrillation, and heart failure. Explain increased need for calories and protein. Adequate rest, exercise, and nutrition are essential to prevent recurrence. Restrict sodium if prednisone or adrenocorticotrophic hormone is given for severe heart inflammation. Side effects include depletion of nitrogen, calcium, potassium, and hyperglycemia. Antibiotics are used. Monitor for specific side effects such as GI distress. Penicillin may be needed for 10 days. Lifelong use of antibiotics before surgery and dental work protects against bacterial invasion of heart valves. Aspirin or nonsteroidal anti-inflammatory drugs may be used to reduce joint pain and inflammation.</p>
<p><b><i>Staphylococcus aureus</i> and methicillin-resistant <i>Staphylococcus aureus</i> (MRSA) infection, Level 1</b></p> <p><i>Staphylococcus aureus</i> is a gram-positive bacterium that developed resistance to the penicillin-derivative methicillin. MRSA emerged as a bacterium that became less susceptible to the actions of methicillin and thus developed the ability to colonize and cause life-threatening infections. <i>S. aureus</i> and MRSA population estimates are in the millions of persons.</p>	<p>MRSA colonization should be contained by infection control measures and not treated. Hand-washing technique is very important. The most potent anti-MRSA drug at the present time is daptomycin, especially to treat endocarditis.</p>
<p><b>Toxic shock syndrome (TSS), Level 1</b></p> <p>TSS is an acute bacterial infection caused by <i>S. aureus</i> and most often is associated with prolonged use of tampons during menses. Symptoms include sudden onset of high fever, severe headache, red eyes, myalgia, vomiting, watery diarrhea, red rash on palms and soles (with desquamation), decreased circulation to fingers and toes, disorientation, peripheral edema, pulmonary edema, respiratory distress syndrome, and sudden hypotension progressing to shock. Anemia, kidney, liver, and muscle damage; septic shock; respiratory distress can occur. Monitor labs for increased levels of WBC, blood urea nitrogen, creatinine, bilirubin, liver enzymes, and creatine phosphokinase. Platelets may be decreased.</p>	<p>Increase fluid intake to 3 L daily, unless contraindicated. Discuss need for adequate fluid intake and small meals, especially with vomiting or nausea. Control diarrhea and vomiting. Improve well-being. Stabilize hydration and electrolyte balance. Prevent renal, heart, and lung problems and other complications. Antibiotics are required. Monitor for GI side effects. Determine how to administer specific drugs (such as with food, water, or milk).</p>
<p><b>Typhoid (enteric) fever, Level 2</b></p> <p>Enteric fever includes typhoid and paratyphoid fever. It is a systemic infection caused by <i>Salmonella enterica</i>, and it is most common among travelers. This infectious fever is spread by contamination of food, water, or milk with <i>S. typhi</i> or <i>paratyphi</i>, which can come from sewage, flies, or faulty personal hygiene. The problem practically has been eradicated in areas of proper sanitary practices. Most infections are found in people who are in contact with carriers who have persistent gallbladder or UTIs. Incubation is 5–14 days. Symptoms include malaise, headache, cough, sore throat, “pea soup” diarrhea, constipation, rose spots, and splenomegaly. Lab work includes stool and urine for Widal test.</p>	<p>Reduce fever and prevent irritation. Replace nutrient losses from diarrhea. Replace tissue losses. Prevent complications such as intestinal hemorrhage or shock and pulmonary or cardiac side effects. Gradually add pectin and other fiber. Especially, include good dietary sources of vitamins A and C. Explain which foods are high-protein, high-calorie sources. Discuss how to prevent future reinfection. For patients with acute fever, use a diet of high-protein, high-calorie liquids. A low-residue diet may be needed temporarily. As treatment progresses, gradually add soft, bland foods. Try small, frequent feedings. First-line therapy is ceftriaxone, and fluoroquinolones can also be given. Monitor for GI distress. Preventive measures include educating travelers about hygiene precautions and vaccinations.</p>

**TABLE 15-6 Virulence Increased by Iron**

To successfully sustain an infection, nearly all bacteria, fungi, and protozoa require a continuous supply of host iron. Iron is a cofactor in oxidation–reduction reactions. Iron deficiency has opposing effects on infectious disease risk, decreasing susceptibility by restricting iron availability to pathogens, and increasing susceptibility by compromising cellular immunocompetence (Wander et al, 2009). Studies suggest that moderate iron deficiency protects against acute infection and may represent a nutritional adaptation to endemic infectious disease stress (Wander et al, 2009). Zinc and manganese may also play a role in host defense mechanisms.

Acid-fast and gram-positive bacteria	<i>Bacillus, Clostridium, Listeria, Mycobacterium, Staphylococcus, Streptococcus</i>
Fungi	<i>Candida, Cryptococcus, Histoplasma, Mucor, Pneumocystis, Rhizopus</i>
Gram-negative bacteria	<i>Campylobacter, Chlamydia, Escherichia, Klebsiella, Legionella, Proteus, Pseudomonas, Salmonella, Shigella, Vibrio, Yersinia</i>
Protozoa	<i>Entamoeba, Leishmania, Plasmodium, Toxoplasma, Trypanosoma</i>

# AIDS AND HIV INFECTION

## NUTRITIONAL ACUITY RANKING: LEVEL 4

Adapted from: Porth CM. *Pathophysiology: Concepts of altered health states*, 5th ed. Philadelphia: Lippincott Williams & Wilkins, 1998.

**DEFINITIONS AND BACKGROUND**

The human immunodeficiency virus (HIV) infects T cells (CD4+) and macrophages. Levels of CD41 (helper) and CD81 (nonhelper) subsets of T cells are used to evaluate immunological competency. After levels have been identi-

fied, staging is identified to plan therapeutic interventions; see Table 15-7. Many people will develop acquired immunodeficiency syndrome (AIDS) after a decade, following an opportunistic infection or a decline in the immune system. Prognosis for AIDS ranges from 1 year, if not treated with antiretroviral therapy (ART), to 5 years, if treated.

HIV is not easily transmitted except by exchange of bodily fluids during sexual contact, by receipt of infected blood through a blood transfusion, by sharing contaminated needles with intravenous drug injection, or from an HIV-infected mother to neonate (children represent 15–20% of the affected population). Persons at high risk include homosexual and bisexual males, hemophiliacs, intravenous drug addicts, heterosexuals with multiple partners, and infants of HIV-positive mothers. Breastfeeding by HIV-infected mothers can result in HIV transmission to the infant, especially with mastitis. In some developing countries, the relative risk of HIV transmission may be less significant than malnutrition for the infant; risks and benefits must be weighed individually.

HIV infection involves multiple organs. It targets the immune system and impairs the ability to mount an adequate immune response. Malnutrition and its complications further impair the body; HIV often depletes nutritional status (Sztam et al, 2010). Immune reconstitution inflammatory syndrome develops in a substantial percentage of HIV-infected patients who have an underlying opportunistic infection and receive ART (Danaher et al, 2010). AIDS-related malignancies are another major complication.

**TABLE 15-7 WHO Clinical Staging of HIV/AIDS for Adults and Adolescents****Clinical stage 1—Asymptomatic**

Acute retroviral syndrome  
Persistent generalized lymphadenopathy

**Clinical stage 2**

Angular cheilitis  
Fungal nail infections of fingers  
Herpes zoster  
Moderate unexplained weight loss (<10% of body weight)  
Papular pruritic eruptions  
Recurrent oral ulcerations  
Recurrent respiratory infections (sinusitis, bronchitis, otitis media, pharyngitis)  
Seborrheic dermatitis

**Clinical stage 3—Clinical signs**

Acute necrotizing ulcerative stomatitis, gingivitis, or periodontitis  
Oral candidiasis  
Oral hairy leukoplakia  
Pulmonary tuberculosis (TB) diagnosed in last 2 years  
Severe infections (e.g., pneumonia, empyema, pyomyositis, bone/joint infection, meningitis, bacteremia)  
Severe weight loss (>10% of body weight)  
Unexplained chronic diarrhea >1 month  
Unexplained persistent fever >1 month  
Diagnostic test needed for: anemia (<8 g/dL), neutropenia (<500/mm<sup>3</sup>), or thrombocytopenia (<50,000/mm<sup>3</sup>) > 1 month

**Clinical stage 4—Clinical signs**

Chronic herpes simplex infection (orolabial, genital, or anorectal >1 month)  
Central nervous system toxoplasmosis  
Esophageal candidiasis  
Extrapulmonary TB  
HIV encephalopathy  
HIV wasting syndrome  
Kaposi sarcoma  
Pneumocystis pneumonia  
Recurrent severe or radiological bacterial pneumonia

**Diagnostic testing needed for:**

Candida of trachea, bronchi or lungs  
Cryptosporidiosis  
Cytomegalovirus infection (retinitis or of an organ other than liver, spleen, or lymph nodes)  
Disseminated mycosis (e.g., histoplasmosis, coccidiomycosis, penicilliosis)  
Disseminated non-tuberculous mycobacteria infection  
Extrapulmonary cryptococcosis including meningitis  
Invasive cervical carcinoma  
Isosporiasis  
Lymphoma (cerebral or B-cell non-Hodgkin)  
Progressive multifocal leukoencephalopathy  
Recurrent non-typhoidal salmonella septicemia  
Visceral herpes simplex infection  
Visceral leishmaniasis

Kaposi sarcoma and Hodgkin and non-Hodgkin lymphomas are the most common malignancies (Wood and Harrington, 2005).

HIV infections are considered pandemic, and AIDS has killed more than 25 million people, especially in the sub-Saharan. Worldwide, hepatitis B virus affects 370 million people, hepatitis C virus (HCV) affects 130 million, and HIV affects 40 million (Alter, 2006). Fortunately, ART has reduced mother-to-child transmission rates.

HIV infection requires lifelong, vigilant polypharmacy. Nutrition directly impacts immune-cell triggering and indirectly impacts DNA and protein synthesis in HIV progression. Decline in body cell mass and deficiencies in vitamins and minerals occur; some clinicians recommend a series of antioxidant supplements to augment cellular immunity. Because of the crucial role that nutrition plays throughout the course of HIV, medical nutrition therapy (MNT) is an integral part of disease management.

During starvation, there is generally a loss of adipose tissue with maintenance of lean body mass (LBM); in HIV/AIDS, there is loss of LBM (wasting) while maintaining body fat. *Wasting syndrome* is defined by the World Health Organization as the involuntary loss of at least 10% of body weight and is a common AIDS-defining diagnosis. Weight loss is an independent prognostic indicator of outcomes, including mortality. Weight loss, fatigue, anorexia, diarrhea, and low-grade fevers may occur. As long as an infection

remains untreated, nutritional support regimens will meet needs with only limited success.

Body composition measures should be accurate, ideally taken prior to the initiation of ART. Bioelectrical impedance analysis is useful, whereas skinfold measurements tend to overestimate fat-free mass and underestimate fat mass. Fat redistribution is part of a syndrome known as *peripheral lipodystrophy* in patients receiving ART; they lose facial and extremity fat with redeposition into visceral and truncal adiposity. Abnormal fatty deposits are disfiguring and are found in the neck and dorsocervical area ("buffalo hump"). These changes can be accompanied by development of hyperlipidemia or diabetes.

Gastrointestinal (GI) complications are common. Weight loss is often multifactorial in etiology, and reduced oral intake is common. Malnutrition further compromises those who have tuberculosis (TB) or persistent diarrhea (Wanke, 2005). Nutritional supplements, dietary counseling, and use of specific nutrients such as vitamin D<sub>3</sub>, are critically important (Villamor, 2006).

While central parenteral nutrition (CPN) is often indicated with HIV patients experiencing severe GI dysfunction, there is a concern over infection with the use of central venous catheters in patients with advanced HIV/AIDS. Medication interactions, coinfection with other infections and diseases, wasting, lipodystrophy, and other issues make individualized nutrition care plans extremely important

**TABLE 15-8 Guidelines for Nutrition Therapy in HIV Management**

<p>I. High risk (see RD within 1 week)</p> <ul style="list-style-type: none"> <li>A. Poorly controlled diabetes mellitus</li> <li>B. Pregnancy (mother's nutrition; infant: artificial infant formula)</li> <li>C. Source: Hayes C et al. Integrating nutrition therapy into medical management of human immunodeficiency virus. Web site accessed February 5, 2010, at <http://www.aidsetc.org/aidsetc?page=etres-display&resource=etres-175>.

(American Dietetic Association, 2010). Although the incidence of most AIDS-defining opportunistic infections, including HIV wasting syndrome, has dramatically decreased since the introduction of ART, weight loss and wasting are still common in HIV-infected persons who use injected drugs; live below the federal poverty level; have a lower CD4 cell count or higher HIV viral load; or have diarrhea, nausea, or fever (Tang et al, 2005).

Work on an HIV vaccine is important. The International AIDS Vaccine Initiative has established a consortium to elucidate mechanisms of protection from such a vaccine (Koff et al, 2006). In addition, a new, inactivated mycobacterial vaccine may significantly reduce TB cases among HIV-positive individuals.

MNT for HIV/AIDS patients can reduce illness, hospital stays, and related medical costs. MNT helps the patient have an improved quality of life along with better CD4 counts and weight gain (American Dietetic Association, 2010). See Table 15-8 for guidelines on risk levels. The American Dietetic Association has recommended three MNT visits per year for adults with stage 1 HIV/AIDS; three to six visits per year for adults with stage 2 or 3 HIV/AIDS; and a minimum of five

visits per year for children or adolescents with HIV/AIDS. Through the Ryan White Comprehensive AIDS Resources Emergency (CARE) Act, treatment is available even when other funds have been depleted.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** HIV-1 has a minimal genome of only nine genes, which encode 15 proteins; the virus depends on the human host for every aspect of its life cycle (Balakrishnan et al, 2009). Polymorphisms cause the 15% of variation in viral load between individuals during the asymptomatic phase of infection. Alleles of the HLA-B5701 gene and the HLA-C gene are affected.

Clinical/History	Opportunistic infections (in AIDS)	C-reactive protein (CRP)
Height	Stool tests for malabsorption	Prealbumin:CRP ratio
Pre-illness weight	Biopsies (lymph nodes, skin lesions)	Aspartate aminotransferase (AST)
Current weight	Dual-energy x-ray absorptiometry scan	Alanine aminotransferase (ALT)
Waist to hip ratio	Bioelectrical impedance analysis	Bilirubin
Body mass index (BMI)		Prothrombin time (PT), international normalized ratio
Skinfolds; fat-free mass (low?)	<b>Lab Work</b>	Hemoglobin and hematocrit (H & H) (decreased?)
Blood pressure (BP)	Complete blood count with differential	Ferritin (increased?)
Intake and output (I & O)	Platelets	Creatine (Creat), blood urea nitrogen (BUN)
Weight changes	Cholesterol (Chol)	Transferrin
Swollen lymph nodes	Triglycerides (Trig) (increased)	Lactose test
Rash	Glucose (Gluc)	Serum B <sub>12</sub> and folate (decreased?)
Sore throat, headache	CD4 lymphocytes (active AIDS, <200 T cells)	Schilling test
Night sweats	CD8 lymphocytes	Serum vitamin A
Dyspnea on exertion, rales, or rhonchi	TLC	Serum testosterone
Nausea, vomiting	Viral load	
Anorexia	Polymerase chain reaction for herpes virus	
Temperature (fever, chills)	Albumin (Alb) or transthyretin (decreased)	
Dysphagia, chewing problems		
Stomatitis		
Diarrhea		
Cyanosis, pneumonia		
Frequent viral or herpes infections		

## INTERVENTION

### OBJECTIVES

- Improve nutrition-related immunity to prevent opportunistic infections, such as oral candidiasis; cirrhosis or hepatocellular carcinoma from chronic infection with hepatitis B or C; and other conditions such as immune reconstitution inflammatory syndrome.
- Enhance response to therapy through continuous counseling, nutritional alterations, and drug effectiveness monitoring. Follow guidelines according to levels of risk (see Table 15-8).
- Use 3-day food records rather than food frequencies (American Dietetic Association, 2010).

## SAMPLE NUTRITION CARE PROCESS STEPS

### Increased Nutrient Needs

**Assessment Data:** Three-day food records. Input and output, weight loss, and medication records. Diagnosis of AIDS 3 years ago. Complaints of GI distress after meals.

**Nutrition Diagnosis (PES):** NI 5.1 Increased nutrient needs related to unintentional weight loss of 21% in 5 months as evidenced by weight only 80% of desirable BMI range.

### Interventions:

Food-Nutrient Delivery.

ND 1.3 Specific foods (yogurt) 2 times daily.

ND 3.1.1 Commercial beverage 3 times daily.

### Education:

E 1.1 Purpose of nutrition education: to explain importance of adequate nutrient intake and compliance with all medical/nutritional/emotional care.

### Counseling:

C2.2 Goal setting—Gain 1–1½ lb per week until ideal body weight (IBW) range is reached.

### Coordination of Care:

RC 1.1 Team meeting—Discuss interventions with interdisciplinary team.

**Monitoring and Evaluation:** Weight records, fewer reports of GI distress and symptoms. Greatly improved intake on 3-day food records.

- Maintain body weight at 95–100% of usual body weight levels. LBM is especially affected; increased resting energy expenditure occurs (American Dietetic Association, 2010).
- Prevent weight loss from fever, poor intake with oral pain, infection, nausea, diarrhea, malabsorption, swallowing difficulties, effects of medications, inflammation, viral load, and lipodystrophy, and vomiting; offer early nutritional intervention (American Dietetic Association, 2010).
- Reduce mealtime fatigue to encourage better intake. Avoid unnecessary distractions and stresses.
- Lower the temperature when febrile.
- Manage altered GI function including diarrhea, malabsorption, vomiting, and HIV-induced enteropathy.
- If necessary, use CPN to prevent further weight loss and potential malnutrition. CPN will stop weight loss, but it will not prevent further immunodeficiency.
- Keep body well hydrated. Fluids are critical to prevent kidney stones and other complications.
- Support depleted levels of nutrients such as linoleic acid, selenium, and vitamin B<sub>12</sub>.
- Counteract problems such as dysphagia, mouth pain, taste alterations (dysgeusia), or difficulty chewing. Alleviate nutritional effect of fatigue, anemia, anorexia, depression, and dyspnea. Optimize nutritional status.
- Maintain fat intake at prudent levels (30–35% total kcal) to maintain or achieve normal lipid levels.
- Alter dietary regimen if there is renal or hepatic impairment.
- Maintain honest discussions regarding use of alternative therapies such as herbs, special diets, and megavitamin therapy.

- Encourage physical activity, which has been shown to improve cardiopulmonary fitness and to reduce symptoms of depression (American Dietetic Association, 2010).
- Comply with food and water safety guidelines.

## FOOD AND NUTRITION

- Maintain diet as appropriate for patient's condition; use a high-energy/high-protein diet with adequate nutritional supplements. Weight gain or maintenance is possible in patients with HIV infection and early stages of AIDS by use of oral liquid supplements.
- From 2–2.5 g protein/kg and 35–45 kcal/kg are needed. Fever and infection may further elevate need for these nutrients. Increase energy intake in cases of infection, fever, and pneumonia. Use indirect calorimetry when available; estimates are often incorrect (Frankenfield et al, 2005).
- Keep the body well hydrated. Estimate 35–40 cc/kg unless there is a reason to restrict fluids.
- Use TF, especially gastrostomy, if warranted. Low-lactose/low-fat TF products may need to be fed continuously to reduce gastroenteritis or reflux. CPN may be necessary if weight loss exceeds 20% of usual body weight.
- Increase use of omega-3 fatty acids and decrease saturated fat intake. There may be advantages to using a medium-chain triglyceride formula in the presence of AIDS-associated malabsorption (American Dietetic Association, 2010).
- Small, frequent feedings (6–9 times daily) are usually better tolerated but may be difficult to achieve given complex medication regimens.
- A general multivitamin–mineral supplement should be recommended, not to exceed 100% of the recommended dietary allowances (RDAs). Low serum micronutrient levels are common and have been associated with immune impairment, HIV disease progression, or mortality (Mehta and Fawzi, 2007). Use of vitamin A and beta-carotene may reduce some of the gut permeability and lessen watery diarrhea (American Dietetic Association, 2010). Vitamin K deficiency is common with antibiotic use.
- Use nutrient-dense snacks, such as pudding, if tolerated, nonacidic juices for sore mouth, ices made with tolerated juices, and sandwiches made with cold meat salads. Add protein powders and glucose polymers, if desired. Use oral supplements when needed.
- With bouts of diarrhea, use small meals and avoid extremes in temperatures; room temperature is often best. Avoid excesses of caffeine, alcohol, and fried and high-fat foods. Use soft cooked chicken, turkey, fish, and lean beef. Replace electrolytes with foods such as broth soups or Gatorade for sodium, potassium, magnesium, and chloride.
- If lactose intolerant, avoid milk and use a low-lactose diet.
- Sucrose and gluten may not be tolerated. Individualize as needed.
- Children present unique nutritional needs, further compounded by HIV infection; see Section 3.

## Common Drugs Used and Potential Side Effects (see Table 15-9)

- Antiretroviral regimens are complicated and difficult. Because nonalcoholic fatty liver disease is a prominent feature induced by ART, hepatitis A and B virus vaccinations and close monitoring of liver parameters are suggested (Kahraman et al, 2006). Malabsorption can occur if antiretroviral agents are taken improperly with regard to meals or if they are taken with certain other drugs or herbal remedies. Suboptimal use of antiretrovirals because of noncompliance or malabsorption can result in viral resistance.
- Recombinant human growth hormone and growth hormone–releasing hormone are options for reducing visceral adipose tissue and coronary heart disease (Cofrancesco et al, 2009).

## Herbs, Botanicals, and Supplements

- Ethical dilemmas may be presented by CAM use. HIV-infected patients often seek complementary therapies due to unsatisfactory side effects, high cost, nonavailability, or adverse effects of conventional medicines (Liu et al, 2005).
- CAM use is nearly 100% in the HIV-infected population, with half reporting daily use of a dietary supplement (especially vitamin C, vitamin E, and soy) as an adjunct to other treatments (Milan et al, 2008). However, there may be risks for herb–drug and herb–nutrient interactions. Many herbals may also interact with prophylactic medicines, such as antibiotics.
- Herbs and botanical supplements should not be used without discussing with the physician. Older, college-educated, or insured patients are more likely to disclose their CAM use to health care providers, and there is a need to find ways to discuss CAM between more patients and their providers (Liu et al, 2009).
- Licorice, capsaicin, astragalus, and burdock are not confirmed; large, rigorous trials are needed (Liu et al, 2005).
- Rosemary and marjoram have pentacyclic triterpenoid acids with anti-inflammatory, hepatoprotective, gastroprotective, antiulcer, anti-HIV, cardiovascular, hypolipidemic, antiatherosclerotic, and immunoregulatory effects. There would be no harm in seasoning foods with these herbs.
- Echinacea is not recommended as an antiviral agent. Do not use with warfarin or immunosuppressants.
- Garlic and St. John's wort may make saquinavir or indinavir less effective.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the role of nutrition in infection and immunity; patients should also decrease the use of drugs and cigarettes because of their effects on overall health status and immunocompetence. They should avoid sharing razors, toothbrushes, tweezers, nail clippers or piercing jewelry with others.

**TABLE 15-9 Medications Used for HIV Infections and AIDS**

Class and Purpose	Generic Name	Brand and Other Names	Nutritional Implications and Comments
<b>Nucleoside reverse transcriptase inhibitors (NRTIs)</b> — <i>faulty versions of building blocks that HIV needs to make more copies of itself; when HIV uses an NRTI instead of a normal building block, reproduction of the virus is stalled</i>	<b>Abacavir</b>	Ziagen, ABC	Can cause severe bone marrow depletion and anemia, altered taste, constipation, nausea, indigestion, or vomiting. Adequate folate and vitamin B <sub>12</sub> may prevent toxicity. NRTIs can cause lactic acidosis, hypersensitivity reactions, neuropathies, pancreatitis, anemia, and neutropenia.
	<b>Abacavir, lamivudine</b>	Epzicom	Diarrhea may be a side effect. Malaise, fever, rash, and liver inflammation can occur.
	<b>Abacavir, lamivudine, zidovudine</b>	Trizivir	Diarrhea may be a side effect. Malaise, fever, rash, and liver inflammation can occur.
	<b>Adefovir</b>	Hepsera, ADV, Preveon	Often used in chronic hepatitis B virus treatments. Has nephrotoxic potential. Nausea, diarrhea, and vomiting can occur.
	<b>Aptivus</b>	Tipranavir	For the adjunctive treatment of HIV-1 infections.
	<b>Didanosine</b>	Videx, ddI Videx EC	May cause liver toxicity in low-weight patients. Neuropathy and pancreatitis may result.
	<b>Emtricitabine</b>	Emtriva, FTC, Coviracil	Well tolerated. Anorexia and fatigue are side effects.
	<b>Emtricitabine, tenofovir DF</b>	Truvada	May cause diarrhea, nausea, and vomiting. Take with food.
	<b>Lamivudine</b>	Epivir, 3TC	May cause nausea and vomiting, pancreatitis, and depression. Avoid alcohol. Take without regard for meals.
	<b>Lamivudine, zidovudine</b>	Combivir	Headache, liver inflammation, and fatigue can occur. Take with meals.
	<b>Stavudine</b>	Zerit, d4 T	Severe anemia may occur. Avoid alcohol.
	<b>Tenofovir DF</b>	Viread, TDF	Gastrointestinal (GI) distress, hypophosphatemia, acute renal failure.
	<b>Zalcitabine</b>	Hivid, ddC	Can cause oral ulcers, nausea, vomiting, dry mouth, and neuropathy. Take on empty stomach. Avoid taking with antacids.
	<b>Zidovudine</b>	Retrovir, AZT, ZDV	Can cause severe bone marrow depletion and anemia, altered taste, constipation, nausea, indigestion, or vomiting. It works better in sequence with acyclovir. Adequate folate and vitamin B <sub>12</sub> may prevent toxicity. Take with food.
			Nausea, vomiting, and diarrhea are common side effects. Liver inflammation may occur; avoid alcohol and St. John's wort. NNRTIs can cause rashes and hepatotoxicity.
<b>Nonnucleoside reverse transcriptase inhibitors (NNRTIs)</b> — <i>bind to and disable reverse transcriptase, a protein that HIV needs to make more copies of itself</i>	<b>Delavirdine</b>	Rescriptor, DLV	Monitor for abnormal liver enzymes. Headaches are common.
	<b>Efavirenz, emtricitabine, and tenofovir DF</b>	Atripla	Hyperlipidemia can occur. Contains two NRTIs and one NNRTI.
	<b>Nevirapine</b>	Viramune, NVP	Take with food or on an empty stomach; fever, headache, hepatitis, general fatigue, mouth sores, and rash can occur.
<b>Protease inhibitors (PI)</b> — <i>disable protease, a protein that HIV needs to make more copies of itself</i>			Associated with hyperlipidemia, hyperglycemia, GI symptoms, and body fat distribution abnormalities. Disguising their taste is important; add a small amount to cold foods such as ice cream, shakes, and fruit ices; thick sweet foods such as honey, jellies, and frozen juice; or small amounts of peanut butter, pudding, applesauce, or yogurt.
	<b>Atazanavir</b>	Reyataz	May cause a tendency to bleed. Take with food.
	<b>Darunavir</b>	Prezista	May cause GI distress.
	<b>Fosamprenavir</b>	Lexiva, FPV	May cause a tendency to bleed. Take without regard for meals.

(continued)

**TABLE 15-9 Medications Used for HIV Infections and AIDS (continued)**

Class and Purpose	Generic Name	Brand and Other Names	Nutritional Implications and Comments
<b>Entry inhibitors:</b> <b>Integrase inhibitors</b> —stop HIV from inserting its own genetic code into the cell by slowing integrase, the chemical HIV needs to unlock the CD4 command center.	<b>Indinavir</b>	Crixivan, IDV	Best absorbed on an empty stomach or with a light, nonfat snack and increased fluids (but not skim milk, coffee, or tea), even juice if calories are needed. Nausea and vomiting, change in taste, and diarrhea can occur.
	<b>Lopinavir/ritonavir</b>	Kaletra, LPV/r	Elevated lipid levels and GI distress may occur. Take with food. Abnormal mouth sensations are noted. Hyperglycemia can occur.
	<b>Nelfinavir</b>	Viracept, NFV	Take with food; flatulence, loose stools, or diarrhea can occur. Hyperglycemia may result.
	<b>Ritonavir</b>	Norvir, RTV	Take with a high-energy, high-fat meal. Side effects include weakness, diarrhea, nausea and vomiting, loss of appetite, abdominal pain, abnormal mouth sensations of burning or prickling, dyslipidemia, and coronary events.
	<b>Saquinavir</b>	Invirase	Best absorbed after a high-energy, high-fat meal; contains some lactose; may cause GI distress, diarrhea, or nausea.
	<b>Tipranavir</b>	Aptivus	May cause GI distress.
	<b>Raltegravir</b>	Isentress	
<b>Entry inhibitors:</b> <b>Fusion inhibitors</b> —prevent HIV entry into cells.	<b>Enfuvirtide</b>	Fuzeon, T-20	Pneumonia has been one side effect. Take without regard for meals. Nausea, diarrhea, fatigue, and pancreatitis are possible side effects.
<b>Antineoplastic agents</b> —for Kaposi sarcoma	<b>Maraviroc</b>	Selzentry	May cause GI distress.
	<b>Adriamycin, bleomycin, vincristine</b>		Numerous side effects include nausea and vomiting, diarrhea, anorexia, stomatitis, and weight loss.
	<b>Doxorubicin</b>		Administer with riboflavin to decrease toxicity. Dry mouth, esophagitis, stomatitis, nausea, and vomiting are common.
<b>Other medications</b> —to manage other side effects of HIV.	<b>Acyclovir</b>	Zovirax	May cause headache, nausea, anorexia, sore throat, fatigue, altered taste, and diarrhea.
	<b>Antidepressants</b>	Zoloft, Wellbutrin, others	May be useful before interferon therapy if there is a history of depression.
	<b>Antifungals</b>	Amphotericin-B, clotrimazole, flucytosine, ketoconazole	May cause nausea and vomiting, diarrhea, weight loss, metallic taste, and GI distress.
	<b>Antioxidants</b>	Multivitamin–mineral supplement that meets 100% DRI levels	Antioxidant supplementation may decrease markers of oxidative stress. Selenium may enhance immune function by modulating cytokine production.
	<b>Cidofovir</b>	Vistide	A cytosine nucleotide analog for treatment of cytomegalovirus (CMV), herpes simplex, papilloma, and pox viruses.
	<b>Corticosteroids</b>	Prednisone, others	Sodium retention and potassium, calcium, and vitamin C depletion can occur; protein malnutrition can occur with extended use. Glucose intolerance also may result.
	<b>Foscarnet</b>	Foscavir	Used for CMV retinitis (used intravenously only) and may cause anorexia, nausea and vomiting, abdominal pain, and diarrhea.
	<b>Ganciclovir</b>	Cytovene	Approved for use with CMV. May cause diarrhea, fever, neuropathy, elevated blood urea nitrogen and creatinine levels, and hypoglycemia.

(continued)

**TABLE 15-9 Medications Used for HIV Infections and AIDS (continued)**

Class and Purpose	Generic Name	Brand and Other Names	Nutritional Implications and Comments
<b>Appetite stimulants and anabolic steroids—to improve appetite and intake</b>	<b>Pancreatic enzymes</b>	Various	May be used with malabsorption.
	<b>Peginterferon-<math>\alpha</math> plus ribavirin</b>		Standard for hepatitis C virus/HIV coinfection. Flu-like symptoms, fatigue, weight loss, and depressive mood changes are frequent.
	<b>Topical microbicides</b>	Many microbicides are in development. Alkyl sulfate microbicides, such as sodium dodecyl sulfate agents	Proposed to break the chain of transmission by providing chemical, biological, and physical barriers to infection by blocking or inactivating pathogens at the mucosal surface.
	<b>Trimethoprim-sulfamethoxazole</b>	Bactrim, Septra	Used for <i>Pneumocystis carinii</i> pneumonia for 1 month; may cause hepatitis, azotemia, anorexia, stomatitis, and thrombocytopenia. Monitor carefully. Folate may be needed.
	<b>Valganciclovir</b>	Valcyte	Approved for CMV.
	<b>Dronabinol</b>	Marijuana derivative	Appetite stimulants and anabolic steroids lead to significant increase in body weight and fat-free mass. Takes 4–6 weeks to show effects; somnolence and impaired memory can occur.
	<b>Megestrol acetate</b>	Megace	Useful for stimulating appetite.
	<b>Anabolic steroids: oxandrolone, nandrolone decanoate</b>	Oxandrin	Synthetic testosterone (anabolic steroid) that promotes weight gain, linear growth in children, and increased muscle mass. Hepatic changes or tumors have been reported. Elevation of low-density lipoprotein can occur with prolonged use; this may have cardiovascular effects. Nutritional status and the quality of life can improve.

For more information, see the FDA Web site. Accessed February 6, 2010, at <http://www.fda.gov/ForConsumers/ByAudience/ForWomen/FreePublications/ucm118597.htm#nucleo>

- Patients and caregivers should report all weight loss, anorexia, and fever to doctor. Even a 5% weight loss in 6 months markedly increases the risk of death (Tang et al, 2005).
- Diet must be altered whenever necessary. Evaluation of nutrition assessment parameters on a regular basis requires a comprehensive process. Continuing contact with a dietitian is essential regarding alternative feeding methods, changes in medications, need for home-delivered meals, simplified menu planning, and treatment of GI side effects.
- Aversion to meat may be countered by use of cold protein foods such as cottage cheese, yogurt, skim milk, and cheeses.
- Education should address any decline in self-care abilities, as well as alternative therapies and consequences.
- Address the consequences of protease-inhibiting therapy, such as hyperlipidemia. Studies show that managing fat, alcohol, and fiber intakes and increasing exercise can be very beneficial (American Dietetic Association, 2010).
- Resistance and strengthening exercises should be maintained. Twenty minutes three times weekly is quite effective (American Dietetic Association, 2010; Cade et al, 2007).
- New mothers who are HIV positive will want to use formula or milk from a surrogate mother instead of breastfeeding.
- In the short term, nutrition counseling and oral supplements can achieve a substantial increase in energy intake. Importance of maintaining a balanced, nutritious diet should be addressed. Dietary patterns in HIV-positive individuals may be reflected in changes in BMI, CD4 counts, and viral load (Hendricks et al, 2008). Rest periods before and after meals are suggested.
- Patients are living longer because of ART therapy, and they may be susceptible to other age-related diseases (Gerrior and Neff, 2005). They should receive appropriate nutrition counseling to meet their individual needs. A new standard of care is also needed where malnourished patients may easily access nutritional therapies within HIV treatment (Sztam et al, 2010).
- Patients should be screened and treated for depression (Kacanek et al, 2010).
- Use of stress management and coping mechanisms will be important to maintain nutritional health (Tromble-Hoke et al, 2005). Massage therapy may also be beneficial.
- In home care, continuing education should be offered to caregivers to prevent transmission of the disease and to reduce other infections.

### Patient Education—Food Safety

- Educate about food safety issues. Studies show that education helps to reduce the instances of foodborne illness in this vulnerable population (American Dietetic Association, 2010).
- Reducing infections is very important. Meticulous hand washing is essential because immune-compromised individuals are more susceptible to foodborne illness. Preparation and home delivery methods must also be scrupulously clean (American Dietetic Association, 2010).
- Tips include the following:
  - Separate raw meats from other raw foods such as fruits and vegetables.
  - Avoid cross-contamination from raw meats by storing and preparing raw meat so it does not come in contact with fruits, vegetables, and uncooked foods.
  - Use separate cutting boards and cooking utensils so that juices from raw meats are not allowed to contact uncooked foods.
  - Keep hot foods hot ( $>140^{\circ}\text{F}$ ) and cold foods cold ( $<40^{\circ}\text{F}$ ). Limit the amount of time that food is left at room temperature to prevent germs from growing in it.
  - Wash all fruits and vegetables with warm water and a soft bristle brush.
  - Thaw frozen meat or poultry in a refrigerator or under cold running water, not at room temperature.
  - Avoid raw fish or shellfish, unpasteurized juices or milk, and uncooked eggs (and dishes containing uncooked eggs).
- Exceptional hand-washing techniques should be used by all caregivers and by patient. Safe food-handling techniques are imperative to reduce exposure to *Cryptosporidia*, *Giardia*, and *Salmonella*.

# BURNS (THERMAL INJURY)

## NUTRITIONAL ACUITY RANKING: LEVEL 3 (MINOR), LEVEL 4 (MAJOR BURNS)

Adapted from: Fleisher GR, MD, Ludwig S, MD, Baskin MN, MD. *Atlas of Pediatric Emergency Medicine*. Philadelphia: Lippincott Williams & Wilkins, 2004.

### DEFINITIONS AND BACKGROUND

Electrical, thermal, chemical, or radioactive agents can cause burns. Burns are the third leading cause of accidental death in the United States; 35% of burn victims are children. Unfortunately, a significant proportion of critically ill children admitted to pediatric intensive care units (ICUs) present with nutritional deficiencies; younger age, burn injury, and need for mechanical ventilation support are some factors that are associated with worse nutritional deficiencies (Mehta and Duggan, 2009).

With a first-degree burn, simple redness of epidermis occurs. In a second-degree burn, redness and blistering occur. In a third-degree burn, skin and tissue destruction occurs. The hypermetabolic response to burn injury is mediated by hugely increased levels of circulating catecholamines, prostaglandins, glucagon, and cortisol. This response causes profound skeletal muscle catabolism, immune deficiency, peripheral lipolysis, reduced bone mineralization, reduced linear growth, increased energy expenditure, and marked increase in metabolic rate. Local cytokines are released from inflammatory cells, attracting more to the affected area. Interleukin (IL)-1, IL-6, and tumor necrosis factor (TNF) are involved. Fever, evaporative losses, and infections may occur. Determination of total body surface area (TBSA) burned is often documented in the medical record by using charts such as the Lund-Browder chart, shown in Figure 15-3 ([http://www.rch.org.au/clinicalguide/cpg.cfm?doc\\_id=5158](http://www.rch.org.au/clinicalguide/cpg.cfm?doc_id=5158)).

Before the modern era of early enteral nutrition therapy, significant weight loss led to impaired wound healing, infectious morbidity, and increased mortality (Lee et al, 2005). Loss of 1 g of nitrogen equals a 30 g loss of LBM. Therefore, nitrogen balance becomes a matter of life and death in a major burn victim. Survival depends on medical treatment and early, effective nutritional support. Weight loss of up to 10% is acceptable; 40–50% shows great catabolism and hypermetabolism. Systemic inflammation, acute lung injury,

and multiple organ failure (MOF) are common causes of mortality (Magnotti and Deitch, 2005).

Early institution of enteral feeding can attenuate the stress response, abate hypermetabolism, and improve patient outcome (Lee et al, 2005). Adding high doses of ascorbic acid (25 mg/mL) to resuscitation fluid during the first 24 hours after severe burns significantly reduces edema and severity of respiratory dysfunction.

Thermal injury produces a profound hypermetabolic and hypercatabolic stress response characterized by increased endogenous glucose production via gluconeogenesis and glycogenolysis, lipolysis, and proteolysis (Jeschke, 2009; Jeschke et al, 2005). Severity of thermal injury and presence of systemic infection increase risk for developing ischemic bowel disease. If the GI tract becomes nonfunctional, parenteral support may be needed.

Estimating the percentage of total body burned is important because total burn thickness affects metabolic rate more than body surface area. A 25–30% TBSA burn leads to systemic edema and catabolic responses. A 90% TBSA burn is usually fatal; 60% or more in an older person is also usually fatal. The Harris–Benedict equation (with or without activity and stress factors), the Mifflin–St. Jeor equation, the 1997 Ireton–Jones equation, and the Fick equation should not be considered for use in resting energy expenditure (REE) determination, as these equations do not have adequate prediction accuracy (American Dietetic Association, 2010). If a

**Figure 3.** LifeART image copyright © 2010 Lippincott Williams & Wilkins. All rights reserved.

metabolic cart is not available, the following Penn State equation may be used for nonobese patients, where V is ventilation per minute (American Dietetic Association, 2010):

$$\text{PENN STATE EQUATION RMR} = \text{BMR} (0.85) + V_E (33) + T_{\max(175)} - 6433.$$

The liver, with its metabolic, inflammatory, immune, and acute phase functions, plays a pivotal role in patient survival and recovery by modulating multiple pathways (Jeschke, 2009). Healing takes place in three stages: establishment of the epithelial barrier, scar tissue formation (dermal replacement), and contraction (shrinkage). Eschars cut off blood supply to an extremity or may impair breathing; they are often cut open in a surgical escharotomy. Bleeding occurs, but because the burn causing the eschar has destroyed the nerve endings in the skin, there is little pain. Hepatic acute phase proteins are strong predictors for postburn survival (Jeschke, 2009).

The burn patient is best cared for in a dedicated burn center where resuscitation and monitoring focus is on the pathophysiology of burns, inhalation injury, and edema management (Latenser, 2009). Most dietitians working in burn centers report having advanced training or education (Graves et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Burns are an injury and not genetic in origin.

<b>Clinical/History</b>	Urine acetone, sugars	Chloride $K^+$
Height	Ability to chew	Total urinary N (TUN)
Preburn weight	Ability to swallow	$Ca^{++}$ , $Mg^{++}$
Weight changes	Hypovolemic shock = tachycardia, low BP, decreased urinary output	Partial pressure of carbon dioxide ( $pCO_2$ )
Daily weight (beware of heavy exudate, edema)		Partial pressure of oxygen ( $pO_2$ )
BMI		Transferrin
Diet history		Chol, Trig
Measured energy expenditure (MEE)	<b>Lab Work</b>	WBC, TLC
Percentage body burned	Alb	Serum catecholamines (increased)
Burn classification (first, second, third degree)	Prealbumin: CRP ratio	Ceruloplasmin
Edema	CRP	Alkaline phosphatase (Alk phos)
I & O	Transthyretin (decreased)	N balance
BP	BUN, Creat	
Temperature	H & H	
	Gluc (increased)	
	AST (increased)	
	$Na^+$ (decreased)	

## SAMPLE NUTRITION CARE PROCESS STEPS

### Unintentional Weight Loss

**Assessment Data:** Analysis of preferences, dislikes, and allergies; intake compared with measured or estimated requirements; confirmation of severity and extent of burn from medical record; recorded weights.

**Nutrition Diagnosis (PES):** NC-3.2 Unintentional weight loss related to inadequate intake after burns of 45% of upper extremities as evidenced by weight loss of 10 lb in past 14 days.

**Intervention:** Food-Nutrient Delivery—If needs cannot be met by oral route due to extent and severity of burn, patient will need nutrition therapy or feeding assistance. Eliminate distractions at mealtime and avoid lab work and painful procedures before meals. Educate family and nursing staff about not using empty-calorie foods or beverages and offering nutrient-dense beverages, especially with medication passes. Counsel about long-term nutritional implications, as appropriate.

**Monitoring and Evaluation:** Monitor and evaluate weights. Determine whether nutritional needs are being met. Anticipate 2–3 months total for optimal recovery time.

## INTERVENTION

### OBJECTIVES

- Restore fluid and electrolyte balance to prevent hypovolemic shock and to stabilize body temperature. Fluid resuscitation during the first 24–48 hours after injury remains a significant challenge (White and Renz, 2008).
- Prevent renal insufficiency or failure from decreased plasma volume, cardiac output, and excessive pigment overload from necrosis, toxins, or hemolysis. Exudate losses may be as high as 20–25% of total daily nitrogen losses.
- Promote wound healing and graft retention while minimizing loss of LBM (Lee et al, 2005). Close wound surface with grafts to reduce the likelihood of organ failure. Grafts may be autograft (own body) or from cultured keratinocytes.
- Provide early operative intervention and wound closure, metabolic interventions, early enteral nutrition, and intensive glucose control (Latenser, 2009).
- Anabolic steroid, glutamine, and glucose protocols ( $\leq 120$  mg/dL) are widely used (Graves et al, 2009).
- Avoid weight losses greater than 10% of preburn weight. Minimize catabolism of protein tissues to avoid consequences of impaired immunity, decreased wound healing, decreased vigor and muscle strength, retarded synthesis of blood proteins and hemoglobin, and increased rates of infection.
- Use indirect calorimetry where possible. Patients require only small adjustment for physical activity levels; bedridden patients may need only 1.0–1.2 times the determined REE. Patients who are also malnourished benefit from a gradual increase in intake of 1.1–1.3 times the REE.
- Achieve positive nitrogen balance and minimize losses. Albumin therapy may be considered for the management

of ascites and volume resuscitation (Mendez et al, 2005). In children, growth must continue.

- Prevent ischemic gut, sepsis, and organ failure (Magnotti and Deitch, 2005). Prevent hypothermia and other complications.
- Reduce evaporative water losses, especially with occlusive wound dressings.
- Correct syndrome of inappropriate antidiuretic hormone, hypertonic dehydration, or overhydration.
- Relieve pain and alleviate problems such as postburn pruritus, deep venous thrombosis, peptic ulceration, or pressure ulcers.
- Manage psychosocial problems such as acute stress syndrome, depression, and posttraumatic stress syndrome, and reduce their effect on intake.
- Avoid overfeeding and minimize the negative consequences of hyperglycemia.
- Restore skin's protection to reduce infection. Sepsis is a major cause of mortality, often occurring 2–3 weeks after injury.

## FOOD AND NUTRITION

- Immediately use intravenous fluids to replace deficits; prevent gastric distention and paralytic ileus. Prevent overhydration (Kattelman et al, 2006). Add vitamin C (25 mg/mL) to promote healing.
- If hemodynamically stable with a functional GI tract, then EN is recommended over parenteral nutrition (PN) to lower sepsis and complication rates (American Dietetic Association, 2010; Chan and Chan, 2009). Start within a few hours to decrease the hypermetabolic response to injury (Magnotti and Dietch, 2005).
- A duodenal placement, especially in the early postburn phase, is superior to gastric feeding. Use specialty immunoenhanced products with peptides and glutamine to preserve gut function (De-Souza and Greene, 2005). Provide the feeding at a 45-degree angle, where possible, to reduce risks for pneumonia and aspiration; do not use blue dye to test for aspiration (American Dietetic Association, 2010).
- Protein intake should be from 2–3 times the RDA or 1.5–3 g/kg body weight; adjust for children. Add modular protein supplements as needed, especially glutamine. Leucine-supplemented nutrition is also very promising (De Bandt and Cynober, 2005).
- Use 20% protein, 50–60% carbohydrates (CHOs), and 20–30% fat (2–4% essential fatty acids and slight increase in omega-3 fatty acids). CHO may be given at rate of 5 mg/kg/min. Intravenous lipids can be given at 4 g/kg maximum in pediatric population.
- Gradually progress to oral diet when possible; use a high-calorie, high-protein diet with 5–6 small meals and snacks. Add CHO additives as needed. Suitable snacks may include peanut butter cookies, brownies, cake, shakes, pasteurized eggs in milkshakes or eggnog, protein in broths, and dextrins added to coffee. (See tips for adding protein and calories to the diet in Section 5).
- Supplemental glutamine granules with oral feeding or TF can abate glutamine depletion, promote protein syn-

thesis, inhibit protein decomposition, improve wound healing, and reduce hospital stay (Peng et al, 2005).

- Provide adequate fluid intake: encourage intake of fruit juices (cranberry, grapefruit, prune, or orange juice) for adequate supplies of potassium. Water losses may be 10–12 times normal during first few weeks.
- Supplement diet with 5–10 times the RDA of vitamin C; 2 times the RDA of zinc sulfate; and 2–3 times the RDA of B-complex vitamins. Two times the RDA for vitamins A and D may be useful at first. Vitamins K and B<sub>12</sub> may need to be given weekly; check serum levels as needed.
- For children, vitamins should be given at twice the RDA until recovery.
- Provide adequate copper (for collagen cross-linkage). Arginine (up to 2% of kilocalories) and carnitine also may be beneficial. Phosphorus should be added intravenously as potassium phosphate, enterally, or orally as Neutra-Phos.
- Essential fatty acids are included to reduce inflammation and promote wound healing. Omega-3 fatty acids help to promote a healthy balance of proteins in the body and to reduce inflammation.
- Administration of high-calorie total enteral nutrition in any highly septic phase should be avoided. Avoid large doses of linoleic acid, iron, and zinc, which can depress immunocompetence.
- Do not discontinue nutritional support because of watery diarrhea; this type of diarrhea is likely to occur for reasons other than CHO intolerance (Thakkar et al, 2005).

## Common Drugs Used and Potential Side Effects

- See Table 15-10.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Large amount of vitamin C supplements may be considered in severe burns because of increased requirements resulting from oxidative stress and wound healing; a 3-g dose/day may be needed to restore normal plasma ascorbate concentrations (Berger, 2009).
- Calendula may be used topically as an ointment or a tea. Gotu kola and bee resin (propolis) may also be useful. Aloe vera has some merit but should never be taken orally.
- Probiotic supplements containing *Lactobacillus acidophilus* can help restore GI and immune health.
- Vitamin E helps to promote healing; it may also be recommended for topical use. However, avoid excessive doses before any surgery.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Considering possible consequences of long-term immobilization (renal calculi, pneumonia, contractures, and pressure ulcers), increase activity as pain tolerance allows. Discuss importance of the balance between appetite, nutritional intake, and physical activity.

**TABLE 15-10 Pharmacotherapy for Burns**

Antimicrobial control, analgesia, sedation, and anxiety management are required for burn management. Given acutely and during rehabilitation, supportive therapy uses growth hormone, insulin and related proteins, oxandrolone, and propranolol.

Medication	Description
Anabolic steroids	Oral oxandrolone 0.1 mg/kg twice daily increases protein synthesis, lean body mass accretion, and muscle strength; improves serum visceral protein concentrations; promotes weight gain; and increases bone mineral content (Miller and Btaiche, 2008). Close monitoring of liver transaminase levels should be undertaken.
Analgesics	Pain medications may have some effect on gastrointestinal (GI) function and appetite.
Antacids	Used to prevent Curling ulcer. Cimetidine is also useful.
Antibiotic ointments	Early burn wound excision and complete coverage with autograft will reduce septic complications. Bacitracin may be used for first-degree burns, but other ointments (silver sulfadiazine, silver nitrate, mafenide, or povidone-iodine) may also be used. If Silvadene is used, nutrients may be leached out (i.e., sodium, copper, potassium, magnesium, calcium, and B-complex vitamins).
Antibiotics, oral	Oxacillin, mezlocillin, and gentamicin are used to treat infection.
Growth hormone	Growth hormones may be used to decrease the catabolic effect of burns.
Insulin	Used for stress-induced hyperglycemia.
Interferon-gamma or -alpha-2b	Used to decrease keloid formation. Dry mouth, stomatitis, nausea and vomiting, diarrhea, and abdominal pain may result.
Pain medicine	Prescription medications (acetaminophen with codeine, morphine, or meperidine) are used for severe burns.
Promotility agents (metoclopramide)	If the patient has gastroparesis or repeated high gastric residuals, a promotility agent may help increase GI transit and improve feeding tolerance.

From Miller JT, Btaiche IF. Oxandrolone in pediatric patients with severe thermal burn injury. *Ann Pharmacother*. 42:1310, 2008.

- Review the fact that fat is high in energy while low in volume. Fat is helpful in normalizing elimination; however, excesses may negatively affect immunocompetence.
- Explain that adequate intake of fiber is important.
- The family's attitude toward patient's dietary intake should be firm but understanding. A daily nutrient intake record may be a good way to track goals and to assess total intake. Discuss problems to monitor and report, such as fever or wound drainage.
- Offer a written care plan for home use.

### Patient Education—Food Safety

- Educate about food safety, reducing risk of infection, and meticulous hand washing.
- Reinforce kitchen fire safety issues. Clean cooking surfaces to prevent food and grease buildup. Turn pan handles inward to avoid hot food spills. Avoid wearing loose clothing while cooking. Stay in the kitchen while cooking.
- Burn patients are more susceptible to minor illnesses, including foodborne illness. Tips include the following:
  - Separate raw meats from other raw foods such as fruits and vegetables.
  - Avoid cross-contamination from raw meats by storing and preparing raw meat so it does not come in contact with fruits, vegetables, and uncooked foods.
  - Use separate cutting boards and cooking utensils so that juices from raw meats are not allowed to contact uncooked foods.
  - Keep hot foods hot (>140°F) and cold foods cold (<40°F). Limit the amount of time that food is left at room temperature to prevent germs from growing in it.
- Wash all fruits and vegetables with warm water and a soft bristle brush.
- Thaw frozen meat or poultry in a refrigerator or under cold running water, not at room temperature
- Avoid raw fish, shellfish, unpasteurized juices, and uncooked eggs (and dishes containing uncooked eggs).

## FRACTURES

### NUTRITIONAL ACUITY RANKING: LEVEL 2

Adapted from: Koval KJ, MD and Zuckerman, JD, MD. *Atlas of Orthopaedic Surgery: A Multimedial Reference*. Philadelphia: Lippincott Williams & Wilkins, 2004.

### DEFINITIONS AND BACKGROUND

**Stress fractures** occur from prolonged stress on normal bones. Here, broken bones result from a physical force

greater than stress that cannot be withstood. They are common in athletes, especially gymnasts, runners, and basketball or tennis players. *Simple (closed) fractures* involve bones that do not protrude. A *compound (open) fracture* allows bone to protrude. A *long-bone fracture* generally is an emergency and may be complicated by shock, wound infection, bleeding, or inadequate hydration; traction is used for internal immobilization. The most commonly broken bones are the collarbone (clavicle) and the bones of the wrist. In persons older than 75 years, the hip is more commonly broken.

A *complete fracture* has separated bone fragments complete, whereas they are still partially joined in an *incomplete fracture*. In *comminuted fractures*, the bones are split into multiple pieces. Orthopedic surgeons have elaborate nomenclature for the type of fracture, its location, and its geometric shape (transverse, oblique, spiral, and so on). After a break, edema of surrounding tissue causes discomfort, and muscle spasms occur to hold the bone in place.

Healing occurs in stages, starting with the *inflammation phase*, a blood clot (fracture hematoma) between the bone fragments, followed by new blood vessels with phagocytosis to remove dead tissue. Fibroblasts can then produce collagen fibers and new tissue. The second, *reparative stage* begins approximately 2 weeks after the fracture. In this stage, proteins produced by the osteoblasts and chondroblasts form new bone matrix (soft callus) from calcium hydroxyapatite crystals. This healing shows on a radiograph after approximately 4–6 weeks. The soft callus hardens forms into a hard callus over a 6- to 12-week period. In the third, *remodeling phase*, mature lamellar bone replaces the woven bone in the period of 3–18 months after the injury. Both osteoblasts and osteoclasts are involved.

Good nutrition is essential during all phases of healing. With multiple fractures, metabolic rate may increase by 20% or more for several weeks. Aggressive refeeding can decrease morbidity and mortality in malnourished patients (Bonjour, 2005).

**Compression fractures** involve weakened bones breaking from osteoporosis or from bone cancer. Incidence increases

after 60 years of age, especially in women. Osteoporosis is responsible for more than 1.5 million fractures annually, including more than 300,000 hip fractures; 700,000 vertebral fractures; 250,000 wrist fractures; and 300,000 fractures at other sites. Bone resorption markers at levels above the upper limit of the premenopausal range are associated with an increased risk of hip, vertebral, and nonvertebral fracture; the most sensitive markers include serum osteocalcin, bone-specific alkaline phosphatase, the N-terminal propeptide of type I collagen for bone formation, and the cross-linked C- (CTX) and N- (NTX) telopeptides of type I collagen for bone resorption (Garnero, 2008).

A *broken hip* includes fractures of the femur head (intracapsular), femur neck (extracapsular), and greater Hesser trochanter. Osteoporotic fractures lower one's quality of life. Up to 50% of women and 20% of men at the age of 50 years may have a fragility fracture in their remaining lifetimes (Earl et al, 2010). The most common risk factors for osteoporotic fracture are advanced age, low bone mineral density, and previous fracture as an adult (NAMS, 2010). Women with one hip fracture are at a fourfold greater risk of having a second one.

Maternal nutrition may have critical and far-reaching persistent consequences for offspring health; reduced maternal fat stores and low levels of circulating 25-hydroxyvitamin D in pregnancy are associated with reduced bone mass in the offspring (Earl et al, 2010). Low birth-weight and poor childhood growth are also linked to risk of hip fracture later in life (Cooper et al, 2006). Clearly, optimizing nutrition throughout life is protective. Deficiency in dietary proteins causes marked deterioration in bone mass, microarchitecture, and strength (Bonjour, 2005). Vitamin A in amounts greater than 5000 IU/day may increase the risk of hip fractures; intake should be limited to 100% RDA levels.

After hip fracture, aligning the bone through an open "reduction" with internal fixation (ORIF) may be necessary. In spinal fracture, vertebroplasty involves inserting glue (methylmethacrylate) into the center of the collapsed spinal vertebra to stabilize and strengthen the crushed bone. Here, adequate nutrition must be provided to heal and to reduce infectious processes. Sometimes the medical team uses electrical bone growth stimulation or osteostimulation to support bone recovery. Once healed, it is important to return to some level of physical activity if possible.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** Bone density and family history can predict fracture risk (Cosman, 2005). Many genes are implicated. BMD candidate genes, ADAMTS18 (ADAM metalloproteinase with thrombospondin type 1 motif, 18) and TGFBR3 (transforming growth factor, beta receptor III) seem to predict bone density and risk for skeletal fracture (Xiong et al, 2009).

## INTERVENTION

## OBJECTIVES

- Support formation of bone matrix. Complete union may take 4–8 months.
- Supply adequate nutrition for collagen formation and calcium deposition.
- Prevent side effects of long-term immobilization, such as renal calculi, pressure ulcers, urinary tract infections, embolus, contractures, and neurovascular dysfunction.
- Use fluoridated water. Monitor bottled waters and well water, which are often not fluoridated.
- For long-bone fracture, meet energy needs, which are increased by 20–25%. Keep nearby joints as active as possible and prevent complications such as pressure ulcers, renal calculi, and effects from spinal anesthesia.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Oral Food and Beverage Intake

**Assessment Data:** Diet history and intake records showing intake of <50% at most meals following hip fracture and ORIF. Weights not available at that time. Medications include morphine and heparin. Patient shows signs of depression and anorexia.

**Nutrition Diagnosis (PES):** NI-2.1 Inadequate oral food and beverage intake related to anorexia and depression as evidenced by food records showing <50% oral intake at most meals for past 5 days.

**Intervention:** Food-Nutrient Delivery—Consider use of tube feeding if oral intake continues to be low. Offer liquid nutritional supplements between meals to enhance protein and calorie intake. Educate patient and family about the importance of nutrition for healing. Counsel about ways to increase nutrient density without increasing the total amount of food consumed. Coordinate care with medical team for gradual increments of physical activity, which should help with depression and anorexia; review medications and determine whether morphine can be decreased to lessen sleepiness during the day.

**Monitoring and Evaluation:** Improved oral intake for total protein and calories. Gradual improvement in cognition and the ability to participate in physical activity. Decline in signs of depression.

## FOOD AND NUTRITION

- Use a high-protein, high-energy diet; needs may increase as much as 20–25%.
- Use adequate levels of calcium, phosphorus, and vitamins D, C, and K. Encourage these nutrients to be taken in diet; if a supplement is used, avoid levels >100% RDA for vitamin A.
- Although the main source of dietary calcium is dairy products, calcium contained in mineral water is highly bioavailable and can provide another valuable source.
- Supply zinc for wound healing after surgical procedures.
- Prevent or correct fever, pneumonia, and possible embolism.
- Ensure adequate fluid intake to excrete calcium excesses.

### Common Drugs Used and Potential Side Effects

- Pharmacological therapy can reduce the risk of fractures, but many patients take their medication incorrectly, stop it prematurely, or have malabsorption (Hamdy et al, 2010).
- Bisphosphonates (alendronate, risedronate, and ibandronate), selective estrogen-receptor modulators (raloxifene), parathyroid hormone, estrogens, and calcitonin may be necessary (NAMS, 2010). Parathyroid hormone (teriparatide) is an anabolic agent that stimulates new bone formation, repairs architectural defects, and improves bone density.
- Some drugs, such as thiazolidinedione, anticonvulsants, and opioids, significantly reduce bone mineral density. Selective serotonin reuptake inhibitors may also have an undesirable effect on bone health; their use should be carefully monitored (Haney et al, 2010).
- Pain medications such as morphine or meperidine (Demerol) may cause vomiting, nausea, and constipation. When analgesics are needed, monitor for GI distress or bleeding.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Creatine supplementation, with and without resistance training, has the potential to influence bone biology; however, the longer-term effects of creatine supplementation are not known (Candow and Chilibeck, 2010).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Emphasize nutrition, especially adequate calcium, vitamin D, protein, and vitamin K (Earl et al, 2010).
- Encourage activity and the use of physical therapy after the healing has progressed. Use of oral supplements with resistance training can be very beneficial (Miller et al, 2006).

- Refer to appropriate agencies, such as home health, Visiting Nurses Association, or Meals-on-Wheels, as needed.
- All women should have a bone density test by the age of 65 years or at the time of early menopause.
- Discourage smoking. Smoking cigarettes hinders the healing of bones by decreasing collagen production and oxygen availability.
- Prevention focuses first on measures such as a balanced diet, adequate calcium and vitamin D intake, adequate exercise, smoking cessation, avoidance of excessive alcohol intake, and fall prevention (NAMS, 2010). Encourage frequent fish consumption, especially in winter, for vitamin D (Nakamura, 2006).

### Patient Education—Food Safety

- Educate about basic food safety and hand washing.

# INTESTINAL PARASITE INFECTIONS

## NUTRITIONAL ACUITY RANKING: LEVEL 1

### DEFINITIONS AND BACKGROUND

Intestinal parasite infections cause significant morbidity and mortality. These infections, especially from helminths and untreated water, represent major health problems that increase iron-deficiency anemia in developing countries (Alaofe et al, 2008). Protein-energy malnutrition causes immune deficiency, especially in developing countries. Newborns are especially vulnerable, where morbidity is often secondary to intestinal parasites (Steer, 2005). In addition, transmission of parasites is common in refugee or displacement camps. *Cryptosporidium parvum*, *Giardia lamblia*, *Entamoeba histolytica*, *Ascaris lumbricoides*, hookworm infection, *Schistosoma haematobium*, *S. mansoni* and *Strongyloides stercoralis* are important intestinal parasites that are common among children, the immunocompromised, and displaced populations (Gbakima et al, 2007). Infections caused by *Enterobius vermicularis*, *G. lamblia*, *Ancylostoma duodenale*, *Necator americanus*, and *E. histolytica* occur in the United States (see Table 15-11).

Mucin-secreting intestinal goblet cells are an important component of the innate defense system (Hasnain et al, 2010). Parasites modulate GI immunity, possibly by inhibiting migration of CD8 $\alpha$  to the draining lymph nodes while increasing IL-6, TNF- $\alpha$ , and, in particular, IL-10 (Balic et al, 2009). Activation of the mucosal immune system of the GI tract results in altered intestinal physiology, which changes in intestinal motility and mucus production (Kahn and Collins, 2004). The protective immune response that develops following infection with intestinal parasites is characterized by increased numbers of CD4<sup>+</sup> T cells, granulocytes, and macrophages (Patel et al, 2009).

Toxoplasmosis is considered to be the third leading cause of death attributed to foodborne illness in the United States. More than 60 million men, women, and children in the United States carry the *Toxoplasma* parasite, but very few have symptoms because their healthy immune system usually keeps the parasite from causing illness. Washing vegetables thoroughly before eating them and cooking meat to the recommended temperatures are just a few ways to reduce risk of toxoplasmosis.

**TABLE 15-11 Intestinal Parasites and Treatments**

Parasite	Description and Treatment
<i>Ancylostoma duodenale</i> , <i>Necator americanus</i> (hookworms)	Cause blood loss, anemia, pica, and wasting. Finding eggs in the feces is diagnostic. Treatments include albendazole, mebendazole, pyrantel pamoate, iron supplementation, and blood transfusion. Preventive measures include wearing shoes and treating sewage.
Ascariasis (intestinal roundworms)	Common in warm or humid climates or when personal hygiene is inadequate. Adult worms live in the small intestine, with eggs that pass out in human feces. These eggs become infective within 2–3 weeks. When ingested by humans through fecally contaminated food or water, the eggs hatch and penetrate the intestines. Eventually, they reach the heart. Larvae mature within 2–3 months, and adult worms may live for 1 year or more. Hemorrhage can occur in lung tissue and cause pneumonitis. Vague abdominal discomfort can occur with small intestine involvement. Malnutrition can cause an imbalance in T-cell subpopulations that may lead to a defective T-cell maturation, thereby increasing susceptibility to parasitic infection (Di Pentima, 2009).
<i>Enterobius vermicularis</i> (pinworm)	Causes irritation and sleep disturbances. Diagnosis can be made using the “cellophane tape test.” Treatment includes mebendazole and household sanitation.
<i>Giardia</i>	<i>Giardia intestinalis</i> is one of the most common intestinal parasites in the world, and it contributes to diarrhea, nutritional deficiencies, stunting, and cognitive impairment in children in developing regions (CDC, 2010). It causes nausea, vomiting, malabsorption, diarrhea, and weight loss. Stool ova and parasite studies are diagnostic. Treatment includes metronidazole. Sewage treatment, proper hand washing, and consumption of bottled water can be preventive.
<i>Entamoeba histolytica</i>	Can cause intestinal ulcerations, bloody diarrhea, weight loss, fever, gastrointestinal obstruction, and peritonitis. Amebas can cause abscesses in the liver that may rupture into the pleural space, peritoneum, or pericardium. Stool and serological assays, biopsy, barium studies, and liver imaging have diagnostic merit. Therapy includes luminal and tissue amebicides to attack both life-cycle stages. Metronidazole, chloroquine, and aspiration are treatments for liver abscess. Careful sanitation and use of peeled foods and bottled water are preventive.
<i>Trichinella spiralis</i>	<i>T. spiralis</i> is a roundworm that causes an acute infection (trichinosis) and is usually acquired by eating encysted larvae in raw or undercooked pork. Larvae mature and mate in the small intestine; larvae reaching striated muscle will encyst and live for years. Usual incubation is 5–15 days. The disorder has a 4% prevalence in the United States. Symptoms and signs include swelling of the upper eyelids, bleeding under the nails, skin rash, diarrhea, abdominal cramps, and malaise; later, low-grade fever, edema, sweating, dyspnea, cough, and muscle pain occur. In nonstriated muscle tissues such as the heart, brain, kidney, or lung, death can follow in 4–6 weeks, if untreated. Most symptoms disappear by the third month.

 Di Pentima C. Burden of non-sexually transmitted infections on adolescent growth and development in the developing world. *Adolesc Med State Art Rev*. 20:930, 2009.

Risks are more significant for individuals with AIDS and for pregnant women. Most intestinal protozoan infections can cause acute or chronic diarrhea in healthy individuals but may result in intractable, life-threatening illness in patients with immunosuppressive diseases such as AIDS (Escobedo et al, 2009). Vaccines or immunotherapies may be developed to treat these pathogens.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The T-helper (Th) 2-type immune response causes infection-induced intestinal muscle hypercontractility and goblet cell hyperplasia (Kahn and Collins, 2004). The genetics of this form of immunity are under study.

Clinical/History	Positive skin and serological tests for eosinophilia and leukocytosis	Alb, transthyretin Prealbumin:CRP ratio CRP H & H Serum Fe, ferritin Transferrin TIBC Na <sup>+</sup> , K <sup>+</sup> , Cl <sup>-</sup> Ca <sup>++</sup> , Mg <sup>++</sup> TLC, WBC Gluc
Height		
Weight		
BMI		
Diet history		
Temperature		
I & O	Trichinosis—biopsy of skeletal muscle after fourth week (for larvae or cysts)	
BP		
Lab Work		
Stool examination		

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Altered GI Function

**Assessment Data:** Diet history and intake records showing normal intake of all macronutrients. History of (Hx) explosive diarrhea for the past month. Tested positive for *G. lamblia* after a camping trip where patient drank untreated water from a stream. Other family members tested negative.

**Nutrition Diagnosis (PES):** NC-1.4 Altered GI function related to infection with *Giardia* as evidenced by explosive diarrhea for the past month and no changes in usual dietary intake.

**Intervention:** Food-Nutrient Delivery—discuss options for decreasing fiber and tolerating medications while under treatment for *Giardia*. Educate patient and family about the importance of drinking only treated water while camping. Counsel about monitoring tolerance for fiber-rich foods when infection has resolved. Coordinate care with medical team for pharmacotherapy and any nutritional side effects.

**Monitoring and Evaluation:** Resolution of *Giardia* infection and diarrheal disease. No undesirable side effects from medications.

## INTERVENTION

### OBJECTIVES

- Differentiate symptoms and correctly identify condition as rapidly as possible; treat as needed.
- Treat infections and diarrhea.
- Prevent or correct malnutrition; prevent stunting and allow growth in children.
- Prevent blockage, inflammation, volvulus, and bowel perforation.
- Correct any complications such as anemia, pneumonia, and cardiac failure.
- Teach ways to prevent further infections.

### FOOD AND NUTRITION

- Provide balanced intake of all macronutrients. Protein intake, especially lysine, is important. Adequate, but not excessive, iron and zinc are also useful.
- Encourage adequate intake of food sources of vitamins A and C, especially from fruits, juices, and vegetables. Vitamin E and selenium may be especially protective (Smith et al, 2005). Supplements with retinol may be used in some cases.
- Ensure an adequate fluid intake, especially with diarrheal losses. Replace electrolytes with broths and juices.
- With poor appetite, offer small, frequent meals and snacks to correct malnutrition or weight loss that is undesirable.
- Ensure safe food handling at all meals.

### Common Drugs Used and Potential Side Effects

- The albendazole-praziquantel combined regimen is a useful single-dose therapy for **giardiasis** in children.
- Pyrantel pamoate (Povan) may be used for **ascariasis**. Rarely, vomiting or diarrhea may occur.
- For **trichinosis**, mebendazole or thiabendazole may be used. GI distress is a common side effect. Aspirin or analgesics may be needed for muscular pain.
- Corticosteroids such as prednisone are often used temporarily to reduce inflammation of the heart or brain.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. Chincona, elecampane, golden seal, ipecac, and papaya are not proven through clinical trials.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss the importance of personal hygiene in maintaining a sanitary environment and in preventing reinfection.
- Children who play outside should always wash their hands before eating meals or snacks. Diarrhea caused by

parasites such as *Cryptosporidium* may be severe in malnourished or immunodeficient children; recovery is achieved only after sufficient nutritional repletion.

- Protozoa intestinal infection is still frequent in some marginalized populations; improvement in sanitation might decrease the prevalence of these diseases (Korkes et al, 2009). A mass campaign to educate about the role of sanitation in reducing intestinal parasite infection is recommended (Mehraj et al, 2008).

#### Patient Education—Food Safety

- Educate about food safety issues. Reducing new infection is very important. Meticulous hand washing is essential.
- Many of these parasites can be transmitted by food, water, soil, or person-to-person contact. Occasionally, helminthic roundworms, tapeworms, and flukes are transmitted in foods such as undercooked fish, crabs, and mollusks; undercooked meat; raw aquatic plants such as watercress; raw vegetables that have been contaminated by human or animal feces; and foods contaminated by food service workers with poor hygiene or working in unsanitary facilities.

## MULTIPLE ORGAN DYSFUNCTION SYNDROME

### NUTRITIONAL ACUTY RANKING: LEVEL 4

Adapted from: Sherwood L. Gorbach, John G. Bartlett, et al. *Infectious Diseases*. Philadelphia: Lippincott Williams & Wilkins, 2004.

## DEFINITIONS AND BACKGROUND

Multiple organ dysfunction syndrome (MODS) involves two or more systems in failure at the same time (e.g., renal, hepatic, cardiac, or respiratory). The condition is also called MOF.

Etiology may be from sepsis (gram-positive/negative bacteria, fungal or viral,) shock, hemorrhage, allergy, burns, or trauma. Conditions leading to MOF may also include unnecessary deep sedation, excessive blood glucose levels, prolonged immobilization, or corticosteroid use (de Jonge et al, 2009).

Cytokines are direct mediators. MODS is triggered by TNF- $\alpha$  and by a cytokine cascade with IL-6 and other ILs, platelets, endothelial cells, and leukocytes. Lactate level is often used as a prognostic indicator of problems with tissue perfusion. High baseline serum cortisol level is also a marker of severity and poor prognosis. Cortisol levels  $<20$  g/dL in a highly stressed patient (with respiratory failure, hypotension) may diagnose adrenal insufficiency, which should be treated (Marik et al, 2005). Early aggressive resuscitation of critically ill patients limits or prevents progression to MODS.

Gut injury and impaired gut barrier function have a high impact on the development of MODS. Mucosal lesions and increased intestinal permeability cause translocation of bacteria and endotoxins and initiate a local or systemic inflammatory response syndrome (SIRS). There are sequential metabolic changes following induction of SIRS, with an elevation in REE from 4–21 days and loss of LBM. Some experts suggest use of the phrase “nutrition therapy” versus “nutrition support” to strengthen the role in attenuating this metabolic response, preventing oxidative stress, and modifying the immune response with the use of appropriate lipids, glutamine, arginine, and antioxidants. Indeed, the quality of nutrition therapy is more important than the quantity.

Specific nutrients to modify immune, inflammatory, and metabolic processes have been helpful (Heys et al, 2005). In critical illness, glutamine levels are much higher in the duodenal mucosa; glutamine supplementation may be beneficial (De-Souza and Greene, 2005). While arginine supplementation may improve outcomes, controversy continues surrounding its long-term use in septic patients. In general, immune-enhanced products do not decrease ICU length of stay or improve rates of recovery (American Dietetic Association, 2010).

Maintaining adequate tissue oxygenation and cellular nutrition are priorities. Trace elements, omega-3 fatty acids, and antioxidant nutrients, especially vitamin E and selenium, are important and may reduce mortality (Grimble, 2005; Heyland et al, 2005). Enteral nutrition provides the intestinal mucosa with nutrients, which reduces bacterial translocation and septic complications. There may be beneficial effects of immune-enhancing diets for MODS, especially after trauma or surgery. However, overall mortality remains high at 30–100%, especially if multiple organs are involved.

The treatment of MODS is complex. Treatment includes correction of ischemia through fluid resuscitation and mechanical ventilation; antibiotics; and stabilization of water, electrolyte, and acid–base imbalance. Stress hyperglycemia promotes the proinflammatory response, whereas insulin has the opposite effect; therefore, tight glycemic control is important.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The development of techniques for measuring the expression level of all of a person's genes may make it possible to develop an injury scoring system based on the degree of gene activation related to having more infections and organ failure (Warren et al, 2009).

Clinical/History	Lab Work	
Height	Serum procalcitonin (PCT)	Lactic acid (elevated?)
Weight	BUN (often elevated)	Serum pH $<7.35$ (acidosis)
BMI	Creat (often elevated)	Alanine, pyruvate (retention?)
Dry weight	ALT, AST (elevated)	Serum cortisol
Weight changes	Alb, transthyretin	pCO <sub>2</sub> , pO <sub>2</sub>
Edema, ascites	Albumin:CRP ratio	Chol, Trig
Diet history	CRP	Glomerular filtration rate
Temperature	Na <sup>+</sup> , K <sup>+</sup>	TLC, WBC
I & O	Ca <sup>++</sup> , Mg <sup>++</sup>	H & H
BP	Cl <sup>-</sup>	Serum Fe
Acute Physiology and Chronic Health Evaluation (APACHE)	Creatine kinase (CK)	TIBC
Injury Severity Score (ISS)	Phosphorus	Serum phosphorous
Ultrasonography	Gluc—serum, urine	Serum folate
Echocardiography	Serum insulin	Serum zinc
Electroencephalogram (EEG)		

## INTERVENTION

### OBJECTIVES

- Stabilize electrolyte and hemodynamic balances. Remove or control sources of organ dysfunction, such as bacterial translocation. Early identification and aggressive management of MODS is essential.
- Provide continuous administration of at least minimal enteral nutrition to prevent gut mucosa atrophy.
- In patients with a functional GI tract, enteral nutrition is preferred over parenteral nutrition (Casaer et al, 2008). Enteral or oral nutrition preserves the gut and immune system integrity.
- Support organs with appropriate substrate. “Immunonutrition” provides formulas supplemented with arginine, omega-3 fatty acids, ribonucleic acids, and glutamine; however, there is no clear evidence that these products promote faster recovery (American Dietetic Association, 2010).
- Control hyperglycemia to decrease infection and sepsis.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Infusion of Parenteral Nutrition

**Assessment Data:** Patient in ICU for 3 days, on CPN with order changed Day 2 to provide CHO and lipid in excess of estimated requirements. Indirect calorimetry identifies needs as 1400 kcal/day; patient receiving 1800 kcal/day. Admitted with acute pancreatitis; now showing signs of heart and liver failure. Glucose >200 mg/dL; fever with temperature of 102° F.

**Nutrition Diagnosis (PES):** Excessive infusion of parenteral nutrition related to current CPN order as evidenced by solution providing 1800 kcal/day with CHO and lipid exceeding daily requirements.

**Intervention:** Food-Nutrient Delivery—Decrease CPN order to 1400 kcal/day; lipid calculated at 30% total calories and CHO calculated as 50% total kilocalories. Patient may benefit from jejunostomy instead of CPN because of MODS.

Coordinate care with medical team—discuss importance of not overfeeding CPN solution. Discuss merits of using jejunostomy feeding instead of parenteral feeding.

**Monitoring and Evaluation:** CPN order discontinued. Jejunostomy tube placed; new feeding order that meets needs of 1400 kcal and 50% CHO, 30% fat, and 20% protein with extra fluid. Glucose monitoring and use of insulin to bring levels back below 120 mg/dL. Patient tolerating jejunostomy. Fever gradually subsiding. Signs of improvement in MODS.

- Promote prompt and immediate responses to all changing parameters. Until organ dysfunction resolves, monitor weight, relevant laboratory parameters, and nutrient intake.
- Consider short- and long-term consequences of all actions (e.g., treatments must incorporate a consensus of opinions about which therapy precedes another).
- Manage complications such as anemia, gastric reflux, or delayed bowel motility.
- Promote wound healing if surgery is required. Prevent additional sepsis.
- Promote recovery and improved well-being.

### FOOD AND NUTRITION

- If there is gastric reflux or delayed bowel motility, a nasoduodenal or jejunal feeding tube or feeding jejunostomy is required. Ensure that the formula is appropriate.
- The recommended energy intake is 20–30 kcal/kg/day with a protein intake of 1.2–1.5 g/kg/day (Casaer et al, 2008). Evaluate organ function and provide a correctly calculated feeding and product for patient's diagnosis and condition.
- Immunoenhanced or glutamine-enriched products used to preserve gut integrity do not necessarily speed rates of recovery or reduce time in ICUs (American Dietetic Association, 2010).
- Review current vitamin and mineral intakes; adjust according to changing needs. Antioxidants may play a role in supporting recovery.
- Avoid excesses of iron, zinc, polyunsaturated fatty acids (PUFAs), and linoleic acid—especially parenterally—because of their effects on the immune system.

- When possible, return to oral feeding to acquire the benefits of phytochemicals from whole foods.
- Patients requiring ventilator support may need a higher lipid content in their feeding, even with cardiac failure.

### Common Drugs Used and Potential Side Effects

- Hypertonic saline solution is commonly used.
- Anti-inflammatory treatment is vital for intervention in severe infectious disease.
- All medications should be reviewed for potential drug–nutrient incompatibility and stability with formulas. Try to avoid inclusion of medications with EN products because of drug–nutrient interactions and because drugs may then be less available to the patient.
- Drug metabolism with the liver cytochrome P-450 (CYP450) system can result in drug toxicities, reduced pharmacological effect, and adverse drug reactions. Foods such as grapefruit, alcoholic beverages, teas, and herbs may inhibit or induce the activity of CYP3A4 (Flanagan, 2005).
- Review all vitamin and mineral supplements and enteral products to determine whether the potential of hypervitaminosis and mineral toxicities exists.
- Insulin may be required because of the hyperglycemia that occurs with stress.
- With continuous seizures, lorazepam or anticonvulsants may be needed. Weight and appetite changes are common if used long term.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. Herbs often possess the ability to inhibit or induce the activity of CYP3A4.
- Chinese herbs for reducing inflammatory reaction are being studied.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- When possible, discuss implications of MODS in relation to nutritional support. Include a realistic assessment of potential for recovery and use of EN in the home setting, as discussed with the physician.
- Family should be included in discussions about nutritional support measures that are taken. As appropriate, prepare patient and family for home nutritional needs and total parenteral nutrition/EN/oral diet requirements.
- Alleviate fears associated with eating or nutritional support therapies.
- Discuss any signs or problems that should require professional intervention.

### Patient Education—Food Safety

- Educate about food safety issues. Reducing more infection is very important.

- Meticulous hand washing is essential because immunocompromised individuals are more susceptible to minor illnesses, including foodborne illness.

## SEPSIS AND SYSTEMIC INFLAMMATORY RESPONSE SYNDROME

### NUTRITIONAL ACUITY RANKING: LEVEL 4

Adapted from: Sherwood L. Gorbach, John G. Bartlett, et al. *Infectious Diseases*. Philadelphia: Lippincott Williams & Wilkins, 2004.

#### DEFINITIONS AND BACKGROUND

**Sepsis** involves a SIRS, with infection that has spread to other areas from its original site. Similar to the stress response, the inflammatory reaction is crucial for survival and is meant to be tailored to the stimulus and time (Elenkov et al, 2005). Sepsis may be a complication of vascular access devices or intravenous catheters and may be bacterial or fungal in origin. The most common sources of infection are lung and abdominal infections (Russell, 2008). The stages of sepsis are listed in Table 15-12.

Natural killer cells are a crucial component of the innate immune response to various viruses, fungi, parasites, and bacteria (Fauci et al, 2005). Systemic inflammation stimulates an

acute-phase reaction and the stress response, mediated by the hypothalamic–pituitary–adrenal axis and the sympathetic nervous system (Elenkov et al, 2005). GI tract dysmotility increases permeability of intestinal mucosa and bacterial translocation, contributing to sepsis and MODS (Ukleja, 2010). Synergistic effects of TNF- $\alpha$ , IL-1 $\beta$ , other cytokines, and nitric oxide are also implicated. In SIRS, reduced TNF production occurs; this is immunosuppression rather than an excessive inflammatory response (Cavaillon et al, 2005).

In sepsis, activated phagocytes release leukocytic endogenous mediators; hepatic uptake of amino acids and increased prostaglandin synthesis occur. Hormonal responses include increases in adrenocorticotrophic hormone (ACTH), aldosterone, and catecholamines (with increased gluconeogenesis, glycolysis, proteolysis, and lipolysis). Decreased triiodothyronine (T<sub>3</sub>) cause tissue degradation and mobilized triglycerides.

Host defense peptides modulate inflammation (Bowdish and Hancock, 2005). While albumin, transthyretin, and transferrin have a transport role in the body, acute-phase proteins (CRP,  $\alpha$ -acid glycoprotein, and  $\alpha$ -trypsin) help with host defense. These parameters drop in sepsis independent of nutritional status; monitor all protein levels as markers of inflammation in this population.

Vitamin D<sub>3</sub> plays a role in immune activation of endothelial cells during gram-negative bacterial infections (Equils et al, 2006). It may enhance the innate immune response by induction of cathelicidin (LL-37), an endogenous antimicrobial peptide produced by macrophages and neutrophils (Jeng et al, 2009).

Enteral feeding is preferred over parenteral feeding, where catheter infection is a risk. A key issue in providing nutrition to critically ill patients is intolerance of enteral feeding as a result of impaired GI motility (Ukleja, 2010). Overfeeding sometimes increases sepsis.

**TABLE 15-12 Stages of Sepsis**

Definitions of the various stages of sepsis can be summarized as follows:

- Infection is a microbial phenomenon in which an inflammatory response to the presence of microorganisms or the invasion of normally sterile host tissue by these organisms is characteristic.
- Bacteremia is the presence of viable bacteria in the blood.
- Systemic inflammatory response syndrome (SIRS) may follow a variety of clinical insults, including infection, pancreatitis, ischemia, multiple trauma, tissue injury, hemorrhagic shock, or immune-mediated organ injury.
- Sepsis is a systemic response to infection. This is identical to SIRS, except that it must result from infection.
- Septic shock is sepsis with hypotension (systolic blood pressure <90 mm Hg or a reduction of 40 mm Hg from baseline) despite adequate fluid resuscitation. Concomitant organ dysfunction or perfusion abnormalities (e.g., lactic acidosis, oliguria, coma) are present in the absence of other known causes.
- Multiple organ dysfunction syndrome (MODS) is the presence of altered organ function in a patient who is acutely ill such that homeostasis cannot be maintained without intervention. Primary MODS is the direct result of a well-defined insult in which organ dysfunction occurs early and can be directly attributable to the insult itself. Secondary MODS develops as a consequence of a host response and is identified within the context of SIRS. The inflammatory response of the body to toxins and other components of microorganisms causes the clinical manifestations of sepsis.

Sepsis syndrome is recognized clinically by the presence of two or more of the following:

- Temperature >38°C or <36°C
- Heart rate >90 beats/min
- Respiratory rate >20 breaths/min or partial pressure of carbon dioxide in arterial gas <32 mm Hg
- White blood cell count >12,000 cells/μL, <4000 cells/μL, or >10% band forms

Adapted from: American College of Chest Physicians/Society of Critical Care Medicine Consensus Panel guidelines. Web site accessed February 11, 2010 at <http://chestjournal.chestpubs.org/content/101/6/1644.abstract>.

Management of septic shock requires an ABCDEF approach: Airway, Breathing, Circulation, Drugs, Evaluate, and Fix the source of sepsis (Russell, 2008). Improvements in the management of sepsis and MODS have resulted from improvements in critical care practices (Sullivan et al, 2005). Yet, the incidence of septic shock is increasing; mortality ranges from 30% to 70% (Russell, 2008). Severe sepsis leading to shock is still a common cause of death in critically ill patients.

Sepsis may involve the bloodstream from gram-negative or gram-positive bacteria. Diseases caused by group A *Streptococcus* include acute rheumatic fever, rheumatic heart disease, poststreptococcal glomerulonephritis, and invasive infections. Pathogenic *Escherichia coli* causes infections such as urinary tract infection and meningitis, which are prevalent (Kim et al, 2005). *Yersinia enterocolitis* can cause bacteremia or abdominal abscess, especially in states of iron overload. Neonatal sepsis is a major cause of death, especially in low birth-weight infants. In addition, while sepsis during pregnancy is uncommon, it is potentially fatal (Fernandez-Perez

et al, 2005). In the elderly, poor immune response and poor functional status may be indicators of sepsis (Gavazzi et al, 2005).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** The genetics involved with various inflammatory responses to sepsis are being studied. A variety of polymorphisms may play a role in sepsis.

Clinical/History	Lab Work	
Height	Elevated WBC	Plasma lactate
Weight	Alb,	Transferrin
BMI	transferritin	Trig (increased)
Diet history	Albumin: CRP	AST (increased)
I & O	ratio	BUN, Creat
BP (hypotension?)	CRP	Urinary urea
Fever, chills	Chol	nitrogen
Fatigue, malaise	(decreased)	Na <sup>+</sup> , K <sup>+</sup>
Decreased urine output	pO <sub>2</sub> , pCO <sub>2</sub>	Ca <sup>++</sup> , Mg <sup>++</sup>
Skin rash?	Gluc (altered)	Cl <sup>-</sup>
Mild confusion	Decreased glucose tolerance?	H & H
Catabolism of lean body mass	Glucagon (increased)	Serum Fe
Tachycardia	Serum insulin	N balance
	Plasma	T3 (decreased)
	25(OH)D—	5-Hydroxyindole
	low?	acetic acid
		(5-HIAA)
		(increased)
		Phosphate
		(decreased)
		Osmolality

## INTERVENTION

### OBJECTIVES

- Prevent septic shock with increased cardiac output, tachycardia, low blood pressure, decreased renal output, and warm flushed skin. Support medical, goal-directed resuscitation of the septic patient and use of broad-spectrum antibiotic therapy within 1 hour of diagnosis of septic shock (Dellenger et al, 2008).
- Support the body's antimicrobial defense system and keep the environment as germ free as possible to prevent MODS. Use strict guidelines and protocols for insertion, care, and maintenance of any catheters and feeding tubes.
- Meet increased energy needs. Mild infection elevates resting energy expenditure between 15% and 40%; sepsis increases it by 40–70% and doubles nitrogen losses. Use indirect calorimetry whenever possible, and do not overfeed.

Asset provided by Anatomical Chart Co.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Increased Nutrient Needs**

**Assessment Data:** Nursing home resident with urosepsis; fever with temperature 101°F; albumin 2.4 g/dL; requires feeding assistance; hip replacement surgery 1 month ago.

**Nutrition Diagnosis (PES):** NI 5.1 Increased nutrient needs for protein related to urosepsis and recent surgery as evidenced by albumin 2.4 g/dL and intake <50% of dairy-meat items at meals.

**Intervention**

**Food-Nutrient Delivery—ND** 3.1.1 Commercial high-protein beverage

**Education E** 2.1 Adding protein powder, 30 mL BID for increased protein

**Counseling C** 2.2 Goal setting—meet protein needs daily (1.5 g/kg)

**Coordination of Care RC** 1.1 Team meeting—nursing to focus on better intake of dairy and meat items on trays.

**Monitoring and Evaluation:** Improved oral intake of protein sources from dairy products, meat group choices, and protein powder; 75–100% at meals. Meeting daily protein needs of 1.5 g/kg. Resolution of urosepsis. Wound healing continues.

- Promote tissue repair and wound healing. Protein turnover is often 30–50% higher than normal.
- Treat nausea, vomiting, and anorexia.
- Prevent or treat metabolic derangements such as hyperglycemia, glycosuria, hyperosmolar/nonketotic coma, electrolyte abnormalities (e.g., decreased potassium, decreased phosphate, elevated chloride), osmotic diarrhea, and fluid overload. Glycemic control, targeting a blood glucose <150 mg/dL after initial stabilization (Dellenger et al, 2008).
- Correct anemia, which prevents tissue oxygenation. Target a hemoglobin level of 7–9 g/dL (Dellenger et al, 2008). Prevent or manage stress ulcers and upper GI bleeding.

**FOOD AND NUTRITION**

- Protein should be provided in levels of 1.5–2.0 g/kg daily. Branched-chain amino acids (BCAAs) are useful for energy because they do not need to be metabolized to glucose.
- Provide calories at 30–35 kcal/kg. Monitor daily actual intake.
- Enteral nutrition should be initiated within 48 hours of injury or admission and average intake actually delivered within the first week should be **at least** 60–70% of total estimated energy requirements as determined by patient assessment (American Dietetic Association, 2010).
- When patient can eat, soft diet and liquids of high nutrient and energy value are beneficial.
- Vitamins A, C, D, K, thiamin, and folic acid may become depleted with infection. Urinary excretion of phosphorus, potassium, magnesium, zinc, and chromium also occur; monitor for signs of malnutrition. Replace in feedings or diet as appropriate.

- Include omega-3 fatty acids (Babcock et al, 2005). Inclusion of fish oil in parenteral nutrition provided to septic ICU patients increases plasma eicosapentaenoic acid, modifies inflammatory cytokine concentrations, improves gas exchange, and shortens the length of hospital stay (Barbosa et al, 2010).
- Monitor fluid requirements and intake carefully to excrete wastes properly.
- If tube feeding is needed, there are no benefits for using immune-enhancing formulas (American Dietetic Association, 2010).

**Common Drugs Used and Potential Side Effects**

- Antibiotics are used for bacterial sepsis; monitor for side effects and GI distress.
- Activated protein C, a vitamin K-dependent serine protease, is an anticoagulant that is also cytoprotective and has anti-inflammatory role for use in septic shock (Russell, 2008).
- Antiseptic-impregnated catheters, such as those with minocycline-rifampicin or chlorhexidine/silver sulfadiazine, may be needed to reduce catheter-related sepsis.
- Insulin may be needed for hyperglycemia; glucose control is important.
- Iron and zinc are bacterial nutrients; omit them in CPN solutions in septic patients.
- Prevent upper GI bleeding by using H2 blockers or proton pump inhibitors (Dellenger et al, 2008).
- Steroids may be used. Greater nitrogen depletion and hyperglycemia, sodium retention, and potassium losses can occur. Monitor carefully. Corticosteroid therapy induces potentially detrimental hyperglycemia in septic shock (COITSS Study Investigators, 2010).

**Herbs, Botanicals, and Supplements**

- Herbs and botanical supplements should not be used without discussing with physician.
- Optimal vitamin D is important for innate immunity in the setting of sepsis (Jeng et al, 2009).
- Fish oil may play an important role in reducing the hospital length of stay in septic patients (Barbosa et al, 2010).

**NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- Use of aseptic techniques for feedings and meals will be essential.
- Need for a well-managed convalescence and gradual refeeding process will be needed to support patient's resistance and immunity. Terminate the cycle of infection, malnutrition, reinfection, and further protein-energy malnutrition.

**Patient Education—Food Safety**

- Educate about food safety issues. Reducing infections is very important.

- Meticulous hand washing is essential; immunocompromised individuals are more susceptible to minor illnesses, including foodborne illness.

# TRAUMA

## NUTRITIONAL ACUITY RANKING: LEVEL 3

### DEFINITIONS AND BACKGROUND

Physical trauma is caused by major injury or accidents; 50% are from traffic accidents. Trauma is the third leading cause of death and the number one killer of people younger than 45 years (Compton and Rhee, 2005). Multiple traumas involve at least two injuries. Long-bone fractures, pelvic or vertebral fractures, and damage to body cavities (head, thorax, or abdomen) generally are involved. The first assessment by emergency medical technicians involves airway, breathing, and circulation (A-B-C), followed by disability and exposure (D-E). For a neurological disability evaluation, clinicians use the Glasgow Coma Scale (GCS) to determine the level of consciousness; see Table 15-13.

Metabolic changes may include increased oxygen consumption and energy expenditure; increased secretion of ACTH, cortisol, epinephrine, norepinephrine, insulin, and growth hormone; and decreased total T3 levels (Jakob and Stanga, 2010). Reperfusion injury, a potential life-threatening disorder, is an acute inflammatory response after periods of ischemia resulting from trauma (Zhang et al, 2006). The heart and brain are the organs most affected.

The first 60 minutes, or the “golden hour” after trauma, may involve early deaths from severe brain or spinal cord injuries. Days later, death may occur from subdural or epidural hematoma. Late deaths may occur after several

weeks. Therefore, nutritional support is an integral part of the management of trauma victims. Skeletal muscle is a major protein source for catabolism; BCAAs are cannibalized (Laviano et al, 2005). Nitrogen excretion increases after injury, peaks after 7 days, and eventually stabilizes. Insulin has been shown to increase synthesis and decrease degradation of skeletal muscle protein when amino acids are provided intravenously. Malnutrition caused by hypercatabolism and hypermetabolism parallels the severity of illness (Wooley et al, 2005).

Trauma is best managed by emergency department or critical care teams. Most countries have adopted measures known as Advanced Trauma Life Support (ATLS). In this process, teams address the most life-threatening issues first.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Trauma is not genetic in origin, but individuals respond to trauma while using their innate and acquired immune systems accordingly.

<b>Clinical/History</b>	GCS	Serum Fe
Height	Respiratory rate	TLC
Weight before trauma	Arteriography	WBC
Weight after trauma	Radiographs, computed tomography	Serum lactate
Percentage weight change	<b>Lab Work</b>	Chol, Trig
Resting energy expenditure (indirect calorimetry)	Alb,	Phosphorus
BMI	transthyretin (monitor fluid levels)	BUN, Creat
Diet history	Albumin:CRP ratio	Gluc (increased?)
Temperature	CRP	Creatine phosphokinase (increased)
I & O	Na <sup>+</sup> , K <sup>+</sup>	pCO <sub>2</sub> , pO <sub>2</sub>
BP	Ca <sup>++</sup> , Mg <sup>++</sup>	Bilirubin, AST (increased)
ISS	Cl <sup>-</sup>	Serum amino acids
	H & H	N balance

## INTERVENTION

### OBJECTIVES

- Assess and monitor extent of injury and resulting problems. Restore hemodynamic and metabolic functions and acid–base and fluid balance.
- Prevent infection, respiratory failure, shock, sepsis, and reperfusion injury.
- Determine GI function; provide nutrients in the most effective mode. Use the gut if possible. Enteral nutrition

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Oral Food and Beverage Intake

**Assessment Data:** Car accident victim; closed head injury and comatose. Indirect calorimetry measures REE at 1800 kcal.

**Nutrition Diagnosis (PES):** Inadequate oral food and beverage intake related to inability to eat orally as evidenced by comatose state and ventilator dependency.

**Intervention:** Food–Nutrient Delivery—Initiate enteral tube feeding at slow rate, gradually increasing to meet needs of 1800 kcal/24 hours. Avoid overfeeding and monitor hydration status carefully. Coordinate care with medical team to follow progress.

**Monitoring and Evaluation:** Tube feeding tolerance: glucose, BUN, other lab values; hydration without excess.

is more efficacious and poses lower risks than parenteral nutrition; it reduces infection rates and shortens hospital length of stay (American Dietetic Association, 2010).

- Decrease nitrogen losses; promote nitrogen balance. Glutamine and arginine may be indicated.
- Meet elevated energy requirements (up by 20–45%). Spare proteins and LBM.
- Prevent overfeeding with respiratory distress from increased carbon dioxide production.
- Determine and monitor fluid requirements and balance. Do not overhydrate; persistent positive fluid balance in older surgical patients prolongs mechanical ventilation (Epstein and Peerless, 2006).
- Promote healing and rapid recovery.

**TABLE 15-13 Glasgow Coma Scale (GCS)**

The GCS is a neurological scale for recording the conscious state of a person, for initial and subsequent assessments. A patient is assessed against the criteria of the scale, and the resulting points give patient a score between 3 (indicating deep unconsciousness) and either 14 (original scale) or 15 (the more widely used modified or revised scale). The scale comprises three tests: eye, verbal, and motor responses. The three values are considered separately, as well as their sum. The lowest possible GCS score (the sum) is 3 (deep coma or death), whereas the highest score is 15 (fully awake person). The lower the score, the worse the prognosis.

Key:  
Severe, with GCS ≤ 8  
Moderate, GCS 9–12  
Minor, GCS ≥ 13

**Glasgow Coma Scale**

	1	2	3	4	5	6
<b>Eyes</b>	Does not open eyes	Opens eyes in response to painful stimuli	Opens eyes in response to voice	Opens eyes spontaneously	N/A	N/A
<b>Verbal</b>	Makes no sounds	Incomprehensible sounds	Utters inappropriate words	Confused, disoriented	Oriented, converses normally	N/A
<b>Motor</b>	Makes no movements	Extension to painful stimuli (decerebrate response)	Abnormal flexion to painful stimuli (decorticate response)	Flexion/withdrawal to painful stimuli	Localizes painful stimuli	Obeys commands

From Teasdale G, Jennett B. Assessment of coma and impaired consciousness. A practical scale. *Lancet*. 2:81, 1974.

- Treat ileus, fistula, glucose abnormalities, and other complications such as venous thromboembolism (VTE). VTE causes major morbidity in adults after trauma and occurs in up to 50% of patients without prophylaxis (Hanson et al, 2010).
- Promote rehabilitation.
- Correct anorexia and depression; improve the quality of life.

## FOOD AND NUTRITION

- **Day 1: Immediately**—Intravenous feedings are given for fluid resuscitation for approximately 24 hours until stable. Life support measures and careful monitoring are required.
- **Days 2–5: Transition Phase**—Assess changing status. Implement nutrition by the most effective means, dictated by injury location and extent. Controversy exists regarding the optimal nutrition regimen; therefore, individualize for each patient (Thompson and Fuhrman, 2005). When goals are not achieved enterally, early PN use may be associated with a greater risk of nosocomial infection and worse clinical outcomes (Sena et al, 2008). Initiation of enteral feedings within 24–48 hours of injury or admission to ICU generally reduces infectious complications (Kattelman et al, 2006). Feed patients in the semirecumbent rather than supine position to reduce aspiration pneumonia and formula reflux (Kattelman et al, 2006). Provide adequate energy and nutrients: 35–45 kcal/kg and 1.5–2 g protein/kg. Advance feeding rate over several days; gastrostomy may be useful in head/neck trauma. Actual delivery of 14–18 kcal/kg/day or 60–70% of goal is associated with improved outcomes, whereas greater intake may not be beneficial (Kattelman et al, 2006). Blue food coloring should not be used to detect aspiration with enteral feedings (American Dietetic Association, 2010).
- **Days 5–10: Adaptive Phase**—Use products with glutamine, arginine, and high percentage of BCAAs; include lipids. Osmolarity should be monitored to be close to 300 mOsm. In general, 25 kcal/kg/d is an acceptable and achievable target intake, but patients with trauma may require almost twice as much energy during the acute phase of their illness. Provide 1.5–2 g protein/kg. CHOs should be given as 5 mg/kg/min. A diet providing 50% CHO, 15% protein, and 35% fat should be adequate. A slight increase in vitamin–mineral intake should be addressed, with vitamins A, B-complex, and C in particular. Avoid large doses of iron and zinc.
- **Day 11 Onward: Rehabilitative Phase**—Patient can be weaned to oral diet, if possible, and off the ventilator support. Liquid to regular diets are usually tolerated at this time.

## Common Drugs Used and Potential Side Effects

- Analgesics may have an effect on nutritional status. Evaluate individually. Lidocaine can be used to alleviate neuropathic pain.
- Antibiotics generally are used to reduce bacterial infection. Monitor for GI distress and side effects.
- Barbiturates, used for closed head injury, will decrease metabolic rate.
- Intensive insulin therapy and the use of a continuous glucose sensor may be used for hyperglycemia (Mraovic, 2009).
- Promotility agents may reduce gastric residual volume in tube-fed patients (Kattelman et al, 2006).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Capsaicin and resveratrol have been used for some patients to decrease inflammation after trauma.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Need for specific nutrients should be discussed, according to the mode tolerated.
- Rehabilitation should progress according to individual requirements and injury sites, side effects, and complications.

## Patient Education—Food Safety

- Educate about food safety issues. Reducing infections is very important. Meticulous hand washing is essential because immunocompromised individuals are more susceptible to minor illnesses, including foodborne illness.

# Renal Disorders

## CHIEF ASSESSMENT FACTORS

### Ten Symptoms of Kidney Disease

- Changes in urination
- Confusion
- Feeling dizzy
- Headache
- High blood pressure
- Loss of appetite or change in taste
- Nausea or vomiting
- Severe itching not related to a bite or rash
- Shortness of breath
- Swelling of face, hands, and/or feet

### Other Factors

- Altered Lipid and Amino Acid Levels
- Abnormal Blood Urea Nitrogen (BUN):Creatinine Ratio
- Anorexia
- Bone Pain, Altered Height, or Lean Body Mass
- Burning or Difficulty During Urination
- Changes in Glomerular Filtration Rate (GFR)
- Chronic Inflammation
- Flank Pain
- Frequent Weight Shifts
- Ghrelin and Obestatin Ratios
- Insomnia
- Itching, Dry Skin
- Leg Cramps
- More Frequent Urination and Nocturia
- Pain in Small of Back Just Below Ribs, Not Aggravated by Movement
- Passage of Bloody-Appearing Urine (Hematuria)
- Presence or History of Urinary Tract Infections or Stones
  - Proteinuria, Microalbuminuria
  - Protein–Energy Malnutrition or Wasting
  - Puffiness Around Eyes
  - Serum Creatinine 1.7 mg/dL
    - Unbalanced Calcium:Phosphorus Ratios
    - Uremia
    - Weakness, Pallor, Anemia

## OVERVIEW OF RENAL NUTRITION

According to the National Institute of Diabetes and Digestive and Kidney Diseases, more than 16% of adults 20 years and older (23 million people) have evidence of chronic kidney disease (CKD), with moderately or severely reduced glomerular filtration rate (GFR) (NIDDK, 2010). The Kidney Disease Outcomes Quality Initiative (KDOQI) classifies CKD on the basis of the level of kidney function. Simple blood tests, as follows, can be done to determine renal status but are not always ordered (Aase, 2010):

- Reduction of kidney function—eGFR < 60 mL/min/1.73 m<sup>2</sup> and/or
- Evidence of kidney damage/persistent albuminuria—≥30 mg of urine albumin per gram of urine creatinine (UACR)
- Kidney failure eGFR < 15 mL/min/1.73 m<sup>2</sup>

The kidney plays an important role in blood pressure management through the renin-angiotensin system and identifies the damage from inflammation following scarlet fever, flu, or tonsillitis. Table 16-1 gives a brief background about the kidneys.

A registered dietitian (RD) with renal experience should be a central and integral part of the management of both pediatric and adult patients (NKF, 2010). In pediatrics, the evaluation of growth as well as physical, developmental, educational, and social needs is essential. Table 16-2 lists terms and abbreviations commonly used in renal disorder management.

Renal patients need a detailed nutritional assessment by dietitians (Chauveau, 2009). Subjective Global Assessment (SGA) is used and includes weight change over the past 6 months, dietary intake, gastrointestinal (GI) symptoms, visual assessment of subcutaneous tissue and muscle mass. While weight change is assessed by evaluating weights during the past 6 months, edema might obscure a greater

amount of weight loss. Dietary intake is evaluated by using a comparison of the patient's usual or recommended intakes to current intake. Duration and frequency of GI symptoms (e.g., nausea, vomiting, and diarrhea) are also assessed. The interviewer rates a 7-point scale with higher scores if the patient has little or no weight loss, a better dietary intake, better appetite, and the absence of GI symptoms. See Appendix B for the SGA questionnaire.

Nutritional interventions and specifically supplemented diets have many advantages in terms of managing the progression of renal failure, better metabolic and endocrine control, and decreased proteinuria (Chauveau, 2009). Because anorexia and weight loss are associated with wasting, morbidity, and mortality, dietitians must be aware of the impact of hormones, such as the orexigenic ghrelin and the anorexigenic obestatin, on intake (Mafra et al, 2010). In addition, the role of inflammation must be understood. Inflammation causes increased levels of cytokines (interleukin [IL]-6 and tumor necrosis factor [TNF]-α) and acute-phase proteins (C-reactive protein [CRP] and serum amyloid A); loss of muscle mass; changes in plasma composition; decreases in serum albumin, transthyretin, and transferrin; altered lipoprotein structure and function to favor atherogenesis. Knowing that fish oils may decrease the loss of renal function by affecting eicosanoid and cytokine production, altering renal dynamics, and decreasing inflammation is important for all dietitians to understand.

Renal replacement therapy (RRT) includes dialysis and renal transplantation. RRT is designed to normalize the volume and composition of the body fluids and to remove uremic toxins. But because renal disease is often related to diabetes and hypertension, a multidisciplinary approach is warranted.

Not everyone with CKD needs a strict hemodialysis (HD) diet. Appropriate, individualized use of one- and two-page information sheets on sodium, phosphorous, potassium,

**TABLE 16-1 Human Kidney Functions**

**Waste excretion:** Kidneys remove the waste products of metabolism (urea, uric acid, creatinine).

**Acid–base balance:** Kidneys regulate pH by eliminating excess hydrogen ion concentration and controlling composition of the blood. Blood plasma pH is maintained by the kidney at a neutral pH of 7.4. Urine is either acidic (pH 5) or alkaline (pH 8). Potassium and phosphate require renal control as well.

**Blood pressure control:** Sodium ions are controlled in a homeostatic process involving aldosterone, which increases sodium ion absorption in the distal convoluted tubules. When blood pressure is too low, *renin* is secreted by cells of the distal convoluted tubule. Renin acts on the blood protein, *angiotensinogen*, converting it to *angiotensin I*. Angiotensin I is then converted by the angiotensin-converting enzyme in the lung capillaries to *angiotensin II*, which stimulates the secretion of *aldosterone* by the adrenal cortex. Aldosterone stimulates increased reabsorption of sodium ions from the kidney tubules, which causes an increase in the volume of water that is reabsorbed from the tubule. This increase in water reabsorption increases the volume of blood, which ultimately raises the blood pressure.

**Plasma volume and osmolality:** Any rise or drop in blood osmotic pressure due to a lack or excess of water is detected by the *hypothalamus*, which notifies the *pituitary gland* via negative feedback. A lack of water causes the *posterior pituitary gland* to secrete *antidiuretic hormone*, which results in water reabsorption and an increase in urine concentration. Tissue fluid concentration thus returns to normal. Body fluid is two thirds extracellular and one third intracellular.

**Hormone secretion:** *Erythropoietin* is secreted for red blood cell production; deficiency is common in chronic renal anemia. *Urodilatin* is a natriuretic peptide that mediates natriuresis. *Vitamin D<sub>3</sub>* is converted from an inactive form (D<sub>2</sub>) for calcium:phosphorus homeostasis; the final stage of conversion of vitamin D to its active form, 1,25-dihydroxyvitamin D occurs in the proximal tubule.

**Carnitine synthesis:** Carnitine carries fatty acids from cytoplasm to mitochondria for heart and skeletal muscle fuel. Lysine, methionine, vitamin C, iron, vitamin B<sub>6</sub>, and niacin are needed to produce carnitine.

**Glucose homeostasis:** The kidney plays a role in gluconeogenesis and glucose counterregulation.

**Prostaglandin E<sub>2</sub>:** It is a major renal cyclooxygenase metabolite of arachidonic acid that impacts renal hemodynamics and salt and water excretion.

**TABLE 16-2 Renal Abbreviations**

Abbreviation	Description	Abbreviation	Description
a1-AG	a1-Acid Glycoprotein	IPAA	Intraperitoneal Amino Acids
aBWef	Adjusted Edema-Free Body Weight	Kt/V <sub>urea</sub>	A measure of dialysis; K is the dialyzing membrane clearance, t is the time of dialysis delivered in minutes, and V <sub>urea</sub> is the volume of distribution of urea
AMA	Arm Muscle Area	MAC	Midarm Circumference
APD	Automated Peritoneal Dialysis	MAMA	Midarm Muscle Area
BIA	Bioelectrical Impedance Analysis	MAMC	Midarm Muscle Circumference
BUN	Blood Urea Nitrogen	MD	Maintenance Dialysis
CANUSA	Canada/United States Peritoneal Dialysis Study	MHD	Maintenance Hemodialysis
CAPD	Continuous Ambulatory Peritoneal Dialysis	NHANES	National Health and Nutrition Evaluation Survey
CCPD	Continuous Cyclic Peritoneal Dialysis	nPCR	Protein Catabolic Rate normalized to body weight
CoA	Coenzyme A	nPNA	Protein Equivalent of Total Nitrogen Appearance normalized to body weight
CPD	Chronic Peritoneal Dialysis	PCR	Protein Catabolic Rate
CPN	Central Parenteral Nutrition	PNA	Protein Equivalent of Total Nitrogen Appearance
CrCl	Urinary Creatinine Clearance	PTH	Parathyroid Hormone
CRF	Chronic Renal Failure (GFR < 20 mL/min)	RTA	Renal Tubular Acidosis
CRI	Chronic Renal Insufficiency (GFR less than normal but >20 mL/min)	SBW	Standard Body Weight
CRP	C-Reactive Protein	SDS	Standard Deviation Score
CVVHD	Continuous Venovenous Hemofiltration with Hemodialysis	SGA	Subjective Global Assessment
DXA	Dual Energy X-Ray Absorptiometry	SUN	Serum Urea Nitrogen
ESRD	End-Stage Renal Disease	TBW	Total Body Water
GFR	Glomerular Filtration Rate	TNA	Total Nitrogen Appearance
HD	Hemodialysis	TSF	Triceps Skinfold
IDWG	Interdialytic Weight Gain	UBW	Usual Body Weight
IDPN	Intradialytic Parenteral Nutrition	UNA	Urea Nitrogen Appearance
IGF-I	Insulin-Like Growth Factor-I		

and protein will enable dietitians to advise their clients more effectively than using complex documents (Aase, 2010).

Ideally, dietitians who work with renal patients are certified renal dietetic specialists (“CS-R” credential), which requires experience and a successful examination score. However, because there is a gap between the dialysis unit (where renal dietitians practice) and the doctor’s office (where gradual changes in CKD may not be detected), all dietitians must be comfortable with the basics of renal intervention (Aase, 2010).

While **diabetic renal disease** (diabetic nephropathy) is the leading cause of end-stage renal failure, the process cannot be reversed by glycemic control but by control of blood pressure and protein restriction. Therefore, specific nutrition care is needed for all renal patients—whether before starting dialysis, while on dialysis, or after a kidney transplant. Early dietary intervention is most critical to reduce sodium intake, control blood pressure, manage diabetes, and reduce excessive protein intake in early stages of CKD (Aase, 2010).

Standards of professional performance and standards of practice for dietitians in nephrology care set the expectations for renal practice (Brommage et al, 2009; Joint Standards

Task Force, 2009). In addition, the American Dietetic Association evidence analysis library provides regular updates on research in the field. Medicare CKD-related medical nutrition therapy (MNT) reimbursement requires use of these evidence-based guidelines (EBGs) and currently begins at approximately stage 3 (GFR between 13 and 50 mL/min/1.73 m<sup>2</sup>).

The National Kidney Disease Education Program (NKDEP) has developed multiple tools, tear-off sheets, and guidelines that can be used (see Web site <http://nkdep.nih.gov/professionals/index.htm>). There are clever lists of “kidney-friendly” foods, supermarket tips, and other simplified ways to enhance patient understanding. Once NKDEP brings primary care clinicians up to speed, referrals to RDs and rates of reimbursement for qualified CKD-related MNT should increase (Aase, 2010). Go to the Medicare MNT reimbursement Web site for more details at [http://www.cms.hhs.gov/MedicalNutritionTherapy/01\\_Overview.asp#TopOfPage](http://www.cms.hhs.gov/MedicalNutritionTherapy/01_Overview.asp#TopOfPage).

# COLLAGEN-IV NEPHROPATHIES: ALPORT SYNDROME AND THIN GLOMERULAR BASEMENT MEMBRANE NEPHROPATHY

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

### DEFINITIONS AND BACKGROUND

**Alport syndrome (ATS)** is a progressive inherited (usually X-linked) nephritis. ATS is characterized by irregular thinning, thickening, and splitting of the renal glomerular basement membrane. It is often associated with hearing loss and ocular symptoms (Longo et al, 2006). Both ATS and **thin glomerular basement membrane nephropathy (TBMN)** are genetically heterogeneous conditions with initial presentation that usually involves hematuria (Haas, 2009). In ATS, kidney function is lost, with eventual progression to end-stage renal disease (ESRD) between adolescence and age 30 years (Tan et al, 2010). Mutational analysis of the affected genes will be a valuable adjunct to the treatment options, avoiding the need for transplantation and dialysis (Thorner, 2007).

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Both ATS and TBMN can be considered as genetic diseases of the glomerular basement membrane (GBM) involving the alpha3/alpha4/alpha5 network of type IV collagen (Thorner, 2007).

<b>Clinical/History</b>	Body mass index (BMI)	Input and output (I & O)
Height	Diet history	
Weight		

Edema-free adjusted body weight (aBWef)	<b>Lab Work</b>	Aspartate aminotransferase (AST) $\text{Ca}^{++}$
Edema, ankles and feet	Blood urea nitrogen (BUN)	Proteinuria
Abnormal urine color	Creatinine (Creat)	Hemoglobin and hematocrit (H & H)
Hypertension?	Chloride ( $\text{Cl}_2$ )	Serum Fe, ferritin
Hearing loss before age 30? (males)	GFR	Total iron-binding capacity (TIBC), percentage saturation
Cataracts?	Creatine clearance (CrCl)	Parathormone (PTH)
Microscopic hematuria?	Cholesterol (Chol)—increased?	Serum Cu (decreased?)
Temperature	Albumin (Alb), transthyretin	
Renal biopsy, genetic testing	CRP	
	$\text{Na}^+$ , $\text{K}^+$	
	Phosphorus	

## INTERVENTION

### OBJECTIVES

- Reduce renal workload. Improve or control excretion of waste products such as urea and sodium.
- Manage edema resulting from sodium and fluid retention.
- Prevent uremia from nitrogen retention.
- Adjust electrolyte intakes (sodium, potassium, and chloride) if needed.
- Prevent systemic complications, where possible, and protein catabolism, as from poor intake.

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Sodium Intake

**Assessment:** Dx of ATS at age 11, now 20 and away from home at college. Recent admission to hospital with edema and hypertension, despite use of a diuretic each day. Diet history indicates frequent use of canned soups and a bag of chips with a sandwich at lunch every day. Normally uses a lower sodium breakfast and dinner.

**Nutrition Diagnosis (PES):** NI-5.10.7 Excessive sodium intake related to the use of canned soups, chips, and sandwich for lunch every day as evidenced by recent severe edema and hypertension.

#### Interventions:

**Food-Nutrient Delivery:** Low-sodium diet plan for lunch; alternatives identified that are easy to pack and take to college or campus.

**Education:** Review the requirements for the low sodium diet; has had previous teaching two times by a RD back in hometown.

**Counseling:** Supportive counseling about food choices that are lower in sodium.

**Coordination of Care:** Work with medical team to determine whether diuretic is indicated.

**Monitoring and Evaluation:** Improvement in edema and blood pressure. No further problems following the low sodium diet; change in lunch choices well received.

- Manage hypertension.
- Recommend genetic counseling for those with ATS. A family history and a renal biopsy may be needed (Thorner, 2007).

## FOOD AND NUTRITION

- Determine fluid intake (measured output plus 500 mL insensible losses).
- Restrict sodium intake to 2–3 g if patient has hypertension or edema.
- In the case of renal failure, protein intake should be low, as 0.6–0.8 g/kg of adjusted edema-free BW. Use 50% high biological value proteins to ensure positive nitrogen balance. If needed, follow dialysis guidelines.
- Check need for vitamin A, which may be low.
- Decrease elevated phosphorus levels with a low-phosphate diet (5–10 mg/kg/d) as needed.
- Provide adequate energy intake (35 kcal/kg BW).
- Use fish oils to reduce inflammation.

## Common Drugs Used and Potential Side Effects

- Antihypertensive, antibiotic, and immunosuppressive medications are commonly used. Monitor for specific side effects, especially with long-term use.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Discuss the varied sources of fish oil supplements and how much to take.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Ensure dietary measures are appropriate for patient's current status.
- Discuss ways to include more omega-3 fatty acids and fish in diet.

## Patient Education—Food Safety

- Foodborne illness can occur when there is contamination of food at any point during the preparation process. Because renal patients are at high risk for foodborne illness, follow the four-step guidelines established by the U.S. Department of Agriculture: clean, separate, cook, and chill.
- Details are available at the Kidney Foundation Web site at <http://www.kidney.org/atoz/content/foodsafety.cfm>.

# CHRONIC KIDNEY DISEASE AND RENAL FAILURE

## NUTRITIONAL ACUITY RANKING: LEVEL 4

## DEFINITIONS AND BACKGROUND

CKD is characterized by the inability of kidney function to return to normal after acute kidney failure or progressive renal decline from disease. Excess urea and nitrogenous wastes accumulate in the bloodstream (azotemia). CKD causes permanent reduction in function, eventually leading to end-stage ESRD. Early stages of CKD are defined by GFR and urinary albumin:creatinine ratio (Castro and Coresh, 2009). Table 16-3 describes the five stages of CKD.

Approximately 23 million Americans have some degree of CKD. Fifty percent of individuals with CKD have diabetes; hypertension is the second highest risk factor. Other risk factors include cardiovascular disease, family history of CKD, use of certain medications, and age >60 years. Undiagnosed CKD is especially common in people who have diabetes. The Pima Indians of Arizona have the world's highest incidence of type 2 diabetes and ESRD. Incorporating estimated GFR into screening for CKD would identify individuals earlier and enable early effective treatment (Middleton et al, 2006).

Depending on the form of disease, renal function may be lost in a matter of days or weeks, or may deteriorate slowly and gradually over the course of decades. Potentially modifiable risk factors in CKD include proteinuria, hypertension, dyslipidemia, anemia, oxidative stress, infections, depression, hyperglycemia, bone disease, and obesity. A low-protein diet (LPD) and low phosphorus intake may retard the progression of kidney disease and should be used in the renal population (Kent, 2005). Studies have shown that LPDs can reduce patient

morbidity, preserve renal function, relieve uremic symptoms, improve nutritional status, postpone the start of dialysis for 6 months, and entail substantial cost-savings (Eyre et al, 2008).

**Acute renal failure (ARF)** involves abrupt decline in renal function with waste retention. ARF occurs when the kidneys fail to function because of circulatory, glomerular, or tubular deficiency resulting from an abrupt cause. ARF is caused by diabetes or hypertension in most cases. Other causes include glomerulonephritis (GN), polycystic kidney disease (PKD), and other causes (burns, severe crush injuries, transfusions, antibiotics, nephrotoxicity from drugs such as tacrolimus or cyclosporine, surgery or anesthesia, cardiac transplantation, shock, or sepsis). In children, ARF has been caused by hemolytic uremic syndrome from a specific strain of *Escherichia coli* (0157:H7) that is associated with undercooked ground beef. ARF occurs also in approximately 5% of surgical or trauma cases; frequently, this is reversible. Intermittent HD and continuous RRT are equally beneficial for patients with ARF (Pannu et al, 2008). In ARF, the patient gradually improves, although some loss of function may be permanent. If toxic accumulation occurs, ARF may be fatal. The phases of ARF include the following:

- Prodrromal phase—varies in duration depending on cause—urine output may be normal
- Oliguric (average 10–14 days)—output typically between 50 and 400 mL/d
- Postoliguric phase (average 10 days)—urine output gradually returns to normal
- Recovery (from 1 month or up to 1 year).

**TABLE 16-3 Stages, Symptoms, and Preventive Measures for Chronic Kidney Disease (CKD)**

Stage	Glomerular Filtration Rate (GFR)	Symptoms and Preventive Measures
<b>Stage 1</b>	$\geq 90$ mL/min/1.73 m <sup>2</sup>	Kidney damage with normal or increased GFR occurs. Blood flow through the kidney increases (hyperfiltration), and the kidneys are larger than usual. A person with stage 1 CKD usually has no symptoms. Regular testing for protein in the urine and serum creatinine can show whether the kidney damage is progressing. Living a healthy lifestyle can help slow the progression of kidney disease.
<b>Stage 2</b>	60–89 mL/min/1.73 m <sup>2</sup>	A person with stage 2 CKD has kidney damage with a mild decrease in GFR. Filtration rate remains elevated or nearly normal. Glomeruli show signs of damage. Blood pressure is usually normal. Albuminuria is $<30$ mg/d. If people find out they have stage 2 CKD, it is usually because they were being tested for diabetes or high blood pressure.
<b>Stage 3</b>	30–59 mL/min/1.73 m <sup>2</sup>	A person with stage 3 CKD has kidney damage with a moderate decrease in the GFR. Microalbuminuria becomes constant. Losses increase to 30–300 mg/d. This can occur after about 7 years of having diabetes. As kidney function declines, uremia occurs. Complications such as high blood pressure, anemia, and early bone disease may occur. Consult a nephrologist to perform specific lab tests. Limit protein from diet to 0.8 g/kg.
<b>Stage 4</b>	15–29 mL/min/1.73 m <sup>2</sup>	A person with stage 4 CKD has advanced kidney damage with a severe decrease in the GFR. Nephropathy occurs with passage of large amounts of protein in the urine ( $>300$ mg/d); blood pressure continues to rise. Creatinine rises $>1.1$ – $1.3$ mg/dL and waste products build up (uremia). New symptoms include nausea, taste changes, uremic breath, anorexia, difficulty concentrating, and numbness in fingers and toes. Visits to the nephrologist every 3 months will be needed to test for creatinine, hemoglobin, calcium, and phosphorus levels and for management of hypertension and diabetes. An arteriovenous (AV) fistula and AV graft are created surgically and need a few months or so to mature before dialysis is needed. By doing everything possible to help prolong kidney function and overall health, the goal is to put off dialysis or transplantation for as long as possible. Limit protein to 0.8 g/kg.
<b>Stage 5</b>	$<15$ mL/min/1.73 m <sup>2</sup>	A person with stage 5 CKD has end-stage renal disease where kidney failure occurs. The kidneys have lost all their ability to do their job effectively. Renal replacement therapy (RRT) is initiated with dialysis or renal transplantation. Dialysis is started when renal Kt/V (urea) falls below 2.0/wk or when kidney function is 15% or less. New symptoms that can occur in stage 5 CKD include anorexia, nausea or vomiting, headaches, fatigue, anuria, swelling around eyes and ankles, muscle cramps, tingling in hands or feet, and changing skin color and pigmentation.

**REFERENCES**

National Kidney Foundation. Clinical practice guidelines for nutrition in chronic renal failure. Accessed February 15, 2010, at <http://www.kidney.org/professionals/kdoqi/guidelines>.  
 Nephron Online. Web site accessed February 16, 2010, at <http://www.nephronline.org/management/ckd.html>

**Chronic renal failure (CRF)** is the slow, gradual loss of kidney function. Causes include lupus, ATS, chronic hypertension, prolonged urinary obstruction, nephrotic syndrome, PKD, cystinosis, or diabetes. Diabetic nephropathy may be delayed by tightly controlling blood glucose levels and using angiotensin-converting enzyme (ACE) inhibitors.

Some forms of CRF can be controlled or slowed down but never cured. Partial loss of renal function means that some of the patient's nephrons have been scarred and cannot be repaired. In patients with progressive CRF who consume uncontrolled diets, progressive declines in spontaneous protein and energy intake, serum proteins, cholesterol, total creatinine excretion, and anthropometric values are evident below a CrCl of approximately 25 mL/min. Mortality increases greatly with serum albumin levels below 3.5 g/dL and low cholesterol level ( $<150$ – $180$  mg/dL).

Chronic inflammation predicts mortality in the CKD population; IL-6 is a significantly better predictor of mortality than CRP, albumin, or TNF- $\alpha$  (Barreto et al, 2010).

Most CKD patients also have elevated serum total homocysteine (tHcy) and low selenium levels. Suggest a multivitamin supplement that contains 800  $\mu$ g folic acid, adequate vitamins B<sub>6</sub> and B<sub>12</sub> and selenium if needed. Glutathione peroxidase helps prevent generation of free radicals and

decreases the risk of oxidative damage to tissues, including the kidney and its vascular supply.

The African American Study of Kidney Disease and Hypertension (AASK) supports tight blood pressure control ( $<130/80$  mm Hg) in CKD. Adherence to practices known to be of clinical benefit not only improves patient outcomes but also reduces costs of care. A multidisciplinary effort is needed.

ESRD is stage 5 CKD. Care involves early detection of progressive renal disease, interventions to retard its progression, prevention of uremic complications, control of related conditions, adequate preparation for RRT, and timely initiation of dialysis. Higher blood pressure and lower income are associated with a higher incidence of ESRD in both white and African American men. Mortality is remarkably high in ESRD, usually from cardiovascular disease (Shen et al, 2006). Decreasing complications may reduce death rates.

Wasting and protein–energy malnutrition (PEM) are complications of ESRD. Cachexia from anorexia, acidosis, and inflammation can lead to the **Malnutrition-Inflammation Complex Syndrome**. The decline in nutritional status may be caused by disturbances in protein and energy metabolism, hormonal derangement, and spontaneous reductions in dietary energy and protein intake. Factors that can worsen PEM include poor dentition, infections or sepsis,

### Causes of End-Stage Renal Disease

multiple medications, and pain. Worsening of PEM over time is associated with a greater risk for cardiovascular death from the **cardiorenal syndrome**.

Other CKD complications that should be managed include metabolic acidosis due to reduced acid (hydrogen ion) excretion, anemia due to impaired erythropoiesis and low iron stores, hyperkalemia, and dyslipidemia. In addition, secondary hyperparathyroidism (HPT) and **bone and mineral metabolism disorder** may start as early as stage 2 or 3 CKD, and dietitians must monitor vitamin D and calcium levels and restrict dietary phosphorous intake (Aase, 2010). Vitamin D receptor activation improves endothelial function in CKD, and this area of research is very promising (Wu-Wong et al, 2010).

The Kidney Early Evaluation Program (KEEP) is a free screening program designed to detect CKD early, promote follow-up evaluation with clinicians, and ultimately improve outcomes (Vassolotti et al, 2010). The program screens individuals with diabetes, hypertension, or those with a first-degree relative with diabetes, hypertension, and/or kidney disease. African Americans, Native Americans, Hispanics, and Asians/Pacific Islanders have a 3 times higher risk for CKD and anemia (McFarlane et al, 2008; Vassolotti et al, 2010). Such health disparities must be addressed (NKF, 2009).

Management of CKD is costly, yet adverse effects can be prevented. Early nutritional intervention may delay or prevent rapid progression of many complications. KDOQI guidelines recommend that patients on dialysis achieve an albumin level of 3.7 g/dL. SGA scores and other nutritional indicators, such as BMI, handgrip strength for measures of muscle mass, waist circumference, serum albumin level, and serum creatinine level are a good place to start; see Table 16-4. All patients with diabetes and CKD should receive nutritional interventions (NKF, 2007).

Current EBGs should always be followed. The NKF-KDOQI guidelines address strategies for diabetes, hyperten-

sion, dyslipidemia, bone disease, anemia, and heart disease in CKD patients. Guidelines are also available for managing CKD in children.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Potential markers of CKD include asymmetric dimethylarginine, factors involved in calcium-phosphate metabolism, adrenomedullin, A-type natriuretic peptide, N-terminal pro-brain natriuretic peptide, liver-type fatty acid-binding protein, kidney injury molecule 1, neutrophil gelatinase-associated lipocalin, apolipoprotein A-IV, adiponectin, and genetic polymorphisms (Kronenberg, 2009). Apolipoprotein E polymorphisms are relevant, with e2 allele conferring risk and e4 providing protection; these associations differ between ethnic groups (Chu et al, 2009).

#### Clinical/History

Height  
Weight  
aBWef  
Pitting edema in hands and legs  
BMI  
Waist circumference  
Waist:hip ratio  
Diet history  
BP (increased)

K<sup>+</sup> (goal, 3.5–5.5 mEq/L)  
Ca<sup>++</sup> (goal, 8.5–10.2 mg/dL)  
Phosphorus (increased?)  
Uric acid (increased?)  
Mg<sup>++</sup> (increased?)  
Serum bicarbonate  
PTH  
Hemoglobin (goal, 12 g/L for men; 11 g/L for women)

**TABLE 16-4 Protein–Energy Malnutrition (PEM) in Renal Patients**

<b>Etiology</b>	<b>Comments</b>
<b>Blood loss</b>	Loss of blood may be due to gastrointestinal bleeding, frequent blood sampling, and blood sequestered in the hemodialyzer and tubing.
Dialysis	The process promotes wasting by removing such nutrients as amino acids, peptides, protein, glucose, water-soluble vitamins, and other bioactive compounds, and may promote protein catabolism, due to bioincompatibility.
Endocrine changes	Endocrine disorders of uremia include resistance to the actions of insulin and IGF-I, hyperglucagonemia, and hyperparathyroidism.
Inadequate food intake	Poor intake is secondary to anorexia caused by the uremic state; altered taste sensation; intercurrent illness; emotional distress or illness; impaired ability to procure, prepare, or mechanically ingest foods; and unpalatable prescribed diets.
Inflammation and the catabolic response	Chronic inflammation from cardiovascular disease, diabetes mellitus, and other illnesses may produce anorexia, hypercatabolism, and malnutrition. Diminished appetite relates to high concentrations of proinflammatory cytokines. Inflammatory cytokines, such as tumor necrosis factor- $\alpha$ and interleukin-6, are associated with protein synthesis and catabolism in the body, and they downregulate albumin synthesis. Serum albumin is altered by systemic inflammation; a low serum albumin concentration is strongly associated with mortality in CKD.
Other issues	Sleep disturbances, pain, erectile dysfunction, patient dissatisfaction with care, depression, symptom burden, and perception of intrusiveness of illness may all lead to poor quality of life, resulting in poor appetite and intake. Suggest psychotherapy, anti-depressants, or other treatments.
Oxidative stress	PEM and low body mass index may be associated with increased oxidative stress and impaired endothelium-dependent vasodilation with reduced bioavailability of nitric oxide. Elevated C-reactive protein is a risk factor for mortality in chronic kidney disease (Menon et al, 2005).
Toxins	There may be accumulation of endogenously formed uremic toxins or the ingestion of exogenous toxins.
Wasting	Wasting may be due to anorexia, nausea, emesis, uremia, inflammation, infections, diabetes, underdialysis, or dental problems. Supplementation with branched-chain amino acids spares lean body mass during weight loss, promotes wound healing, may decrease muscle wasting with aging, and may have beneficial effects in renal disease (Tom and Nair, 2006).
<b>Assessments</b>	<b>Comments</b>
Lab values—BUN: creatinine ratio	BUN:creatinine ratio is altered by catabolic stress, low urine volume, and muscle mass changes.
Lab values—creatinine	Creatinine is a waste product that comes from muscle activity. When kidneys are working well, they remove creatinine from the blood. As kidney function slows, blood levels of creatinine rise. Serum creatinine concentration reflects muscle mass, somatic protein stores, and dietary protein intake. Because it predicts outcome in CKD, it may be a useful marker of nutritional status or loss of muscle mass in CKD. However, creatinine levels are affected by inflammation, age, sex, race, residual kidney function, variation in creatinine metabolism, and dialysis. The assessment of dietary intake is more commonly used to assess protein status.
Lab values—creatinine index	The creatinine index is directly related to the normalized protein equivalent of total nitrogen appearance (nPNA) and independent of the dialysis dose. A low or declining creatinine index correlates with mortality independently of the cause of death. People with catabolic diseases may have larger and faster declines in the creatinine index before death.
Lab values—glomerular filtration rate (GFR)	GFR is a good measure of kidney function. A math formula using the person's age, race, gender, and serum creatinine is used to calculate the GFR.
Lab values—nitrogen balance	Because the nitrogen content of protein is relatively constant at 16%, the protein equivalent of total nitrogen appearance (PNA) can be estimated by multiplying total nitrogen appearance (TNA) by 6.25 (PNA is mathematically identical to the protein catabolic rate or PCR). In the clinically stable patient, PNA can be used to estimate protein intake. However, PNA approximates protein intake only when the patient is in nitrogen equilibrium (steady-state). In the catabolic patient, PNA will exceed protein intake to the extent that there is net degradation and metabolism of endogenous protein pools to form urea.
Lab values—serum cholesterol	Low serum cholesterol is an indicator of chronically inadequate protein–energy intake. It may be an indicator for mortality in maintenance hemodialysis patients.
Lab values—transthyretin (prealbumin)	Transthyretin is a good index of liver protein synthesis, but it is reabsorbed and metabolized by the proximal tubule; serum levels rise as kidney function declines. Transthyretin levels correlate strongly with serum albumin.

(continued)

**TABLE 16-4 Protein–Energy Malnutrition (PEM) in Renal Patients (continued)**

Assessment Frequency	Suggested Evaluation for PEM Status
Monthly assessments	Predialysis or stabilized serum albumin Percentage of usual postdialysis (MHD) or postdrain (CPD) body weight In hemodialysis: nPNA
Every 3–4 months	In peritoneal dialysis: nPNA
Every 4 months	Percentage of standard (NHANES II) body weight
Every 6 months	Subjective global assessment Dietary interview and/or diary
As needed to confirm or extend the data obtained earlier	Predialysis or stabilized serum prealbumin Skinfold thickness Midarm muscle area, circumference, or diameter Dual-energy x-ray absorptiometry
If low, to identify the need for more rigorous examination	Low predialysis or stabilized serum creatinine level (<10 mg/dL) Low or declining creatinine index Low predialysis or stabilized serum urea nitrogen level Low predialysis or declining serum cholesterol level (150–180 mg/dL)

Serum Fe, serum ferritin Mean cell volume (MCV)	Serum 23- hydroxyvita- min D (goal, >30 ng/mL)	Serum chloride Chol (goal, >160–<200 mg/dL)
Red blood cell (RBC) folate (≥200 ng/mL)	pH CO <sub>2</sub> (goal, 24–32 mEq/L)	Triglycerides (goal, <150 mg/dL)

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Inadequate Enteral Nutrition Infusion

**Assessment Data:** Dietary recall and I & O records, nursing flow sheets. Renal lab values: K<sup>+</sup> 6.0 mEq/L, BUN 60 mg/dL, serum creat 1.5 mg/dL. On tube feeding with fluid restriction.

**Nutrition Diagnosis (PES):** NI-2.3 Inadequate intake from enteral nutrition (EN) infusion related to volume restriction as evidenced by recorded infusion of 900 mL of enteral formula over the past 24 hours providing only 70% of estimated energy and protein needs.

#### Interventions:

**Food-Nutrient Delivery:** Increase tube feeding by concentrating formula and increasing protein.

**Coordinate Care:** Work with the medical team to monitor for tolerance and lab changes.

**Monitoring and Evaluation:** Monitor by I & O intake to monitor change in enteral formula administration, output, and serum creatinine levels.

### INTERVENTION

#### OBJECTIVES

- Postpone dialysis as long as possible. Work with high-risk conditions, such as diabetes or when urine albumin:creatinine ratio is abnormal (>30). Start working with other patients when serum creatinine is >1.5 mg/dL (women) or >2.0 mg/dL (men) to limit further renal impairment and reduce kidney workload. Patients should see a renal team, including a dietitian.
- Maintain or improve nutritional status. Protect lean body mass, minimize tissue catabolism. Consume adequate calories to spare protein.
- Keep protein intake at 0.6–0.75 g/kg/d to postpone dialysis (Eyre et al, 2008). Provide amino acids in proportion to protein status; attempt to keep serum albumin level of 4.0 g/dL.
- Control uremic symptoms and reduce complications from accumulation of nitrogenous waste. Evaluate the BUN:creatinine ratio; typically, a 10:1 ratio is desirable (urinary creatinine doubles when renal function is <50%).
- Treat hypertension aggressively. Limit dietary sodium, use moderate alcohol intake, obtain regular exercise, lose weight in those with a BMI >25, and reduce saturated fats. Blood pressure goal is <130 mm Hg systolic and <80 mm Hg diastolic for all CKD patients.
- Keep blood glucose under control with HbA1c ≤ 7%. Control carbohydrate (CHO) intake if needed.
- Include a variety of grains, especially whole grains, fresh fruits, and vegetables. Limit intake of refined and processed foods high in sugar and sodium.

- Choose low saturated fat, low cholesterol, and moderate total fat foods to normalize lipid profiles.
- Restore and maintain electrolyte balance; correct acidosis. Individualize potassium and phosphorus plans if blood levels are high.
- Consume the dietary recommended intake (DRI) for vitamins and minerals; preventing osteodystrophy.
- Have regular checkups and take medicines as prescribed. Exercise regularly, stop smoking, and eat a healthy diet.
- Aim for a healthy weight and include physical activity each day; obesity causes a decline in kidney function.
- Treat anemia, defined as a hematocrit <36% in women and <39% in men.
- Maintain growth in children with adequate calories, vitamins, and minerals.
- Correct other physiological changes such as constipation, diarrhea, blurred vision, pruritus, ecchymosis, pallor, crackles in the lungs, loss of muscle tone, and tingling of lips or fingertips.

## FOOD AND NUTRITION

- Consume adequate calories. Nondialyzed patients younger than 60 years with advanced CKD (GFR <25 mL/min) need 35 kcal/kg/d; those older than 60 years need 30–35 kcal/kg.
  - CHO should be 50–60% of total calories per day (Burrowes, 2008). CHO intolerance is common; fructose, galactose, or sorbitol may be better tolerated than sucrose.
  - With diabetes or heart disease, limit total fat to 30% or less of total calories per day; saturated fat less than 10% of the total calories; 200 mg cholesterol per day (Burrowes, 2008).
  - In stages 1, 2, or 3 of CKD, limit protein to 12–15% of calories per day. Use 0.8 g to 1.0 g protein/kg BW from high-quality protein sources.
  - In stage 4 CKD, reduce protein to 10% of calories per day. For nondialyzed patients with GFR <25 mL/min, use 0.6 g protein/kg/d, 50% from high-biological value sources. Amino acid analogs (CHO skeleton of amino acids minus the amino group) may also be used.
  - Limit sodium to 2.3 g/d for those with diabetes, high blood pressure, or fluid retention. Limit intake of processed foods high in sodium. Use less salt at the table and fewer high-sodium ingredients. See Table 16-5 for seasoning ideas instead of salt.
  - Phosphorus and potassium are modified on the basis of the stage of CKD (Burrowes, 2008):  
Phosphorus: stages 1–2: 1.7 g/d; stages 3–4: 0.8–1.0 g/d  
Potassium: stages 1–2: less than 4 g/d; stages 3–4: 2.4 g/d
- See Table 16-6 for tips on managing these potassium and phosphorus in the diet. Limit use of salt substitutes. Liberalize K<sup>+</sup> when there is diarrhea or vomiting.
- Limit elemental calcium to <2000 mg, including that from phosphorus binders, as needed. Initiate vitamin D therapy if PTH is high, calcium is <9.5 mg/dL, or phosphorus is <4.6 mg/dL.
  - Fluid intake should be output plus 500–1000 mL for insensible losses. Monitor regularly.
  - Avoid over-the-counter dietary supplements unless approved by the nephrologist. Supplement with the DRI for the water-soluble vitamin B complex, and limit vitamin C to 100 mg/d from supplemental sources. Vitamin A and iron may not be desirable, levels can build up as kidney function declines.
  - EN significantly increases serum albumin concentrations and improves total dietary intake (Stratton et al, 2005). Renal-specific enteral products may be needed; monitor content according to lab data. Because EN can help infants and children overcome malnutrition and promote catch-up growth, nocturnal feedings may be useful. If central parenteral nutrition (CPN) is needed, avoid excesses of micronutrients.
  - Work with the interdisciplinary team, as shown on page 871.

## Common Drugs Used and Potential Side Effects

- See Table 16-7.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. Some products may actually contribute to renal failure, such as aristolochic acid, found in Mu Tong or Fangchi in Taiwanese prescription medicines (Lai et al, 2010).
- Probiotic dietary supplements are being designed to metabolize nitrogenous waste that has diffused from the bloodstream into the bowel.

**TABLE 16-5 Spices and Condiment Substitutes for Salt**

Allspice	Dry mustard	Paprika
Bay leaf	Garlic, fresh or powder	Rosemary
Black pepper	Ginger	Scallions
Caraway seeds	Green bell pepper	Shallots
Celery seed	Lemons and limes	Sugar substitute
Chili powder	Mint	Sweet basil
Chives	Mrs. Dash	Tabasco sauce
Cinnamon	Nutmeg	Thyme
Cloves	Onions	Turmeric or cumin
Curry powder	Oregano	Vanilla extract
Dill	Pan spray, nonstick	Vinegar

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Counseling interventions should include aggressive blood pressure control, reduction of dietary protein to

**TABLE 16-6 Tips for Managing Potassium and Phosphorous in the Diet**

Most high-potassium foods come from plants (fruits and vegetables). High-phosphorus foods are mainly from animals (meats, poultry, fish, eggs, cheese, dairy foods), but dried beans and peas also tend to be high in phosphorus. Foods that are high in both potassium and phosphorus are dairy foods, nuts, seeds, chocolate, and whole grain foods.

Category	Tips and Alternatives for Lowering Potassium (K <sup>+</sup> )
Beverages	Drink ice water with sliced lemon and cucumber, instead of drinking tomato or vegetable juices.
Cooking	Cook with onion, bell peppers, mushrooms, or garlic, instead of tomatoes, tomato or chili sauces.
Desserts and snacks	Choose vanilla- or lemon-flavored desserts, instead of chocolate desserts. A plain donut is acceptable. Choose unsalted popcorn or pretzels, rice cakes, jelly beans, red licorice, or hard candies. Avoid products made with molasses and nuts.
Fruit	Choose apples, berries, canned peaches, canned pears, dried cranberries, fruit cocktail, grapes, pineapple, and plums. Avoid bananas, oranges, cantaloupe, honeydew, dried fruits, mango, or kiwi.
Fruit juice	Drink apple, cranberry, pineapple, or grape juice, instead of orange or prune juice.
Potatoes	Leach potatoes by cooking in water first to lower the potassium content. Prepare mashed potatoes or hash browns from leached potatoes instead of eating a baked potato, sweet potatoes, yams, or French fries.
Pumpkin or squash	Use summer squashes such as crookneck or zucchini, instead of pumpkin or winter squashes (acorn, banana, hubbard).
Seasonings	Season with pepper, lemon, or low-sodium herb and spice blends, instead of salt substitutes or seeds.
Vegetables	Choose green beans, wax beans, carrots, cabbage, cauliflower, or snow peas, instead of spinach, dried beans or peas.
Vegetables for dips, salads	Prepare salads and vegetable appetizers with cucumber, cauliflower, eggplant, lettuce and sweet peppers. Avoid avocado and artichokes.
High K <sup>+</sup> and High Phosphorus	Alternatives for a Lower K <sup>+</sup> /Phosphorus Diet
Cheese	Vegan rella cheese, low-fat cottage cheese, sprinkle of parmesan cheese; very small amounts of extra sharp cheeses for the maximum flavor
Chocolate	Desserts made with lemon or apple, white cake, rice-crispy treats
Cream soup	Broth-based soups made with pureed vegetables or make soups with Mocha Mix® nondairy creamer, Rich's Coffee Rich®, or Dairy Delicious® milk
Dried beans and peas	Green beans, wax beans
Ice cream	Mocha Mix® frozen dessert, sorbet, sherbet, popsicles
Milk	Dairy Delicious® milk, Mocha Mix® nondairy creamer, Coffeemate®, Rich's Coffee Rich®, Rice Dream® original, unenriched rice beverage
Nuts	Low-salt snack foods including pretzels, tortilla chips, popcorn, crackers, Sun Chips®
Peanut butter	Low-fat cream cheese, jam, or fruit spread

Derived from: Davita Dialysis Centers, <http://www.davita.com/diet-and-nutrition/c/diet-basics>, accessed February 22, 2010.

- recommended levels, weight loss, and control of hyperlipidemia. Referral to a qualified dietitian is important.
- For diabetic kidney disease (DKD), provide tips on controlling CHOs from the diet. The NKF recommends intense measures to manage hyperglycemia, hypertension, and dyslipidemia (NKF, 2007). Maintain HbA1c <7.0% regardless of the stage of CKD. Keep high blood pressure controlled (<130/80 mm Hg); low-density lipoprotein (LDL) cholesterol <100 mg/dL; dietary protein intake at 0.8 g/kg BW per day. Avoid high-protein diets with 20% of calories from protein.
- As eGFR declines, renal metabolism of insulin and oral medication is reduced, potentially causing hypoglycemia; cranberry juice cocktail, grape, apple juice, or glucose tablets may be helpful (Aase, 2010).

- Teach the Dietary Approaches to Stop Hypertension (DASH) diet that emphasizes sources of protein other than red meat for hypertension, diabetes, and CKD stages 1–2 (NKF, 2007).
- Discuss reading food labels, measuring portions, reading restaurant menus, planning box lunch foods, and dining away from home.
- LPDs are safe when properly planned. They reduce the accumulation of metabolic products and can suppress progressive loss of kidney function (Mitch, 2005). Have patient consume the designated proteins throughout the day. Low-protein wheat starch, hard candy, and jelly can be used to increase calories.
- Foods with sharp, distinct flavors may be needed. Lack of interest in red meats is common, and taste changes can occur.

## INTERDISCIPLINARY NUTRITION CARE PLAN

### End-Stage Renal Disease (Hemodialysis)

**Client Name:** \_\_\_\_\_ **#:** \_\_\_\_\_ **Initiated by:** \_\_\_\_\_ **Date:** \_\_\_\_\_

#### SCREENING

Nutrition Screen diagnosis: End-Stage Renal Disease (or dialysis)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### GOALS (Check any/all):

☐ Maintain or improve nutritional status in \_\_\_\_ (goal time).

☐ Improve serum albumin in \_\_\_\_ (goal time).

☐ Maintain or improve adherence to renal diet in \_\_\_\_ (goal time).

Weight ☐ maintained, or ☐ loss/ ☐ gain of \_\_\_\_ lb in \_\_\_\_ (goal time).

#### ASSESS (Check any/all)

##### Blood chemistries

- ☐ Serum albumin
- ☐ Serum transferrin, iron, or ferritin
- ☐ Total iron-binding capacity (TIBC)
- ☐ Serum ferritin
- ☐ Hematocrit, hemoglobin
- ☐ RBC indices, reticulocyte count
- ☐ BUN, creatinine
- ☐ Potassium/phosphorus, calcium
- ☐ Glucose
- ☐ Other: \_\_\_\_\_

##### Weight/BMI

- ☐ Weight loss >3 lb/wk or > 5%/mo or >10%/6 mo
- ☐ Weight gain >2 lb/d (fluid weight gain)
- ☐ BMI <20 (High Risk)

##### Poor Oral Intake Symptoms

- ☐ Complex diet order
- ☐ Nausea/vomiting
- ☐ Poor appetite/early satiety
- ☐ Problems chewing/swallowing
- ☐ Depression/anxiety
- ☐ GI distress

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### MODERATE-RISK INTERVENTIONS (Check any/all)

☐ Hemodialysis and Your Renal Diet provided and explained

##### Obtain Dr. orders as needed:

- ☐ RD chart consult
- ☐ Social Services chart consult
- ☐ Monitor blood chemistry
- ☐ Monitor weight q: \_\_\_\_\_
- ☐ Medication adjustments
- ☐ BID/TID supplement or sole source

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

None

1 or more

#### HIGH-RISK INTERVENTIONS (Check any/all)

☐ Hemodialysis and Your Renal Diet provided and reviewed

##### Obtain Dr. orders as needed:

- ☐ RD referral for home visit(s)
- ☐ Social Services referral for home visit(s)
- ☐ Labs: \_\_\_\_\_
- ☐ Monitor weight q: \_\_\_\_\_
- ☐ Medication adjustments
- ☐ BID/TID supplement or sole source

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

1 or more

#### ASSESS RESPONSE (Check any/all)

- ☐ Abnormal blood chemistries
- ☐ Exhibiting Poor Oral Intake Symptoms
- ☐ Weight change not appropriate per goal
- ☐ Declining strength

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

None

#### OUTCOMES ACHIEVED

- ☐ Weight maintained or improved
- ☐ Adherence to renal diet
- ☐ Normal blood chemistries
- ☐ Other: \_\_\_\_\_  
(See notes for documentation.)
- ☐ Repeat Nutrition Screen in \_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

Next visit

#### ASSESS RESPONSE (Check any/all)

- ☐ Abnormal blood chemistries
- ☐ Continued Poor Oral Intake Symptoms
- ☐ Weight change not appropriate per goal
- ☐ Declining strength

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

None

#### OUTCOMES ACHIEVED

- ☐ Weight maintained or improved
- ☐ Adherence to renal diet
- ☐ Normal blood chemistries
- ☐ Other: \_\_\_\_\_
- ☐ Repeat Nutrition Screen in \_\_\_\_ days  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

1 or more

#### OUTCOMES NOT ACHIEVED

Reassess acuity/evaluate need for further nutrition support. Document on Nutrition Variance Tracking form.

**TABLE 16-7** Drugs Used in Chronic Kidney Disease (CKD) and Dialysis Patients

Medication	Comments
Angiotensin-converting enzyme (ACE) inhibitor or angiotensin receptor blocker	First-line pharmacological intervention should be an ACE inhibitor or angiotensin receptor blocker in those with >200 mg protein/g creatinine on a urine sample.
Antidepressants	Depression is common in this population. Antidepressant treatment may be needed to improve appetite and intake.
Carnitine	Carnitine is formed from lysine and methionine, requiring adequate vitamin C, niacin, iron, and vitamin B <sub>6</sub> . Red meat and dairy products are typical dietary sources. Because the kidneys cannot make it, carnitine supplements are sometimes recommended.
Cinacalcet	<b>Cinacalcet (Sensipar)</b> has been approved to treat secondary hyperparathyroidism. Cinacalcet can be used to lower PTH despite elevations in calcium and/or phosphorus. Parathyroidectomy may be needed to lower PTH when pharmacologic intervention fails.
Growth hormone	Pharmacological doses of recombinant human growth hormone constitute an effective anabolic therapy.
Insulin	Insulin may be needed to control blood glucose levels. It is an anabolic hormone and can protect lean body mass for some patients.
Iron supplements and epoetin	<b>Recombinant human erythropoietin (rHuEPO)</b> is used to treat anemia; an iron supplement will be necessary. Be careful not to overload with excesses, and do not take supplements at the same time as calcium. <b>Retacrit (epoetin zeta)</b> is being evaluated for intravenous administration.
Lipid-lowering medications	Lipoprotein metabolism is often impaired in CKD. Patients with low-density lipoprotein $\geq 100$ mg/dL should be treated with diet and a statin.
Phosphate binders	Phosphate binders offer options for phosphorus reduction; newer binders are available that will not increase serum calcium. Nausea or vomiting may occur. <b>Aluminum-containing binders</b> are effective but can accumulate in tissues or may lead to bone disease, encephalopathy, or anemia. <b>Calcium-containing binders</b> (gluconate, carbonate, or lactate) may increase calcium intake, which may be otherwise inadequate if milk is limited. They are widely used but can lead to hypercalcemia or calcification. <b>Lanthanum carbonate (Fosrenol)</b> has good potency and minimal absorption; long-term studies on tolerability needed. Does not cause hypercalcemia. <b>Magnesium carbonate</b> can lead to hypermagnesemia, but long-term studies are lacking. It has the potential to minimize calcium load. <b>Sevelamer (Renagel)</b> causes less vascular calcification than calcium binders; it also reduces triglycerides and LDL cholesterol. It is costly and tolerability is variable.
Vitamin supplement	Renal multivitamins (such as Diatx) may be useful in providing B-complex vitamins (especially folic acid, B <sub>6</sub> , and B <sub>12</sub> ) for hyperhomocysteinemia and CKD.
Vitamin D	In CKD, the patient's kidney is unable to convert vitamin D to its active form; osteodystrophy can result. Take the supplements with extra water if possible because constipation may be a problem. <b>Calcitriol (Calcijex®, Rocaltrol®)</b> is the active vitamin D form that increases calcium and phosphorus absorption; it loses effectiveness with high serum P. The active form should not be taken if calcium or phosphorus levels are too high; it can increase phosphorus deposits in soft tissues such as arteries, lungs, eyes, and skin. Vitamin D analogs lower parathyroid hormone and increase bone mineralization but may raise calcium and phosphorus. <b>Paricalcitol (Zemlar®)</b> and <b>Doxercalciferol (Hectorol®)</b> are active vitamin D analogs that are less calcemic.

- Check for weights daily. Offer tips for maintaining fluid balance and managing thirst; see Table 16-8.
- Discuss dietary sources of vitamin D (see Appendix A).
- Manage high levels of phosphorus by dietary changes and prescribed medicines.
- Teach the patient how to monitor for signs of hyperkalemia, including nausea, weakness, numbness, tingling, slow pulse, or irregular heartbeat.

- Exercising regularly, maintaining a healthy weight, and not smoking prolong kidney health. Patients should talk to their doctors about an exercise plan.

#### **Patient Education—Food Safety**

- Foodborne illness can occur when there is contamination of food at any point during the preparation process.

**TABLE 16-8 Tips for Managing Thirst and Fluid Restrictions**

Fluid Equivalents	Sample Fluid Content
30 mL = 1 fluid oz = 2 tablespoons	1 whole popsicle = 90 mL
240 mL = 8 fluid oz = 1 cup	4 oz soup = 120 mL
2 cups = 1 lb fluid weight	6 oz juice = 180 mL
2.2 lb = 1 kg fluid weight	8 oz beverage = 240 mL
1 kg fluid weight = 4 cups liquid	12 oz soda = 360 mL
	16 oz milkshake = 480 mL

*Tips for Managing Thirst*

Control high blood glucose; thirst is a side effect of hyperglycemia.

Limit foods that contain hidden or large amounts of fluid (popsicles, soup, gravy, watermelon, and ice cream).

Reduce intake of salty and spicy foods.

Rinse often with mouthwash or suck on a lemon to decrease dry mouth.

Sipping beverages will make them last longer.

Stay cool in warm weather; drink cool instead of warm beverages.

Take medicines with applesauce instead of beverages.

Using ice instead of beverages may seem more satisfying; freeze the allotted amount of beverages (such as fruit juice) and track intake accordingly.

Derived from: Davita Dialysis Centers, <http://www.davita.com/diet-and-nutrition/diet-basics/a/477>, accessed February 22, 2010.

- To prevent contamination from *E. coli* bacteria (0157:H7) that is associated with undercooked meats, cook until juices run clear (155°F for ground meat or hamburger).
- Because renal patients are at high risk for foodborne illness, follow the four-step guidelines established by the U.S. Department of Agriculture: clean, separate, cook, and chill. See the Kidney Foundation Web site at <http://www.kidney.org/atoz/content/foodsafety.cfm>.

## DEFINITIONS AND BACKGROUND

**Dialysis** specifically involves artificial filtering of blood by a machine. It is a catabolic process. Among patients on dialysis, 33% have diabetes, and 50% of deaths are related to cardiovascular disease. Morbidity is largely related to physical fitness at the start of therapy. Chronic long-term dialysis can aggravate bone disease, anemia, endocrine disorders and can lead to malnutrition if not monitored carefully.

**Peritoneal dialysis (PD)** involves artificial filtering of the blood by a hyperosmolar solution (with osmosis to remove water and diffusion for glucose exchange/waste removal). The patient and doctor select continuous ambulatory PD (CAPD) or intermittent PD. CAPD does not require a machine. Continuous cycler-assisted PD (CCPD) requires a machine called a *cycler* to fill and drain the abdomen, usually during sleep; this is called *automated PD (APD)*. PD removes metabolic wastes and excess fluid from the body but not so thoroughly that diet therapy is unnecessary. Between dialysis treatments, the patient must return to a strict renal diet. Sometimes alternative methods are required. Intradialytic parenteral nutrition (IDPN) is convenient since it is administered during dialysis treatment. Overweight is more prominent in this population than malnutrition, which occurs frequently in HD patients.

HD is the more common method used to treat advanced and permanent kidney failure. In HD, blood flows through a special filter that removes wastes and extra fluids and then is returned to the body. With HD, less protein is lost than with PD; nevertheless, amino acid losses still occur. Approximately 40% of patients undergoing **maintenance HD** suffer from varying degrees of PEM. Causes of PEM include the catabolic effects of HD treatments, acidemia associated with ESRD, comorbid conditions, and uremia-induced anorexia (Ohlrich et al, 2005). Toxins accumulate with renal failure that suppress appetite and contribute to nutritional decline. Pica (mostly ice but also starch, dirt, flour, and aspirin) has also been found in many dialysis patients.

Nutritional status in these patients should be assessed by a panel of measures rather than by any single measure. Criteria often used to diagnose malnutrition in dialysis patients include serum albumin <3.4 g/dL, average BW <90% of desired goal, or documented protein intake <0.8 g/kg. The NKF Kidney Disease Guidelines for Nutrition provide many clinical practice guidelines for adults and separate guidelines for children.

Higher dietary phosphorus intake and higher dietary phosphorus:protein ratios are each associated with increased death risk in HD patients, even after adjustments for serum phosphorus, phosphate binders and their types, and dietary protein, energy, and potassium intakes (Noori et al, 2010). Control of phosphorus levels must, therefore, be a priority. Nutritional intervention can decrease both malnutrition and mortality in HD. The first step is careful evaluation of protein–energy status, followed by intensive nutrition counseling and then by oral nutrition supplementation, appetite stimulation, or enteral tube feedings (Ohlrich et al, 2005). Prealbumin concentrations <20 mg/dL are a concern, and a fall in serum prealbumin level over 6 months is independently associated with increased death risk (Rambod et al, 2008). However, albumin is more of a marker of illness severity than nutritional status (Friedman and Fadem, 2010).

EN or PN support may be needed; PN should be limited to patients who do not respond to other medical, psychiatric, and nutritional interventions.

Anemia can lead to chronic fatigue and debility if not corrected. Recombinant human erythropoietin beta (rHuEPO) is often given to improve nutritional status. Patients who do not respond to erythropoietin replacement may suffer from malnutrition and inflammation (Locatelli et al, 2006). Higher serum hemoglobin levels are associated with fewer hospitalizations and fewer hospital days (O'Connor et al, 2005).

CKD disrupts calcium homeostasis and causes high PTH, low calcitriol, reduced intestinal calcium absorption, low serum calcium, and high serum phosphorus at low GFR. In this secondary HPT, not enough phosphate is cleared from the body; phosphate is released from bone. Vitamin D is not produced. Absorption of calcium in the gut is low, and blood levels of calcium are lowered. Fortunately, treatment of secondary HPT has improved in recent years, and skeletal pain, disabling fractures, tendon ruptures, and other symptoms can be avoided. Parenteral vitamin D is associated with improved survival among long-term HD patients (Shoben et al, 2008).

Dyslipidemia is common; dialysis patients have increased cardiovascular morbidity and mortality. Excessive cardiovascular mortality of dialysis patients is related to chronic inflammation and muscle wasting (Kuhlmann and Levin, 2005; Workeneh and Mitch, 2010). The ATP-dependent ubiquitin–proteasome system causes skeletal muscle wasting not only from inflammation but also from metabolic acidosis, angiotensin II, and defective insulin signaling (Workeneh and Mitch, 2010). Elevated CRP levels can predict cardiovascular mortality. Eventually, 14-kD actin levels can be a marker of excessive muscle wasting (Workeneh and Mitch, 2010).

Children need adequate protein to encourage growth, and an intensive program of dialysis and nutrition intervention can be used in children on maintenance RRT. Monitor potassium and phosphorus restrictions carefully; protein choices are often high in these nutrients. For all patients, monitor trends and not just single biochemical numbers to identify the need for more education and counseling.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Dialysis may be necessary for some of the genetic causes of renal failure.

Clinical/History	Waist circumference	Midarm circumference
Height	Waist:hip ratio	(MAC)
Weight	BP	Midarm muscle
aBWef	I & O	circumference
Edema	Triceps skinfold	(nonaccess
BMI	(TSF)	arm in HD)
Diet history		

Temperature	Serum PTH	Metabolic
DEXA scan	(goal, 100–200 pg/mL)	acidosis, hyperchloremia
<b>Lab Work</b>	Serum vitamin D	Uric acid
BUN	Serum Ca <sup>++</sup>	Alb, transthyretin
Creat	(goal, 9.2–9.6 mg/dL)	Urea
GFR	Mg <sup>++</sup>	Serum folacin
CrCl (on HD, it will be <10)	Gluc, HgbA1c	Serum B <sub>12</sub>
Urine urea nitrogen (UUN) or Kt/V	Transferrin	Chol, Trig
Serum phosphorus (goal, <5.5 mg/dL)	Serum bicarbonate (low?)	AST (decreased)
CRP (usually elevated)	Na <sup>+</sup>	Hemoglobin
	K <sup>+</sup> (levels >6 mg/dL can trigger heart failure)	Hematocrit—target of 33–36%
		Serum Fe, ferritin
		N balance
		Serum zinc

## INTERVENTION

### OBJECTIVES

- Normalize the volume and composition of the body fluids and remove uremic toxins.
- Compensate for lost amino acids without causing uremic symptoms.
- Spare protein adequately to allow for tissue repair and synthesis; ensure sufficient total energy intake. Inflammation may elevate resting energy expenditure levels (Utaka et al, 2005); monitor accordingly.
- In PD only: alter calorie intake according to glucose absorption from the solution (e.g., 20 kcal/L in 1.5% solution; 60 kcal/L in 2.5% solution; and 126 kcal/L in 4.5% solution).

### SAMPLE NUTRITION CARE PROCESS STEPS

#### Excessive Mineral Intake

**Assessment Data:** HD patient returning to clinic; most labs within normal range, but phosphorus level at 7 mg/dL. Diet history indicates increased intake of dairy foods in the past week.

**Nutrition Diagnosis (PES):** NI-5.1.6 Excessive mineral (phosphorus) intake related to high intake of dairy foods in the past days as evidenced by serum phosphorus level of 7 mg/dL.

#### Interventions:

Food-Nutrient Delivery: Encourage return to renal dietary protocol.

Education: Review effects of hyperphosphatemia on quality of life.

Counseling: Discuss alternatives to dairy foods and provide recipes, menus, and other tips.

Coordination of Care: Review care plan with medical team and plan follow-up for the next clinic visit.

**Monitoring and Evaluation:** Improvement in serum phosphorus. No complaints with renal diet or dairy substitutes. Better able to plan menus and use recipes that are suitable and acceptable.

- Promote growth in children.
- Maintain fluid balance; modify electrolytes and fluid intake according to tolerance and lab values.
- Prevent or correct anorexia, constipation, growth delay, muscle weakness, cardiac arrhythmias, and hypertriglyceridemia.
- Correct metabolic acidosis to suppress muscle protein losses and improve bone metabolism (Workeneh and Mitch, 2010).
- Prevent the consequences of mineral dysregulation, including renal osteodystrophy, hyperphosphatemia, cardiovascular calcification, extraskeletal calcification, endocrine disturbances, neurobehavioral changes, compromised immune system and altered erythropoiesis. Severe dietary restrictions to control serum phosphorus reduce protein intake and can lead to protein–energy wasting and poor survival (Shinaberger et al, 2008). Dialysate concentrations should be prescribed with reference to plasma electrolyte levels. The KDOQI goals include the following:

Serum PTH	150–300 pg/mL
Serum Ca (albumin-corrected)	8.4–9.5 mg/dL
Serum P	3.5–5.5 mg/dL
Calcium-phosphorus (Ca-P) product	<55 mg/dL

- Improve patient survival, reduce morbidity, increase efficiency of care, and improve quality of life.
- Maintain follow-up contact for consistency of care in other settings or at home.

## FOOD AND NUTRITION

- In many hospitals, a standard renal diet provides 60 g protein, 2 g sodium, and 2 g potassium, but this may not be appropriate for dialysis. Most dialysis patients are required to limit their intake of phosphorus to 800–1200 mg/d and total (dietary and medication) elemental calcium to ≤ 2000 mg/d.
- Keep open communication with the nephrologist to determine how to best manage the patient. See Table 16-9 for guidelines on managing dialysis nutrition.

### Common Drugs Used and Potential Side Effects

- The drugs listed in Table 16-6 are used.
- Vitamin D deficiency is a common problem. In one study, 79% of the dialysis population was vitamin D deficient (25-hydroxyvitamin D < 30 ng/mL); black race, female sex, winter season, and serum albumin level <3.1 g/dL were the strongest predictors of vitamin D deficiency (Bhan et al, 2010). Vitamin D repletion guidelines are shown in Table 16-10.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician. These products

**TABLE 16-9 Nutrition Therapy for Dialysis Patients**

Nutrient	Hemodialysis (HD)	Peritoneal Dialysis (PD)
Protein for adults (50% from high biologic value sources)	1.2 g protein/kg/d. Urea kinetic modeling may also be used to devise a protein prescription.	1.2–1.3 g protein/kg/d. If there is peritonitis, 1.5 g/kg may be needed until infection subsides.
Protein for children	For children, base initial protein intake on recommended dietary allowance (RDA) for age plus an increment of 0.4 g/kg/d.	Children undergoing PD should be given RDA levels of protein, plus increments based on anticipated losses.
Energy	35 kcal/kg/d for patients who are <60 years of age and 30–35 kcal/kg for patients ≥60 years of age.	35 kcal/kg/d for patients who are <60 years of age and 30–35 kcal/kg for patients ≥60 years of age. Include dialysate calories in calculations. Extra calories may be needed in peritonitis.
Energy for children	For children, follow RDA levels by age for energy.	Same as HD
Carbohydrate (CHO) and fat	After protein is calculated, assess patient needs (e.g., less CHO in diabetes, fewer lipids with dyslipidemia), and calculate percentages accordingly. Try oral supplements before using other modes of feeding such as enteral or parenteral nutrition (PN).	Total energy intake increases from glucose in the dialysate in continuous ambulatory PD. This extra 300–450 kcal of glucose can increase weight and triglyceride levels. CHO absorption calculations must be individualized and altered as the diet prescription changes. Limit simple sugars and saturated fats.
Fluid	With ≥1 L fluid output = 2 L fluid needed. With <1 L fluid output = 1–1.5 L fluid needed. With anuria = 1 L fluid needed.	Fluid restriction is less common in PD; 1–3 L/d is suggested. Fluid intake should be determined by patient's state of hydration; encourage or restrict according to intake and output. No more than 1 kg should be gained in 1 day.
Potassium and phosphorus	Check levels of potassium and phosphorus; modify diet accordingly. Dialysis removes very little phosphorus; use 800–1000 mg or ≤17 mg/kg ideal body weight (BW). Calculate potassium as 40 mg/kg BW.	Same as HD Adjust phosphorus intake according to serum levels; 800–1000 mg phosphorus or 10–15 mg phosphorus/g protein.
Sodium	Limit sodium intake unless there are large losses in dialysate, vomiting, or diarrhea. Restriction to 2–4 g of sodium is common.	Intake of sodium should be liberal, pending assessment of hydration, blood pressure, losses in dialysate, vomiting, and diarrhea.
Vitamins	Use water-soluble vitamin supplements to replace dialysate losses. Daily replacement may not be needed. Folic acid (often need 1 µg), vitamin B <sub>6</sub> (1.3–1.7 mg), vitamin C (75–90 mg), and vitamin B <sub>12</sub> (2.4 µg) For children use DRI levels for age.	Supplement diet with water-soluble vitamins, especially vitamin B <sub>6</sub> and folic acid. Active vitamin D should be monitored and replaced at recommended levels. Avoid vitamin A excesses.
Minerals	Monitor serum labs as available. Individualize calcium; dialysate concentrations should be prescribed according to plasma levels.	Same as HD Same as HD Same as HD
Enteral nutrition	Try oral supplements first. If tube feeding is necessary, use an appropriate product to meet protein, electrolyte, and volume needs. If low volume is needed, use a product with 1.5–2.0 kcal/mL with small free-water flushes. Monitor electrolytes.	Same as HD
Parenteral nutrition	Before considering PN as an intervention in a dialysis patient, all other methods should be used. Use caution with PN, especially for zinc, and vitamins A and D.	Same as HD
Omega-3 fatty acids	Fish oil supplementation may help reduce prostaglandin synthesis and may help improve hematocrit levels.	Same as HD
Mediterranean diet	A Mediterranean dietary pattern and regular soy intake may be considered.	Same as HD

**TABLE 16-10 Vitamin D<sub>3</sub> Repletion**

Serum 25(OH)D (ng/mL)	Vitamin D Status	Dose (IU)	Route	Duration (months) <sup>a</sup>
<5	Severe deficiency	50,000/wk × 12 weeks; then monthly	po	6
		500,000 once	im	
5–15	Mild deficiency	50,000/wk × 4 weeks, then monthly	po	6
16–30	Insufficiency	50,000/mo	po	6

<sup>a</sup>Duration for all methods is 6 months, after which assay is needed.

contain pharmacologically active compounds that may be hazardous to patients with kidney problems (Burrows and Van Houten, 2005). For example, noni juice has a high potassium content and should be avoided.

- Approximately half of dialysis and transplant patients use CAM. Mineral supplements and vitamins rank first, followed by herbal teas and other products that contain ingredients that may accumulate in renal failure (Nowack et al, 2009).

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

### Dialysis: General

- Public Law 92-603 provides financial assistance via Medicaid to all persons covered by Social Security who have ESRD with dialysis. Table 16-11 discusses the role of dietitians in dialysis care.
- Discuss signs of uremia (nausea, vomiting, hiccups, fatigue, and weakness).

**TABLE 16-11 Role of the Renal Dietitian in Dialysis Care**

Patients with end-stage renal disease often experience malnutrition as a result of decreased dietary intake; inadequate dialysis; loss of nutrients into the dialysate; abnormal protein, carbohydrate, and lipid metabolism; and concomitant diseases, which may contribute to an increase in morbidity and mortality.

Close monitoring of nutritional status is completed by evaluating serum albumin and relevant biochemical data, appetite assessments, dietary energy and protein intakes, consumption of vitamins and minerals, and intake of oral supplemental foods, tube feeding, and parenteral nutrition.

Anthropometry is performed at baseline and on a yearly basis.

Specified changes in serum albumin level or body weight trigger action by the dietitian to prevent protein-energy malnutrition.

Multiple diet parameters are necessary to provide optimal nutritional health, including monitoring of calories, protein, sodium, fluid, potassium, calcium, and phosphorus, as well as other individualized nutrients. Consider all modes of nutritional intervention; use that which is best accepted by the patient and the least invasive.

- Discuss high-energy, low-protein, electrolyte-controlled food choices and supplements. Adequate care must be taken to ingest the designated protein and energy levels, according to current lab reports.
- When patients participate in an exercise program, appetites often improve. Exercise training is a potentially beneficial approach to correct muscle wasting, but more information is needed to optimize exercise regimens (Workeneh and Mitch, 2010).
- Counsel patient regarding managing a healthy diet to prevent or control heart disease or diabetes. A Mediterranean dietary pattern and regular soy intake both have been shown to attenuate chronic inflammation, and this may be useful in CKD patients (Kuhlmann and Levin, 2005).
- If avoiding potassium-rich foods is needed, salt substitutes should be monitored closely. Use of longer cooking times and extra water may help leach out excess potassium.
- Taste alterations are common, especially distaste for red meats, fish, poultry, eggs, sweets, and vegetables. Work individually with the patient to plan meals for adequacy of protein intake.
- Discuss sodium alternatives; see Table 16-5 for spices and condiments to use instead of salt.
- Provide information about dining away from home, home-delivered meals, and meals while traveling.
- Establishing trust, mutual respect, and emotional support are essential to promote a successful set of nutritional outcomes.

### Hemodialysis

- Discuss maximum fluid gain (usually 3–5% of BW) between dialysis sessions. Noncompliance with fluid restriction is common and can lead to systemic and cardiac overload.
- Teach fluid management to motivate patients to comply with their regimens; patients report that they feel better when their weight gains are within acceptable limits.

### Peritoneal Dialysis

- Fluid restrictions are not always needed with PD. Patient should learn how to recognize significant changes in dry weight (adjusted edema-free BW) or food intake. Discuss actions to be taken. Usually, 3–4 lb between intermittent PD is allowed.
- Teach the patient and family about managing diet to control phosphorus levels (goal is <5.5 mg/dL). Increasing patient knowledge may enhance dietary adherence to phosphorus restriction and use of phosphate binders. Avoid use of carbonated beverages that contain phosphates, such as colas.

### Patient Education—Food Safety

Foodborne illness can occur when there is contamination of food at any point during the preparation process. Because renal patients are at high risk for foodborne illness, follow the four-step guidelines established by the U.S. Department of Agriculture: clean, separate, cook, and chill. More details are available at the Kidney Foundation Web site at <http://www.kidney.org/atoz/content/foodsafety.cfm>.

## GLOMERULAR AND AUTOIMMUNE KIDNEY DISEASES

### NUTRITIONAL ACUITY RANKING: LEVEL 2 ACUTE; LEVEL 3 CHRONIC

#### DEFINITIONS AND BACKGROUND

*Glomerulonephritis* is a collective term used for diseases with renal inflammation stemming from the glomeruli; immune mechanisms are involved in all of them (Segelmark and Hellman, 2010). Antigen-antibody complex reactions become trapped in the glomeruli with resulting edema, scarring, and inflamed glomeruli. Resolution can be promoted by anti-inflammatory clearance by macrophages and mesangial cells (Watson et al, 2006). Clinical trials have provided compelling evidence that omega-3 polyunsaturated fatty acid (eicosapentaenoic acid [EPA] and docosahexaenoic acid [DHA] supplementation is useful, although some other studies suggest such supplementation might be without benefit (Pestka, 2010).

**Acute GN** occurs with damage to the glomeruli from infection, lupus, or other forms of kidney disease. GN caused by lupus is classified on the basis of lesions, extent and severity of the involvement, immune complex deposition, activity, and chronicity (Seshan and Jennette, 2009). Postinfectious GN (PIGN) may be related to *Staphylococcus* (Wen and Chen, 2010) or to untreated *Streptococcal* infections. Anuria with <400 mL/24 hours of urinary output may require temporary dialysis. Most acute GN conditions resolve after 3–12 months.

In **chronic GN**, repeated episodes of nephritis lead to the loss of renal tissue and kidney function; glomeruli disap-

pear, and normal filtering is lost. The kidneys can no longer concentrate urine, and more urine is voided in an effort to rid the body of wastes. Protein and blood are lost in the urine. Blood pressure rises, causing vascular changes and CKD. The level and type of proteinuria (only albumin or including other proteins) will determine the extent of damage and whether a patient is at risk for developing CKD. Decreasing proteinuria indicates an improved prognosis, whereas hypertension does not.

GN is the second most common cause of renal failure. Conservative treatment uses protein restriction (0.6 g protein/kg BW) to correct metabolic and hormonal derangements; restriction is contraindicated in cases of protein malnutrition, neoplasm, growth, or infection. Sufficient energy intake is essential. Four forms of primary GN include Goodpasture or anti-GBM disease, IgA nephritis (IgAN, Berger disease), membranous nephropathy, and membranoproliferative GN (MPGN), which occurs in adults of African descent and is a common cause of nephrotic syndrome. Much of the ESRD in African Americans is attributable to variants in the gene that encodes motor protein myosin 2 a (MYH9) in this haplotype (Freedman and Sedor, 2008).

**Glomerulosclerosis** involves hardening (scarring or sclerosis) of the glomeruli from lupus, HIV infection, or diabetes. Significant reduction of renal mass initiates a series of events that lead to proteinuria and glomerulosclerosis

(An et al, 2009). Albumin is lost in the urine, nitrogen waste products are retained, and retinal changes occur. **Focal segmental glomerulosclerosis (FSGS)** may cause nephrotic syndrome secondary to chronic pyelonephritis or diabetes; it is more common in Caucasian adults. Omega-3 fatty acid supplementation may reduce or reverse upregulation of prooxidant, proinflammatory, and profibrotic pathways in the remnant kidney (An et al, 2009).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Both genetics and infection seem to play a role. MYH9 is a gene that promotes MPGN in African Americans. Genes that cause the hereditary forms of FSGS that affect Caucasians include ACTN4, TRPC6, and CD2AP.

<b>Clinical/History</b>	Dark or rust-colored urine	Transferrin
Height	Foamy urine	BUN, Creat
Weight	Yellowish–brown skin discoloration	Proteinuria
aBWef	Renal radiographs	Gluc
BMI	Kidney biopsy	Urinary ketones
Diet history		Chol (increased from proteinuria?)
Waist:hip circumference		Trig
BP		White blood cell (WBC) count
Edema of face, ankles, feet, legs	<b>Lab Work</b>	H & H
Fever?	Alb, transthyretin (low?)	MCV
I & O	CRP	Serum Fe, ferritin
Shortness of breath	GFR	TIBC
Decrease in urine volume (oliguria)	CrCl level	Specific gravity (decreased?)
Urine smell on breath and sweat	Complement levels	PTH
Itching	Anti-glomerular basement membrane antibody test	Na <sup>+</sup> , K <sup>+</sup>
Abdominal pain, vomiting	Uremia (accumulation in the blood of wastes)	Serum phosphorus
		AST
		Ca <sup>++</sup> , Mg <sup>++</sup>
		Serum copper (increased?)

## INTERVENTION

### OBJECTIVES

- Improve renal functioning; prevent systemic complications where possible.
- Monitor abnormal protein status and serum nitrogen retention.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Energy Intake

**Assessment Data:** I & O records. BMI of 21. Diet hx shows an average daily intake of 1300 kcal but requirements of 1750 kcal daily. Intake of protein (60 g) meets needs.

**Nutrition Diagnosis (PES):** Inadequate energy intake NI 1.4 related to poor renal status and sufficient protein intake without calories for sparing as evidenced by diet hx of 1300 kcal, 60 g protein but estimated needs of 1750 kcal/d.

#### Interventions:

**Food-Nutrient Delivery:** Increase the use of CHO and fats to spare protein.

**Education:** Provide instruction and education about the role of protein and the need for sufficient intake of calories from CHO and fat.

**Counseling:** Provide individualized tips for increasing calories to enhance total energy by using preferred foods.

**Coordination of Care:** Work with the medical team to assess the effectiveness of extra calories to keep lab values closer to normal and to gain a few pounds over time.

**Monitoring and Evaluation:** BMI improving; now 23 after 3 months of higher-energy intake. Protein intake remains approximately 60 g, calorie intake between 1700 and 1800 kcal/d. No undesirable side effects.

- Spare protein for tissue repair. Prevent further catabolism of protein to lessen production of urea and other protein waste products.
- Control hypertension and edema.
- Manage hyperglycemia or dyslipidemia.
- Correct metabolic abnormalities. Improve nutritional status and appetite.
- Prevent or correct growth failure in children.
- Reduce inflammation and attenuate oxidative damage.
- Reduce workload of circulatory system by decreasing excess weight, where needed.

## FOOD AND NUTRITION

- Modify patient's diet according to disease progression; maintain sufficient levels of protein as long as kidneys can eliminate waste products of protein metabolism.
- Use sufficient energy to spare protein (60% CHO, 30% fat). For adults, 30–40 kcal/kg adjusted edema-free BW is needed to spare protein for tissue synthesis and wound healing.
- In **uremia**, diet should include 50% high-biologic value proteins (such as from cheese, meats, fish, eggs, and dairy foods), or essential amino acids at 2–3 times the normal should be included. Limit protein to 0.6–0.8 g/kg.
- In **oliguria**, restrict fluid intake to 500–700 mL. Limit protein to 0.6–0.8 g/kg. When urinary output is reduced greatly, restrict phosphorus intakes if needed. Potassium is often controlled by medications, but monitor and

adjust as needed. Some patients will require dialysis to remove waste products.

- With **edema** or **high blood pressure**, restrict sodium intake to 2–3 g/d. In a child, a restriction of 500–1000 mg may be needed. Carefully monitor sodium levels because sodium depletion can occur during the diuretic phase of chronic GN.
- Vegetarian diets, soy products, and use of omega-3 fatty acids may be beneficial for dyslipidemia. Restrict fat and cholesterol if needed; monitor diet carefully.
- Control CHO intake with diabetes or hyperglycemia.
- If patient is obese, use an energy-controlled diet, but avoid fasting and very low-calorie diets.
- Determine vitamins and nutrients provided by therapeutic diet and supplement to meet daily requirements, especially for calcium, niacin, and other B vitamins, which are easily lost in urine. Children with uremia require vitamin D<sub>3</sub> replacement for growth and to improve appetite; adults will need it to maintain bone health.

### Common Drugs Used and Potential Side Effects

- When diuretics such as furosemide are used to reduce edema, watch for potassium wasting or dehydration. Dehydration can elevate BUN; assess carefully.
- ACE inhibitors are useful for reducing hypertension.
- Immunosuppressants may be used.
- See Table 16-6 for more specific medications.

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with physician.
- Omega-3 fatty acid supplementation may be beneficial (An et al, 2009).

#### **NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT**

- A renal dietitian should provide nutrition therapy and counseling. A diet controlled in protein, fluid, phosphorus, sodium, and potassium may be needed; it must be individualized and is likely to change frequently.
- Commitment from the patient and family is needed; extra expense may be incurred for low-protein foods and amino acid analogs.

- Fluid intake should be distributed carefully throughout the patient's waking hours (see Table 16-7). Check for changes needed during diarrhea or related problems.
- Edema is better controlled by sodium restriction than by fluid restriction; monitor patient carefully. Patients with edema are often thirsty; edema water is trapped and unavailable for body's use.
- Encourage frequent doctor or clinic visits to monitor renal functioning.
- Patients with ascites may become anorexic in the upright position. Position patient carefully for food intake.

### Patient Education—Food Safety

- Foodborne illness can occur when there is contamination of food at any point during the preparation process.
- Because renal patients are at high risk for foodborne illness, follow the four-step guidelines established by the U.S. Department of Agriculture: clean, separate, cook, and chill.
- Details are available at the Kidney Foundation Web site at <http://www.kidney.org/atoz/content/foodsafety.cfm>.

# KIDNEY STONES

## NUTRITIONAL ACUITY RANKING: LEVEL 1–2

### DEFINITIONS AND BACKGROUND

Kidney stones are masses made of crystals; when they move down through the ureters, they cause severe pain. Unfortunately, kidney stones are common due to modern lifestyles, dietary habits, and obesity (Straub and Hautmann, 2005). The process is officially known as *urolithiasis* or *nephrolithiasis*. While all humans form calcium oxalate crystals, most do not form stones. However, prevalence is rising in both sexes (Moe, 2006). Annually, approximately 400,000 people are treated for this problem. Stones affect 5% of adults but may even occur in premature infants.

Kidney stones develop when salt and minerals in urine form crystals that coalesce and grow in size. Stones are formed by progressive deposition of crystalline material around an organic nidus. Decreased fluid intake and consequent urine concentration are among the most important factors influencing stone formation. Other major causes of renal stones are urinary tract infections (UTIs), cystic kidney diseases, metabolic disorders such as HPT, and renal tubular acidosis (see Table 16-12). A person who has had kidney stones or has a family history of kidney stones is at high risk.

Fluid is a key factor. It is not the quantity of fluid consumed but that which is voided that is important. Extra fluid intake will be needed by those who live in hot, dry conditions and by those who exercise or perspire significantly. Many stones can be prevented through changes in diet (Grases et al, 2006). Apple or grapefruit juices may aggravate risk whereas wine, beer, and some diet sodas are pro-

**TABLE 16-12 Causes of and Predisposition to Kidney Stones**

Climate	Hot climate and dehydration during summer months
Diet	Low intakes of dietary calcium and fluid, high intakes of sodium in susceptible individuals
Diminished water intake	During sleep, travel, or illness or from poor habits
Family	Family history of kidney stones
Genetic disorders	Gout, primary hyperoxaluria, hyperparathyroidism, renal tubular acidosis, cystinuria, and hypercalciuria
Gender	Three times more common in males
Intestinal changes	Inflammatory bowel disease, intestinal bypass surgery, ostomy surgery
Medications	Certain diuretics, use of the protease inhibitor indinavir, excessive intake of supplemental vitamin D
Urinary tract issues	Urinary tract infection or stagnation from blockage

#### REFERENCE

National Institute of Diabetes and Digestive and Kidney Diseases. Kidney stones in adults, <http://kidney.niddk.nih.gov/kudiseases/pubs/stonesadults/>, accessed February 22, 2010.

tection against stones. Orange and lemon–lime flavors contain alkalis of citrate and malate, which inhibit calcium formation; good choices include Fresca, diet Sunkist orange, diet 7-Up, and diet Canada Dry.

Approximately 80% of stones are composed of calcium oxalate and calcium phosphate (Reynolds, 2005). Ten percent are composed of struvite (magnesium ammonium phosphate produced during infection with bacteria that possess the enzyme urease). The remaining 10% are composed of uric acid, cystine or ammonium acid urate, or melamine. Melamine contamination of infant formula has been noted by the FDA (Skinner et al, 2010).

**Struvite stones** are mostly found in women who have UTIs. **Cystine stones** may form in individuals who have cystinuria, a familial disorder.

**Uric acid stones** may result from purine metabolism, gout, leukemia, cancer, or colectomy; they are more common in men. An abnormally low urinary pH (UpH) contributes to the problem. Creating an alkaline urine is the goal; a UpH of 6.2–6.8 is desirable (Hess, 2006). A lower-purine food intake (such as sardines) is also beneficial.

Most studies show no increase in **calcium oxalate** stone risk with high calcium intake (from either diet or supplements) but a high rate of stone risk from a low calcium intake (Heany, 2008). In the Health Professionals Follow-up Study, the Nurses' Health Study I and II, spinach accounted for >40% of oxalate intake; risks were higher in men with low dietary calcium intake, but dietary oxalate was *not* a major risk factor (Taylor and Curhan, 2007). Therefore, diets need not be excessively low in oxalates (see list in Table 16-12).

Diets high in animal protein provide a high acid load; sufficient potassium and alkali are required to neutralize the effect (Straub and Hautmann, 2005). Vegetarians form

stones at one third of the rate of those eating a mixed diet. Balanced diets containing moderate amounts of meat and plant proteins (legumes, seeds, nuts, and grains) may keep urinary composition within guidelines. Untreated **calcium oxalate stones** can lead to a greater chance of forming additional stones within later decades.

Citrate inhibits calcium oxalate stone formation by complexing with calcium in the urine, inhibiting spontaneous nucleation, and preventing growth and agglomeration of crystals; hypocitraturia is a metabolic abnormality found in 20–60% of stone formers (Zuckerman and Assimos, 2009). A normal calcium, low animal-protein diet with lemonade and citrus juices is effective for these individuals.

Extracorporeal shockwave lithotripsy remains the preferred method of treatment of urinary stones. Medical expulsive therapy is under review as a new treatment.

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Hypercalciuria is inherited, and it may be the cause of stones in more than half of the population who have calcium oxalate stones. Cystinuria runs in families and affects both men and women.

#### Clinical/History

Height	Kidney ultrasound	Urinary sodium
Weight	Intravenous pyelogram	Urinary citrate
BMI	Abdominal radiographs or computed tomography scan	Uric acid
Diet history		UpH
BP		Serum oxalate levels
I & O		Gluc
Excruciating groin or flank pain		Ca <sup>++</sup>
Fever	<b>Lab Work</b>	Mg <sup>++</sup>
Hematuria or mild pyuria	Urinalysis (crystals, RBCs)	Alb
Abnormal urine color	24-hour urine studies:	CRP
Excessive nocturia	Total urine volume	Lactose intolerance
Nausea, vomiting	Urinary calcium (normal, 300–400 mg)	Serum Na <sup>+</sup> , K <sup>+</sup>
Burning and urinary frequency		BUN
		Creat
		H & H
		Serum Fe

## INTERVENTION

### OBJECTIVES

- Determine predominant components and prevent recurrence by normalization of BMI, adequate physical activity,

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Fluid Intake

**Assessment Data:** I & O records showing low intake of fluids throughout the average day (<6 cups total). Recently hospitalized with uric acid stones; Hx of gout for 3 years.

**Nutrition Diagnosis (PES):** NI-3.1 Inadequate fluid intake related to poor daily habits as evidenced by uric acid stones and intake records showing <6 cups of fluid per average day.

#### Interventions:

**Food-Nutrient Delivery:** Increase fluid intake to 10–12 cups per day from water and other liquids.

**Education:** Discuss the importance of fluid intake and taking appropriate medicines as prescribed.

**Counseling:** Discuss purine-rich foods and that diet is seldom needed if the medicine is taken and works properly.

**Coordination of Care:** Work with pharmacist to ensure that medications will suffice.

**Monitoring and Evaluation:** Resolution of high urinary uric acid levels and no more renal stones. Intake of fluid averaging between 11 and 12 cups daily.

balanced nutrition, and sufficient daily fluid intake. Modify diet according to predominant components; there is seldom a single cause.

- To increase excretion of salts, dilute urine by increasing fluid volume to at least 2 L/24 h.
- Prevent scarring, recurrence of stones, obstruction, bone demineralization, or kidney damage.
- Promote use of a heart-healthy diet (Mitka, 2009).
- Repeat urinary studies approximately 6–8 weeks after initial metabolic testing to evaluate effectiveness of dietary changes. Once stable, where the patient's urine demonstrates decreased risk of stone formation, metabolic testing and radiographs should be performed at least annually.

## FOOD AND NUTRITION

- General guidelines: Fluid intake should be high, as tolerated (2 L/d). Colorless urine is sought. Individuals with cystinuria will need 3.5 L/d fluid intake (Reynolds, 2005). Limit the use of apple or grapefruit juices.
- Consume a diet that is balanced. Fruits and vegetables may reduce the low potassium/high sodium intake (Reynolds, 2005). The DASH diet is a good recommendation as it is associated with a marked decrease in kidney stone risk (Taylor et al, 2009).
- A heart-healthy weight loss and exercise plan may be needed if the patient is obese (Mitka, 2009; Taylor et al, 2005).
- Specific guidelines by stone content are provided in Table 16-13.
- Calcium should not be restricted, except in absorptive hypercalciuria where calcium restriction remains beneficial in combination with a drug (Straub and Hautmann, 2005). Hypocitraturia should be managed through a combination of oral alkali, dietary modifications, and

**TABLE 16-13 Dietary Treatment of Specific Renal Stones**

Type	Treatment
Calcium oxalate stones	<p>Calcium intake should be increased to &gt;1000 mg/d; good sources include skim milk, yogurt, low-fat dairy products, broccoli, fortified orange juice, and ricotta or other cheese. Fortified foods and almonds are several nondairy choices.</p> <p>Reducing urinary oxalates has a more powerful effect on stone formation than reduction of urinary calcium. However, diet has a limited role. Omit <b>very high sources</b> from rhubarb, spinach, strawberries, beets, All Bran, Swiss chard, almonds and mixed nuts, chocolate soy milk, miso, tahini, and soybeans. Limit <b>high sources</b>: okra, sweet potatoes, tomatoes, greens, fried potatoes, navy or black beans, apricots, figs, kiwifruit, some grains, soy milk, soy ice cream, chocolate candy bars, poppy seed, and turmeric. See Web site <a href="http://www.ohf.org/docs/Oxalate2008.pdf">http://www.ohf.org/docs/Oxalate2008.pdf</a>.</p>
Citrate stones	Hypocitraturia is found in up to 20% of stone formers and may be idiopathic or secondary to intestinal, renal, dietary, or pharmacological causes.
Cystine stones	Individuals with cystinuria will need 3.5 L of fluid daily. Use a diet low in cystine, methionine, and cysteine. Protein intake should be mildly reduced. Cystine stones usually are the result of a rare hereditary defect. Alkalinize urine with agents like D-penicillamine.
Struvite stones	Struvite stones contain magnesium ammonium phosphate and may form after an infection in the urinary system. They can grow very large and may obstruct the kidney, ureter, or bladder if not removed.
Uric acid stones	Urate stones can be dissolved by urine alkalinization with citrate or bicarbonate. There is no inhibitor of uric acid crystal formation; dietary measures focus on reducing uric acid and increasing urine volume. Non-fat milk, low-fat yogurt, and other dairy products are useful. High intake of fruits such as cherries and vegetable protein may reduce serum urate levels.

lemonade or other citrus juice–based therapy (Zuckerman and Assimos, 2009). Include legumes and dried beans for their health-promoting saponins, which are useful in the treatment of hypercalciuria.

### Common Drugs Used and Potential Side Effects

- Certain medications, such as triamterene (Dyrenium), indinavir (Crixivan), and acetazolamide (Diamox), are associated with urolithiasis.
- Approximately 15% of patients forming stones require specific pharmacological prevention (Straub and Hautmann, 2005).
- For **calcium oxalate** or **uric acid stones**, allopurinol (Zyloprim) and probenecid are usually used; a purine-restricted diet is not always needed (Cameron and Sakhaee, 2007). Drink 10–12 glasses of fluid daily; avoid concomitant intake of vitamin C supplements. Maintain alkaline urine (may need to use sodium bicarbonate). Thiazide diuretics may reduce hypercalciuria (Reynolds, 2005).

- **Hypocitraturia** should be managed through diet and oral alkali (Zuckerman and Assimos, 2009). Potassium citrate and potassium bicarbonate help to alkalinize the urine. Sodium restriction may be inappropriate; sodium supplementation is beneficial in these patients because it results in voluntary increased fluid intake (Stoller et al, 2009).
- For **cystine stones**: D-penicillamine use requires vitamin B<sub>6</sub> and zinc supplementation. Increase fluid intake. Take the drug 1–2 hours before or after meals. Stomatitis, diarrhea, nausea, vomiting, and abdominal pain may occur.
- **Struvite** stones will require use of antibiotics.
- Uric acid stones are often dissolved by using potassium citrate/bicarbonate. Acetazolamide increases UpH in patients with uric acid and cystine stones who are already taking potassium citrate; however, it may be poorly tolerated and can induce calcium phosphate stone formation (Sterrett et al, 2008).
- Potassium citrate (Polycitra K) reduces kidney stone incidence in children treated for seizures with the ketogenic diet (McNally et al, 2009).

### Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- The use of probiotics such as *Oxalobacter formigenes* in the prevention of calcium oxalate stone disease needs further investigation.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- The most important lifestyle change to prevent stones is to drink more liquids, especially water; try to produce at least 2 quarts of urine in every 24-hour period.
- Teach the principles of a heart-healthy DASH diet (Mitka, 2009; Taylor et al, 2009).
- A patient's 24-hour urine chemistry profile should guide the dietary adjustments. Use dietary measures that are appropriate for condition and content of the stone.
- Discuss occupational risks for stone formation, including working in hot, dry environments, or working with metals such as cadmium.

### Patient Education—Food Safety

Foodborne illness can occur when there is contamination of food at any point during the preparation process. Follow standard practices in food safety and handling.

# NEPHROTIC SYNDROME

## NUTRITIONAL ACUITY RANKING: LEVEL 2–3

### DEFINITIONS AND BACKGROUND

Nephrotic syndrome is not a disease but causes massive proteinuria, with 3.5 g or more of protein lost within 24 hours. As much as 30 g can be lost as a result. Serum albumin is especially affected. The common nephrotic syndrome in children is called “minimal change disease.” In approximately 20% of children with nephrotic syndrome, kidney biopsy reveals scarring or deposits in the glomeruli.

Adults who have nephrotic syndrome usually have some form of GN, with renal failure not far behind. FSGS is the most common cause in Caucasians; MPGN is the common cause in African Americans. Other causes include DKD, lupus, amyloidosis, HIV infection, hepatitis B or C, malaria, and heart failure.

Elevated LDL cholesterol is common because of altered lipoprotein production. When the liver makes more albumin in an effort to replace that which is lost, more cholesterol and triglycerides are released.

MNT centers on the problem of salt and water retention, protein depletion, hyperlipidemia, and loss of carrier proteins for vitamins and minerals. Patients have normal anabolic responses to dietary protein restriction (decreased amino acid oxidation) and feeding (increased protein synthesis and decreased degradation). A very high-protein diet will alter GFR; limit protein to decrease hyperfiltration. A moderate-protein diet that provides adequate energy can maintain nitrogen balance in nephrotic syndrome. Immunosuppressive medication is not helpful in the genetic forms of congenital nephrotic syndrome (CNS); a high-energy diet is

needed and kidney transplantation is the only curative therapy (Jalanko, 2009).

### ASSESSMENT, MONITORING, AND EVALUATION

#### CLINICAL INDICATORS

**Genetic Markers:** CNS is a rare kidney disorder caused by genetic defects in the components of the glomerular filtration barrier, especially nephrin and podocin (Jalanko, 2009).

Clinical/History	Lab Work	
Height	Alb,	Ceruloplasmin (decreased)
Weight	transferrin	AST (increased)
Weight gains?	Proteinuria,	Na <sup>+</sup>
aBWef	uremia	K <sup>+</sup> (hypokalemia?)
Edema	CRP	Serum phosphorus
BMI	LDL Chol	Hypovitaminosis D?
Diet history	and Trig (increased)	Ca <sup>++</sup> , Mg <sup>++</sup>
BP	H & H	BUN, Creat
I & O	Serum Fe	GFR, CrCl
Foamy urine	TIBC, percent saturation	
Chest pains	Serum ferritin	
Weakness	Transferrin (increased)	
Renal biopsy		
Renal radiographs		

## INTERVENTION

### OBJECTIVES

- Treat the underlying condition and take appropriate medications.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Inadequate Protein Intake**

**Assessment Data:** Dietary recall and laboratory analysis.

**Nutrition Diagnosis (PES):** NI-5.7.1 Inadequate protein intake, of only 40 g/d, and worsening proteinuria as evidenced by urinary losses of more than 20% of the usual status.

**Intervention:** Education on protein requirements and sources. Counseling about ways to increase protein without exceeding the recommended level.

**Monitoring and Evaluation:** Lab values and dietary intake.

- Prevent thrombotic episodes and manage infectious complications (Jalanko, 2009).
- Ensure efficient utilization of fed proteins, spared by use of adequate calories. Prevent muscle catabolism. Rarely, if protein losses are severe, albumin infusion is used.
- Correct anorexia and prevent malnutrition.
- Reduce edema, control sodium intake, prevent or control renal failure.
- Manage hyperlipidemia and elevated triglycerides.
- Monitor for potassium deficits with certain diuretics.
- Replace any other nutrients, especially those at risk (e.g., calcium, vitamin D).

## FOOD AND NUTRITION

- Use a diet of modest protein restriction (0.8 g/kg in adults, with 50% of high biological value). Children should be given the RDA for their age because high protein levels may worsen proteinuria and will not improve serum albumin levels.
- Diet should provide 35–40 kcal/kg/d. CHO intake should be high to spare protein for lean body mass; use high-complex CHO and high-fiber foods.
- With dyslipidemia, limit saturated fats and cholesterol; decrease intake of concentrated sugars and alcohol. Encourage use of linoleic acid and omega-3 fatty acids. A vegetarian, soy-based diet with amino acid replacements may be beneficial.
- If patient has edema, restrict sodium intake to 2–3 g. The DASH diet may be useful.
- Provide adequate sources of potassium, vitamin D, and calcium. Replace zinc, vitamin C, folacin, and other nutrients. Monitor the need for iron but do not use excesses, especially with infections.
- Fluid restrictions may be necessary if edema is refractory to diuretic therapy.
- Offer appetizing meals to increase intake. If required, use tube feedings (specialty renal products if needed). Nocturnal feedings can help children with growth.

## Common Drugs Used and Potential Side Effects

- ACE inhibitors such as benazepril (Lotensin), captopril (Capoten), and enalapril (Vasotec) are used to lower

blood pressure; they may help prevent protein from leaking into urine and damaging the kidneys. Angiotensin II receptor blockers losartan (Cozaar) and valsartan (Diovan) may also be prescribed.

- Antibiotics may be needed when infection is present. Evaluate effects of diet accordingly on drug effectiveness.
- Blood thinners such as warfarin (Coumadin) are prescribed if blood clots are a risk.
- Cholesterol-lowering drugs are often prescribed. If statins such as atorvastatin (Lipitor), fluvastatin (Lescol), lovastatin (Altoprev, Mevacor), pravastatin (Pravachol), rosuvastatin (Crestor), and simvastatin (Zocor) are used, CoQ10 may be depleted.
- Diuretics are used to excrete excess fluid. Thiazide diuretics such as furosemide (Lasix) will deplete potassium; others may spare or retain potassium (e.g., spironolactone). Monitor closely.
- Immune system-suppressing medications, such as corticosteroids, are used to decrease renal inflammation. With prednisone, sodium restrictions may be needed and losses of potassium, nitrogen, or calcium may result. Muscle wasting, weight gain, and other side effects are common. Cyclophosphamide has fewer side effects (du Boef-Vereijken et al, 2005).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- With cyclosporine, avoid echinacea and St. John's wort because of their counterproductive effects on the drug.
- The use of soy to slow down the progression of diabetic nephropathy and proteinuria warrants further study.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Help patient plan appetizing meals. Sodium restriction is common.
- If patient has abdominal edema, careful positioning may increase comfort at mealtimes.
- Weight management plans will be needed if steroid use will be long-term.
- Nephrotic syndrome can increase the risk of infections and blood clots; medical follow-up is needed.
- In steroid-dependent nephrotic syndrome (SDNS), doses of prednisone lower than 0.75 mg/kg/d do not seem to stunt growth in children (Simmonds et al, 2010).

## Patient Education—Food Safety

Foodborne illness can occur when there is contamination of food at any point during the preparation process. Because renal patients are at high risk for foodborne illness, follow the four-step guidelines established by the U.S. Department of Agriculture: clean, separate, cook, and chill. More details are available at the Kidney Foundation Web site at <http://www.kidney.org/atoz/content/foodsafety.cfm>.

# RENAL METABOLIC DISORDERS: HYPOPHOSPHATEMIC RICKETS AND HARTNUP DISORDER

## NUTRITIONAL ACUITY RANKING: LEVEL 3–4

### DEFINITIONS AND BACKGROUND

**X-linked hypophosphatemic rickets (XLH)** associated with decreased renal tubular reabsorption of phosphorus. A defect in the skeletal response to PTH contributes to HPT in XLH (Levine et al, 2009). Incidence is 1 in 20,000 births. XLH is characterized by low to normal serum levels of 1,25-dihydroxyvitamin D<sub>3</sub>, normocalcemia, and hypophosphatemia. There is abnormal regulation of production and/or degradation of PTH. Because vitamin D is metabolized abnormally, skeletal and dental structures are affected. Hypophosphatemia is responsible for the clinical manifestations, which vary with the age of the patient and the severity of wasting (Laroche and Boyer, 2005). In poorly growing patients, growth hormone therapy improves final height, phosphate retention, and radial bone mineral density.

**Hartnup disorder** is an autosomal recessive abnormality of renal and GI neutral amino acids, especially tryptophan and histidine. It is a rare familial condition characterized by hyperaminoaciduria. A red, scaly, photosensitive pellagra-like skin rash is seen on the face, neck, hands, and legs. Cerebellar changes occur, including delirium. Without the absorption of tryptophan, conversions into serotonin, melatonin and niacin are inefficient. Because niacin is a precursor to nicotinamide, part of NAD<sup>+</sup>, those metabolic functions are also altered. The failure to resorb amino acids in this disorder is compensated by a protein-rich diet (Broer et al, 2005). Bone deformities, pain, and small stature can occur even in children with good compliance, requiring surgical correction and bone lengthening (Fucentese et al, 2008).

mutations of the metalloproteinase PHEX on chromosome Xp22.1; FGF23, DMP1, and ENPP1 may also be involved. Hartnup disorder is an autosomal recessive disorder with alterations in the neutral amino acid transporter B(0)AT1 (SLC6A19) on chromosome 5, the major luminal, sodium-dependent neutral amino acid transporter. Its expression in the kidney depends on collectrin (Tmem27), a protein related to ACE2, which maintains blood pressure and glomerular structure (Camargo et al, 2009).

#### Clinical/History

Birth weight  
Present weight  
Length  
Growth percentile  
BMI  
Diet history  
BP

#### For XLH:

Bowing of lower limbs  
Bone pain  
Seizures  
Short stature, delayed growth  
Skeletal radiograph

For Hartnup disorder:

Red, scaly rash  
Abnormal muscle tone  
Cerebral ataxia

#### Lab Work

Usual Chemistry panels plus those listed

#### For XLH:

Serum phosphorus (low)  
Serum vitamin D

Ca<sup>++</sup> (normal)  
Alk Phos (elevated with high bone turnover)  
PTH  
Hyperphosphaturia (rickets)  
BUN, Creat (normal)  
For Hartnup disorder: Tryptophan-loading test

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** XLH consists of a genetic alteration in the handling of phosphate in the proximal tubule. It is inherited as a sex-linked dominant trait with

### INTERVENTION

### OBJECTIVES

- **XLH:** Correct malabsorption of phosphorus to establish homeostasis with adequate bone and skeletal mineralization. Avoid overly aggressive therapy to avoid hypercalcemia and secondary extraskelatal calcification.

## SAMPLE NUTRITION CARE PROCESS STEPS

## Abnormal Nutritional Labs

**Assessment Data:** Child with low rate of growth, percentile for height and weight at 15th percentile. Genetic testing is positive for XLH. Serum phosphate levels very low; calcium is normal, alk phos level elevated.

**Nutrition Diagnosis (PES):** Abnormal nutritional labs related to new diagnosis of genetic condition (vitamin D-resistant rickets, XLH) as evidenced by very low serum phosphate level with high alk phos and normal calcium levels and genetic test results.

**Interventions:**

**Food-Nutrient Delivery:** Maintain a balanced intake of calcium, phosphorus, and vitamin D-rich foods.

**Education:** Discuss the genetics of this disorder and how diet alone will not correct it.

**Counseling:** Counsel about the importance of taking all prescribed medications as ordered and not taking over-the-counter vitamins and minerals without first discussing with the doctor.

**Coordination of Care:** Discuss with the medical team any implications for diet. Support the importance of taking prescribed phosphate and vitamin D exactly as ordered.

**Monitoring and Evaluation:** Improved serum phosphate. Eventual improvement in growth, which may require growth hormone replacement.

- **Hartnup disorder:** Correct skin changes and behavioral side effects of this pellagra-like condition. Ensure adequacy of protein. Support measures such as psychiatric treatment as needed.

## FOOD AND NUTRITION

- **XLH:** Diet should provide adequate amounts of calcium. Monitor to avoid mineral toxicities.
- **Hartnup disorder:** A high-protein diet with supplements will be needed.

## Common Drugs Used and Potential Side Effects

- In **XLH**, ergocalciferol is a vitamin D analog that is used with phosphate supplements. Organic phosphate should be given every 4 hours along with supportive vitamin D therapy. After growth is completed, the drug is often reduced. If growth hormone therapy is used, monitor for undesirable side effects.

- **Hartnup disorder:** Patients are given oral nicotinamide therapy (40–200 mg/d) and oral neomycin. Psychiatric medications, such as antidepressants or mood stabilizers, may be needed.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain measures that are appropriate to the specific condition. Encourage regular medical visits and nutritionist follow-up.
- Patients with **XLH** will need counseling about desired intake of phosphorus and vitamin D to ensure adequate growth and development.
- Patients with **Hartnup disorder** should use sunscreen and avoid sun exposure as much as necessary. They will need counseling about high-protein diets.

## Patient Education—Food Safety

# POLYCYSTIC KIDNEY DISEASE

## NUTRITIONAL ACUITY RANKING: LEVEL 2

LifeART Super Anatomy Collection 9, CD-ROM. Baltimore: Lippincott Williams & Wilkins.

### DEFINITIONS AND BACKGROUND

PKDs are disorders that cause multiple, fluid-filled, bilateral cysts in the kidneys and may also affect the liver, pancreas, colon, blood, and heart valves. Fluid-filled sacs or cysts of varying sizes that become larger as the disease progresses replace normal kidney tissue. Intracellular calcium signaling is important in kidney development, and defects in this signaling pathway cause the cyst formation. PKD results from loss of function of either of two proteins, polycystin-1 or polycystin-2. Increased understanding of genetic and pathophysiologic mechanisms has laid the foundation for development of more effective therapies.

PKD in its **autosomal dominant form (ADPKD)** affects 600,000 adults in the United States, at a rate of 1 in 400–1000 persons. ADPKD is one of the most common human genetic disorders. The antidiuretic hormone, arginine vasopressin (AVP), operates continuously in ADPKD patients to stimulate the formation of cyclic adenosine monophosphate (cAMP), thereby contributing to cyst and kidney enlargement and renal dysfunction (Torres et al, 2009). Patients with ADPKD remain clinically asymptomatic for decades while significant anatomic and physiologic systemic changes take place (Rizk and Chapman, 2008). Symptoms most often appear between 30 and 40 years of age. There is a close correlation between the extent of hypertension, left ventricular hypertrophy, deterioration of GFR, and progressive enlargement of the cystic kidneys in adult ADPKD (Schrier, 2009).

The rare **autosomal recessive form (ARPKD)** occurs in 1 per 44,000 births. ARPKD is the neonatal form of PKD and

is associated with enlarged kidneys and biliary dysgenesis (Harris and Torres, 2009). Infants who are not treated may die before 1 month of age. Most infants with autosomal recessive PKD have unusual facial features (Potter face) and failure to thrive. Children with ARPKD experience high blood pressure, UTIs, and frequent urination. Their disease affects the liver, spleen, and pancreas, resulting in low blood cell counts, varicose veins, and hemorrhoids. Because kidney function is crucial for early physical development, children with autosomal recessive PKD are usually smaller than average size. Rare, syndromic forms of ARPKD cause defects of the eye, central nervous system, digits, or neural tube (Harris and Torres, 2009).

Treatment of PKD involves efforts to identify patients at greatest risk for disease progression, thus targeting therapy to retard disease progression and renal functional deterioration. The effect of renin-angiotensin-aldosterone system inhibition on renal volume and kidney function is being studied in the Halt Progression of Polycystic Kidney Disease (HALT PKD) trial (Schrier, 2009). Laparoscopic surgery to remove the cysts may be beneficial for some patients. Half of patients with PKD will require dialysis (Barash et al, 2010). For others, transplantation is needed.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** ADPKD is the most common life-threatening hereditary disorder (Belibi and Edelstein, 2010); it is caused by mutations in the *PKD1* gene in 85% of cases and the *PKD2* gene in the rest of the cases.

ARPKD is caused by mutation in *PKHD1*; the ARPKD protein, fibrocystin, is localized to cilia/basal body and complexes with polycystin-2 (Harris and Torres, 2009).

Clinical/History	Liver or pancreatic cysts	Serum AVP
Length or height	Abnormal heart valves	BUN, Creat
Birth weight	Kidney stones	H & H
Present weight	Brain aneurysms	Serum Fe, ferritin
Growth percentile	Diverticulosis, hemorrhoids	Na <sup>+</sup> , K <sup>+</sup>
BMI	Back or side pain	Chol, Trig
Diet history	Ultrasound	Gluc
BP (abnormally high)		Serum vitamin D
Vomiting		Alb, transthyretin
Chronic headaches	<b>Lab Work</b>	CRP
UTIs	Proteinuria, micro-albuminuria	Ca <sup>++</sup> , Mg <sup>++</sup>
Hematuria		Serum phosphorus

## SAMPLE NUTRITION CARE PROCESS STEPS

**Excessive Mineral Intake**

**Assessment Data:** I & O records, nursing flow sheets. Adult 50-year-old male with ADPKD. Blood pressure very high, 190/90 mm Hg on three separate measurements. Diet hx indicates use of bacon every breakfast, luncheon meats and cheese for midday meal, and canned soups for dinner at least four times weekly.

**Nutrition Diagnosis (PES):** NI-5.10.7 Excessive mineral (sodium) intake related to intake of high sodium foods as evidenced by BP 200/90 mm Hg and diet hx of high sodium food choices consumed every day.

**Interventions:**

**Food-Nutrient Delivery:** Suggest alternatives for meal planning that are lower in sodium. Discuss appropriate fluid intake as well.

**Education:** Educate the patient and his family members about the importance of lowering blood pressure by using medications and a lower sodium diet.

**Counseling:** Work with family members to plan menus that are easy to prepare for daily meals; discuss tips for restaurant and shopping choices.

**Coordination of Care:** If high fluid intake is recommended, work with the medical team accordingly.

**Monitoring and Evaluation:** Blood pressure gradually down to 120/80 mm Hg. Sodium intake within 2–3 g guideline on a daily basis.

## INTERVENTION

## OBJECTIVES

- Prevent renal failure; manage CKD.
- Minimize or alleviate nausea, vomiting, and anorexia.
- Bring hypertension under control where present. The goal BP is 120/80 mm Hg.
- Control AVP secretion.
- Correct or alleviate proteinuria or microalbuminuria.
- Manage dialysis when and if needed. Prepare for transplantation if planned.

## FOOD AND NUTRITION

- Modify diet according to symptoms; sodium restriction may be beneficial for lowering blood pressure. The DASH diet may be beneficial.
- Meet protein dietary allowance for age unless proteinuria is excessive, in which case lower levels are needed.
- Fluid intake should be tailored to the individual. Water loading, by suppressing AVP-stimulated cAMP production, is a proposed therapy for ADPKD; more trials are needed (Barash et al, 2010; Torres et al, 2009).
- Use more antioxidant-rich, anti-inflammatory foods, such as berries, apples, soy, flax oil, fish including salmon, and fish oils.

## Common Drugs Used and Potential Side Effects

- ACE inhibitors are most frequently prescribed for hypertension (Jafar et al, 2005). Calcium channel blockers, diuretics, and beta-blockers may also be used. A common combined therapy is a diuretic plus an ACE inhibitor.
- Antibiotics may be used to treat infections; monitor specific medicines for nutritional side effects.
- Analgesics may be useful for pain management.
- Vasopressin V2 receptor antagonists, mTOR inhibitors, and statins that reduce cyst formation and improve renal function are being tested (Belibi and Edelstein, 2010).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Explain measures that are appropriate to specific condition. If high fluid intake is desirable, discuss goals and options with the patient and/or family.
- Encourage regular medical visits and nutritionist follow-up.

## Patient Education—Food Safety

- Renal patients are at high risk for foodborne illness. Follow the four-step guidelines established by the U.S. Department of Agriculture: clean, separate, cook, and chill.
- Details are available at the Kidney Foundation Web site at <http://www.kidney.org/atoz/content/foodsafety.cfm>.

# RENAL TRANSPLANTATION

## NUTRITIONAL ACUITY RANKING: LEVEL 4

### DEFINITIONS AND BACKGROUND

Renal transplantation may be completed in ESRD when GFR drops to 10 mL/min. Persons with poor health or history of cancer often cannot receive a transplantation. Patient and graft survival rates, as well as long-term quality of life, have improved dramatically, a result of advances in surgical techniques, immunosuppression, and perioperative care. Laparoscopic living-donor nephrectomy has improved the possibility of live renal donations. In addition, pediatric kidney transplants are an option for children with ESRD. A child must reach a certain body surface area or weight (such as 20 kg) to receive a parent's kidney; siblings younger than 18 years are generally not allowed to donate a kidney.

Malnutrition prior to transplantation is associated with an increased risk of infection, delayed wound healing, and muscle weakness. Delaying surgery for nutrition therapy (enteral and parenteral) is indicated only if severe malnutrition is present. Preoperative nutrition therapy should be conducted prior to hospital admission to lower the risk of nosocomial infections (Weimann et al, 2009).

An adequate nutritional status may improve outcomes after transplantation. In addition, a weight loss program may be needed prior to surgery if the patient is obese. Orlistat (alli® or Xenical®) and a structured low-fat, low-calorie diet and exercise program may be beneficial (MacLaughlin et al, 2010).

After a renal transplantation, the patient has a functioning donor kidney. High doses of glucocorticoid drugs are given to prevent rejection. Elimination of donor-specific anti-human leukocyte antigen antibodies during antibody-mediated rejection (AMR) is important; proteasome inhibitor-based therapy has been shown to effectively treat refractory AMR (Walsh et al, 2010).

The acute posttransplantation phase lasts up to 2 months; the chronic phase starts after 2 months. Complications of corticosteroid use include new-onset diabetes, osteoporosis, and hyperlipidemia. In the long term, cardiovascular morbidity remains the greatest risk (Roberts et al, 2006), followed by cancer and infections. Complications are listed in Table 16-14.

Early intensive dietary advice and follow-up helps control complications after renal transplantation. Prognosis is good for transplant patients who take care of themselves and attend to medical follow-up.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** Renal transplantation may be needed for some of the inherited disorders, such as PKD.

**TABLE 16-14 Complications After Renal Transplantation**

Complication	Description
Anemia	Posttransplantation anemia is a prevalent and under-treated condition.
Cancer	Lymphomas may occur. Malignancies are rapidly becoming a major cause of mortality.
Cardiovascular complications	Hyperlipidemia is one of the consequences of long-term use of corticosteroids. Elevated triglycerides and metabolic syndrome can also persist. Renal transplantation recipients are at high risk for ischemic heart disease or heart failure and will benefit from lifestyle modifications.
Diabetes	Patients are at risk for posttransplantation diabetes because of the use of corticosteroids. Higher BMI, elevated fasting blood glucose levels, and high blood pressure should be managed carefully.
Infection	Acute meningitis or Guillain-Barré syndrome triggered by <i>Campylobacter jejuni</i> infection are examples of infections in this population.
Neurological complications	Neurotoxic immunosuppressive medications may cause mild symptoms, such as tremors and paresthesia.
Osteoporosis	Bone density declines after long-term use of corticosteroids. Tertiary hyperparathyroidism may occur after kidney transplantation.
Pulmonary complications	Infectious pulmonary complications may occur. Noninfectious pulmonary complications arise because of the toxicity of posttransplantation medications.
Stroke	Stroke may occur in a small number of renal transplant recipients.
Weight gain or obesity	Obesity decreases effectiveness of insulin receptors, increasing the tendency for glucose intolerance. It may also delay wound healing.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Obesity**

**Assessment Data:** Female patient 6 months posttransplant with weight gain of 30#; BMI now 32. Diet history indicates patient is eating small meals every 2–3 hours, consuming 300–400 kcal in excess of goal intake of 1700 kcal/d. Glucose and lipid levels slightly elevated over past reports.

**Nutrition Diagnosis (PES):** Obesity related to excess oral food and beverage intake as evidenced by weight gain of 30# since transplant 6 months ago and current BMI 32.

**Interventions:**

**Education:** Reduce overall energy intake to the goal range of 1700 kcal/d. Suggest lower calorie alternatives for food choices and preparation methods.

**Counseling:** Develop menu plans together to support goal achievement.

**Coordination of Care:** Discuss plans with medical team to support the patient goals during monthly clinic visits. Patient will see RD again in 3 months.

**Monitoring and Evaluation:** Improved weight status; loss of 10# in 3 months. Patient expresses satisfaction with meeting weight loss goal thus far. Lab values within normal limits for glucose and lipids.

## INTERVENTION

## OBJECTIVES

- Promote healing and prevent infections, especially during acute phase.
- Prevent or control AMR.
- Support immunity and prevent new infections.
- Food intake is recommended within 24 hours postsurgery. Modify diet according to drug therapy to enhance outcome.
- Initiate immediate postoperative EN or PN in patients who did not receive oral intake for more than 7 days perioperatively or whose oral food intake is less than 60–80% for more than 14 days (Weimann et al, 2009).
- Prevent abnormalities in calcium or phosphorus metabolism with HPT.
- Monitor for abnormal electrolyte levels (sodium, potassium). Control blood pressure carefully to prevent cardiac problems.
- Maintain good blood pressure control and near-normal fasting blood glucose levels and HbA1c levels. Manage CHO intake, but provide enough energy to spare protein for healing.
- Manage fluid intake according to intake and output. Most patients can return to a normal or increased fluid intake after transplantation.
- Help patient adjust to a lifelong medical regimen during chronic phase. Improve survival rate by supporting immune response.

- Correct or manage complications that occur, such as posttransplantation anemia.
- Minimize long-term weight gain.

## FOOD AND NUTRITION

- Progress to solids as quickly as possibly postoperatively. Monitor fluid status and adjust as needed.
- Energy should be calculated as 30–35 kcal/kg. Needs may increase with postoperative complications.
- Daily intake of protein should be 1.3–2.0 g/kg in the acute phase and 0.8–1.0 g/kg in the chronic phase. Soy proteins can be used in most cases and may help lower LDL cholesterol level.
- Control CHO intake; 50% of total calories is usual. Limit concentrated sweets and encourage the use of complex CHO.
- Encourage monounsaturated fats, omega-3 fatty acids, and the Mediterranean diet. Use more fish and fish oils and olive oil.
- Fluid is not restricted unless there are problems with graft functioning.
- Daily intake of sodium should be 2–4 g until drug regimen is reduced. Careful management of sodium efficiently controls blood pressure in patients who are hypertensive (Keven et al, 2006).
- Adjust potassium levels as needed (2–4 g if hyperkalemic).
- Daily intake of calcium should be 1200–1500 mg. Children especially will need adequate calcium for growth.
- Supplement diet with vitamin D, magnesium, phosphorus, and thiamine if needed. If homocysteine-lowering multivitamin therapy is needed; folic acid and vitamins B<sub>6</sub> and B<sub>12</sub> are needed.
- Reduce gastric irritants as necessary, if GI distress or reflux occurs.
- Encourage exercise and a weight control plan for the long-term recovery phase.

## Common Drugs Used and Potential Side Effects

- See Table 16-15 for a description of immunosuppressive drugs that are used.
- Calcium or vitamin D supplements may be needed to correct osteopenia.
- Most adult renal transplantation recipients develop dyslipidemia within 1 month of the initiation of immunosuppressive therapy. Statins and diet therapy are required.
- Chronic allograft nephropathy remains a cause of graft attrition over time (Afzali et al, 2005). Switching to tacrolimus due to cyclosporine-related side effects improves disease-specific quality-of-life indicators within a short time (Franke et al, 2006).

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.

**TABLE 16-15 Immunosuppressant Drugs Used After Renal Transplantation**

Drugs may be either *induction agents*, powerful drugs at the time of transplant, or *maintenance agents* used for long-term antirejection. Most patients are on a combination of the drugs listed below. Many transplant centers use tacrolimus, mycophenolate mofetil, and prednisone.

Medication	Comments
<b>Antiproliferative agents:</b> (mycophenolate mofetil, mycophenolate sodium, azathioprine)	These drugs lower the number of T cells and may cause leukopenia, thrombocytopenia, oral and esophageal sores, macrocytic anemia, pancreatitis, vomiting, diarrhea, and other complex side effects. Folate supplementation, liquid or soft diet, and use of oral supplements may be needed.
Belatacept	This is an investigational biologic agent, injected following renal transplantation to prevent rejection, maintain kidney function, and sustain lower blood pressure. “Posttransplant lymphoproliferative disorder”—a type of lymphoma associated with organ-transplant patients is one risk.
Corticosteroids (prednisone, Solu-Cortef)	Used for immunosuppression. Side effects include increased catabolism of proteins, negative nitrogen balance, hyperphagia, ulcers, decreased glucose tolerance, sodium retention, fluid retention, and bone thinning/osteoporosis. Cushing syndrome, obesity, muscle wasting, and increased gastric secretion may result. A higher protein intake and controlled carbohydrate intake are needed.
<b>Calcineurin inhibitors:</b> Cyclosporine (Sandimmune, Neoral, Gengraf)	Cyclosporine does not retain sodium as much as corticosteroids. Nausea, vomiting, and diarrhea are common side effects. Hyperlipidemia, hypertension, and hyperkalemia, hyperglycemia, hypertipidemia, hair growth, gum enlargement, or tremors may occur. The drug is also nephrotoxic; a controlled renal diet may be beneficial.
<b>Calcineurin inhibitor:</b> Tacrolimus (Prograf, FK506)	Being 100 times more potent than cyclosporine, smaller doses are required to suppress T-cell immunity. Side effects include gastrointestinal distress, nausea, vomiting, hyperkalemia, headaches, hair loss, tremors, and hyperglycemia.
Monoclonal antibodies (mAbs) (basiliximab, daclizumab)	Less nephrotoxic than cyclosporine but can cause nausea, anorexia, diarrhea, fever, stomatitis, and vomiting. Monitor carefully. Anti-CD25 mAbs (basiliximab and daclizumab) are well tolerated. Anti-CD52 (Campath-1 H), anti-CD20 (rituximab), anti-LFA-1, anti-ICAM-1, and anti-tumor necrosis factor- $\alpha$ (infliximab) show potential.
<b>Proteasome inhibitors</b> (bortezomib, rituximab)	Proteasome inhibitor-based therapy may reduce early graft rejection (Walsh et al, 2010).
mTOR inhibitor (sirolimus)	Side effects may include rash, bone marrow problems (anemia, low white blood cell count and low platelet count), swelling of ankles, and frothy urine because of protein leakage from urine.

**REFERENCE**

Walsh RC, et al. Proteasome inhibitor-based primary therapy for antibody-mediated renal allograft rejection. *Transplantation*. 89:277, 2010.

- With cyclosporine, avoid use with echinacea and St. John’s wort because of counterproductive effects on the drug.
- Patients should learn how to apply self-management and when to seek medical attention. UTIs are the most common infection after renal transplantation.

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Share, as appropriate, details of the DASH diet and Mediterranean diet. Discuss food sources of protein, calcium, magnesium, potassium, and sodium.
- Increase intakes of fiber-rich foods as a primary preventive approach against metabolic syndrome and cardiovascular disease, which are very prevalent after renal transplant (Noori et al, 2010).
- Avoid smoking and keep alcohol intake to a minimum.
- Rigorous efforts should be made to optimize weight before and after solid-organ transplantation by a judicious combination of diet, exercise, minimization of steroid therapy, surgery, and psychological therapies. Encourage moderation in diet; promote adequate exercise.
- Discuss the importance of bone health and how diet affects prevention of osteoporosis. If patient does not drink milk, describe other sources of calcium.

### Patient Education—Food Safety

- Foodborne illness can occur when there is contamination of food at any point during the preparation process. Follow the four-step guidelines established by the U.S. Department of Agriculture: clean, separate, cook, and chill.
- Details are available at the Kidney Foundation Web site at <http://www.kidney.org/atoz/content/foodsafety.cfm>.

# URINARY TRACT INFECTIONS

## NUTRITIONAL ACUITY RANKING: LEVEL 1 (3 IF CHRONIC)

### DEFINITIONS AND BACKGROUND

**UTIs** are associated with significant morbidity (Nanda and Juthani-Mehta, 2009). Single UTI episodes are very common, especially in adult women where there is a 50-fold predominance compared with adult men (Guay, 2009).

**Acute pyelonephritis** affects the renal parenchyma and is the most common cause of UTIs. *E. coli* most often cause upper UTIs; other organisms are found in complicated infections associated with diabetes mellitus (e.g., *Candida* spp), urinary stones, or immunosuppression. With effective antibacterial therapy, the immune response by both T and B lymphocytes supports antibodies that can eradicate the infectious agent.

There are approximately 250,000 cases of acute pyelonephritis each year. When the patient is septic, hospitalization and treatment with parenteral antibiotics may be needed. Indications for inpatient treatment include complicated infections, sepsis, persistent vomiting, failed outpatient treatment, or extremes of age (Ramakrishnan and Scheid, 2005). If patient does not improve rapidly, ultrasound and computed tomography are used to diagnose obstruction, abscess, or emphysematous pyelonephritis. Emphysematous pyelonephritis is a life-threatening infection especially seen in patients with poorly controlled diabetes mellitus. Mortality is high in that population, especially in the elderly. Most complications are treated percutaneously with broad-spectrum antibiotics and fluid resuscitation, followed by surgical therapy if needed.

In acute pyelonephritis in pregnancy, changes in innate immunity are present. Low maternal plasma concentrations of adiponectin are found in these cases; adiponectin has profound anti-inflammatory properties (Mazaki-Tovi et al, 2010). Further study is needed to identify measures that can be taken to enhance immunity during pregnancy.

**Chronic pyelonephritis** results from treatment failure and may be caused by resistant organisms, underlying anatomic/functional abnormalities, or immunosuppressed states (Ramakrishnan and Scheid, 2005). Fibrosis, scarring, and dilatation of the tubules impair renal function. Scarring from chronic pyelonephritis leads to loss of renal tissue and function, even progressing to ESRD. Hypertension is often present in this population.

**Cystitis** affects the lower urinary tract. **Interstitial cystitis (IC)** is a painful bladder syndrome with an inflamed bladder wall, pelvic discomfort, and urinary frequency and urgency. Omission of alcohol, caffeine, citrus beverages, and tomatoes gives relief to some individuals.

Cranberry inhibits the adhesion of uropathogens through anthocyanidin/proanthocyanidin as potent antiadhesion compounds (Guay, 2009). It may decrease the number of symptomatic UTIs over a 12-month period, particularly for women, but it is not clear whether juice, tablets, or capsules are the most effective source (Jepson and Craig, 2008). GI intolerance, weight gain from excessive calorie load, and drug–cranberry interactions due to the inhibitory effect of flavonoids on cytochrome P450-mediated drug metabolism may occur (Guay, 2009).

**Urinary incontinence** requires attention, even if there are no UTIs. Check for vitamin B<sub>12</sub> deficiency, decrease caffeine intake, and try bladder training (use of toilet every 2 hours). Maintain adequate fluid intake to prevent the onset of any UTIs. Women may need guidance on pelvic floor exercises to strengthen those muscles after childbirth or menopause.

### ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** UTIs are not genetic, but many inherited conditions can aggravate them. Elevated prolactin is a biomarker that differentiates lower UTI from pyelonephritis in the pediatric age group (Nanda and Juthani-Mehta, 2009).

<b>Clinical/History</b>	Edema	BP (increased?)
Height	Diet history	Intravenous
Weight	Temperature	pyelogram
BMI	I & O	

<b>Lab Work</b>	Transferrin	Na <sup>+</sup> , K <sup>+</sup>
Urine culture	H & H	Urinary Na <sup>+</sup>
Procalcitonin	Serum Fe, ferritin	Gluc
(elevated?)	Ca <sup>++</sup> , Mg <sup>++</sup>	RBP
Alb, transthyretin	Serum phosphorus	BUN, Creat
CRP		

## INTERVENTION

### OBJECTIVES

- Preserve kidney function.
- Control blood pressure.
- Acidify urine to decrease additional bacterial growth. Prevent bacteremia.
- Force fluids unless contraindicated.

### FOOD AND NUTRITION

- Restrict protein intake only if renal function is decreased. Otherwise, use sufficient amounts of high biological-value proteins, including foods such as meat, fish, poultry, eggs, and cheese.

## SAMPLE NUTRITION CARE PROCESS STEPS

### Inadequate Oral Food-Beverage Intake

**Assessment Data:** I & O records, nursing flow sheets for hospitalized elderly patient, coming from long-term care facility with UTI and temperature of 102°F. Diet Hx reveals poor intake for 3 days related to fever and anorexia. Signs of dehydration.

**Nutrition Diagnosis (PES):** NI-2.1 Inadequate oral food and beverage intake related to UTI with fever and resulting anorexia as evidenced by temperature of 102°F and I & O records showing very low intake for 3 days.

#### Interventions:

**Food-Nutrient Delivery:** Add extra fluids to trays and encourage 4 oz intake with all medications 3 times daily; goal is 30–35 mL/kg daily. Offer preferred foods; enhance with extra calories as needed (such as extra gravy with potatoes, extra margarine on bread). Include yogurt and cranberry juice if tolerated.

**Education:** Discuss the need to increase intake of fluids and nutrient-dense foods to support immunity, fight the infection, and reduce fever.

**Counseling:** Discuss food choices and ways to enhance total intake without being overwhelmed by large quantities of food.

**Coordination of Care:** Support the antibiotic therapy by providing high-quality food choices.

**Monitoring and Evaluation:** Temperature back to normal; resolution of UTI. Improved food and nutrient intake. Able to be discharged from hospital with guidance on how to prevent further dehydration and UTIs.

- Cranberries, plums, and prunes produce hippuric acid, which acidifies urine. Corn, lentils, breads/starches, peanuts, and walnuts also acidify the urine.
- Although vitamin C is not necessarily effective in lowering the UpH, sufficient levels of intake are needed to stimulate the anti-infective process.
- Avoid an excess of caffeine because of its diuretic effect. Stimulants such as caffeine rapidly leave the bladder, a vulnerable site where additional infections may begin.
- Vitamin A may be low; encourage improved intake, especially from beta-carotene-rich foods.
- Non-antimicrobial-based approaches undergoing investigation include probiotics, vaccines, oligosaccharide inhibitors of bacterial adherence and colonization, and bacterial interference with immunoreactive extracts of *E. coli* (Guay, 2009). Offer probiotic choices, such as yogurt or kefir, to replenish good intestinal bacteria.

## Common Drugs Used and Potential Side Effects

- Outpatient oral antibiotic therapy with a fluoroquinolone is successful in most patients with mild uncomplicated pyelonephritis (Ramakrishnan and Scheid, 2005).
- Ceftriaxone and gentamicin are cost-effective because only once-daily dosing is needed. With urinary anti-infectives, sufficient water and fluids should be ingested. Be careful with forced water diuresis, which impairs antibiotic effectiveness. Monitor responses to glucose changes in people with diabetes. Avoid use with alcohol.
- Liposome treatments are under study for interstitial cystitis. The interstitial cystitis-related liposomes coat the bladder and may reduce inflammation there.
- Nitrofurantoin (Furadantin, Macrochantin) should be consumed with food, milk, and a diet adequate in protein. Nausea, vomiting, and anorexia are common; diarrhea is rare.
- Penicillin products such as amoxicillin (Amoxil, Trimox, Wymox) and ampicillin may be used. With penicillin allergy, vancomycin may be used.
- Quinolones include ofloxacin (Floxin), norfloxacin (Noroxin), ciprofloxacin (Cipro), and trovafloxacin (Trovan). If Cipro (ciprofloxacin) is used, avoid taking with calcium supplements, milk, and yogurt; limit use of caffeine and monitor for nausea. If a fluoroquinolone (Floxin, Maxaquin) is used, nausea is a side effect. Take separately from vitamin supplements.
- Sulfisoxazole (Gantrisin) can deplete folacin and vitamin K. Nausea and vomiting may also occur.
- Trimethoprim (Trimex) and trimethoprim/sulfamethoxazole (Bactrim, Septra, Cotrim) may cause diarrhea, GI distress, and stomatitis. Use adequate fluid.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be used without discussing with the physician.
- Probiotics may be useful to prevent and treat recurrent complicated and uncomplicated UTIs. Blueberry, parsley, bearberry, yogurt, birch, and couch grass have been suggested, but no clinical trials have proven efficacy.

- Cranberry juice may be useful for women but not necessarily for the elderly who require catheterization (Jepson and Craig, 2008). It may be useful also for pregnant women (Wing et al, 2008).

### NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Indicate which foods are palatable as sources of nutrients for dietary restrictions and for nutrients that tend to be low.
- Encourage appropriate fluid intake. Schedule voiding frequency and fluid intake if needed.
- Discuss the use of probiotics to support a healthy immune system, especially after antibiotic use.
- Limit caffeine and oral fluid intake at night, if needed.
- Showers, instead of baths, may be preventive.

#### Patient Education—Food Safety

Foodborne illness can occur when there is contamination of food at any point during the preparation process. Because renal patients are at high risk for foodborne illness, follow the four-step guidelines established by the U.S. Department

of Agriculture: clean, separate, cook, and chill. More details are available at the Kidney Foundation Web site at <http://www.kidney.org/atoz/content/foodsafety.cfm>.

# Enteral and Parenteral Nutrition Therapy

## CHIEF ASSESSMENT FACTORS

- Availability of Appropriate Lab Work
- Benefits of Nutritional Intervention Outweigh Risks?
- Inadequate Oral Intake (Mechanical, Gastrointestinal, Psychological, or Surgical Reasons)
- Indirect Calorimetry (IC)<sup>a</sup>
- Nitrogen Balance<sup>b</sup>
- Other Planned Procedures and Impact of Delayed Nutrition Therapy
- Presence or Absence of Sepsis (in EN vs. PN)
- Risk for Refeeding Syndrome in Patients with Poor Intake, Maldigestion, and Malabsorption<sup>c</sup>
- Serial Anthropometric Measures
- Signs of Micronutrient Deficiency (selenium, copper, zinc)
- Systemic Inflammatory Response to Injury or Infection or Protein-Energy Undernutrition
- Surgery Affecting Oral Intake, Digestion, or Absorption
- Treatment, Timing, and Condition:
  - Cancer Having Intake or GI Consequences (Radiation, Chemotherapy, Surgery)
  - Cystic Fibrosis
  - Failure to Thrive, Chronic Malnutrition
  - GI Obstruction, Chronic Diarrhea, Crohn's Disease, Short Bowel Syndrome (SBS)
  - GI Disease from HIV Infection or AIDS
  - Organ Transplantation
  - Pancreatic Disease
  - Pulmonary Aspiration, Complications, or Ventilator Use
  - Sepsis, Trauma, Burns, or Other Causes of High Rates of Catabolism

<sup>a</sup>Indirect Calorimetry = measure of gas exchange based on oxygen used and carbon dioxide released, using the formula  $RQ = VCO_2/VO_2$

<sup>b</sup>Nitrogen Balance = net gain or loss of nitrogen per day; helps to determine if patient is in catabolic or anabolic state. 1 g Nitrogen = 6.25-g protein. N balance calculation = 24 hour protein intake (total g)/6.25 minus (24 hour UUN + 4)

Key: 0 balance implies equilibrium. 4–6 g (+) is anabolic/positive balance. Negative (–) implies catabolism. Goals: To maintain status, use 1-g N:200–300 kcal. For anabolism, use 1-g N:150 kcal. Interpretation: renal disease, liver disease, burns, or trauma may skew the results.

<sup>c</sup>Patients at risk for refeeding syndrome may have low serum levels of phosphorus (<3.0 mg/dL), magnesium (<1.3 mg/dL), and potassium (<3.5 mEq/L) from poor intake. Feeding causes increased demand for these electrolytes so the macronutrients provided can be utilized. The increased metabolic demand causes further drops in these levels

unless they are repleted BEFORE feeding is initiated. Reintroduction of carbohydrate after a period of 24–72 hours of fasting, when blood glucose and insulin levels have both declined, sends out a surge of insulin. This insulin surge pulls glucose and the electrolytes into the cells, leading to hypophosphatemia ( $<1.0$ – $1.5$  mg/dL), hypomagnesemia ( $<1$  mg/dL), and hypokalemia ( $<2.5$  mEq/dL) and life-threatening results, as it has cardiac, pulmonary, hepatic, renal, neuromuscular, metabolic, and hematological consequences (Tresley and Sheean, 2008).

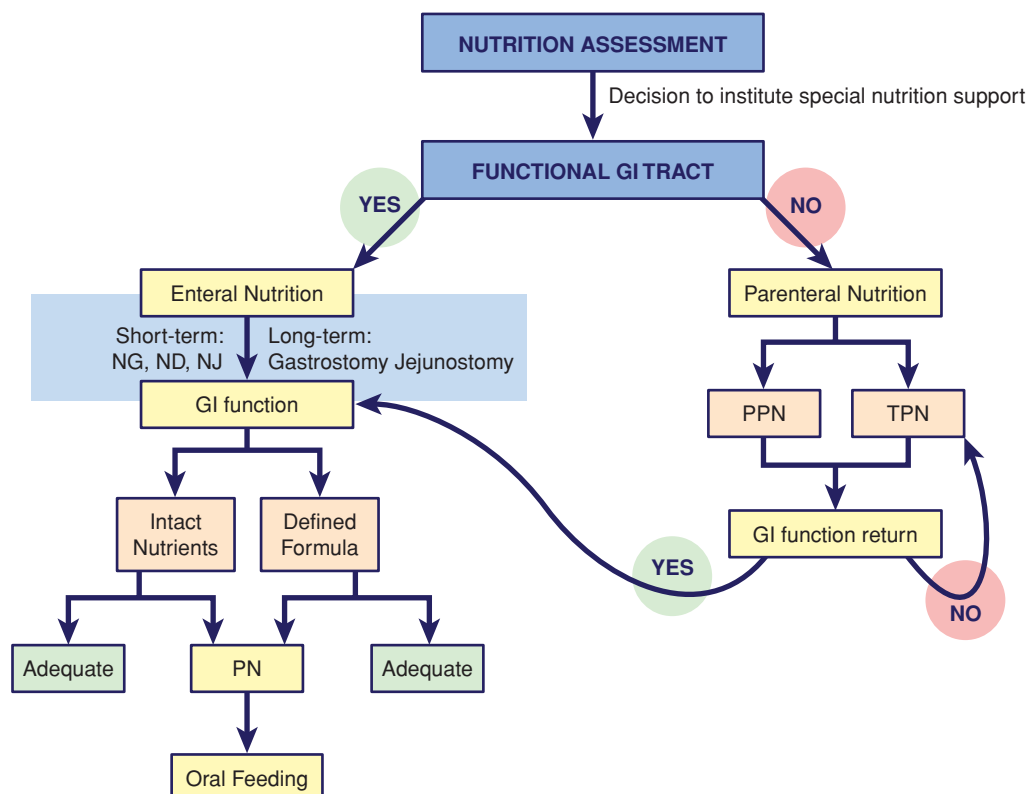

Note: Jensen et al (2009) indicate that the presence or absence of the systemic inflammatory response and whether the inflammation is severe or sustained distinguishes the forms of malnutrition described here. **Sarcopenia** is a smoldering inflammatory state partially driven by cytokines and oxidative stress, cachexia overlapping with failure to thrive. **Cachexia** as a systemic proinflammatory process with associated insulin resistance, increased lipolysis, increased lipid oxidation, increased protein turnover, and loss of body fat and muscle, as in pancreatic cancer or organ failure. **Marasmus** is pure starvation with reduced food intake or assimilation with loss of body cell mass and weight, but no underlying inflammatory condition; visceral proteins are generally preserved and edema is not present. If marasmic individuals subsequently develop inflammatory conditions and edema, the term **marasmic kwashiorkor** is used.

## OVERVIEW OF ENTERAL AND PARENTERAL NUTRITION THERAPY

There are about 1000 kcal available as glucose or glycogen in the muscles, liver, and bloodstream, supplying energy for only 18–24 hours. Daily glucose replacement is crucial for brain and red blood cell survival. When oral feeding is not possible or safe, nutrients should be replaced by other means. Specialized nutrition therapy includes both tube (enteral) and IV (parenteral) feeding methods and must be carefully planned and administered.

Nutrition therapy has grown steadily over the past four decades. Table 17-1 lists definitions important in nutrition therapy. Initially, central parenteral nutrition (CPN, formerly total parenteral nutrition or TPN) was the ultimate standard of care. Later, tube feeding (enteral nutrition [EN]) was

found to protect gut immunity and function more effectively. A critically ill patient who has been inadequately fed for 10–14 days will manifest characteristics of both the systemic inflammatory response and protein-energy undernutrition, even loss of up to 30% of body cell mass; nutrition modulation of the systemic inflammatory response can occur with early feeding (Jensen et al, 2009). Integrated approaches are required, including anti-inflammatory diets, glycemic control, physical activity and resistance training, appetite stimulants, anabolic agents, anti-inflammatory agents, anti-cytokines, and probiotics (Jensen, 2006). Because there are over 500 types of bacteria living in the human gut, the goal is to keep the healthy ones and reduce those that are detrimental. Temperature, osmolality, pH, and substrate availability can alter the host–bacteria relationship very quickly. Probiotics may help maintain the beneficial flora and reduce

**TABLE 17-1 ASPEN Definition of Terms Related to Nutrition Support**

**Admixture:** The result of combining two or more fluids

**Closed Enteral System:** A closed enteral container prefilled with sterile, liquid formula by the manufacturer, which is considered ready to hang

**Compatibility:** The ability to combine two or more products such that the physical integrity and stability of each product is not altered when combined

**Formulation:** A mixture of nutrients suitable for administration to a patient

**Hang Time:** The length of time a formulation is considered safe for administration to the patient beginning with the time the formulation has been compounded, reconstituted, warmed, decanted, or has had the original package seal broken

**Intravenous fat emulsion (IVFE):** An IV oil-in-water emulsion of oils, egg phosphatides, and glycerin; the term is used in preference to lipids

**Nutrition Support Process:** The assessment, diagnosis, ordering, preparation, distribution, administration, and monitoring of nutrition support therapy

**Nutrition Support Service (or Team):** An interdisciplinary group that may include physicians, nurses, dietitians, pharmacists, and/or other healthcare professionals with expertise in nutrition who manage the provision of nutrition support therapy

**Osmolality:** The measured osmotic concentration of a liquid expressed in osmoles or milliosmoles per kilogram of solvent (Osmol per kg or mOsmol per kg, respectively). Osmolality indicates the osmotic pressure exerted by a liquid across a semipermeable membrane

**Modular Enteral Feeding:** Formulation created by combination of separate nutrient sources or by modification of existing formulations

**Multichamber Bag:** A container designed to promote extended stability of a parenteral nutrition formulation by separating some components (e.g., IV fat emulsion) from the rest of the formulation

**Parenteral Nutrition:** The IV administration of nutrients

- **Central (CPN):** Parenteral nutrition delivered into a large-diameter vein, usually the superior vena cava adjacent to the right atrium
- **Peripheral (PPN):** Parenteral nutrition delivered into a peripheral vein, usually of the hand or forearm

**Preparation:** A food, drug, or dietary supplement (or mixtures thereof) compounded in a licensed pharmacy or other healthcare-related facility pursuant to the order of a licensed prescriber

**Product:** A commercially manufactured food, drug, or dietary supplement. Drug products are accompanied by full prescribing information, which is commonly known as the Food Drug Administration-approved manufacturer's labeling or product package insert

**Stability:** The extent to which a product retains, within specified limits and throughout its period of storage and use (i.e., its shelf life), the same properties and characteristics that it possessed at the time of its manufacture

**Standardized Parenteral Nutrition Formulation:** A parenteral nutrition formulation intended to meet the daily maintenance requirements of a specific patient population (e.g., age-, stress-, or disease state specific) and differentiated by the route of administration (central vs. peripheral vein)

**Total Nutrient Admixture:** A parenteral nutrition formulation containing IV fat emulsion as well as the other components of parenteral nutrition (dextrose, amino acids, vitamins, minerals, water, and other additives) in a single container

**Vascular Access Device:** Catheter placed directly into the arterial or venous system for infusion therapy and/or phlebotomy

Adapted from: ASPEN, <http://www.nutritioncare.org/>, accessed March 15, 2010.

those that are pathogenic. This can be especially useful in patients with *Clostridium difficile* or vancomycin-resistant enterococci (VRE) colonization and may even prevent ventilator-associated pneumonia. Taking yogurt containing live *Lactobacillus* GG daily as 100 g for at least 1 month may help. More studies are warranted. The American Society for Parenteral and Enteral Nutrition (ASPEN) recently updated their Clinical Guidelines for various ages and facilities (ASPEN, 2009). ASPEN has published a series of related documents that may be referred to when using these guidelines, available at their web site at: <http://www.nutritioncare.org/Library.aspx>. For pediatrics, where nutrition therapy is needed for many acute or chronic conditions, various guidelines are also available from ASPEN. One of the more recent documents addresses management of the obese, hospitalized pediatric patient (ASPEN, 2010). There are ASPEN guidelines for managing critically ill patients who need nutrition therapy and will be in the ICU for 2–3 days or longer (McClave et al, 2009). Critically ill patients are at high risk for infections, organ dysfunction, and death. Feeding obese, critically ill adults is a bigger challenge; they are at high risk for infectious complications, slow healing postoperative wounds, nosocomial infections, and mortality. Protein stores are mobilized and less protein is synthesized during critical illness. The goal

for feeding the critically ill obese patient is to attenuate hypermetabolism, lessen inflammation, and minimize catabolic losses. If the critically ill ICU patient is hemodynamically stable with a functional gastrointestinal (GI) tract, EN is recommended over parenteral nutrition (PN) because it has benefits such as less septic morbidity, fewer infectious complications, and significant cost savings (American Dietetic Association, 2010). Nutrition therapy is not always applied effectively or consistently, despite scientific evidence and protocols. PN must be carefully managed, especially since overfeeding may aggravate sepsis. Generally, if well managed, CPN is an effective alternative to EN in patients who cannot be fed via the GI tract. Payments for PN infusions, EN formulas, and prosthetic devices are managed under the U.S. federal guidelines. Therefore, prudent use of expensive products is expected. Generally, EN is preferred over PN where possible (American Dietetic Association, 2010; McClave et al, 2009). Advances in nutrition therapy and technology have contributed to improved quality of life for many patients in hospitals, long-term care, and home settings. Note that special guidelines should be used in home care, including an evaluation for sanitary preparation, administration, and storage of the products (Kovacevich et al, 2006). Home preparation tips for EN and parenteral (PN) therapies are available from a number

of hospitals, web sites, and formula companies. Selection of patients in long-term care who could receive tube feeding (TF) must include consideration of long-term goals and ethical issues. Because of the potential complications of permanent enteral access, percutaneous gastrostomy (PEG) or jejunostomy (PEJ) should be considered only when anticipated length of use is 1 month or longer (McMahon et al, 2005). When considering initiation of feedings, the treatment goal should be taken into account, whether palliative, curative, or rehabilitative. Additionally, the patient's wishes should be considered above all. In long-term care, the following flow chart is useful in designing protocols.

In a **coma (persistent vegetative state)**, the patient is completely unaware of self and the environment. This is accompanied by normal sleep-wake cycles and hypothalamic/brainstem autonomic functions. Coma may occur as a complication of an underlying illness or as a result of injury. Everyone who is in a coma has the nutrition diagnosis of "inadequate oral food and beverage intake" and requires some form of nutrition therapy to prevent malnutrition. While medically assisted nutrition can maintain life, it is

considered futile if it cannot improve the prognosis, comfort, or general status of health of an individual (Andrews and Marian, 2006). Nutrition therapy has not necessarily improved outcomes in end-stage cancer, dementia, or other terminal illnesses. Many healthy elderly persons do not desire to be tube fed, especially with advanced disease or dementia. EN is of questionable benefit for nursing home residents with advanced dementia, yet two thirds of U.S. nursing home residents on EN had their feeding tube inserted during an acute care hospitalization; this practice should be discouraged (Teno et al, 2010). Quality of life must be considered. Some patients have "nutritional distress" if they cannot eat orally (Winkler, 2010). Other individuals receiving long-term EN or home PN have expressed anger, anxiety, or depression resulting from losses of independence and control of body functions and from the altered psychological and emotional aspects of eating (Winkler, 2007). Dietitians must help the patient, family, or guardian in deciding whether to initiate, withhold, or withdraw nutrition therapy (Table 17-2). The social, legal, emotional, and ethical needs and wants must be considered

**TABLE 17-2 Ethics of Nutrition Support Therapy and End-of-Life Care**

*ASPEN Guidelines on Withholding or Withdrawing Nutrition Support*

Withholding or withdrawing nutrition support therapy often involves different considerations than other life-sustaining therapies, in part because of emotional, religious, and symbolic meanings

Legally and ethically, nutrition support therapy should be considered a medical therapy

The decision to receive or refuse nutrition support therapy should reflect the autonomy and wishes of the patient. The benefits and burdens of nutrition support therapy, and the interventions required to deliver it, should be considered before offering this therapy

Care providers should be familiar with current evidence of the benefits and burdens of nutrition support therapy

Patients should be encouraged to have living wills and/or advance directives and to discuss with their loved ones their wishes in the event of a serious or terminal accident or disease. This directive should include nutrition support therapy

Competent patients or the legal surrogate of incompetent patients shall be involved in decisions regarding withholding or withdrawing of treatment

Incompetent patients' wishes (as documented in advance directives) shall be considered in making decisions to withhold/withdraw nutrition support therapy.

If there is no family and the patient is not competent, consider a conference with the physician, nursing director, social worker, dietitian to discuss the feeding options

Nutrition support therapy should be modified or discontinued when there are disproportionate burdens or when benefit can no longer be demonstrated

Institutions should develop clear policies regarding the withdrawal or withholding of nutrition support therapy and communicate these policies to patients in accordance with the Patient Self-Determination Act

(continued)

**TABLE 17-2 Ethics of Nutrition Support Therapy and End-of-Life Care (continued)***Artificial Nutrition at the End of Life*

Treat each case individually

When oral feeding is medically appropriate as per swallowing examination, do not artificially feed. Minimize suffering and discomfort; provide comfort foods without dietary restrictions

In dysphagia without complications, recommend as patient usually benefits

In dysphagia with complications, determine if patient will equivocally benefit. Will the benefits outweigh potential risks?

In persistent vegetative state, do not recommend as patients are unable to experience satisfying quality of life

*The Dying Process, Palliative Care, Hospice*

*Dickinson Law School:* Starvation is a long, drawn out, and painful process that can take anywhere from 30 to 60 days. Dying patients who stop taking in food and fluids *do not* starve to death. While the body can sustain itself for up to 2 months without food, it can sustain itself no more than about 2 weeks (at most) without fluid intake. Unlike starvation, dehydration is typically not a painful or even an uncomfortable process, especially when good comfort care measures are undertaken. Many patients report less discomfort, and there is less request for pain medication as dehydration runs its course. Patients who stop taking food and fluids drift into a state of unconsciousness. This phase of the process may take 5–8 days if the patient is fully hydrated when food and fluid intake is stopped. Patients will typically die peacefully several days after that. If the patient is already partly dehydrated when fluid intake is stopped, the dying process will be compressed and may only last a couple of days or less.

*American Academy of Hospice and Palliative Medicine:* While most patients with complex medical conditions at the end of life do not experience hunger even with low energy intake, they do experience dry mouth.

*American Nurses Association:* It is not common to hydrate in the presence of symptoms of edema or vomiting.

*Pediatrics:* There is a need for more ethics education and more interdisciplinary discussion of inherently complex and stressful pediatric end of life cases. Appropriate goals of care and use of medically supplied nutrition and hydration are part of this educational process (Solomon et al, 2005).

with each individual. Full authorization to write diet, EN, and CPN orders expedites patient-centered care and expands the dietitian's responsibilities beyond traditional dietetic practice (Braga et al, 2006). When dietitians are granted full authority to implement nutritional recommendations, they write orders on the physician's order sheets, change existing orders, and implement new orders immediately. While state licensure boards differ on their defined scopes of practice, several have approved order writing capacity by dietitians.

# ENTERAL NUTRITION

## NUTRITIONAL ACUITY RANKING: LEVEL 4 IF AT HOME

Adapted from: Smeltzer SC, Bare BG, *Brunner & Suddarth's Textbook of Medical-Surgical Nursing*, 9th ed. Philadelphia, Lippincott Williams & Wilkins, 2000.

### DEFINITIONS AND BACKGROUND

EN makes it possible to provide important substrates for those who cannot or will not meet daily requirements via oral intake but who have an intact digestive system (Chen and Peterson, 2009). EN involves nutrition therapy via nasogastric tube, orogastric tube, gastrostomy, nasoduodenal or nasoenteric feeding, or jejunostomy. PN is reserved for conditions in which EN is contraindicated, unsuccessful, or inadequate. EN is economical, yields effective nutrient utilization, and maintains gut mucosal integrity. Trophic stimulation of the gut occurs with EN but not with PN. Trophic feedings of 10–30 mL/hr may prevent some gut atrophy but will not yield as much benefit as using a more sufficient quantity for the individual. Prevention of intestinal permeability, faster return of cognitive function, and better outcomes have been noted with EN versus PN. EN has also been associated with a reduction in infection rates, hospital-as-

sociated infectious complications, ventilator dependency, and intensive care use. Immunoglobulin A (IgA) prevents absorption of enteric antigens; IgA levels increase with EN but not with PN. Immunoenhancement occurs when arginine, glutamine, long-chain polyunsaturated fatty acids (PUFAs), omega-3 fatty acids, vitamins A, C, E, and ribonucleic acids have pharmacological effects. Arginine is an intermediary in the urea cycle, making urea and ornithine via arginase. It is also useful for ammonia detoxification and the synthesis of glutamate and nitric oxide. With infection, the body catabolizes more protein to provide substrate (citrulline) for *de novo* arginine synthesis. Thus, in stress, trauma, or catabolic states, arginine becomes conditionally essential. Most people consume 5–6 g daily of arginine from dairy, beef, poultry, seafood, soybeans, nuts, seeds, or wheat germ. Enteral formulas vary in content, with an average of 1–2 g/L; enriched formulas may be 12 g/L or higher. Improved wound healing and net nitrogen retention have

been noted with arginine supplementation. Glutamine is a primary substrate for the GI tract and lymphocytes; it helps to maintain acid–base balance. Because glutamine is a heat shock protein regulator, pneumonia, sepsis, and bacteremia are less frequent among patients who receive supplemented feedings. Glutamine is useful in attenuating the systemic inflammatory response syndrome (SIRS) response in highly stressed, critically ill patients (such as major elective surgery, trauma, burns, head and neck cancer, or ventilator patients). While its supplementation can decrease infectious complications, routine use is not warranted (American Dietetic Association, 2010).

There are some disadvantages of EN. Judicious use of EN should be considered in low birth weight or premature infants because feeding intolerance is common. Although EN is often started to prevent aspiration pneumonia from oral intake in stroke or demented patients, it may also increase the risk if positioning is poor or if tube placement is wrong. Tube dislodgement or occlusion, infection at the gastrostomy or jejunostomy site, hyperglycemia, azotemia, and fluid and electrolyte imbalances may also occur if not managed carefully. In some patients, maldigestion, malabsorption, abdominal distention, high residuals, nausea, vomiting, constipation, and other signs of GI intolerance are present. Home EN (HEN) for SBS, bowel obstruction, chronic pancreatitis, enterocutaneous fistula, cancer, or severe dysphagia requires careful and regular monitoring from the team.

The traditional assessments using albumin, transthyretin, and anthropometry are not useful in critical care settings. Weight loss prior to admission, disease severity, comorbidities or complications, and GI tract function are more useful. When possible, a nutritionally focused physical examination is needed, including state of hydration, abdominal examination for possible GI intolerance, state of consciousness, general overall appearance, body composition, presence of respiratory distress, nausea, vomiting, abdominal distention,

diarrhea, abdominal cramping, constipation, weight changes, hydration status, and abnormal laboratory values. As appropriate, malnourished patients at risk can be fed early without observed negative clinical consequences.

Early EN is beneficial if the patient is hemodynamically stable, depending on where the tube must be placed. Improved clinical outcomes, lower rates of infection, and decreased hospital stays have been observed when EN was initiated within 24 hours and advanced to goal within 48–72 hours. A review of 13 trials with 1173 GI surgical patients found that early commencement of feeding (within 24 hours) reduces risk of post-surgical complications, length of hospital stay, and mortality (Lewis et al, 2009).

Either gastric or small bowel feedings work well; the latter used when aspiration or intolerance is noted. After mechanical ventilator extubation, oral intake is often low and nutrition therapy may be needed (Peterson et al, 2010). When patients are hemodynamically unstable, EN is usually held or combined with PN as needed. Use of an ICU nutrition protocol increases the likelihood of patients receiving the proper nutrition therapy.

Pediatric nutrition therapy protocols are not readily available for critically ill children (Joffe et al, 2009). After intestinal failure with SBS, children are often dependent on PN. However, this dependency can lead to intestinal failure-associated liver disease (IFALD) unless transition to trophic feeds and, eventually, full EN is attempted (Le et al, 2010). Use of omega-3 fatty acids is under study for this population, and more research is needed for pediatric critical care.

Because tube-fed patients in long-term acute-care facilities may be routinely over- or underfed, monitoring how much feeding is actually given to a patient should be done to determine if needs are being met. Both underfeeding and overfeeding affect ventilatory status. Therefore, it is ideal to measure a patient's energy requirements using indirect calorimetry (IC) at least once, especially for the critically ill,

**TABLE 17-3** Consequence Statement: Not Feeding a Resident/Patient When Oral Intake Is Inadequate

"The clinical manifestations of protein-energy undernutrition are related to length of time and extent of nutritional deprivation and the prior health status of the person. On the basis of both animal and human studies, there are serious detrimental effects on the function of every organ system, including the **heart, respiratory muscles, and the brain**. When maintained on a prolonged semi-starvation diet, otherwise healthy individuals experience a **loss of heart tissue** that parallels their loss of body mass. Respiratory rate, vital capacity, and minute volume of ventilation also decrease. These **changes in pulmonary function** are thought to result from reduced basal metabolic rate that accompanies starvation. In addition, **liver function declines, kidney filtration rates decline, and nearly every aspect of the immune system is compromised**. Defective ability to fight bacterial and viral infections occurs. Starvation therefore leads to **increased susceptibility to infection, delayed wound healing, reduced rate of drug metabolism, and impairment of both physical and cognitive function**. If starvation is prolonged, complications develop, **leading eventually to death**."—Sullivan, D. *The role of nutrition in increased morbidity and mortality*. *Clin Geriatr Med*. 11:663, 1995.

Other documented consequences of not tube feeding a resident/patient who *will not or cannot* eat enough orally:

- **Dehydration** with increased risk of urinary tract infections, fever, swollen tongue, sunken eyeballs, decreased urine output, constipation, nausea and vomiting, decreased blood pressure, mental confusion, electrolyte disturbances
- **Decreased awareness** of environment from decreased glucose availability for the brain
- **Development of pressure ulcers** over bony prominences from lack of sufficient protein, calorie, vitamin, and mineral intakes and decreased body fat
- **Decreased ability to participate in activities of daily living** (self-feeding, dressing, bathing, toileting)
- **Low body weight and rapid, involuntary weight loss** that are highly predictive of illness and imminent death. (Note: seniors are especially unable to regain weight after a stress situation)

I, the undersigned, understand and acknowledge that these consequences have been reviewed with me. I am deciding not to tube feed \_\_\_\_\_ (resident/patient) and accept the outcome of this decision.

Signed: \_\_\_\_\_ Date: \_\_\_\_\_ Witness: \_\_\_\_\_ Date: \_\_\_\_\_

Power of Attorney, Guardian or Other Representative Witness: \_\_\_\_\_ Date: \_\_\_\_\_

obese, or in whom estimation of requirements are difficult (American Dietetic Association, 2010).

For terminally ill individuals, consider the patient's advance directives. When a patient's wishes are not known, TF is viewed as humane by many internists. The ramifications of not feeding a patient should be discussed with all parties (see example form in Table 17-3).

The definition of what constitutes gastric residual volumes as indicators of EN tolerance will vary. Volume of gastric residuals, which prompts holding or cessation of feeding, varies from one facility to the next. One high volume should probably not prompt the clinician to stop TF but to monitor carefully and recheck frequently. Optimal patient positioning, use of prokinetic agents to improve gastric emptying, continuous infusion, and abdominal examinations to evaluate for distention are helpful.

Medical nutrition therapy (MNT) for patients who are tube fed saves thousands of dollars per case each year. Nutrition support teams (NSTs) are associated with improved quality and cost-effective care. Teams are often able to decrease complications, decrease lengths of stay, and decrease readmission rates. While it is not beneficial to use EN in the first week for dysphagic stroke patients who are not malnourished, there is reasonable evidence for using it in low birth weight infants (trophic feeding), malnourished geriatric patients, perioperative patients, patients with chronic liver disease, and critically ill patients (Koretz et al, 2007). Fortunately, EN results in clinically relevant, statistically significant risk reduction for infectious complications, pancreatic infections, and mortality in patients with severe acute pancreatitis (Petrov et al, 2008).

The "CNSC" credential indicates basic competency for managing EN therapy. The National Board of Nutrition Support Certification (NBNSC) is responsible for awarding Certified Nutrition Support Clinician (CNSC), to those who pass the exam. The CNSC Registered Dietitian has clinical

expertise in nutrition therapy obtained through education, training, and experience. The CNSC assures optimal therapy for the nutrition diagnosis of "inadequate oral food and beverage intake" from a variety of etiologies. Interventions usually include alternative feeding methods for delivery of nutritional requirements. The CNSC practices in a variety of settings (acute facilities, subacute facilities, ambulatory/out-patient clinics, rehabilitation centers, long-term care facilities, home care, and hospice) and cares for patients of all age groups and types of illness.

Registered dietitians with special training and demonstrated competency in nutrition support therapy are able to evaluate, write, or recommend TF orders. A multidisciplinary approach works best for consideration of all medical, nutritional, and ethical issues. ASPEN published EN Practice Recommendations in 2009 that provide excellent, detailed recommendations (ASPEN, 2009). Standardized forms, protocols, clinical practice guidelines or pathways help provide predictable nutrition therapy outcomes for patients (Table 17-4). The American Dietetic Association (ADA) recommends four or more MNT services for adults who are receiving EN. The ADA Coding and Coverage Committee (CCC) is working diligently to expand coverage and reimbursement.

## ASSESSMENT, MONITORING, AND EVALUATION

## CLINICAL INDICATORS

**Genetic Markers:** The use of EN is not specific to genetic conditions.

Clinical/History	Lab Work	As Needed:	Ca <sup>++</sup> Hemoglobin and hematocrit (H & H) Transferrin	Chloride Respiratory quo- tient (RQ) (>1.0, energy delivery is excessive)	Prothrombin time (PT) International normalized ratio (INR)
Height	Initially and	C-reactive			
Weight	once weekly	protein			
Body mass index (BMI)	thereafter:	(CRP)			
Intake and	Glucose	Partial pressure			
output	(Gluc)	of carbon			
(I & O)	Na <sup>+</sup> and K <sup>+</sup>	dioxide			
Blood pressure	Phosphorus	(pCO <sub>2</sub> )			
(BP)	Magnesium	Partial			
Diarrhea	Blood urea	pressure			
Temperature	nitrogen	of oxygen			
Nausea,	(BUN)	(pO <sub>2</sub> )			
vomiting	Creatinine	Cholesterol			
Chest x-ray	(Creat)	(Chol)			
Residuals	Albumin	Triglycerides			
	(Alb)	(Trig)			

## INTERVENTION

## OBJECTIVES

- Prevent or reverse malnutrition, cachexia, impaired immunity, and loss of lean body mass related to inadequate oral food and beverage intake. If the gut works, use

**TABLE 17-4 Clinical Practice Guidelines for Nutrition Support**

Issue	Considerations or Evidence
EN vs. PN	When considering nutrition support in critically ill patients, strongly recommend that EN be used in preference to PN
Early vs. late EN	Recommend that standard, polymeric enteral formula be initiated within 24–48 hours after admission to an ICU
Formula composition of EN	Standard formula is acceptable for most patients
Positioning of patient for EN	When clinically feasible, patients should be placed in a 30–45° head of bed elevation during gastric feedings to decrease reflux of gastric contents into pharynx and esophagus and possibly to decrease pneumonia
Dose and actual delivery of EN	Actual delivery of threshold intake of approximately 14–18 kcal/kg/d or 60–70% of enteral feeding goal in the first week of ICU admission is associated with improved outcomes (e.g., length of hospital stay, time on ventilator, infectious complications), particularly when initiated within 48 hours of injury or admission
EN in combination with supplemental PN	When initiating EN, strongly recommend that PN not be used in combination with EN
Optimize delivery of EN	Start at the target rate, promotility agents (metoclopramide) or postpyloric feeding should be considered to reduce the gastric residual volume
Minimize risks in EN	Manage rate of advancement, check residuals, use bedside algorithms, consider motility agents, use small bowel vs. gastric feedings when needed, elevate head of the bed, use closed delivery systems, consider use of probiotics, and evaluate bolus administration
Dose of PN and composition of PN	Calculate needs for protein, carbohydrates, IV lipids, additives, vitamins, trace elements, and immune-enhancing substances
Insulin therapy	With elevated glucose levels (as in diabetes, infection, and sepsis), insulin therapy will help to achieve better control
Outcomes	Length of stay (ICU and hospital), quality of life, and specific complications should be considered: EN is associated with decreased infectious complications in comparison to PN
Tube placement	Placement of the tip of the feeding tube in the postpyloric position is associated with decreased gastric residual volume, a factor associated with reduced reflux of formula. Postpyloric feeding tube placement may not be necessary or feasible for all patients but may be useful in patients with large gastric residual volumes
Protocol	An enteral feeding protocol should address the following <ul style="list-style-type: none"> <li>• When to use enteral vs. parenteral feeding</li> <li>• When to initiate enteral feeding</li> <li>• Positioning of patient</li> <li>• Energy goal per kilogram BW per day</li> <li>• Policy not to use blue dye</li> <li>• Indications for holding feedings</li> <li>• Tube placement</li> <li>• Prokinetic/promotility agents</li> </ul>

## SAMPLE NUTRITION CARE PROCESS STEPS

## Swallowing Difficulty

**Assessment:** 71-year-old male recently discharged from hospital for GI bleeding. Status post-cerebral infarction (CVA) resulting in left hemiparesis, moderate dementia, HTN. Admitted to long-term care unit with PEG tube placed secondary to new-onset dysphagia.

**Medical HX:** GI hemorrhage, dementia with behavioral disturbances, hx of aspiration, dysphagia.

**Current Medications:** Aricept, Lasix.

**Height:** 67 in. **Current Weight:** 138.1 lb (62 kg). **IBW Range:** 133–162 lb. **IBW:** 100%. **BMI:** 21.6.

Most laboratories are within normal limits (WNL) except for slightly elevated BUN (25) and low albumin (2.8).

**Estimated Needs:** Energy (25–30 kcal/kg): 1550–1860 kcal; protein (1.0–1.25 g/kg): 62–77 g; fluids (30 mL/kg): 1860 mL.

**TF and Flush Order:** Enteral formula with 1.5 kcal/mL; 1 can or 240 mL, 5 times a day (6 AM, 10 AM, 2 PM, 6 PM, 10 PM). Bolus feeding via syringe. Flush tube with 50-mL water before and after medications. Flush tube with 100-mL water every shift.

**Nutrition Diagnoses:** Swallowing difficulty (NC-1.1) related to recent stroke as evidenced by abnormal video swallow study done by speech language pathologist upon admission to long-term care facility.

Increased need for protein (NI-5.1) related to inflammation and depleted visceral protein status as evidenced by a low albumin level of 2.8.

**Nutrition Interventions:** Administer enteral feeding as ordered (ND-2). Implement nutrition-related medication management (ND-6) of protein additive three times daily (TID).

Goal 1: no significant weight changes; no signs of dehydration.

Goal 2: no episodes of nausea, vomiting, diarrhea, constipation, or aspiration.

Goal 3: albumin level of 3.0 and other laboratories WNL.

**Monitoring and Evaluation:** Tolerating TF well; currently meeting daily estimated nutrition and hydration needs. Monitor monthly weights. Monitor tolerance to TF order. Monitor albumin and significant laboratories as ordered.

it and check tube placement, laboratories, electrolytes, and fluid boluses to be sure the patient is tolerating the product well.

- Write or edit **nutrition prescription** to provide adequate protein, carbohydrate, fat, vitamins, minerals, and water. Nitrogen needs will increase for burn, pressure ulcer, or trauma patients; the percentage of total kilocalories from protein should be increased in these cases. Aim for 100% of dietary reference intakes (DRIs) for vitamins and minerals; provide explanation if order is excessive or insufficient. Additional liquid vitamins and minerals may be needed if formula volume does not meet micronutrient needs. Alter TF prescriptions as appropriate according to results of the nutritionally focused physical examinations.
- Choose **timing** wisely. If the critically ill patient is adequately fluid resuscitated, EN should be started within

24–48 hours following injury or admission to the ICU (American Dietetic Association, 2010).

- Recommend or select **feeding tube** and **site/location** on the basis of clinical condition, GI anatomy, and anticipated length of treatment. For patients at high risk for aspiration, who will be fed longer than 1 month, try a PEG tube with continuous feeding. If aspiration persists, try a transjejunal tube with lower placement in the GI tract. Gastrostomy buttons have minimal complications, acceptable longevity, and good tolerance in children and adults.
- **Formula selection** includes type of feeding needed by individual, the disorder, viscosity, and kcal/mL. Elemental formulas should be limited to specific conditions in which digestion or absorption is impaired or in which polymeric diets have failed. See Table 17-5 for types of formula selections.
- Monitor patient **positioning**. The head of the bed should be elevated 30–45° during feeding. To decrease the incidence of aspiration pneumonia and reflux of gastric contents into the esophagus and pharynx, patients should be placed in a 45-degree head of bed elevation, if not contraindicated (American Dietetic Association, 2010). For the unconscious patient, turn to the side to help with gastric emptying. For intermittent or bolus feedings, keep patient on his/her right side or keep head of bed elevated for 30 minutes after feeding to prevent aspiration.
- Ensure **adequate free water** is provided (usually 30 mL/kg in young adults with normal renal function). Determine percentage of free water in the formula (usually 70–85%), and subtract this amount from estimated needs; flushes should provide the difference.
- Monitor for **signs of intolerance**; adjust formula type, volume, or concentration as needed:
  - With diabetic gastroparesis, tube feeding may not be well tolerated; insulin adjustments may be required.

TABLE 17-5 Sample Types of Formulas

Formula Type	Macronutrient Content
Blenderized	Whole protein, carbohydrates, and fats from regular foods and liquids blended together
Polymeric—1 kcal/mL	Intact proteins, complex carbohydrates, and mainly LCTs
Added fiber	Varies but usually polymeric
Energy Dense—1.5–2.0 kcal/mL	Varies but usually polymeric
Disease specific	Varies by condition (liver, renal, diabetes, HIV-AIDS)
Peptide based (semi-elemental; oligomeric)	Peptides of varying chain length, simple sugars, glucose polymers or starch and fat, combination of LCT/MCT
Elemental (monomeric)	Individual amino acids, glucose polymers, typically low in fat. Some with only 2–3% of fat as LCT
Immune enhancing	Varies but usually polymeric. Usually has arginine, glutamine, or RNA added
High nitrogen	May be polymeric or monomeric
Critical care	May be polymeric or monomeric

LifeART image copyright © 2010 Lippincott Williams & Wilkins. All rights reserved.

- Monitor fluid carefully in organ failure where fluid restriction is needed; a more concentrated product can achieve energy and protein goals.
- Evaluate medications or infection as potential causes of diarrhea or feeding intolerance.
- Fiber-added formulas may be appropriate with diarrhea or constipation.
- Optimal oral health, tight glycemic control, minimal use of narcotics, and continuous feedings are recommended for patients at high risk for aspiration.
- Evaluating **gastric residual volume (GRV)** is an optional part of a monitoring plan to assess tolerance; EN should be held when a GRV greater than or equal to 250 mL is documented on two or more consecutive occasions (American Dietetic Association, 2010). Replace aspirate for the electrolytes and gastric juice. Do NOT use blue dye added to the formula to test for aspiration (American Dietetic Association, 2010).
- **Weights** are also important. Patient should be weighed on same scale at regular intervals, wearing similar clothing. Check twice if weights differ significantly from previous weights.

## FOOD AND NUTRITION

- Calculate energy requirements and protein, fluid, and nutrient needs according to age, sex, and medical status. See Table 17-6 for considerations.
- For weight loss, 20 kcal/kg is recommended. Use 25 kcal/kg to maintain weight, 30 kcal/kg with mild stress factors, and 35–40 kcal/kg in moderately stressed patients.
- Protein is generally 0.8–1.0 g/kg to maintain status, 1.25 g/kg for mild stress, 1.5 g/kg for moderate stress, and

1.75–2.0 g/kg for severe stress, trauma, or burns. The critically ill may need more calories and protein than other patients.

- Estimate fluid needs at 30–35 mL free H<sub>2</sub>O/kg body weight (BW) or 1 mL/kcal.
- Check patient's tolerance and side effects; alter formula content as appropriate. Sample new products to determine costs and convenience for home or institutional use. Numerous EN formulas are currently available, with a large portion of them targeting specific disease conditions (Chen and Peterson, 2009).
- Flush tubing with water (25–100 mL) every 3–6 hours for tube patency and before/after medications are given.
- With a gastrostomy tube, bolus or intermittent feeding is possible. For postpyloric or transpyloric placement, cyclic feedings may be better tolerated than continuous feedings.
- If the patient is in transition back to oral diet or works during the day, night feeding may be used. It may be more energy efficient than continuous feeding over 24 hours.
- Interdisciplinary teamwork is a crucial factor. The following guidelines are useful for managing tube feeding and transitioning from tube to oral feeding. (See figure on page 909)

## Common Drugs Used and Potential Side Effects

Drug–nutrient interactions are complex and can cause malabsorption of either the drug or the nutrient in tube feedings. Depending on the physical properties of a drug, it may be absorbed in a limited area of the GI tract or along much of the entire length. Monitor carefully for toxicity. Flush with 5- to 10-mL water after each medication is administered to prevent clogging.

- Antibiotics, H<sub>2</sub>-receptor antagonists, and sorbitol elixirs alter gut flora and can cause diarrhea because of their high osmolality.
- Antidiarrheal drugs can be used to slow GI motility. Their use should not preclude a carefully planned fiber intake. Dry mouth is one common side effect.
- Metoclopramide (Reglan) has been used to prevent reflux and aspiration in patients who are tube fed. Administration 10 minutes before tube insertion seems to increase success rate of tube passage. Gastric motility and relaxation of the pyloric sphincter are improved with this drug. However, chronic use may dislodge gastrostomy tubes; monitor closely.
- Phenytoin (Dilantin) administration should be separated from TF by 1–2 hours to prevent decreased medication absorption. TF rate may need to be recalculated, accounting for time TF is held before and after phenytoin administration, and adjusted accordingly.

## Herbs, Botanicals, and Supplements

- Herbs and botanical supplements should not be mixed with enteral feedings without discussing with the physician and the pharmacist.
- Gastric feeding supplementation with ginger extract might reduce delayed gastric emptying, but more research is needed.

**TABLE 17-6 Key Enteral Issues**

Issue	Comments
<b>Feeding site selection</b>	Consider any GI impairments or inability to absorb nutrients, vomiting, severe and persistent diarrhea, respiratory disease or skull surgery/fracture, or tendency to remove tubes by choice or inadvertently
Nasogastric	Often used for temporary needs; tube placed into stomach from the nose
Nasoenteric	For patients with impaired gastric emptying or in whom a gastric feeding is contraindicated
Nasojejunal	For patients at risk of pulmonary aspiration or with GI problems that preclude stomach placement such as mechanical problems or problems with gastric emptying or tolerance
Gastrostomy	Surgical incision or endoscopically placed PEG. Allows long-term feeding. A low-profile device (button) can be used for long-term feedings or for improved body image
Jejunostomy	Surgical incision into the jejunum to bypass inaccessible areas of the duodenum such as with SBS or obstructions from cancer, adhesions, stricture, or inflammatory disease. PEJ is a PEG with a transjejunal limb. A jejunostomy tube may cause some bowel necrosis; monitor carefully
Gastrojejunostomy	Good for small bowel feeding when stomach must be decompressed
<b>Contraindications for tube feeding</b>	Severe malabsorption; severe, intractable diarrhea
<b>Formula selection</b>	It is generally more cost effective to have an enteral formulary established, including multiple products, but one main brand of each category (e.g., standard/isotonic, isotonic with fiber, high-nitrogen isotonic, elemental, high-protein/high calorie for stress, critical care products, concentrated for patients with volume intolerance, malabsorption, specialty products for pulmonary or diabetes or immunocompromised, renal, or hepatic patients)
Elemental vs. intact formulas	No superiority has been documented for elemental. Peptides may be used for most patients
Substrates	Carbohydrate, protein, and fat (consider patient's ability to digest and absorb nutrients)
Tolerance factors	Osmolality, calorie, and nutrient densities. In general, more free water is needed with a more concentrated formula
<b>Fluid needs</b>	Generally, 1 mL/kcal is recommended, unless patient needs fluid restriction; 30 mL/kg is most common for adults. Elderly individuals may require slight alterations, depending on organ function. Children must receive adequate fluid, calculated by body weight
Organ failure	Heart failure, renal failure, or liver failure with ascites; 20 mL/kg can also be used initially, progressing to 25 mL/kg as tolerated
Risk for dehydration	Risk of abnormal losses due to GI drainage, diarrhea, and dehydration, and for those with other needs for extra water, 35–40 mL/kg may be used
<b>Delivery methods</b>	Patient tolerance is a key. Goal: meet needs without complications such as nausea, vomiting, diarrhea, or glucosuria
Bolus	Set amount given every 3–4 hours as a rapid syringe feeding; this closely resembles an oral diet for patients who are ambulatory or with long-term and well-established feedings
Continuous	Controlled delivery of feeding over 24 hours. Less nausea and diarrhea are likely. Once stable, most patients may transfer to intermittent
Cycled	Controlled delivery over 8–16 hours, allowing some rest periods for patient during 24 hours. Cyclic is well tolerated by ambulatory patients
Intermittent	Prescribed amount given every 3–4 hours by drip over 20–30 minutes
<b>Complications</b>	Evaluate for metabolic complications. Electrolyte shifts and elevated glucose may occur; an insulin regimen may be needed until hyperglycemia is resolved
Aspiration	Proper positioning greatly reduces risks of pulmonary aspiration
GI side effects	For GI concerns, check for residuals and hold feedings for amounts greater than 150 mL; stop for 4 hours and recheck. For diarrhea, check osmolality of feeding, rate, albumin level, and medications (e.g., sorbitol, magnesium)
Mechanical ventilation	Use enteral nutrition with H <sub>2</sub> antagonists to facilitate gastric emptying
PEG tube problems	Possible complications include pain at the PEG site, leakage of stomach contents around the tube site, dislodgment or malfunction of the tube, aspiration, bleeding, and perforation
Tube clogging	Small-bore tubes are associated with clogging. To prevent or correct mechanical clogging in small-bore tubes, flush regularly with water before and after all medications

## INTERDISCIPLINARY NUTRITION CARE PLAN

### Transitioning from Tube Feeding to Oral Diet

Client Name: \_\_\_\_\_ #: \_\_\_\_\_ Initiated by: \_\_\_\_\_ Date: \_\_\_\_\_

#### SCREENING

Nutrition Screen diagnosis: Transition From Enteral Tube Feeding to Oral Intake

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### ASSESS (Check any/all)

☐ Oral feeding readiness

☐ Dehydration

☐ Poor strength

##### Weight/BMI

☐ Weight change >3 lb/wk, >5%/mo, or >10%/6mo

☐ BMI <20

☐ BMI <27

##### Poor Oral Intake Symptoms

☐ Lack of appetite

☐ Complex diet order

☐ Vomiting

☐ Decreased ability to chew/swallow

☐ Nausea

☐ Depression/anxiety

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

1 or more

#### HIGH-RISK INTERVENTIONS (Check any/all)

☐ 4 Ways to Improve Nutrition

provided and explained

☐ Food Record provided and explained

☐ Fluid intake stressed

##### Obtain Dr. orders as needed:

☐ RD referral for home visit/nutrient analysis

☐ Speech Language Pathologist (SLP) referral for oral feeding readiness/problems

☐ Tube feeding

☐ Monitor weight q: \_\_\_\_\_

☐ Monitor I & O q: \_\_\_\_\_

☐ BID/TID supplements

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

Next visit

#### ASSESS RESPONSE (Check any/all)

☐ Further weight loss

☐ Continued dehydration

☐ Continued loss of strength

☐ Cannot tolerate oral feeding

☐ Exhibiting Poor Oral Intake Symptoms

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

1 or more

#### OUTCOMES NOT ACHIEVED

Reassess/evaluate need for further enteral feeding. Document on Nutrition Variance Tracking form.

#### GOALS (Check any/all):

☐ Maintain or improve nutritional status in \_\_\_\_\_ (goal time).

☐ Increase weight by \_\_\_\_\_ lb in \_\_\_\_\_ (goal time).

☐ Successful transition from enteral tube feeding in \_\_\_\_\_ (goal time).

☐ Maintain or improve hydration status in \_\_\_\_\_ (goal time).

☐ Increase oral intake to meet nutritional needs in \_\_\_\_\_ (goal time).

#### MODERATE-RISK INTERVENTIONS (Check any/all)

☐ H4 Ways to Improve Nutrition provided and explained

☐ Food Record provided and explained

☐ Fluid intake discussed and encouraged

##### Obtain Dr. orders as needed:

☐ RD chart consult

☐ SLP chart consult

☐ Monitor Weight q: \_\_\_\_\_

☐ BID/TID supplements

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

Next visit

#### ASSESS RESPONSE (Check any/all)

☐ Further weight loss

☐ Dehydration

☐ Poor strength

☐ Cannot tolerate oral feeding

☐ Exhibiting Poor Oral Intake Symptoms

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES ACHIEVED

☐ Oral diet tolerated

☐ Weight gained

☐ Hydration status maintained or improved

☐ Absence of Poor Oral Intake Symptoms

☐ Strength maintained or improved

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

☐ Repeat Nutrition Risk Screen in \_\_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

#### OUTCOMES ACHIEVED

☐ Oral diet tolerated

☐ Weight gained

☐ Hydration status maintained or improved

☐ Absence of Poor Oral Intake Symptoms

☐ Strength maintained or improved

☐ Other: \_\_\_\_\_  
(See notes for documentation.)

☐ Repeat Nutrition Screen in \_\_\_\_\_ days

Signed: \_\_\_\_\_ Date: \_\_\_\_\_

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Patient/caretaker should be taught to review signs and symptoms of intolerance, how to manage simple problems, when to call for registered dietitian (RD) guidance versus when to call the physician.
- At least one follow-up phone call or home visit should be made to patients on HEN.
- Patient should be allowed and encouraged to maintain social contacts at mealtime.
- When transitionally weaning young children to an oral diet, oral-motor, sensory, and developmental feeding problems may occur. Check for feeding readiness via oral stimulation and develop a feeding plan.

### Patient Education—Formula Safety

- Safe preparation of TF is essential. Homemade feedings are not recommended in most cases.
- Table 17-7 describes a Hazard Analysis Critical Control Points (HACCP) procedure for maintaining a safe enteral

feeding system in the hospital setting. Hang time for open-system containers (feeding bags) is 4 hours; hang time for closed-system containers is 24–48 hours.

- Always wash hands carefully and sanitize counter before handling the equipment or preparing the formula. Use a clean tube each time; wash in dishwashing liquid and rinse well between uses.
- Wash feeding bags with water. Do not use soap as it will stick to the inside of the bag and get into the formula and may lead to diarrhea and other unpleasant consequences.
- Temperature standards for refrigeration and storage of enteral feeding product must be met.
- Open cans of formula could be kept in the refrigerator and discarded if not used within 24 hours. Take out and allow to warm up to room temperature 15–20 minutes before a feeding. Feedings should be given at room temperature to minimize risk of cramping or diarrhea. Unopened commercially prepared formulas do not require refrigerated storage.
- Always flush the feeding tube with water after a feeding to prevent dehydration and prevent the food from getting clogged. The RD should always monitor that the feeding

**TABLE 17-7 Critical Control Point Checklist for Tube Feedings**

#### *Purchasing, Receiving, and Storage*

- Enteral feeding product(s) received according to specification
- Temperature standards for refrigeration and dry storage of enteral feeding product(s) met
- Product usage according to FIFO (first in, first out); those exceeding expiration date returned/discarded
- Liquid protein module and frozen shakes (labeled with date) placed in refrigerator for thawing
- Open cartons discarded after 48 hours
- Unopened and unused thawed liquid protein module discarded after 5 days
- Unopened and unused thawed shakes discarded after 12 days
- Medium-chain triglyceride oil, dry carbohydrate powder, and protein powder stored at room temperature; labeled with date opened. Opened cases and unused bottles/cans discarded after 1 month
- Inventory of reconstituted, mixed enteral formulas and portioned protein, fat, and carbohydrate modules reveals none are past expiration date
- Prepared enteral feedings kept separate from raw or processed food items and cleaning compounds

#### *Preparation and Delivery*

- Employees wash hands prior to preparing enteral feedings or modular components
- Cleaned and sanitized surface and equipment used to prepare enteral feedings or modular components
- Enteral formula prepared according to recipe
- Tap water used to reconstitute pediatric powdered formulas and Ceralyte; distilled or sterile water used in the preparation of enteral formulas upon specific order
- Reconstituted mixed enteral formulas and portioned protein, fat, and carbohydrate modules sealed and labeled (formula, rate of administration, patient name and room number, date prepared)
- Temperature standards for refrigerated storage of reconstituted, mixed enteral formulas and portioned protein, fat, and carbohydrate modules met
- Nursing staff washes hands prior to handling feedings and administration systems
- Nursing staff avoids touching any part of the container or administration system that will come in contact with the feeding
- Nursing staff assembles feeding system on a disinfected surface and inspects seals/reservoirs for damage
- Medications are not added to feeding unless necessary. If added, tube is flushed with tap water (or as specified) after administration
- Date/time each component of feeding system; also feeding bag is labeled with patient name and formula
- Hang time of feeding limited to 4 hours
- Feeding bags completely emptied of product prior to pouring newly opened product into the bag
- Disconnected sets are capped
- Container is positioned to prevent reflux of feeding up set
- Feeding tube is irrigated with tap water (or as specified)
- Administration sets changed every 24 hours

and flushes provide sufficient water. If the tube clogs, try 100 mL of cola or a small amount of meat tenderizer to rinse.

## PARENTERAL NUTRITION

### NUTRITIONAL ACUITY RANKING: LEVEL 4 (HOME)

Adapted from: Neil O. Hardy, Westpoint, CT.

### DEFINITIONS AND BACKGROUND

PN refers to IV nutrient admixture administered into the blood with a catheter placed in a vein. PN contains protein, carbohydrate, fat, vitamins, minerals, or other nutrients and is referred to as CPN if it meets the needs of the patient.

CPN can meet estimated nutritional needs, promote nitrogen balance, and improve anabolism. When there is a risk of malnutrition and EN is not tolerated or where there is gut failure, CPN is safe and encouraged. Start CPN only if EN attempts have failed; delay for at least a week unless malnour-

ished before admission to a critical care unit. Short-term CPN is not recommended, especially for 1–2 days. Some medications can be infused into a parenteral solution, such as heparin, insulin, ranitidine; Y-site coinfusion saves time for the nursing staff.

Disadvantages of PN include pneumothorax, infection from the central line, metabolic complications, and the potential for overfeeding. Overfeeding may lead to sepsis. Finally, PN is more expensive than EN and oral diets and does not provide support for healthy gut immunity.

CPN and peripheral PN (PPN) are options for IV feeding. Indications for PPN include temporary losses of GI function (e.g., acute ileus) and occasions when short-term use is indicated such as after minor GI surgery. CPN may be most useful in patients undergoing surgery for esophageal or stomach cancers, in preoperative GI patients who are severely malnourished, and in patients with prolonged GI tract failure. Other indications for adults are listed in Table 17-8.

PN is used judiciously in metastatic cancer or chronic obstructive pulmonary disorder (COPD) because of complications, costs, and decreased quality of life (Ferreira et al, 2005; Joque and Jatoti, 2005). The limited nutritional response of cancer patients to PN reflects the metabolic derangements of cachexia; in nonsurgical, well-nourished oncologic patients, routine PN is not recommended because it offers no advantage and is associated with increased morbidity (Bozzetti et al, 2009). It may sometimes be used in long-term home care to manage radiation enteropathy.

Initiation of PN and metabolic complications are best managed by an expert in nutrition therapy. The skills that distinguish them from other practitioners include competency in fluid and electrolyte monitoring, acid-base monitoring, metabolic monitoring, management of refeeding syndrome, and related areas. Specially trained and certified registered

**TABLE 17-8 Candidates for Central Parenteral Nutrition (CPN) in Adults**

1. Someone with a nonfunctional or inaccessible gastrointestinal tract
  - a. Massive bowel resection or SBS
  - b. Radiation enteritis
  - c. Ischemic bowel or bowel obstruction
  - d. Chronic, severe malabsorption
  - e. Inflammatory bowel disease, gastrointestinal obstruction, inflammatory adhesions
  - f. Severe diarrhea as in AIDS when enteral feeding is not successful
  - g. Enterocutaneous fistula—high-output, proximal fistula
2. Someone who cannot be adequately nourished with an oral diet or enteral nutrition (EN)
  - a. After bone marrow transplantation, specifically in cases of graft vs. host disease accompanied by inadequate oral intake
  - b. Intractable vomiting such as hyperemesis gravidarum
  - c. In pregnancy when oral intake is compromised and when EN is not tolerated, as with SBS
  - d. After major surgery when enteral access cannot be established
3. Someone with inadequate oral and enteral intake anticipated to persist for at least 7–14 days
  - a. Severely catabolic patients whose gut cannot be used within 3–5 days (such as closed head trauma, fractures, burns)
  - b. Cases with a high risk of aspiration
  - c. Severe acute necrotizing pancreatitis when EN fails after a trial of 5–7 days
  - d. Home parenteral nutrition (HPN) may be suggested for malnourished cancer patients who have a reasonable prognosis and cannot have EN

dietitians may write PN orders if granted clinical privileges by their institution or facility. To determine energy and nutrient requirements accurately, IC and use of programmed calculation software are recommended to prevent administration of excessive glucose and energy. The main consideration when administering fat and carbohydrates in PN is to prevent overfeeding the patient. (Braga et al, 2009).

Perioperative nutritional therapy can minimize negative protein balance by avoiding starvation; maintaining muscle, immune, and cognitive function; and enhancing postoperative recovery. Giving 7–10 days of preoperative PN improves postoperative outcome in patients with severe undernutrition who cannot be adequately orally or enterally fed (Braga et al, 2009).

Adequate nutrition therapy criteria include reaching a nutritional goal within 72 hours after initiation. PN may be given by continuous or cyclic infusion, altered according to patient tolerance. In most cases, gradual transition from PN to EN or oral nutrition is required to prevent periods of inadequate nutrition. The energy deficit accumulated by underfed ICU patients during the first days of stay may play an important role in outcomes for long-staying patients; how to reach calorie requirements by PN without harming the patient is a subject of debate (Singer et al, 2010).

With proper training and monitoring, CPN may be performed safely at home. CPN will drip through a needle or catheter placed into the central vein for 10–12 hours, once a day or five times a week. However, dependence on PN significantly impacts quality of life. Travel, sleep, exercise, and

leisure activities are altered by home PN; quality of life issues must be addressed for each individual (Winkler, 2010).

## ASSESSMENT, MONITORING, AND EVALUATION

### CLINICAL INDICATORS

**Genetic Markers:** PN is used for a variety of conditions; some of which have a genetic origin.

Clinical/History	Transthyretin	Hemoglobin
Height	Triglycerides	and
Weight	(if receiving	hematocrit
(measure	IVFEs)	(H & H)
daily)	Urinary Gluc	Transferrin
BMI	Twice Weekly at	Chloride
Resting energy	First, Then As	Respiratory quo-
expenditure	Needed:	tient (RQ)
(REE)	Albumin	(>1.0, energy
BP	(Alb)	delivery is
I & O (monitor	Calcium (Ca <sup>++</sup> )	excessive)
continuously)	Magnesium	Prothrombin
Edema	(Mg <sup>++</sup> )	time (PT)
Skin turgor	Phosphate	International
Chest x-ray	Aspartate	normalized
Physical signs of	aminotrans-	ratio (INR)
malnutrition	ferase	Serum and
	(AST)	Urine Osmo-
	Alanine amino-	lality
	transferase	N balance
Daily:	(ALT)	Serum selenium
Glucose	As Needed:	Amylase, lipase
(Gluc)—	C-reactive	Bilirubin
every 6 hours	protein	Serum ammonia
until stable	(CRP)	Serum Fe
CBC, Na <sup>+</sup> and	Partial pressure	Serum folacin,
K <sup>+</sup> , Blood	of carbon	B <sub>12</sub>
urea nitrogen	dioxide	White blood cell
(BUN)—daily	(pCO <sub>2</sub> )	count, TLC
for in-patients	Partial pressure	
Initially and	of oxygen	
once weekly	(pO <sub>2</sub> )	
thereafter:	Cholesterol	
Creatinine	(Chol)	
(Creat)		

## INTERVENTION

### OBJECTIVES

- If early EN is not feasible in first 7 days of hospitalization for a malnourished patient, consider PN to replete lean body mass.
- Assess estimated needs using IC, where possible. Determine appropriate patient requirements for calories, protein, vitamins, minerals, and fluid.

## SAMPLE NUTRITION CARE PROCESS STEPS

**Inadequate Oral Food and Beverage Intake**

**Assessment:** BMI: 23. Loss of 12# in past year from inflammatory bowel disease and recent intestinal surgery to remove a small segment of the colon. Status 1 week postoperation; not tolerating enteral feedings at this time. Central line placed for CPN feedings. Most laboratories are WNL.

**Estimated Needs:** Energy (30–35 kcal/kg): 1700–1920 kcal; Protein (1.25 g/kg): 75 g. Fluids (30 mL/kg): 1700 mL. PN Order: Start CPN as directed by RD consultation.

**Nutrition Diagnoses:** NI-2.1 Inadequate oral food and beverage intake related to inability to eat orally because of IBD, GI distress, intestinal surgery as evidenced by weight loss of 12# in past year and intolerance for enteral feeds.

**Nutrition Interventions:** Write and administer CPN infusion to meet energy, protein, and fluid requirements without overfeeding.

Goal 1: very gradual increase in weight; no signs of dehydration or refeeding syndrome

Goal 2: no sepsis, fever

Goal 3: laboratories WNL

**Monitoring and Evaluation:** Tolerating CPN well; currently meeting daily estimated nutrition and hydration needs. Monitor weekly weights, tolerance to CPN order, significant laboratories as ordered.

- Fat and carbohydrate (CHO) make the balance of non-protein calories after protein needs are estimated. When hypertonic dextrose is provided in substantial amounts without protein, mortality is high; CPN should provide balanced macronutrients and micronutrients (Jensen et al, 2009).
- Formulate solutions according to individual needs. For renal patients, review fluid and electrolytes and monitor essential amino acids (EAAs) in the solution. For hepatic patients, evaluate needs for fluid, electrolytes, and specialty amino acid solutions. For pulmonary conditions and diabetes, increased fat content and decreased dextrose may be needed.
- Maintain aseptic technique in all procedures for safe parenteral therapy. IVFEs support rapid growth of microorganisms, and PN solutions containing these fat emulsions should be changed every 12 hours. All PN solutions regardless of IVFE content should be used within 24 hours.
- Avoid substrate shifts. Because glucose abnormalities occur in >90% of patients, monitor plasma glucose often and adjust the insulin dose as needed.
- Avoid suddenly stopping constant concentrated dextrose infusions, which can cause hypoglycemia.
- Prevent refeeding syndrome. The hallmark sign is hypophosphatemia, along with neurologic, pulmonary, cardiac, neuromuscular, and hematologic complications. Dextrose infusion followed by increased insulin release causes shifts in phosphorus, potassium, and magnesium, often within 2–4 days of starting to feed. This sudden shift from fat to carbohydrate metabolism increases the

basal metabolic rate and may lead to confusion, coma, convulsions, or death.

- Prevent or correct other complications associated with PN: weight gain over 2 lb or 1 kg daily, indicating syndrome of inappropriate antidiuretic hormone; mouth sores; skin changes; poor night vision; fluid overload; cardiac arrhythmias; metabolic bone disease. Catheter-related sepsis occurs in about 50% of patient cases. Manage liver complications that are common in young children.
- Select patients carefully. The incidence of inappropriate PN prescription is low when multidisciplinary NSTs are closely involved and when written guidelines are used (Kohli-Seth et al, 2009).
- Maintain fluid requirements. Avoid fluid overload that is more common than dehydration.
- Prevent essential fatty acid deficiency (EFAD); need 2–4% linoleic acid (LA) (as from soybean, corn, sunflower, or safflower). Avoid excesses.
- For home PN, support patient goals to continue usual activity, employment, and a pleasant daily life.
- Transition back to EN or oral intake, when and if feasible.

## FOOD AND NUTRITION

- Calculate needs for PN related to requirements for energy, protein, fluid, vitamins, and minerals. The commonly used formula of 25 kcal/kg ideal body weight furnishes an approximate estimate of daily energy expenditure and requirements; in severe stress, requirements may approach 30 kcal/kg (Braga et al, 2009). CPN usually provides water (30–40 mL/kg/d), energy (30–60 kcal/kg/d, depending on estimated needs), amino acids (1–2.0 g/kg/d, depending on catabolism), essential fatty acids, vitamins, and minerals.
- Children need energy (up to 120 kcal/kg/d) and amino acids (up to 2.5 or 3.5 g/kg/d). They may also need a different fluid requirement. For neonates, use lower dextrose concentrations (17–18%).
- In older patients, lower glucose tolerance, electrolyte and micronutrient deficiencies, and lower fluid tolerance are common (Sobotka et al, 2009). In heart or renal failure, patients may need a fluid restriction.
- Dextrose monohydrate in CPN yields 3.4 kcal/g, not 4 kcal/g. For unstable blood glucose, use fat at 10–20% of energy intake; avoid overfeeding and consider use of insulin. Maximum rate of glucose infusion should not exceed 5–6 mg/kg/min, the rate of glucose oxidation or utilization.
- Amino acid infusions should not include enhanced arginine in sepsis, whereas it can be beneficial in postsurgical patients. Glutamine deficiency is common in critical illness, inflammatory bowel disease and stress; it is available for IV use but not in the United States. Glutamine infusion should not be used in hepatic encephalopathy. For liver failure or non-dialyzed renal insufficiency, reduce protein content and use a high percentage of EAAs.
- Fat should be given daily as an energy source. A 10% IVFE generally yields 1.1 kcal/mL. IVFE should not exceed 2.5 g/kg in adults or 1 g/kg in septic patients.

- Give 2–4% total kilocalories as LA to prevent EFAD. Avoid excessive use of LA, which is metabolized to the immuno-suppressive and proarrhythmic arachidonic acid and to prostaglandins, thromboxanes, and leukotrienes. The omega-3 fatty acids (alpha-linolenic [ALA], docosapentanoic acid [DPA], DHA, EPA, gamma linolenic acid [GLA]) promote vasodilation, enhanced immunity, decreased inflammation and platelet aggregation, and antiarrhythmic effects.
- Medium-chain triglyceride (MCT) oil is made from coconut or palm oils but contains no EFA. In sepsis, transport of long-chain triglycerides (LCT) is impaired; MCT may be useful because no carnitine or lipases are needed.
- Structured lipids that contain a mixture of fish oil (Omegaven) and olive oil (Clinoleic) may provide better tolerance and fewer infections (Hardy and Puzovic, 2009). They are useful for decreasing the time needed for ventilator support in respiratory patients. Fish oil IV lipids are available in Europe and Asia but not necessarily in the United States or Canada. EPA and DHA help to stabilize NFκB in the cytoplasm, which decreases an excessive inflammatory response; they also increase vagal tone that improves GI motility.
- Sample nutrient requirements are listed in Table 17-9. Antioxidants are important; assure sufficient infusion of vitamins. IV vitamin A is only 25–33% available because it attaches to the plastic bags; vitamin E may also be less available. Vitamin E may be given as 1000 IU every 8 hours, sometimes orally. IV vitamin C is often given as 1000 mg every 8 hours; vitamin D is given as ergocalciferol. Vitamin K is part of the multivitamin infusate. Choline is important in metabolic pathways but is not generally given daily.
- Zinc, glutathione (from selenium), beta carotene, lipoic acid, melatonin, and N-acetylcysteine are other antioxidants that are important. However, avoid toxic IV mineral levels (e.g., >50 mg/d zinc; >1000 μg/d selenium for more than 10 days).
- Iodine deficiency has adverse effects on thyroid hormone production, and because most PN formulations do not contain iodine, monitoring is recommended (Zimmerman and Crill, 2009).
- Osmolality is important to monitor to prevent dehydration and other complications. For example, D5 W 5 has an osmolality of 252 mOsm/L, whereas D20 W 5 has an osmolality of 1008 mOsm/L.
- Special considerations will vary according to the patient's condition. Examples include:
  1. Short-chain fatty acids, soy, and fermentable fiber may be needed to reduce CPN-induced bowel atrophy.
  2. For respiratory failure, suggest a lipid emulsion that provides most of the nonprotein calories to lower the RQ.
- Follow practice guidelines, especially for children and home care patients (Kovacevich et al, 2005; Wessel et al, 2005). The increasing numbers of older (>65 years) Americans will increase the demand for home health services including support services (nursing, physical therapy, occupational therapy, durable medical equipment, respiratory therapy), infusion therapies, palliative care, and hospice; certification in gerontological care is encouraged and ASPEN Guidelines should be followed for optimal outcomes (Fuhrman, 2009).
- For management of complications of PN, see Table 17-10.

**TABLE 17-9 Sample Basic Adult Daily Requirements for CPN**

Nutrient	Amount
Water (/kg body wt/d)	30–40 mL
Energy <sup>a</sup> (/kg body wt/d)	
Medical patient	30 kcal
Postoperative patient	30–45 kcal
Hypercatabolic patient	45–60 kcal
Amino acids (/kg body wt/d)	
Medical patient	1.0 g
Postoperative patient	2.0 g
Hypercatabolic patient	3.0 g
Minerals	
Acetate/gluconate	90 mEq
Calcium	15 mEq
Chloride	130 mEq
Chromium	15 μg
Copper	1.5 mg
Iodine	120 μg
Magnesium	20 mEq
Manganese	2 mg
Phosphorus	300 mg
Potassium	100 mEq
Selenium	100 μg
Sodium	100 mEq
Zinc	5 mg
Vitamins	
Ascorbic acid	100 mg
Biotin	60 mcg
Cobalamin	5 μg
Folate (folic acid)	400 μg
Niacin	40 mg
Pantothenic acid	15 mg
Pyridoxine	4 mg
Riboflavin	3.6 mg
Thiamin	3 mg
Vitamin A	4000 IU
Vitamin D	400 IU
Vitamin E	15 mg
Vitamin K	200 μg

<sup>a</sup>Requirements for energy increase by 7% per 1°F or 12% per 1°C of fever.

Reference: Merck–Total Parenteral Nutrition, <http://www.merck.com/mmpe/sec01/ch003/ch003c.html>, accessed March 11, 2010.

- Do not overfeed; hyperglycemia, fatty liver, and excessive CO<sub>2</sub> production may occur. Monitor phosphate levels to assess levels of anabolism, risk for refeeding syndrome, and malnutrition.
- Provide weaning when patient is ready; use TF for interim nourishment if necessary. Progress to liquids and solids when patient is ready. Infusion of PN nutrients may suppress appetite, excessively prolonging PN use.

**TABLE 17-10 Complications in Parenteral Nutrition (PN)**

Complication	Comments
Catheter occlusion, venous thrombosis, phlebitis, sepsis	Contact physician or designated member of health care team for evaluation, diagnosis, and treatment of lines. For air embolism, place patient on his or her left side and lower head of the bed until resolved. Monitor for pneumothorax and ensure that trained staff handles catheters
Dehydration	Elevated BUN is noted. MD gives free water as 5% dextrose via peripheral vein Calculate needs as 30 mL/kg body weight or as 1 mL/kcal given. Alter as needed for diarrhea, medications used, ostomy, and losses from exudates such as burns or pressure ulcers
Electrolyte abnormalities	Monitor fluid status, organ system function, and serum sodium, potassium, phosphorus, calcium and magnesium regularly. Determine relevant cause or mechanism
Fluid overload	Greater than 1-kg gain per day is noted. Calculate needs and decrease volume to meet needs; diuretics or dialysis may be needed; a higher concentration of dextrose or lipids may be needed if fluid restriction is required
Gallbladder disorder	Cholelithiasis, gallbladder sludge, or cholecystitis can be caused or worsened by prolonged gallbladder stasis. Stimulate contraction by providing about 20–30% of calories as fat and stop glucose infusion several hours a day. Oral or enteral intake also helps. Treatment with metronidazole, ursodeoxycholic acid, phenobarbital, or cholecystokinin helps some patients with cholestasis
Hypocalcemia	Consider endocrine causes. Evaluate for hypoalbuminemia. Add additional calcium if needed
Hypercalcemia	Consider endocrine causes. Evaluate vitamin D, use isotonic saline, and add inorganic phosphate to solution until normal
Hypoglycemia	Administer more dextrose; reduce or discontinue insulin use; gradually taper infusion rate during weaning
Hyperglycemia	Reduce total grams of dextrose in the solution; add or increase insulin; consider use of lipids as partial substrate; advance feedings more slowly. Sometimes use of PN with a small amount of EN or oral intake can be helpful. Blood glucose >220 mg/dL can cause hyperinsulinemia, increased intracellular transport of potassium and phosphate with hypokalemia and hypophosphatemia. Impaired phagocytosis and neutrophil clearance may also occur
Hypokalemia	Increase potassium in solution and monitor potassium-depleting diuretic use such as furosemide. Add additional potassium if needed
Hyperkalemia	Evaluate renal function; decrease potassium in solution and evaluate medications used; reduce exogenous supplements
Hypomagnesemia	Increase magnesium in solution and monitor refeeding. Consider if magnesium-wasting medications are being used. Additional magnesium may be needed
Hypermagnesemia	Decrease magnesium in solution
Hyponatremia	Sometimes this occurs with fluid overload and total body water excess. Only occasionally is added sodium required
Hypernatremia	Replace fluids with a more dilute CPN solution; decrease sodium
Hyperphosphatemia	Evaluate renal function; decrease phosphate in solution and use phosphate binders if necessary
Hypophosphatemia	Increase phosphate in solution and monitor for refeeding syndrome
Lipid abnormalities	Decrease lipids if triglycerides are higher than 300 mg/dL; infuse over a longer time period; calculate that total kilocalories are not greater than 60% from lipids. Lipids over 2 g/kg/d can increase congestion of reticuloendothelial system and impair clearance of triglycerides. Some studies suggest use of omega-3 fatty acids to reverse cholestasis
Liver function changes	Altered liver function from excess energy may cause fatty infiltration and increased alkaline phosphatase. Liver dysfunction may be transient, evidenced by increased transaminases, bilirubin, and alkaline phosphatase; it commonly occurs when CPN is started. Delayed or persistent elevations may result from excess amino acids. Pathogenesis is unknown, but cholestasis and inflammation may contribute. Progressive fibrosis occasionally develops. Reducing protein delivery may help. For painful hepatomegaly, reducing CHO infusion may be needed
Metabolic Bone Disease	Bone demineralization develops in some patients given CPN for >3 months. Temporarily or permanently stopping CPN is the only known treatment
Pulmonary complications	Calculate needs and avoid overfeeding. Minimal kilocalories may be best, e.g., 20–25 kcal/kg. CHO provision should not exceed 4–5 mg/kg/min; avoid fluid excesses. Respiratory failure may occur in patients with limited pulmonary reserve. Prolonged mechanical ventilation can occur with carbon dioxide retention associated with overfeeding
Renal function changes	Protein excesses >2 g/kg daily can increase ureagenesis and decrease renal function or cause dehydration

### Common Drugs Used and Potential Side Effects

- Basic CPN solutions are prepared using sterile techniques, usually in liter batches. Normally, 2 L/d of the standard solution is needed for adults. An effective, standardized PN process uses standardized formulations and products, ordering, labeling, screening, compounding, and administration (Kochevar et al, 2007).
- Contact the pharmacy for a list of drugs that are stable and compatible with PN solutions or nutrient additives. Often, H<sub>2</sub>-blockers, steroids, and insulin are added to PN solutions.

- Intestinal tropic factors, such as recombinant human growth hormone (r-hGH), are used for SBS patients as part of intestinal rehabilitation regimens (Matarese et al, 2005).
- There are potential therapeutic roles for growth hormone, testosterone, oxandrolone, and megestrol acetate (Gullett et al, 2010).
- Loss of muscle mass occurs from increased protein degradation (cachexia), decreased rate of muscle protein synthesis (inactivity or bed rest), or both (sarcopenia). Nutrition therapy with an emphasis on high-quality protein plus use of an anabolic agent can slow or prevent muscle loss (Evans, 2010).
- Parenteral omega-3 fatty acids, such as Omegaven, may benefit patients with SBS who develop PN-associated liver disease (PNALD) with their CPN (Diamond et al, 2009).

## Herbs, Botanicals, and Supplements

- Obesity creates a low-grade SIRS with lipotoxicity and cytokine dysregulation that may respond to arginine, fish oil, and carnitine at the molecular level (Cave et al, 2008).
- Herbs and botanical supplements should not be added to any IV feedings.
- Prescription and nonprescription medications are commonly used together; nearly 1 in 25 individuals may be at risk for a major drug-drug interaction (Qato et al, 2008).
- Prebiotics or probiotics may be useful for the prevention of infection.

## NUTRITION EDUCATION, COUNSELING, CARE MANAGEMENT

- Discuss with patient/caretakers the goals of the PN, especially if home CPN will be used. Discuss aseptic technique, input and output records, CPN pump use, medications, additives, and complications. Long-term consequences should be discussed, such as trace element deficiencies and metabolic problems.
- Teach transition processes when and if patient is ready. Nutrition therapy is challenging; the objective is to restore enteral autonomy to a patient with a complex medical and surgical history, and a coordinated team effort is needed to wean from PN eventually (Weseman and Gilroy, 2005). Assistance from a registered dietitian is recommended.
- Wean from CPN to TF if patient tolerates one third to one half of kilocalorie needs by that route.
- To wean from CPN to oral diet, start with sips of clear liquids and advance, if tolerated, to lactose-free full liquids by the second day. When intake is >500 kcal orally, reduce CPN by 50%. When patient is consuming two thirds to three fourths of estimated needs orally, discontinue CPN by tapering (first hour by 50%, second hour by 75%, and third hour 100%). Nausea and vomiting may occur; eating some type of concentrated CHO during transition to oral diet is helpful.
- Discuss potential problems and when to call the doctor, the dietitian, the pharmacist, or the nurse.
- Discuss psychosocial issues related to adaptation to PN, oral deprivation, sense of loss, grief, and lifestyle changes. Quality of life tends to decline with long-term CPN use (Winkler, 2010). Encourage the patient to participate in favorite activities and physical activity as much as possible (Oz et al, 2008).
- Promote positive communications and collaboration among members of the health care team. A safe PN system must minimize procedural incidents; clinicians with nutrition therapy expertise are essential team members (Kochevar et al, 2007).

## Patient Education—Infusion Safety

- Solutions must always be prepared and handled under sterile conditions. A standardized process for PN must be explored to improve patient safety and clinical appropriateness and to maximize resource efficiency (Kochevar et al, 2007).
- Home CPN requires aseptic technique and meticulous catheter care. Discuss infection control measures because catheter-related bloodstream infections are serious, critical complications.
- Change bag, tubing, and cassette every 24 hours or as recommended by the facility or agency.

# Nutritional Review

## RECOMMENDED DIETARY ALLOWANCES AND DIETARY REFERENCE INTAKES

The Dietary Reference Intakes (DRIs) are nutrient-based reference values for use in planning and assessing diets and for other purposes (IOM, 2010). DRIs replaced older tools first published by the National Academy of Sciences in 1941. The DRI values comprise seven reports with more detailed guidance than the old system. The DRIs are composed of the following:

- **Estimated average requirements (EAR)**, expected to satisfy the needs of 50% of the people in that age group.
- **Recommended dietary allowances (RDA)**. After computing the EARs for each age/gender category, the Food and Nutrition Board (FNB) then established RDAs to meet the nutrient requirements of each category.
- **Adequate intake (AI)**, where no RDA has been established
- **Tolerable upper intake levels (UL)**, to caution against excessive intake of nutrients (like vitamin D) that can be harmful in large amounts.

## REFERENCE

IOM. Institute of Medicine, National Academy of Sciences. Dietary Reference Intakes, 2001. Web site accessed 3/14/10. <http://www.iom.edu/Object.File/Master/7/294/0.pdf>

**Reader Please Note:** All tables in this Appendix A are derived from the ARS Nutrient Database for Standard Reference, Release 17.

Foods are from single nutrient reports, sorted either by food description or in descending order by nutrient content in terms of common household measures. Mixed dishes are not included here. The food items and weights in these reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods.

## MACRONUTRIENTS

Acceptable macronutrient distribution ranges for individuals have been set for carbohydrate, fat, *n*-6 and *n*-3 polyun-

saturated fatty acids, and protein on the basis of evidence through the Institute of Medicine.

## Carbohydrates and Fiber

Carbohydrates (CHO) are essential for life and to provide energy to the body. The brain and central nervous system (CNS) require a continuously available glucose supply. When it is necessary, lean body mass is metabolized to provide glucose for these tissues. Generally, 90% of carbohydrates are absorbed from a mixed diet. The RDA for carbohydrate is set at 130 g/d for adults and children, based on the average minimum amount of glucose used by the brain. The median intake of carbohydrates is approximately 220–330 g/d for men and 180–230 g/d for women. To plan a balanced intake between 45 and 65% of kcal/d, it would equal 135 to 195 g carbohydrate on a 1200 kcal diet; 202–292 g CHO on an 1800 kcal diet; or 270–390 g CHO for a 2400-kcal diet.

No recommendations based on glycemic index have been made. Intensely flavored artificial sweeteners that are approved for use in the United States include aspartame (NutraSweet), acesulfame-K (Sunette), neotame, saccharin (Sweet n Low), sucralose (Splenda), and stevia (Truvia). These are many times sweeter than natural sugars. Sugar replacers are natural sugar-free sugar alcohols such as mannitol, erythritol, isomalt, lactitol, maltitol, xylitol, and sorbitol. Unlike artificial sweeteners, these are used in the same amount as sugars and have the same bulk and volume. Labels indicate “sugar free” or “no sugar added. Sorbitol has a sweetness value of 60; mannitol has sweetness value of 50, or half that of table sugar.

Both soluble and insoluble fiber play an important role in maintenance of health. Except in a few therapeutic situations, fiber should be obtained from food sources (20 and 35 g/d for adults). Men up to age 50 need 38 g/d; over age 50, 30 g/d. Women up to age 50 need 25 g fiber per day, women over age 50, 21 g fiber per day. All dietary fibers, regardless of type, are readily fermented by microflora of the small intestines, producing short-chain fatty acids (acetate, propionate, and butyrate). An overview of carbohydrate and fiber classifications is provided in Table A-1. A food list of fiber sources can be found in Table A-2.

**TABLE A-1 Carbohydrate and Fiber**

Class	Type	Food Sources	Comments
Monosaccharides	Glucose (dextrose)	Corn syrup, honey, fruits, vegetables	Most important; most widely distributed. Sweetness value = 74.
	Fructose (levulose, fruit sugar)	High-fructose corn syrup, honey, fruits, vegetables	Sweetest, especially when fruit ripens. Most fruits contain 1–7%. Makes up 40% of the weight of honey. Sweetness value = 173.
	Galactose	Milk sugar	Part of the lactose molecule. Sweetness value = 32.
	Mannose	Found in poorly digested fruit structures	Of little nutritional value
Disaccharides	Sucrose (table sugar)	Cane or beet sugars, maple sugar, grape sugar, some natural fruits and vegetables	Formed when glucose and fructose are linked together. Honey is a form of sucrose known as an invert sugar. Sweetness value = 100.
	Lactose (milk sugar)	Milk, cream, whey	Glucose + galactose molecules in the mammary glands of lactating mammals. 7.5% of the composition of human milk, 4.5% of cow's milk. Sweetness value = 16.
	Maltose (malt sugar)	Malt, sprouting grains, partially digested starch	Made of two glucose molecules. Sweetness value = 32.
Polysaccharides—digestible	Starch (amylose and amylopectin)	Modified food starch, potatoes, beans, breads, rice, pasta, starchy products such as tapioca	Most starches require cooking for best digestion. When cooked and cooled, they are effective thickeners (such as modified food starch).
	Glycogen	No foods	Muscle and liver storage form of glucose; only 18 hours can be stored in one day.
Polysaccharides—indigestible (fiber)	<b>Insoluble fibers:</b> Cellulose	Soybean hulls, fruit membranes, legumes, carrots, celery, broccoli, and many other vegetables. The most abundant organic compound in the world.	Insoluble fibers increase fecal volume (bulk) and decrease colonic transit time by their ability to increase water-holding capacity; excess may deplete mineral status.
	Insoluble hemicelluloses (xylan, galactan, mannan, arabinose, galactose)	Corn hulls, wheat and corn brans, brown rice, cereal	The predominant sugar is used to name it.
	Algal polysaccharides (carrageenan)	Processed foods such as baby food, ice cream, sour cream	Extracted from seaweed and algae.
	Lignin (noncarbohydrate)	Wheat straw, alfalfa stems, tannins, cottonseed hulls	Polymer made of phenylpropyl alcohols and acids. Flaxseed lignin is an excellent antioxidant. Lignin may lower serum cholesterol levels.
	Cutin (noncarbohydrate)	Apple or tomato peels, seeds in berries, peanut or almond skins, onion skins	
	<b>Soluble fibers:</b> Pectin (polygalacturonic acid)	Citrus pulp, apple pulp, strawberries, sugar beet pulp, banana, cabbage and <i>Brassica</i> foods, legumes (such as kidney beans), sunflower heads	Soluble fibers decrease serum cholesterol by decreasing the enterohepatic recycling of bile acids and increasing use of cholesterol in bile synthesis. This stabilizes blood glucose levels and maintains mineral nutriture. Little effect on fecal bulk or transit time.
	Beta-glucans (glucopyranose)	Oat and barley bran; soy fiber concentrate.	Lowers serum cholesterol
	Gums (galactose and glucuronic acid)	Oats, guar gum, legumes, barley, xanthan from prickly ash trees	Useful for gel formation which slow digestion and slows down transit time; helpful in diarrhea.
	Psyllium	Extracted from psyllium seeds or plantains	High water binding capacity (choking hazard)
	Raffinose and stachyose	Beans and other legumes	Low-molecular-weight polymers containing 2–20 sugar molecules.
Oligosaccharides	Fructans [fructooligosaccharides (FOSs), inulin, oligofructose]	Wheat, onions, garlic, bananas, chicory, tomatoes, barley, rye, asparagus, and Jerusalem artichokes	They add flavor and sweetness to low-calorie foods and provide prebiotics to stimulate the growth of intestinal bacteria, especially <i>bifidobacteria</i> . May be used as a fat replacer.
	Chitin (Glucopyranose)	Supplement made from crab or lobster shells	May reduce serum cholesterol
	Polydextrose, polyols (sorbitol, mannitol, etc.)	Synthesized	Bulking agent or sugar substitute.
Miscellaneous carbohydrates	Algal polysaccharides (carrageenan)	Isolated from algae and seaweed	Forms a gel used as thickening agent. Can be toxic.

**TABLE A-2 Food Sources of Dietary Fiber<sup>a</sup>**

Food, Standard Amount	Dietary Fiber (g)	Calories	Food, Standard Amount	Dietary Fiber (g)	Calories
Navy beans, cooked, 1/2 cup	9.5	128	Potato, baked, with skin, one medium	3.8	161
Bran ready-to-eat cereal (100%), 1/2 cup	8.8	78	Soybeans, green, cooked, 1/2 cup	3.8	127
Kidney beans, canned, 1/2 cup	8.2	109	Stewed prunes, 1/2 cup	3.8	133
Split peas, cooked, 1/2 cup	8.1	116	Figs, dried, 1/4 cup	3.7	93
Lentils, cooked, 1/2 cup	7.8	115	Dates, 1/4 cup	3.6	126
Black beans, cooked, 1/2 cup	7.5	114	Oat bran, raw, 1/4 cup	3.6	58
Pinto beans, cooked, 1/2 cup	7.7	122	Pumpkin, canned, 1/2 cup	3.6	42
Lima beans, cooked, 1/2 cup	6.6	108	Spinach, frozen, cooked, 1/2 cup	3.5	30
Artichoke, globe, cooked, one each	6.5	60	Shredded wheat ready-to-eat cereals, various, ~1 ounce	2.8–3.4	96
White beans, canned, 1/2 cup	6.3	154	Almonds, 1 ounce	3.3	164
Chickpeas, cooked, 1/2 cup	6.2	135	Apple with skin, raw, one medium	3.3	72
Great northern beans, cooked, 1/2 cup	6.2	105	Brussels sprouts, frozen, cooked, 1/2 cup	3.2	33
Cowpeas, cooked, 1/2 cup	5.6	100	Whole-wheat spaghetti, cooked, 1/2 cup	3.1	87
Soybeans, mature, cooked, 1/2 cup	5.2	149	Banana, one medium	3.1	105
Bran ready-to-eat cereals, various, ~1 ounce	2.6–5.0	90–108	Orange, raw, one medium	3.1	62
Crackers, rye wafers, plain, two wafers	5.0	74	Oat bran muffin, one small	3.0	178
Sweet potato, baked, with peel, one medium (146 g)	4.8	131	Guava, one medium	3.0	37
Asian pear, raw, one small	4.4	51	Pearled barley, cooked, 1/2 cup	3.0	97
Green peas, cooked, 1/2 cup	4.4	67	Sauerkraut, canned, solids, and liquids, 1/2 cup	3.0	23
Whole-wheat English muffin, one each	4.4	134	Tomato paste, 1/4 cup	2.9	54
Pear, raw, one small	4.3	81	Winter squash, cooked, 1/2 cup	2.9	38
Bulgur, cooked, 1/2 cup	4.1	76	Broccoli, cooked, 1/2 cup	2.8	26
Mixed vegetables, cooked, 1/2 cup	4.0	59	Parsnips, cooked, chopped, 1/2 cup	2.8	55
Raspberries, raw, 1/2 cup	4.0	32	Turnip greens, cooked, 1/2 cup	2.5	15
Sweet potato, boiled, no peel, one medium (156 g)	3.9	119	Collards, cooked, 1/2 cup	2.7	25
Blackberries, raw, 1/2 cup	3.8	31	Okra, frozen, cooked, 1/2 cup	2.6	26
			Peas, edible-pod, cooked, 1/2 cup	2.5	42

<sup>a</sup>Food sources of dietary fiber are ranked by grams of dietary fiber per standard amount; also calories in the standard amount. All are  $\geq 10\%$  of AI for adult women, which is 25 g/d.

## Fatty Acids and Lipids

The usual American diet contains 35–40% fat kcal. Fats are carriers for fat-soluble vitamins and essential fatty acids (EFAs). Fat is essential for cell membranes (especially the brain) serves as an insulating agent for organs and is a rich energy source. Generally, 95% of fat from the diet is absorbed. One to two percent of calories should be available as linoleic acid to prevent EFA deficiency. People with low body fat stores, very malnourished persons, psychiatric patients, and premature low birth weight (LBW) infants are at risk for EFA deficiency.

Lipase is needed to metabolize long-chain triglycerides (LCT) into free fatty acids (FFAs). When parenteral fat emulsions contain LCT, large doses may compromise immune function, elevate serum lipids, impair alveolar diffusion capacity, or decrease reticular endothelial system function. Medium-

chain fatty acids (MCFAs) are produced from medium-chain triglycerides (MCTs). MCTs are transported to the liver via the portal vein and, therefore, do not require micelle or chylomicron formation.

Omega-3 fatty acids reduce inflammation and help prevent certain chronic diseases. These essential fatty acids are highly concentrated in the brain. Two to three servings of fatty fish per week (about 1250 mg EPA and DHA per day) are beneficial for most people. If using fish oil supplements, 3000–4000 mg standardized fish oils would be needed per day. Safe and effective doses of omega-3 fatty acid supplements have not been established in children. EPA and arachidonic acids are transformed into eicosanoids for prostaglandin, leukotriene, thromboxane, and prostacyclin synthesis. Prostaglandins are used in many diverse hormone-like compounds. Omega-3 fatty acids should be used cautiously by people who have a bleeding disorder, take

blood thinners, or are at an increased risk for hemorrhagic stroke.

It is very important to maintain a balance between omega-3 and omega-6 fatty acids in the diet. The Mediterranean diet consists of a healthier balance between omega-3 and omega-6 fatty acids than the typical American diet. Omega-6 fatty acids play a role as proinflammatory agents and are useful when initiating a stress response.

Sphingolipids are hydrolyzed throughout the GI tract to regulate growth, differentiation, apoptosis, and other cellular functions. They reduce low-density lipoprotein (LDL) levels and increase high-density lipoprotein (HDL) levels. Dietary constituents such as cholesterol, fatty acids, and mycotoxins alter their metabolism.

The recommended intakes of total fat per day equal 20–35% of kcal. Of this, consume 1–2% from omega-3 fatty

acids and 5–8% from omega-6 fatty acids. Table A-3 describes more details.

### Proteins and Amino Acids

Amino acids and proteins are the building blocks of life. All growth and repair functions of the body require utilization and availability of amino acids in the proper proportion and amounts. Average total essential amino acid needs are as follows: infants, 40% essential; children, 36% essential; and adults, 19% essential. This translates into 52 g protein for teenaged boys aged 14–18 years and 46 g for teenaged girls aged 14+, and women. Pregnant or nursing women need 71 g/d. Men aged 19+ need 56 g protein per day. Need increase with injury, trauma, and certain medical conditions.

**TABLE A-3 Fats and Lipids**

Class	Fatty Acid Component	Key Food Sources	Comments
<b>Simple lipids</b> <i>Neutral fats (acyl-glycerols)</i>	Mono- and diglycerides	Additive in low-fat foods	Glycerol with one or two esterified fatty acids
	Triglycerides (triacylglycerols)	Fats and oils	Glycerol with three esterified fatty acids
<i>Fatty acids, polyunsaturated</i> Omega-3 family	Alpha linolenic acid (ALA)	Vegetable oils (soybean, canola, or rapeseed), flaxseeds, flaxseed oil, soybeans, pumpkin seeds, pumpkin seed oil, purslane, perilla seed oil, walnuts, walnut oil. Flaxseed and flaxseed oil should be kept refrigerated; whole flaxseeds should be ground within 24 hours of use.	<b>An essential fatty acid.</b> Once eaten, the body converts ALA to EPA and DHA, the two types of omega-3 fatty acids more readily used by the body. The adequate daily intake of ALA should be 1.6 and 1.1 g for men and women, respectively.
	Eicosapentaenoic acid (EPA) and Docosahexanoic acid (DHA)	Cold-water fish such as salmon, mackerel, eel, tuna, herring, halibut, trout, sardines, and herring. Fish oil capsules should be refrigerated.	EPA and DHA (1 g/d) from fatty fish can reduce CHD and some types of cancer. Infants who do not receive sufficient DHA from their mothers during pregnancy are at risk for nerve or vision problems.
	Omega-6 family		<b>An essential fatty acid</b>
<i>Monounsaturated</i> Omega-9 family	Linoleic acid	Safflower, sunflower, corn, soybean, peanut oils.	Group of isomers produced by rumen bacteria. CLA may have a role in weight management and other functions.
	Conjugated linoleic acid (CLA)	Naturally rich in milk fat	
	Arachidonic acid	Animal tissues (very low). There is no good dietary source.	
<b>Compound lipids</b> <i>Phospholipids</i>	Oleic acid	Olive oil, canola oil, peanut oil, sunflower oil, and sesame oil. Avocados, olives, nut butters, such as peanut butter, nuts and seeds, such as macadamia nuts, pecans, and almonds	
	Glycerophosphatides (lecithins, cephalins, plasmalogens)	Egg yolks, liver, wheat germ, peanuts	Glycerol with two fatty acids and a nitrogen
	Glycosphingolipids (ceramides, sphingomyelins)	Low in the food supply, mainly in dairy products, eggs, soybeans. Fruit has a tiny bit.	Sphingosine with one esterified fatty acid (a ceramide). Found in myelin of nerve tissue.
<i>Glycolipids</i>	Cerebrosides, gangliosides	Low in the food supply.	Found in nerve and brain tissue. A ceramide linked to a monosaccharide or an oligosaccharide

(continued)

**TABLE A-3 Fats and Lipids (continued)**

Class	Fatty Acid Component	Key Food Sources	Comments
<i>Lipoproteins</i>	Protein–lipid combination	Made by the liver	VLDL, LDL, HDL have various roles in health maintenance.
<b>Miscellaneous lipids</b>	Cholesterol	Liver, heart, and other organ meats	Steroid nucleus (synthesized from acetyl-coenzyme A). Technically a wax.
<i>Sterols</i>			
<i>Fat-soluble vitamins</i>	A, D, E, and K	Various food sources	Lipid soluble; some are esterified with 1 fatty acid
<i>Trans fatty acids</i>		Margarines, some cookies and crackers. The new food label includes the amount of trans fat in a serving.	These are made by hydrogenation of vegetable oils to form more solid products (i.e., margarine). The process increases the amount of saturation and converts natural <i>cis</i> double bonds to <i>trans</i> double bonds. To decrease intake, use leaner cuts of meat, fewer cold cuts. Choose skim milk, fat-free products in food choices and in cooking.
<b>Fat-related substances</b>	Carnitine	Produced in the liver from essential amino acids lysine and methionine.	Carnitine transports fatty acids into mitochondria, where they undergo beta-oxidation. When in short supply, production of ATP slows down or halts altogether, affecting heart or skeletal muscle. In renal failure, it is a useful additive to improve fatty acid metabolism.
	Myo-inositol	Found as phospholipid in animals, phytic acid in plants.	Inositol phosphates liberated from glycerophosphatides acts as a secondary messenger in the release of intracellular calcium, which in turn causes activation of certain cellular enzymes and produces hormonal responses. Possible role in diabetes mellitus or in renal failure.

The main protein source in the American diet is animal protein from beef and poultry.

To produce the nonessential amino acids from dietary intake of the essentials, it is recommended that the limited amino acids be consumed within a 24-hour period of each other. Protein synthesis requires all amino acids; an insufficient amount of any one may impede or slow formation of the polypeptide chain. For valine, leucine, and isoleucine, the requirement of each is increased by excess of the other branched-chain amino acids (BCAAs).

Protein requirement is inversely related to calories when the latter are deficient. Generally, more than 90% of protein is absorbed from the diet. Foods of high biological value (HBV) contain approximately 40% EAAs. Table A-4 indicates which amino acids are essential and which can be made by the body (nonessential). Eight amino acids are generally regarded as essential for humans: threonine, valine, tryptophan, isoleucine, leucine, lysine, phenylalanine, methionine (names of these amino acids are easy to remember by the phrase “TV TILL PM”). Foods that contain all of the essential amino acids are called complete proteins. Incomplete proteins tend to be deaminated for sources of energy rather than being available for new tissue, healing, and growth. For biological value of proteins see Table A-5 and see Table A-6 for sources of protein.

## MICRONUTRIENTS

### Minerals

Minerals are inorganic compounds containing no carbon structures. There are 22 essential minerals known to be needed from the diet. Macrominerals (needed in large amounts) include calcium, phosphorus, magnesium, potassium, sodium, chloride, and sulfur. Trace minerals include iron, copper, selenium, fluoride, iodine, chromium, zinc, manganese, molybdenum, cobalt, and others.

### Major Minerals

Minerals that are needed at levels of 100 mg daily or more are known as macrominerals.

**Calcium:** Calcium absorption is dependent upon the calcium needs of the body, foods eaten, and the amount of calcium in foods eaten. Vitamin D, whether from diet or exposure to the ultraviolet light of the sun, increases calcium absorption. Calcium absorption tends to decrease with increased age for both men and women. *RDA for calcium is 1000 mg for most adults, 1300 mg for teenagers, and 1200 mg for those over 50 years.*

**TABLE A-4 Amino Acids**

Essential Amino Acids	Type	Food Sources	Comments: Must be Consumed
Histidine	Aromatic	Dairy, meat, poultry, fish.	Precursor of histamine. Important for red and white blood cells. An important source of carbon atoms in the synthesis of purines. Histidine is needed to help grow and repair body tissues, and to maintain the myelin sheaths that protect nerve cells. It also helps manufacture red and white blood cells, and helps to protect the body from heavy metal toxicity. Histamine stimulates the secretion of the digestive enzyme gastrin. Extra is needed by infants and renal failure patients.
Isoleucine	Neutral	Meats, fish, cheeses, nuts	Belongs to the branched-chain amino acid group (BCAAs), which help maintain and repair muscle tissue. Important for stabilizing and regulating blood sugar and energy levels. Needed for synthesis of hemoglobin and energy regulation. Need 20 mg/kg body weight
Leucine	Neutral	Soybeans, cowpeas, lentils, beef, peanuts, pork salami, salmon, shellfish, chicken, eggs	Belongs to the branched-chain amino acid group (BCAAs). Second most common amino acid found in proteins; necessary for the optimal growth of infants and for the nitrogen balance in adults. Needed for wound healing and healthy skin and bones. Need 39 mg/kg body weight
Lysine	Basic	Limited in corn, wheat, and rice.	It is an essential building block for all protein, and is needed for proper growth and bone development in children. Lysine helps the body absorb and conserve calcium, form collagen and muscle protein, and synthesize enzymes and hormones. Need 30 mg/kg body weight
Methionine	Sulfur	Limited in soy products.	Helps to initiate translation of messenger RNA by being the first amino acid incorporated into the N-terminal position of all proteins. Methionine supplies sulfur and other compounds required by the body for normal metabolism and growth. Reacts with ATP to form S-adenosyl methionine (SAM) which is the principal methyl donor in the body. It contributes to the synthesis of epinephrine and choline. Need 10.4 + 4.1 (15 total) mg/kg body weight
Phenylalanine	Aromatic	Soybeans, lentils, nuts, seeds, chicken, fish, eggs.	Exhibits ultraviolet radiation absorption properties with a large extinction coefficient. Phenylalanine is part of the composition of aspartame, a common sweetener found in prepared foods (particularly soft drinks, and gum). Key role in the biosynthesis of other amino acids and some neurotransmitters. Healthy nervous system, memory and learning. Useful against depression. Need, along with tyrosine, 25 (total) mg/kg body weight
Threonine	Neutral	Soybeans, pork, lentils, beef, fish.	Important component in the formation of protein, collagen, elastin and tooth enamel. It is also important for production of neurotransmitters and health of the nervous system and the immune system. Need 15 mg/kg body weight
Tryptophan	Aromatic	Rich in flaxseed, salami, lentils, turkey, nuts, eggs. Limited in corn.	Formed from proteins during digestion by the action of proteolytic enzymes. Tryptophan is also a precursor for serotonin (a neurotransmitter) and melatonin (a neurohormone). Precursor of niacin. Tryptophan may enhance relaxation and sleep, relieve minor premenstrual symptoms, soothe nerves and anxiety, and reduce carbohydrate cravings. Need 4 mg/kg body weight.
Valine	Neutral	Meat, eggs, milk, cereal proteins.	Belongs to the branched-chain amino acid group (BCAAs). Constituent of fibrous protein in the body. Useful in treatments involving muscle, mental, and emotional upsets, and for insomnia and nervousness. Valine may help treat malnutrition associated with drug addiction. Needed for muscle development. Need 26 mg/kg body weight

(continued)

**TABLE A-4 Amino Acids (continued)**

Conditional Amino Acids	Type	Food Sources	Comments: Must be Consumed in the Diet During Stress or Illness
Arginine, citrulline, ornithine	Basic	Peanuts, almonds, seeds	These three amino acids are part of urea acid cycle. Arginine plays an important role in cell division, wound healing, removing ammonia from the body, immune function, and the release of hormones. Extra needed in growing children. Citrulline supports the body in optimizing blood flow through its conversion to L-arginine and then nitric oxide (NO). Ornithine is a precursor of citrulline, glutamic acid, and proline; it is an intermediate in arginine biosynthesis.
Cysteine	Sulfur	Can be made from homocysteine but cannot be synthesized on its own. Limited in soy products.	Spares methionine. Component of nails, skin and hair. Antioxidant when taken with vitamin E and selenium. Extra needed in infancy, liver failure. Naturally occurring hydrophobic amino acid with a sulfhydryl group; found in most proteins. <i>N</i> -acetyl cysteine (NAC) is the most frequently used form and it helps toxify harmful substances in the body. Both cysteine and NAC increase levels of the antioxidant glutathione.
Glutamine	Acidic	Beef, chicken, milk, eggs, wheat.	One of the 20 amino acids generally present in animal proteins; the most abundant amino acid in the body. Over 61% of skeletal muscle tissue is glutamine. It contains two ammonia groups, one from precursor glutamate, and the other from free ammonia in the bloodstream. Glutamine is converted to glucose when more glucose is required by the body as an energy source. Glutamine assists in maintaining the proper acid/alkaline balance in the body, and is the basis for the synthesis of RNA and DNA.
Glycine	Neutral	Abundant in fish, meat, dairy products, beans.	The simplest amino acid; it has no stereoisomers. The body uses it to help the liver in detoxification of compounds and for helping the synthesis of bile acids. Glycine is essential for the synthesis of nucleic acids, bile acids, proteins, peptides, purines, adenosine triphosphate (ATP), porphyrins, hemoglobin, glutathione, creatine, bile salts, one-carbon fragments, glucose, glycogen, and L-serine and other amino acids. Beneficial for skin and wound healing. It has a sweet taste.
Hydroxyproline			Derived from proline and used almost exclusively in structural proteins including collagen, connective tissue in mammals, and in plant cell walls. The nonhydroxylated collagen is commonly termed procollagen.
Proline	Cyclic	A diet low in ascorbic acid may lead to low levels of hydroxyproline. Derived from L-glutamate.	Needed for intracellular signaling. Involved in the production of collagen and in wound healing. Proline is the precursor for hydroxyproline, which the body incorporates into collagen, tendons, ligaments, and the heart muscle. Important component in certain medical wound dressings that use collagen fragments to stimulate wound healing.
Serine	Neutral; also an alcohol	Synthesized from glycine	Important for healthy brain and immunity. Variety of biosynthetic pathways including those involving pyrimidines, purines, creatine, and porphyrins. Serine has sugar-producing qualities, and is very reactive in the body. It is highly concentrated in all cell membranes, aiding in the production of immunoglobulins and antibodies. Need extra for hemodialysis patients.
Taurine		Found in seafood and meat.	Functions with glycine and gamma-aminobutyric acid as a neuroinhibitory transmitter. Also needed for brain function and metabolism of magnesium, calcium and potassium. Extra needed for infants and in trauma, infection, renal failure.
Tyrosine	Aromatic	Soy, poultry, dairy and other high protein foods.	Metabolically synthesized from phenylalanine to become the para-hydroxy derivative. Tyrosine is a precursor of the adrenal hormones epinephrine, norepinephrine, and the thyroid hormones L-tyrosine, through its effect on neurotransmitters, is used to treat conditions including mood enhancement, appetite suppression, and growth hormone (HGH) stimulation. Extra is needed for infants and in chronic renal failure.

(continued)

**TABLE A-4 Amino Acids (continued)**

Nonessential and Other Amino Acids/Proteins	Type	Food Sources	Comments: Made by the Body if Enough Nitrogen is Available
Alanine	Neutral		Removes toxic substances released from breakdown of muscle protein during intensive exercise. Part of glucose–alanine pathway. Alanine comes from the breakdown of DNA or the dipeptides, anserine and carnosine, and the conversion of pyruvate for carbohydrate metabolism.
Asparagine	Acidic	Seafood, meat, casein, dairy products, eggs, beans, seeds, nuts, corn.	Healthy CNS. Asparagine is synthesized from aspartic acid and ATP. One of the principal and frequently the most abundant amino acids involved in the transport of nitrogen and in amination/transamination. It serves as an amino donor in liver transamination.
Aspartic acid	Acidic		Used for immunity and removal of toxins and ammonia from the body. Aspartic acid is alanine with one of the $\beta$ hydrogens replaced by a carboxylic acid group. It supports metabolism during construction of asparagine, arginine, lysine, methionine, threonine, isoleucine, and several nucleotides.
Carnitine			Produced in the liver, brain and the kidneys from methionine and lysine; responsible for the transport of long-chain fatty acids into the energy-producing mitochondria. Carnitine helps maintain a healthy blood lipid profile and promote fatty acid utilization within heart muscle.
Creatine			Synthesized in the liver, kidneys and pancreas out of arginine, methionine and glycine; increases the availability of cellular ATP. Donates a phosphate ion to increase the availability of ATP. Stored in muscle cells as phosphocreatine; helps generate cellular energy for muscle contractions.
Glutamic acid	Acidic		Gamma-aminobutyric acid (GABA) is formed from glutamic acid with the help of vitamin B <sub>6</sub> , is found in almost every region of brain, and is formed through the activity of the enzyme glutamic acid decarboxylase (GAD). GABA serves as an inhibitory neurotransmitter to block the transmission of an impulse from one cell to another in the CNS. The crystalline salt of glutamic acid, monosodium glutamate, contributes to the flavor called umami.
Glutathione		Seaweed	Glutathione (GSH) is a tripeptide composed of three different amino acids, glutamate, cysteine and glycine, which has numerous important functions within cells. Glutathione plays a role in such diverse biological processes as protein synthesis, enzyme catalysis, transmembrane transport, receptor action, intermediary metabolism, and cell maturation. Glutathione acts as an antioxidant used to prevent oxidative stress in most cells and help to trap free radicals that can damage DNA and RNA.
Theanine			L-theanine is the predominant amino acid in green tea and makes up 50% of the total free amino acids in the plant; the main component responsible for the taste of green tea. L-theanine is involved in the formation of the inhibitory neurotransmitter, gamma amino butyric acid (GABA). GABA influences the levels of two other neurotransmitters, dopamine and serotonin, producing a relaxation effect.

**TABLE A-5 Biological Value of Proteins**

Food Source	Biological Value	Food Source	Biological Value
Whey protein	104	Casein	77
Egg	100	Soybean	74
Cow's milk	95	Rice, white	67
Cottonseed	81	Wheat, whole	53
Beef	80	Sesame	50
Fish	79	Corn	49

From the Joint FAO/WHO Ad Hoc Expert Committee. Energy and protein requirements. WHO technical report no. 522. Geneva: World Health Organization, 1973, p. 67.

**TABLE A-6 Protein Sources**

Food	Serving	Weight (g)	Protein (g)
Hamburger, extra lean	6 ounces	170	48.6
Chicken, roasted	6 ounces	170	42.5
Fish	6 ounces	170	41.2
Tuna, water packed	6 ounces	170	40.1
Beefsteak, broiled	6 ounces	170	38.6
Cottage cheese or ricotta cheese	1 cup	225	28.1
Beef, fish, pork, chicken or turkey	3 ounces	85	21
Cheese pizza	2 slices	128	15.4
Yogurt, low fat	8 ounces	227	11.9
Tofu or vegetarian burger patty	1/2 cup	126	10–15
Lentils, cooked	1/2 cup	99	9
Skim milk	1 cup	245	8.4
Split peas, cooked	1/2 cup	98	8.1
Whole or chocolate milk	1 cup	244	8
Peanut or other nut butters	2 tablespoons	Varies	8
Kidney beans, cooked	1/2 cup	87	7.6
Cheddar cheese	1 ounce (1 slice)	28	7.1
Macaroni, cooked	1 cup	140	6.8
Soy milk	1 cup	245	6–9
Egg	1 large	50	6.3
Whole wheat bread	2 slices	56	5.4
White bread	2 slices	60	4.9
Rice, cooked	1 cup	158	4.3
Broccoli, cooked	5-inch piece	140	4.2
Nuts or seeds	2 tablespoons	Varies	3–5
Baked potato	2 × 5 inches	156	3
Corn, cooked	1 ear	77	2.6
Bread, cooked cereal or rice or pasta	1 slice	Varies	2

From: U. S. Department of Agriculture. Nutrient database, <http://www.ars.usda.gov/SP2UserFiles/Place/12354500/Data/SR22/nutrlst/sr22w203.pdf>, accessed January 22, 2010.

**Roles.** For strong bones and teeth, nerve irritability, muscle contraction, heart rhythm, blood coagulation, enzymes, osmotic pressure, intercellular cement, maintenance of cell membranes, and protection against high blood pressure. About 60% is bound to protein, mostly albumin. About 30–60% absorption occurs with intakes of 400–1000 mg.

**Sources.** Milk and cheese products remain the primary source of calcium for Americans. Phytates and excessive protein or zinc decrease absorption. Calcium from soy milk is absorbed only 75% as efficiently as from cow's milk. Calcium is lost in cooking some foods, even under the best conditions. To retain calcium, cook foods in a minimal amount of water and for the shortest possible time. Table A-7 lists both dairy and nondairy sources of calcium.

**Signs of Deficiency.** In hypocalcemia, there may be tetany, paresthesia, hyperirritability, muscle cramps, convulsions, and stunting in growth. No consistent data suggests that a high-protein diet depletes calcium.

**Signs of Excess.** With hypercalcemia, milk alkali syndrome, kidney stones or renal insufficiency can occur. Recommending excessive calcium use among the general, unsupervised public is not advisable. For bone health, vitamin D is the priority and should be given along with calcium.

**Chloride:** Chloride constitutes about 3% of total mineral content in the body. It is the main extracellular ion, along with sodium. *No RDA levels have been established for chloride. The upper limit (UL) for adults is 3.6 g/d.*

**Roles.** Digestion (HCl in stomach), acid–base balance, O<sub>2</sub>/CO<sub>2</sub> exchange in red blood cells (RBCs), and fluid balance.

**Sources.** Table salt, salt substitutes containing potassium chloride, processed foods made with table salt, sauerkraut, snack chips, and green olives.

**Signs of Deficiency.** Hypochlorhydria and disturbed acid–base balance.

**TABLE A-7 Dairy Sources of Calcium<sup>a</sup>**

Dairy Food, Standard Amount	Calcium (mg)	Calories	Dairy Food, Standard Amount	Calcium (mg)	Calories
Plain yogurt, nonfat (13 g protein/ 8 ounces), 8-ounce container	452	127	Feta cheese, 1.5 ounces	210	113
Romano cheese, 1.5 ounces	452	165	Cottage cheese, one cup	150	
Pasteurized process Swiss cheese, 2 ounces	438	190	Frozen yogurt or ice cream	100	Varies
Plain yogurt, low-fat (12 g protein/ 8 ounces), 8-ounce container	415	143	Non-food, standard amount	Calcium (mg)	Calories
Fruit yogurt, low-fat (10 g protein/ 8 ounces), 8-ounce container	345	232	Fortified ready-to-eat cereals (various), 1 ounce	236–1043	88–106
Swiss cheese, 1.5 ounces	336	162	Soy beverage, calcium fortified, one cup	368	98
Ricotta cheese, part skim, 1/2 cup	335	170	Sardines, Atlantic, in oil, drained, 3 ounces	325	177
Pasteurized process American cheese food, 2 ounces	323	188	Fortified orange juice, one cup	300	120
Provolone cheese, 1.5 ounces	321	150	Tofu, firm, prepared with calcium, 1/2 cup	253	88
Mozzarella cheese, part-skim, 1.5 ounces	311	129	Bread, calcium-fortified, one slice	200	70
Cheddar cheese, 1.5 ounces	307	171	Pink salmon, canned, or sardines, with bone, 3 ounces	181	118
Fat-free (skim) milk, one cup	306	83	Collards, cooked from frozen, 1/2 cup	178	31
Muenster cheese, 1.5 ounces	305	156	Molasses, blackstrap, one tbsp	172	47
Pudding, ready to eat, one cup	300	Varies	Spinach, cooked from frozen, 1/2 cup	146	30
Macaroni and cheese, one cup prepared	300	Varies	Soybeans, green, cooked, 1/2 cup	130	127
1% low-fat milk, one cup	290	102	Turnip greens, cooked from frozen, 1/2 cup	124	24
Low-fat chocolate milk (1%), one cup	288	158	Ocean perch, Atlantic, cooked, 3 ounces	116	103
2% reduced fat milk, one cup	285	122	Oatmeal, plain and flavored, instant, fortified, one packet prepared	99–110	97–157
Reduced fat chocolate milk (2%), one cup	285	180	Cowpeas, cooked, 1/2 cup	106	80
Buttermilk, low-fat, one cup	284	98	Almonds, 1 ounce	100	164
Chocolate milk, one cup	280	208	White beans, canned, 1/2 cup	96	153
Whole milk, one cup	276	146	Broccoli or kale, cooked from frozen, 1/2 cup	90–100	20
Yogurt, plain, whole milk (8 g protein/ 8 ounces), 8-ounce container	275	138	Okra, cooked from frozen, 1/2 cup	88	26
Ricotta cheese, whole milk, 1/2 cup	255	214	Soybeans, mature, cooked, 1/2 cup	88	149
Blue cheese, 1.5 ounces	225	150	Blue crab, canned, 3 ounces	86	84
Mozzarella cheese, whole milk, 1.5 ounces	215	128	Beet greens, cooked from fresh, 1/2 cup	82	19

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

<sup>a</sup>Food sources of calcium ranked by milligrams of calcium per standard amount; also calories in the standard amount. All are  $\geq 20\%$  of AI for adults 19–50, which is 1,000 mg/d. Those containing 300 mg or more are highlighted in salmon, those with 200–299 mg are shaded lighter, and those with the lightest shading have 80–199 mg.

Note: Both calcium content and bioavailability should be considered when selecting dietary sources of calcium. Some plant foods have calcium that is well absorbed, but the large quantity of plant foods that would be needed to provide as much calcium as in a glass of milk may be unachievable for many. Many other calcium-fortified foods are available, but the percentage of calcium that can be absorbed is unavailable for many of them.

**Signs of Excess.** Disturbed acid–base balance.

**Magnesium:** Magnesium is a mineral needed by every cell of the body; half of the stores are found inside cells of body tissues and organs, and half are combined with calcium and phosphorus in bone. Only 1% of magnesium in the body is found in blood. The body works hard to keep blood levels of magnesium constant. Results of two national surveys indicated that the diets of most adult men and women do not provide the recommended amounts of magnesium. Adults aged 70 years and over eat less magnesium than younger adults, and non-Hispanic black subjects consume less mag-

nesium than either non-Hispanic white or Hispanic subjects. Despite poor intakes, magnesium deficiency is rarely seen in the United States in adults. *RDA varies by age but is typically 420 mg for men and 320 mg for women. UL for supplemental magnesium for adolescents and adults is 350 mg/d.*

**Roles.** Magnesium is needed for more than 300 biochemical reactions including normal muscle contraction, nerve transmission and function, heart rhythm, energy metabolism and protein synthesis, enzyme activation (ADP, ATP), glucose utilization, bone matrix and growth, and normal  $\text{Na}^+/\text{K}^+$  pump. Maintaining an adequate magnesium intake is a

**TABLE A-8 Food Sources of Magnesium<sup>a</sup>**

Food, Standard Amount	Magnesium (mg)	Calories	Food, Standard Amount	Magnesium (mg)	Calories
Pumpkin and squash seed kernels, roasted, 1 ounce	151	148	Bulgur, dry, 1/4 cup	57	120
Brazil nuts, 1 ounce	107	186	Oat bran, raw, 1/4 cup	55	58
Bran ready-to-eat cereal (100%), ~1 ounce	103	74	Soybeans, green, cooked, 1/2 cup	54	127
Halibut, cooked, 3 ounces	91	119	Tuna, yellowfin, cooked, 3 ounces	54	118
Quinoa, dry, 1/4 cup	89	159	Artichokes (hearts), cooked, 1/2 cup	50	42
Spinach, canned, 1/2 cup	81	25	Peanuts, dry roasted, 1 ounce	50	166
Almonds, 1 ounce	78	164	Lima beans, baby, cooked from frozen, 1/2 cup	50	95
Spinach, cooked from fresh, 1/2 cup	78	20	Beet greens, cooked, 1/2 cup	49	19
Buckwheat flour, 1/4 cup	75	101	Navy beans, cooked, 1/2 cup	48	127
Cashews, dry roasted, 1 ounce	74	163	Tofu, firm, prepared with nigari, <sup>b</sup> 1/2 cup	47	88
Soybeans, mature, cooked, 1/2 cup	74	149	Okra, cooked from frozen, 1/2 cup	47	26
Pine nuts, dried, 1 ounce	71	191	Soy beverage, one cup	47	127
Mixed nuts, oil roasted, with peanuts, 1 ounce	67	175	Hazelnuts, 1 ounce	46	178
White beans, canned, 1/2 cup	67	154	Oat bran muffin, 1 ounce	45	77
Pollock, walleye, cooked, 3 ounces	62	96	Great northern beans, cooked, 1/2 cup	44	104
Black beans, cooked, 1/2 cup	60	114	Oat bran, cooked, 1/2 cup	44	44
			Brown rice, cooked, 1/2 cup	42	108
			Haddock, cooked, 3 ounces	42	95

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

<sup>a</sup>Food Sources of Magnesium ranked by milligrams of magnesium per standard amount; also calories in the standard amount. (All are  $\geq 10\%$  of RDA for adult men, which is 420 mg/d).

<sup>b</sup>Calcium sulfate and magnesium chloride.

positive lifestyle modification for preventing and managing high blood pressure. Elevated blood glucose levels increase the loss of magnesium in the urine, which in turn lowers blood levels of magnesium; this explains why low blood levels of magnesium are seen in poorly controlled type 1 and type 2 diabetes.

**Sources.** Magnesium is present in many foods but usually in small amounts. Eating a wide variety of foods, including five servings of fruits and vegetables daily and plenty of whole grains, helps to ensure an AI. The center of the chlorophyll molecule in green vegetables contains magnesium. Intake from a meal may be 45–55% absorbed. Beware of excess phytates. Water can provide magnesium, but the amount varies according to the water supply. “Hard” water contains more magnesium than “soft” water. Dietary surveys do not estimate magnesium intake from water, which may lead to underestimating total magnesium intake and its variability (see Table A-8).

**Signs of Deficiency.** When magnesium deficiency occurs (hypomagnesemia), it is usually due to excessive loss of magnesium in urine from diabetes, antibiotics, diuretics, or excessive alcohol use; gastrointestinal (GI) system disorders; chronically low intake of magnesium; chronic or excessive vomiting, diarrhea, and fat malabsorption. Magnesium deficiency can cause metabolic changes that may contribute to heart attacks,

strokes, and postmenopausal osteoporosis. Poor growth, confusion, disorientation, loss of appetite, depression, tetany with muscle contractions and cramps, tingling, numbness, abnormal heart rhythms, coronary spasm, abnormal nerve function with seizures or convulsions, hyperirritability, and even death can occur.

**Signs of Excess.** Magnesium toxicity (hypermagnesemia) is often associated with kidney failure, when the kidney loses the ability to remove excess magnesium. Mental status changes, nausea, osmotic diarrhea, appetite loss, muscle weakness, difficulty breathing, respiratory failure, extremely low blood pressure, and irregular heartbeat can occur. High doses of magnesium from laxatives can promote diarrhea, even with normal kidney function. The elderly are at risk of magnesium toxicity; kidney function declines with age and use of magnesium-containing laxatives and antacids is common.

**Phosphorus:** Phosphorus is second only to calcium in quantity in the human body. About 80% is in the skeleton and teeth as calcium phosphate; 20% is in extracellular fluid and cells. About 10% is bound to protein. *RDA for adult men and women is 700 mg/d. UL for adults varies from 3–4 g/d.*

**Roles.** Energy metabolism (ADP, ATP); fat, amino acid, and carbohydrate metabolism; calcium regulation; vitamin utilization; bones and teeth; osmotic pressure; DNA coding; buffer

salts; fatty acid transport; oxygen transport and release; leukocyte phagocytosis; and microbial resistance.

**Sources.** Protein-rich foods such as meat, poultry, fish, egg yolks, dried beans and nuts, whole grains, enriched breads and cereals, milk, cheese, and dairy products. Also found in peas, corn, chocolate, and seeds. Excessive intake of soft drinks increases phosphorus intake, often causing an unbalanced intake of calcium. About 70% of oral intake is absorbed. In the United States, milk and cheese products contribute the main sources of phosphorus for infants, toddlers, and adolescents; meat, poultry, and fish products contribute more to the diets of adults.

**Signs of Deficiency.** Hypophosphatemia leads to neuromuscular, renal and hematological changes, as well as rickets or osteomalacia. Deficiency is rare but may occur in those persons who take phosphate binders, persons receiving total parenteral nutrition without phosphate, and prematurity.

**Signs of Excess.** Hyperphosphatemia is especially problematic in renal failure. Nutritional secondary hyperparathyroidism may occur, with fragile bones and fractures.

**Potassium:** Potassium constitutes about 5% of total mineral content in the body. It is the main intracellular ion. *No specific RDA exists.*

**Roles.** Nerve conduction, muscle contraction, glycolysis, oxygen formation, protein synthesis and utilization, acid-base balance, cellular enzyme functioning, and water balance.

**Sources.** Fruits and vegetables, dried beans and peas, whole grains, and whole and skim milk. In the United States, milk and cheese products, meat, poultry, and fish products contribute the most; vegetables follow. Table A-9 provides a list of foods that contain over 500 mg potassium per serving.

**Signs of Deficiency.** Hypokalemia includes muscle weakness, cardiac arrhythmia, paralysis, bone fragility, decreased growth, weight loss, and even death.

**Signs of Excess.** Hyperkalemia promotes paralysis, muscular weakness, arrhythmias, heart disturbances, and even death.

**Sodium:** Sodium constitutes about 2% of total mineral content in the body. It is the main extracellular ion, along with chloride. *No specific RDA is set; 2300 mg/d is the UL for adults.*

**Roles.** Nerve stimulation, muscle contraction, acid-base balance, regulation of blood pressure, and glucose transport into cells. Sodium is the major extracellular fluid cation.

**Sources.** Milk, cheese, eggs, meat, fish, poultry, beets, carrots, celery, spinach, chard, seasoned salts, baking powder and soda, table salt (NaCl), many drugs and preservatives, some drinking water. High-sodium processed foods include: salty snack foods; ketchup and mustard; cured and processed meats; processed cheese; canned soups, vegetables, beans, and meats; soup, rice, and pasta mixes; soy sauce or hoisin sauce; monosodium glutamate (MSG); garlic salt, onion salt, celery salt, and seasoned salts. More than 95% of sodium from a mixed diet is absorbed.

**TABLE A-9 Food Sources of Potassium<sup>a</sup>**

Food, Standard Amount	Potassium (mg)	Calories
Sweet potato, baked, one potato (146 g)	694	131
Tomato paste, 1/4 cup	664	54
Beet greens, cooked, 1/2 cup	655	19
Potato, baked, flesh, one potato (156 g)	610	145
White beans, canned, 1/2 cup	595	153
Yogurt, plain, nonfat, 8-ounce container	579	127
Tomato puree, 1/2 cup	549	48
Clams, canned, 3 ounces	534	126
Yogurt, plain, low-fat, 8-ounce container	531	143
Prune juice, 3/4 cup	530	136
Carrot juice, 3/4 cup	517	71
Blackstrap molasses, one tbs	498	47
Halibut, cooked, 3 ounces	490	119
Soybeans, green, cooked, 1/2 cup	485	127
Tuna, yellowfin, cooked, 3 ounces	484	118
Lima beans, cooked, 1/2 cup	484	104
Winter squash, cooked, 1/2 cup	448	40
Soybeans, mature, cooked, 1/2 cup	443	149
Rockfish, Pacific, cooked, 3 ounces	442	103
Cod, Pacific, cooked, 3 ounces	439	89
Banana, one medium	422	105
Spinach, cooked, 1/2 cup	419	21
Tomato juice, 3/4 cup	417	31
Tomato sauce, 1/2 cup	405	39
Peaches, dried, uncooked, 1/4 cup	398	96
Prunes, stewed, 1/2 cup	398	133
Milk, nonfat, one cup	382	83
Pork chop, center loin, cooked, 3 ounces	382	197
Apricots, dried, uncooked, 1/4 cup	378	78
Rainbow trout, farmed, cooked, 3 ounces	375	144
Pork loin, center rib (roasts), lean, roasted, 3 ounces	371	190
Buttermilk, cultured, low-fat, one cup	370	98
Cantaloupe, 1/4 medium	368	47
1-2% milk, one cup	366	102-122
Honeydew melon, 1/8 medium	365	58
Lentils, cooked, 1/2 cup	365	115
Plantains, cooked, 1/2 cup slices	358	90
Kidney beans, cooked, 1/2 cup	358	112
Orange juice, 3/4 cup	355	85
Split peas, cooked, 1/2 cup	355	116
Yogurt, plain, whole milk, 8-ounce container	352	138

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods.

<sup>a</sup>Food sources of potassium ranked by milligrams of potassium per standard amount, also showing calories in the standard amount. The AI for adults is 4700 mg/d potassium.

**Signs of Deficiency.** Hyponatremia occur from water intoxication with resulting anorexia, nausea, muscle atrophy, poor growth, weight loss, confusion, coma, and even death.

**Signs of Excess.** Hypernatremia may cause confusion, high blood pressure, calcium excretion from bones, heart failure, edema, and coma.

**Sulfur:** Sulfur exists as part of the amino acids methionine, cystine, and cysteine and as part of the antioxidant glutathione peroxidase and other organic molecules. *No specific RDA is set.*

**Roles.** Amino acids (methionine, cystine, cysteine), thiamin molecule, coenzyme A, biotin and pantothenic acid, connective tissue metabolism, penicillin, sulfa drugs, insulin molecule, heparin, and keratin of skin, hair, and nails.

**Sources.** Meat, poultry, fish, eggs, dried beans and legumes, *Brassica* family vegetables (broccoli, cabbage, cauliflower, Brussels sprouts), and wheat germ.

**Signs of Deficiency.** Not specific but likely to occur with hypoalbuminemia.

**Signs of Excess.** Uncommon because excess is excreted in the urine as sulfate, usually in combination with calcium. This may result in hypercalciuria (often after a high-protein meal).

## Trace Minerals

Trace minerals are elements that are found in minute amounts in body tissues and are specific to the function of certain enzymes. They are typically not found in free ionic state but are bound to other proteins.

**Copper:** Copper is an antioxidant. Concentrations of copper are highest in the liver, brain, heart, and kidney; skeletal muscle also contains a large percentage because of total mass. About 90% of copper is bound as ceruloplasmin and is transported to other tissues mainly by albumin. Absorption occurs in the proximal jejunum. *RDA is 900 mg daily for men and women. UL was set at 10 mg/d.*

**Roles:** Skeletal development, immunity, formation of RBCs and leukopoiesis, phospholipid synthesis, electron transport, pigmentation, aortic elasticity, connective tissue formation, and CNS and myelin sheath structure. Part of metalloenzymes including cytochrome c-oxidase.

**Sources:** Barley and whole grains, oysters and shellfish, nuts, dried beans and legumes, cocoa, eggs, prunes, and potatoes. Note: Milk is low in copper. Daily intake of copper in the United States is 2–5 mg; however, many persons have a lower intake than this because fresh foods are low in copper. Meat, poultry, and fish are primary sources in the United States. Approximately 30–60% of oral intake is absorbed, enhanced by acid and decreased by calcium. 94% of copper is tightly bound to ceruloplasmin.

**Signs of Deficiency.** Hypochromic anemia, cardiomyopathy, leukopenia, neutropenia, skeletal abnormalities and osteo-

porosis, decreased skin and hair pigmentation, Menke's steel hair (kinky-hair) syndrome, and reduced immune response. Deficiency is rare in adults, except with celiac disease, protein-losing enteropathies, and nephrotic syndrome. Requirement is increased by excessive zinc intake.

**Signs of Excess.** Excess is rare, but liver cirrhosis, biliary cirrhosis, and Wilson's disease may contribute to the retention of copper. Abnormalities in RBC formation, copper deposits in the brain, diarrhea, tremors, and liver damage occur. Eye rings are present in Wilson's disease. Excesses may decrease vitamin A absorption.

**Fluoride:** Fluoride is found in nearly all drinking waters and soils. The American Dietetic Association affirms that fluoride is an important element for all mineralized tissues and that appropriate consumption aids bone and tooth health (American Dietetic Association, 2005). Eighty to ninety percent of oral intake is absorbed. *RDA is 3–4 mg/d for men and women. UL is set at 10 mg/d.*

**Roles:** Calcium uptake; some role in prevention of calcified aortas; resistance to dental caries, collapsed vertebrae, and osteoporosis; formation of hydroxyapatite; and enamel growth.

**Sources.** Fluoridated water, tea, mackerel, salmon with bones, infant foods to which bone meal has been added.

**Signs of Deficiency.** Dental caries, calcification of aorta, and anemia. Possibly bone thinning and osteoporosis.

**Signs of Excess.** Bony outgrowths at the spine. Tooth mottling, pitting, and discoloration (fluorosis) occur at doses of greater than 2–3 ppm in the drinking water. Excess can result in neurological problems; this feature is used in rat poison, for example.

## Iron

Functional iron is found in hemoglobin (two-thirds), myoglobin (almost one-third), and enzymes. Storage iron is found in ferritin, hemosiderin, and transferrin. Iron is conserved and reused at a rate of 90% daily; the rest is excreted, mainly in bile. Dietary iron must be consumed to meet the 10% gap to prevent deficiency. To increase iron absorption, use sulfur amino acids and vitamin C (especially with nonheme foods); cook foods in an iron skillet; choose iron-enriched rice and do not rinse before cooking. Take iron separately from calcium supplements. Excessive calcium intake and oxalic, tannic, and phytic acids can reduce absorption. Avoid coffee and tea for 1 hour after eating; the tannic acid blocks iron absorption. Serum iron is largely bound to transferrin. About 5–15% is absorbed as ferrous iron; 15–25% of oral intake of heme iron is absorbed (meat, fish, and poultry); 2–20% of oral intake of nonheme iron is absorbed (legumes, grains, and fruit). *The RDA is 8 mg for men and postmenopausal women; 18 mg for premenopausal women. Pregnant women need 27 mg/d and breastfeeding women need 9 mg. Teenage girls (ages 14–18 years) need 15 mg iron per day (27 mg if pregnant; 10 mg if breastfeeding). Teenage boys (ages 14–18 years) need 11 mg iron per day. The UL for iron is 45 mg/d.*

**Roles.** Responsible for carrying oxygen to cells through hemoglobin and myoglobin, skeletal muscle functioning, cognitive functioning, leukocyte functions and T-cell immunity, cellular enzymes, and cytochrome content for normal cellular respiration.

**Sources:** Beans, beef, dried fruit, enriched grains, fortified cereals, pork. In the United States, grain products provide the highest amount of dietary iron (see Table A-10).

**Signs of Deficiency.** Hypochromic and microcytic anemia, fatigue and weakness, pallor, pale conjunctiva, koilonychia (thin, spoon-shaped nails), impaired learning ability, cheilosis, glossitis, pica, tachycardia. Deficiency is defined as having an abnormal value for two of three laboratory tests of iron

status (erythrocyte protoporphyrin, transferrin saturation, or serum ferritin). Iron deficiency anemia is defined as iron deficiency plus low hemoglobin. Iron deficiency anemia is the most common nutrient deficiency in the world, especially among toddlers, teenage girls, and women of child-bearing age.

**Signs of Excess.** Iron deposits (hemosiderosis); vomiting or diarrheas with GI distress, hemochromatosis, drowsiness. Excess may occur from taking iron supplements daily or from consuming multiple sources, including transfusion overload with sickle cell anemia or thalassemia major.

**Zinc:** Zinc is distributed in the body with proteins such as albumin, transferrin, ceruloplasmin, and gamma-globulin.

**TABLE A-10 Food Sources of Iron<sup>a</sup>**

Food, Standard Amount	Heme (H) or Nonheme (N)	Iron (mg)	Calories
Clams, canned, drained, 3 ounces	H	23.8	126
Fortified ready-to-eat cereals (various), ~1 ounce	N	1.8–21.1	54–127
Oysters, eastern, wild, cooked, moist heat, 3 ounces	H	10.2	116
Organ meats (liver, giblets), various, cooked, 3 ounces <sup>b</sup>	N	5.2–9.9	134–235
Fortified instant cooked cereals (various), one packet	N	4.9–8.1	Varies
Soybeans, mature, cooked, 1/2 cup	N	4.4	149
Pumpkin and squash seed kernels, roasted, 1 ounce	N	4.2	148
White beans, canned, 1/2 cup	N	3.9	153
Blackstrap molasses, one tbsp	N	3.5	47
Lentils, cooked, 1/2 cup	N	3.3	115
Spinach, cooked from fresh, 1/2 cup	N	3.2	21
Beef, chuck, blade roast, lean, cooked, 3 ounces	H	3.1	215
Beef, bottom round, lean, 0 inch fat, all grades, cooked, 3 ounces	H	2.8	182
Kidney beans, cooked, 1/2 cup	N	2.6	112
Sardines, canned in oil, drained, 3 ounces	H	2.5	177
Beef, rib, lean, 1/4 inches fat, all grades, 3 ounces	H	2.4	195
Chickpeas, cooked, 1/2 cup	N	2.4	134
Duck, meat only, roasted, 3 ounces	H	2.3	171
Lamb, shoulder, arm, lean, 1/4 inches fat, choice, cooked, 3 ounces	H	2.3	237
Prune juice, 3/4 cup	N	2.3	136
Shrimp, canned, 3 ounces	H	2.3	102
Cowpeas, cooked, 1/2 cup	N	2.2	100
Ground beef, 15% fat, cooked, 3 ounces	H	2.2	212
Tomato puree, 1/2 cup	N	2.2	48
Lima beans, cooked, 1/2 cup	N	2.2	108
Soybeans, green, cooked, 1/2 cup	N	2.2	127
Navy beans, cooked, 1/2 cup	N	2.1	127
Refried beans, 1/2 cup	N	2.1	118
Beef, top sirloin, lean, 0 inch fat, all grades, cooked, 3 ounces	H	2.0	156
Tomato paste, 1/4 cup	N	2.0	54

Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

<sup>a</sup>Food Sources of iron ranked by milligrams of iron per standard amount; also calories in the standard amount. All are  $\geq 10\%$  of RDA for teen and adult females, which is 18 mg/d.

<sup>b</sup>High in cholesterol.

Animal sources are better utilized; vegetarian diets must be monitored for zinc deficiency. Ten to forty percent of zinc from meals is absorbed in the duodenum and the jejunum. Vitamin D can increase bioavailability. Phytates, excess copper, and fiber form complexes and reduce absorption, as do calcium and phosphate salts. Zinc absorption is affected by level of zinc in the diet and interfering substances, such as phytates, calcium, cadmium, folic acid, copper, or excessive fiber. Albumin is the major plasma carrier. *RDA is 11 mg for men and 8 mg for women. UL is 40 mg.*

**Roles.** ACTH-stimulated steroidogenesis in adrenals; sexual maturation; fatty acid, carbohydrate, protein, and nucleic acid metabolism; CO<sub>2</sub> transport; amino acid breakdown from peptides; oxidation of vitamin A; reproduction; growth; enzymes including alcohol dehydrogenase, alkaline phosphatase, and lactic acid dehydrogenase; wound healing; catalyst for hydrogenation; immunity; night vision; alcohol detoxification in the liver; heme synthesis; taste and smell acuity; synthesis of glutathione; and collagen precursors. Zinc supplementation has been shown to be effective in reducing morbidity and mortality from diarrhea, malaria, HIV infection, sickle cell anemia, renal disease, and GI disorders. Zinc gluconate lozenges do not always alleviate cold symptoms in children and adolescents but may be somewhat helpful.

**Sources.** Beans, seafood (e.g., lobster, shrimp, oysters), poultry, meat (red meat such as beef and liver especially), eggs, milk, peanuts, oatmeal, whole grains (e.g., whole wheat, rye bread, wheat germ), and yeast. The average American diet contains 10–15 mg/d. Meat, poultry, and fish are the primary sources of zinc.

**Signs of Deficiency.** Zinc is so prevalent in cellular metabolism that even minor impairment in supply is likely to have multiple biological and clinical effects. Deficiency reduces antibody responses and cell-mediated immunity and may cause dermatitis, skin lesions, growth failure (dwarfism), hypogonadism, decreased taste acuity (hypogeusia), alopecia, diarrhea, glossitis, stomatitis, and impaired wound healing. Zinc deficiency has a significant impact on development and on immune function; premature infants and children are at greatest risk. In children with zinc deficiency, severe growth depression is seen. Strict vegetarians, preschoolers who do not eat meat, adolescent females, and those on a chronically high-phytate diet may also be at risk, especially if other disease states are present.

**Signs of Excess.** Vomiting, diarrhea, low levels of serum copper, hyperamylasemia may result. Excessive zinc intake is probably self-limiting because of GI distress that occurs. Zinc toxicity can occur in renal dialysis if not carefully monitored.

### Ultra-Trace Minerals

**Boron:** Boron can be found in the brain and the bone; it is also found in the spleen and thyroid. It is found in foods such as sodium borate; it is absorbed at a rate of 90%. *No RDA has been set, but a UL of 20 mg was established.*

**Roles.** Mineral metabolism in animals and humans, cell membrane functioning. It may function in a role similar to estrogen in bone metabolism and strengthening.

**Sources.** Drinking water, wine, cider and beer, noncitrus fruits, potatoes, peanuts, and legumes. Note: Protein foods and grains are low in boron. Infant foods, fruits and fruit juices, milk and cheese foods, and beverages provide the most.

**Signs of Deficiency.** None known at this time.

**Signs of Excess.** Reproductive and developmental effects are possible.

**Chromium:** Chromium is closely related to insulin action. Absorption ranges from 0.5 to 2%. Chromium needs transferrin for distribution. *RDA is 20 mg/d for women and 35 mg/d for men.* No UL has been set.

**Roles.** Insulin molecule (part of glucose tolerance factor known as chromodulin); fatty acid, triglyceride, and cholesterol metabolism; normal glucose metabolism; nucleic acid stability; regulation of gene expression; and peripheral nerve functioning.

**Sources.** Oysters, liver, potatoes, eggs, vegetable oil, brewer's yeast, whole grains and bran, shortening, nuts, and peanuts. Dairy products, fruits, and vegetables are low in chromium. Phytates and oxalates can decrease absorption.

**Signs of Deficiency.** Hyperglycemia refractory to insulin, weight loss, glucosuria, peripheral neuropathy, encephalopathy. Deficiency may be found in severe malnutrition, in diabetes, or in elderly patients with cardiovascular disease.

**Signs of Excess.** Dermatological allergy, nausea, vomiting, convulsions, irritation, gastrointestinal ulcers.

**Cobalt:** Most cobalt is in vitamin B<sub>12</sub> stores in the liver. Cobalt may share intestinal transport with iron and is increased in patients with low iron intake and iron stores. *No specific RDA is set.*

**Roles.** Treatment of some anemias, part of structure of cobalamin in vitamin B<sub>12</sub>, role in immunity, and healthy nerves and RBCs.

**Sources.** Seafood (such as oysters and clams), meats (such as liver), poultry, some grains, and cereals. Note: Cow's milk is very low. More than 50% of dietary cobalt is absorbed.

**Signs of Deficiency.** Weakness, anemia, and emaciation. Deficiency is usually in conjunction with vitamin B<sub>12</sub> deficiency and low intake of protein foods. Lack of intrinsic factor, gastrectomy, or malabsorption syndromes may also cause deficiency.

**Signs of Excess.** Polycythemia, bone marrow hyperplasia, reticulocytosis, and increased blood volume may result.

**Iodine:** With the iodization of salt, iodine deficiency has been almost eliminated in the United States and Western nations. Fortification results in fewer goiters and less cretinism, stillbirths, spontaneous abortions, and mental or

growth retardation. Millions of people are at risk in other nations. The thyroid gland maintains 75% of the body's iodine; the rest is in the gastric mucosa and bloodstream. Iodide content of vegetables varies by the content of the local soil. Absorption is 50–100% from the gut. *RDA is 150 mg/d for both men and women. UL is 1.1 mg/d.*

**Roles.** Energy metabolism, proper thyroid functioning, normal growth and reproduction, prevention of goiter, and regulation of cellular metabolism and temperature. Iodine is found with T3 and T4 distribution.

**Sources.** Iodized salt, seaweed, and seafood (clams, oysters, sardines, lobster, and saltwater fish). Other lesser sources may include cream (in milk), eggs, drinking water in various areas, plant leaves (broccoli, spinach, and turnip greens), cranberries, and legumes. Iodized salt should be encouraged for pregnant women. Goitrogens in cabbage, turnips, rapeseeds, peanuts, cassava, and soybeans may block uptake of iodine by body cells; heating and cooking inactivate them.

**Signs of Deficiency.** Enlarged thyroid gland or related goiter; hypercholesterolemia; weight gain; cold intolerance; thinning hair; cognitive impairment; deafness; decreased metabolic rate; neuromuscular impairments. In infants, abnormal fetal growth, brain development, and cretinism can result.

**Signs of Excess.** Excess may depress thyroid activity and elevate thyroid-stimulating hormone (TSH) levels. High levels of thyroid hormone with goiter or myxedema can occur.

**Manganese:** Manganese affects reproductive capacity, pancreatic function, and carbohydrate metabolism. Less than 5% is absorbed from diet. It is transported bound to a macroglobulin, transferrin, or transmanganin. Manganese, cobalt, and iron compete for pathways. Human milk tends to be low in manganese levels. *An AI level has been set at 2.3 mg for men and 1.8 mg for women. The UL has been established at 11 mg.*

**Roles.** Polysaccharide and fatty acid metabolism, enzyme activation, tendon and skeletal development, possible role in hypertension, fertility and reproduction (role in squalene as a precursor of cholesterol and sex hormones), melanin and dopamine production, energy and glucose production.

**Sources.** Tea, coffee, whole grains, wheat germ and bran, blueberries, peas, beans and dried legumes, nuts, spinach, and cocoa powder. Sources of manganese are plant foods, not animal foods. In the United States, grain products are primary sources.

**Signs of Deficiency.** Nausea, vomiting, transient dermatitis, weight loss, ataxia, skeletal and cartilage abnormalities occur. Beware of excess calcium, phosphorus, iron, or magnesium supplementation.

**Signs of Excess.** Excesses accumulate in the liver and CNS. Parkinsonian tremors, difficulty in walking, facial muscle spasms, ataxia, hyperirritability, or hallucinations can occur.

**Molybdenum:** Molybdenum is important mostly for its role in xanthine oxidase. About 40–100% of intake is absorbed from the duodenum in protein-bound form. It is readily absorbed

from the stomach and small intestine and excreted in the urine. *RDA is 45 mcg for both men and women. The UL is 2 mg.*

**Roles.** Flavoproteins; copper antagonist; component of sulfite oxidase, aldehyde oxidase, and xanthine oxidase; iron storage; energy metabolism; and degradation of cysteine and methionine through sulfite oxidase.

**Sources.** Legumes, whole-grain breads and cereals, dark green leafy vegetables, milk and dairy products, and organ meats. Milk and cheese products and grains provide the most from diet.

**Signs of Deficiency.** Tachycardia, tachypnea, visual and mental changes, elevated plasma methionine, low-serum uric acid, headache, lethargy, nausea, and vomiting. Long-term parenteral nutrition that is deficient in molybdenum is a concern.

**Signs of Excess.** Hyperuricemia and gout-like syndrome can occur. Excesses are rare.

**Selenium:** Cellular and plasma glutathione are the functional parameters for measuring selenium status. Selenium intake in the United States is generally very good; deficiency is rare. More than 50% dietary intake is absorbed (average range, 35–85%). It is transported via albumin from the duodenum. *RDA level for selenium was set at 55 mg/d; UL was set at 400 mg.*

**Roles.** Selenium functions within mammals primarily as selenoproteins. Glutathione catalyzes the reduction of peroxides that can cause cellular damage. Protein biosynthesis (selenomethionine and selenocysteine), sparing of vitamin E, protection against mercury toxicity; some role in thyroid function and immunity.

**Sources.** Seafood and fish, chicken, egg yolks, meats (especially kidney and liver), whole-grain breads and cereals, wheat germ, foods grown in selenium-rich soil including garlic, dairy products, Brazil nuts, and onions. Dietary selenium is found with protein in animal tissue (muscle meats, organ meats, and seafood). Grains and seeds have variable amounts dependent on the soil.

**Signs of Deficiency.** Muscle weakness and pain, carcinogenesis, and cardiomyopathy. Keshan's disease with cardiomyopathy is a selenium deficiency in China where soil levels are quite low. Kashin-Beck's disease occurs in preadolescents and adolescents; it has effects similar to osteoarthritis with stiffness and swelling of the elbows, knees, and ankles.

**Signs of Excess.** Selenosis causes garlicky odor on the breath and decaying of teeth. Nausea, vomiting, hair and nail loss, fatigue, headache, and chronic dermatitis can also occur.

### Less-Studied Ultra-Trace Minerals

**Aluminum, Arsenic, Cadmium, Lead, Lithium, and Tin:** Not much is known about the roles, functions, or purpose in the human body of these minerals. For all age groups, grain products (mainly cornbread, pancakes, biscuits, muffins, and yellow cake) provide the highest amount of aluminum in the

diet. Organic arsenic is found in dairy products, meats, poultry, fish, grains and cereal. Inorganic arsenic is toxic.

**Nickel:** There may be roles in iron and zinc metabolism, hematopoiesis, DNA and RNA, and enzyme activation. Less than 10% of nickel is absorbed. It is transported by serum albumin. Nickel hypersensitivity can occur from prior dermal contact. *No RDA has been set, but UL was established at 1 mg/d.*

**Sources.** Nuts, legumes, cereals, sweeteners, chocolate candy, and chocolate milk powders.

**Silicon:** There may be roles in normal bone growth and calcification; collagen and connective tissue formation in the presence of calcium.

Natural food and water sources do not seem to cause adverse health effects. *No RDA or UL have been established.*

**Sources.** Most plant-based foods. Grains and beer are good sources.

**Vanadium:** Vanadium seems to have a role in thyroid metabolism. High doses may cause biochemical changes that precede cancer. *No RDA has been set. UL was established at 1.8 mg/d.*

**Sources.** Shellfish, whole grains, mushrooms, black pepper, parsley, and dill seed.

## VITAMINS

Vitamins were first named “vital amines” in 1912 because they seemed to be important to life. Once it was known that they contain few amine groups, the “e” was dropped. There are 13 known vitamins (four fat-soluble and nine water-soluble vitamins). They are organic compounds, containing carbon structures. The best nutritional strategy for promoting optimal health and reducing the risk of chronic disease is to obtain adequate nutrients from a wide variety of foods. Eating more whole grains, fruits and vegetables is the recommendation, rather than taking supplements. Supplements are needed in special cases, such as in pregnancy and in some medical conditions. Supplements are most useful when taken as a multivitamin supplement that meets 100% of the daily recommended values. Although fat-soluble vitamins should not be consumed above UL doses, meeting 100% DRI levels is safe.

### Fat-Soluble Vitamins

**Vitamin A (Retinol, Retinal, Retinoic Acid):** Vitamin A is best known for its role in vision and skin integrity. From 7–65% of vitamin A from the diet is absorbed in the mucosal cells of the small intestine. There, dietary retinyl esters are hydrolyzed by pancreatic triglyceride lipase (PTL), and the intestinal brush border phospholipase. Once in the cell, retinol is complexed with cellular retinol-binding protein type 2 (CRBP2), a substrate for reesterification of the retinol by the enzyme lecithin/retinol acyltransferase (LRAT). Retinol-binding protein (RBP) is used for transport. Retinyl esters are incorporated into chylomicrons. Stress can increase excretion; zinc or

protein deficiency can decrease transport. Dietary vitamin A is transported via chylomicrons; 90% of vitamin A is stored in the liver. Its provitamins include beta-carotene and cryptoxanthin. *AI for infants is based on the amount of retinol found in human milk. RDA is 900 mg for men and 700 mg for women, adjusted for differences in average body size. UL is 3000 mg/d.*

**Functions.** Vision (especially night), gene regulation, growth, prevention of early miscarriage, immunity against infection (measles and many others), corticosterones, weight gain, proper bone, tooth, and nerve development, membrane functions, and epithelial tissue integrity in lungs and trachea especially. Vitamin A supplementation is used to treat some forms of cancer and degenerative retinitis pigmentosa.

**Sources.** See Table A-11 for sources.

**TABLE A-11 Food Sources of Vitamin A<sup>a</sup>**

Food, Standard Amount	Vitamin A ( $\mu$ g RAE)	Calories
Organ meats (liver, giblets), various, cooked, 3 ounces <sup>b</sup>	1490–9126	134–235
Carrot juice, 3/4 cup	1692	71
Sweet potato with peel, baked, one medium	1096	103
Pumpkin, canned, 1/2 cup	953	42
Carrots, cooked from fresh, 1/2 cup	671	27
Spinach, cooked from frozen, 1/2 cup	573	30
Collards, cooked from frozen, 1/2 cup	489	31
Kale, cooked from frozen, 1/2 cup	478	20
Mixed vegetables, canned, 1/2 cup	474	40
Turnip greens, cooked from frozen, 1/2 cup	441	24
Instant cooked cereals, fortified, prepared, one packet	285–376	75–97
Various ready-to-eat cereals, with added vitamin A, ~1 ounce	180–376	100–117
Carrot, raw, one small	301	20
Beet greens, cooked, 1/2 cup	276	19
Winter squash, cooked, 1/2 cup	268	38
Dandelion greens, cooked, 1/2 cup	260	18
Cantaloupe, raw, 1/4 medium melon	233	46
Mustard greens, cooked, 1/2 cup	221	11
Pickled herring, 3 ounces	219	222
Red sweet pepper, cooked, 1/2 cup	186	19
Chinese cabbage, cooked, 1/2 cup	180	10

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

<sup>a</sup>Food Sources of vitamin A ranked by micrograms. Retinol Activity Equivalents (RAE) of vitamin A per standard amount; also calories in the standard amount. (All are  $\geq 20\%$  of RDA for adult men, which is 900 mg/d RAE).

<sup>b</sup>High in cholesterol.

**Signs of Deficiency.** Impaired vision is the first sign. Xerophthalmia, night blindness (nyctalopia), follicular hyperkeratosis or thickening of skin around hair follicles, drying of the whites of the eyes, eventual blindness, spots on the whites of the eyes, infections, and death.

**Vulnerable Populations.** Anorexia nervosa, burns, biliary obstruction, cancer, cirrhosis, celiac disease, cystic fibrosis, drug use (cholestyramine, mineral oil, and neomycin), hookworm, hepatitis of infectious origin, giardiasis, kwashiorkor, malaria, measles, pancreatic disease, pneumonia, pregnancy, prematurity, rheumatic fever, tropical sprue, and zinc deficiency.

**Signs of Excess.** Headache, anorexia, abdominal pain, blurred vision, muscle weakness, drowsiness, irritability, peeling of skin, peripheral neuritis, papilledema, serum vitamin A >100 µg/dL. Long-term supplementation with retinol (such as 25,000 IU/d) may have adverse effects on blood lipid levels and bone health. Vitamin A is known for its teratogenic effects; pregnant women should consider taking it in the form of beta-carotene. Caution should be given to supplement use in women of childbearing age because many women don't know they are pregnant in the earliest stages; supplements with retinol should be avoided during the first trimester.

**Carotenoids:** There are more than 500 natural carotenoids. Two beta-carotene molecules are equivalent to one molecule of vitamin A. The bioavailability of carotenoids from vegetables is low; fat is required for adequate absorption. Between 9 and 17% of dietary carotenes are absorbed. Dietary carotenoids may prevent some types of cancer through enhancement of immune response, inhibition of mutagenesis, and protection against oxidative damage to cells; alpha-carotenes, beta-cryptoxanthin, lutein, zeaxanthin, and lycopene contribute to these important functions. Persons at risk for developing lung cancer (i.e., current smokers and workers exposed to asbestos) should *not* take beta-carotene supplements. *No specific RDA recommendations were made for beta-carotene.*

**Sources.** Beta-carotene is found in deep yellow, orange, or dark green fruits and vegetables such as pumpkin, sweet potato, carrots, spinach, kale, turnip greens, cantaloupe, apricots, romaine lettuce, broccoli, papaya, mango, and tangerine.

**Signs of Excess.** Hypercarotenoderma involves yellowing of skin and the whites of eyes.

**Vitamin D (Calcitriol, D<sub>3</sub>):** Vitamin D for humans is obtained from sun exposure, food and supplements. It is biologically inert and has to undergo two hydroxylation reactions to become active as Calcitriol (1,25-dihydroxycholecalciferol), or 1,25-dihydroxyvitamin D<sub>3</sub>. Steps in metabolism include 7-dehydrocholesterol → previtamin D<sub>3</sub> → cholecalciferol (D<sub>3</sub>) → 25-hydroxycholecalciferol → calcitriol (1,25-dihydroxycholecalciferol, the active form). Bile salts are required for absorption; 90% of dietary intake is absorbed. Dietary vitamin D is absorbed with lipid into the intestine by passive diffusion; it is synthesized in the skin from cholesterol that enters the capillary system.

Transport occurs via chylomicrons to the liver. Although five forms of vitamin D have been discovered, the two forms that matter are vitamins D<sub>2</sub> (ergocalciferol) and D<sub>3</sub> (cholecalciferol). There is decreased production from the skin with aging. *2.5 mcg of vitamin D is considered sufficient to prevent vitamin D-deficiency rickets, higher levels of 5 µg/d are recommended for infants and children throughout the period of skeletal development. The AI increases to 10 µg/d for adults aged 51 and older and to 15 µg/d for adults 71 years and older. The UL for infants is 25 µg/d and for children and adults, 50 µg/d.*

**Functions.** The main functions of vitamin D are bone metabolism, calcium homeostasis, and expression of hundreds of genes. Calcitriol plays a key role in the maintenance of many organ systems; the volume and acidity of gastric secretions; growth of soft tissues including skin and pancreas; bone calcification, growth and repair; tooth formation; parathormone (PTH) management; and renal/intestinal phosphate absorption.

**Sources.** Brief and casual exposure (10–20 minutes daily) to natural sunlight can be encouraged. Check nutrition labels for vitamin D fortification when using soy or rice milks. Food sources of vitamin D are listed in Table A-12.

**TABLE A-12 Food Sources of Vitamin D**

Foods with Naturally Occurring Vitamin D	International Units
Herring, 3 ounces	1384
Cod liver oil, one tablespoon	1350
Halibut, 3 ounces	510
Catfish, 3 ounces	425
Salmon, canned, 3 ounces	390
Mackerel, 3 ounces	306
Sardines, canned in oil, 1.75 ounces	250
Tuna, canned in oil, 3 ounces	200
Egg yolk, one yolk	20
Beef liver, 3 ounces	15
Swiss cheese, 1 ounce	12
<i>Vitamin D-Fortified Foods</i>	
Soy milk, one cup	119
Milk, one cup	100
Fortified orange juice, one cup	100
Fortified breakfast cereal, one cup	20–100
Fortified yogurt, one cup	80
Fortified margarine, one tablespoon	60

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

**Signs of Deficiency.** Hypocalcemic tetany is a low calcium condition in which the patient has overactive neurological reflexes, spasms of the hands and feet, cramps and spasms of the voice box (larynx). Vitamin D from sunlight exposure is low during the winter months. Hypovitaminosis D is related to lowered vitamin D intake, less exposure to ultraviolet light (UVB), anticonvulsant use, renal dialysis, nephrotic syndrome, hypertension, diabetes, winter season, and high PTH and alkaline phosphatase levels. Hypovitaminosis D is common in general medical in-patients. Bowed legs, rickets in children, and osteomalacia in adults may occur.

**Vulnerable Populations.** The prevalence of vitamin D deficiency is high. The National Health and Nutrition Examination Survey (NHANES) team found that 9% of U. S. children were vitamin D deficient (<15 ng/mL of blood) and another 61% were vitamin D insufficient (15–29 ng/mL). Those individuals with dark skin or who wear protective clothing may also not absorb sufficient vitamin D from sun exposure alone. Living near the North or South Pole in winter is a risk for deficiency. Biliary obstruction, celiac disease, cystic fibrosis, drug use (bile salt binders, glucocorticoids, phenobarbital, primidone, and mineral oil), end-organ failure, Fanconi's disease, hepatic disease, hypertension, primary hypophosphatemia, hypoparathyroidism, inflammatory bowel disease, intestinal malabsorption, lymphatic obstruction, multiple sclerosis, nephrotic syndrome, neurological and psychiatric conditions such as depression and bipolar disorders, pancreatitis, parathyroid surgery, postmenopausal status, prematurity, renal disease and dialysis, small bowel resection, and tropical sprue. Pregnant women should enjoy a few minutes in the sun each day, if possible. Low levels may increase the risk of breast, colon, and prostate cancers; depression, poor brain function, severe dementia in older adults; tuberculosis; pneumonia; bacterial infections and gum disease; autoimmune diseases, such as multiple sclerosis and type 1 diabetes.

**Signs of Excess.** Patients often complain of headache and nausea, and infants given excessive amounts of vitamin D may have GI upset, bone fragility, and retarded growth. Stupor, confusion, anorexia, nausea, vomiting, constipation, weakness, hypertension, renal stones, polyuria, polydipsia, cardiac arrhythmias, itchy skin, increased bone density on x-ray, calcium deposits throughout the body, increased serum calcium, increased calcium in the urine, elevated serum 25-hydroxycholecalciferol or elevated serum 1,25-dihydroxycholecalciferol levels. In the absence of sufficient vitamin K, excessive vitamin D can cause soft tissue calcification.

**Vitamin E (Tocopherol, Tocotrienols):** Tocotrienols plus other forms affect cholesterol metabolism, carotid arteries, and immunity against cancer. The natural form is D-alpha-tocopherol (need 22 IU). The DL-alpha-tocopherol form is synthetic and less effective. Vitamin E is absorbed in the upper small intestine by micelle-dependent diffusion. Overall, 20–40% is absorbed with meals; bile and pancreatic secretions are needed and VLDLs and LDLs carry it to tissues. An IU of vitamin E is equal to 0.67 mg of RRR-alpha-tocopherol and 1 mg of all-rac-alpha-tocopherol. *RDA is 15 mg for adults. UL is 1000 mg.*

**Functions:** The main function of vitamin E is as a lipid-soluble membrane antioxidant, along with vitamin C and selenium. It

protects unsaturated phospholipids of the membrane from oxidative degradation through free-radical scavenging. Other roles include anticoagulant and vitamin K antagonist; intracellular respiration; hemopoietic agent; roles in muscular, vascular, reproductive, and CNS systems; some role in reproduction; neutralizes free radicals; protects against cataracts; may relieve discomforts of rheumatoid arthritis; protects against effects of the sun, smog, and lung disease; protects brain cell membranes.

**Sources.** Tocopherols and tocotrienols are synthesized only by plants so plant products, especially oils, are the best sources of Vitamin E.

Requirements increase with use of PUFAs; if normal needs are 15 mg/d, normal requirements double daily with high PUFA intakes. Gamma-tocopherol is more common in the U. S. food supply (as from soybean oil); it is less useful to the body (see Table A-13).

**Signs of Deficiency.** Symptoms of deficiency in humans are rare, but can manifest clinically as loss of deep tendon reflexes, impaired vibratory and position sensation, changes in balance and coordination, muscle weakness and visual disturbances. Other targets of deficiency include the vascular and reproductive systems. Rupture of RBCs, impaired vitamin A storage, and prolonged blood coagulation may also occur. For supplementation, pharmacists evaluate equivalent vitamin E dosing as follows:

DL-alpha-tocopheryl acetate	1 mg	1 IU
DL-alpha-tocopherol	0.91 mg	1.1 IU
DL-alpha-tocopheryl acid succinate	1.12 mg	0.89 IU
D-alpha-tocopheryl acid succinate	0.826 mg	1.21 IU

**Vulnerable Populations.** Alzheimer's disease, arthritis, biliary cirrhosis, bronchopulmonary dysplasia, cardiovascular diseases, cystic fibrosis, drug use (cholestyramine, clofibrate, oral contraceptives, and triiodothyronine), high intake of PUFA in diet, malabsorption syndromes, malnutrition, musculoskeletal disorders, pancreatic diseases, pregnancy, prematurity, pulmonary diseases, and steatorrhea.

**Signs of Excess.** Vitamin E is one of the least toxic vitamins, but at high doses, it can antagonize the utilization of other fat-soluble vitamins. Excessive intake has caused isolated cases of dermatitis, fatigue, pruritus ani, acne, vasodilation, hypoglycemia, GI symptoms, increased requirement for vitamin K, impaired coagulation, and muscle damage.

**Vitamin K:** First isolated from alfalfa, the forms of vitamin K are **phyloquinone (K<sub>1</sub>)** in green plants; **menaquinone (K<sub>2</sub>)** from human bacterial synthesis and **menadione (K<sub>3</sub>)** in pharmaceutical form. Vitamin K absorption is optimal with bile and pancreatic juice; 10–70% of dietary intake is usually absorbed. The phyloquinones are absorbed by an energy-dependant process in the small intestine; the menaquinones and menadione are absorbed in the small intestine and colon by passive diffusion. Because intestinal bacteria make about 50% of the bodily requirement, a sterile gut or malabsorption can create deficiency. Vitamin E excesses can reduce absorption of vitamin K. Warfarin (Coumadin) blocks regeneration of active, reduced vitamin K, thus prolonging clotting time,

**TABLE A-13 Food Sources of Vitamin E<sup>a</sup>**

Food, Standard Amount	AT (mg)	Calories
Fortified ready-to-eat cereals, ~1 ounce	1.6–12.8	90–107
Sunflower seeds, dry roasted, 1 ounce	7.4	165
Almonds, 1 ounce	7.3	164
Sunflower oil, high linoleic, one tbsp	5.6	120
Cottonseed oil, one tbsp	4.8	120
Safflower oil, high oleic, one tbsp	4.6	120
Hazelnuts (filberts), 1 ounce	4.3	178
Mixed nuts, dry roasted, 1 ounce	3.1	168
Turnip greens, frozen, cooked, 1/2 cup	2.9	24
Tomato paste, 1/4 cup	2.8	54
Pine nuts, 1 ounce	2.6	191
Peanut butter, two tbsp	2.5	192
Tomato puree, 1/2 cup	2.5	48
Tomato sauce, 1/2 cup	2.5	39
Canola oil, one tbsp	2.4	124
Wheat germ, toasted, plain, two tbsp	2.3	54
Peanuts, 1 ounce	2.2	166
Avocado, raw, 1/2 avocado	2.1	161
Carrot juice, canned, 3/4 cup	2.1	71
Peanut oil, one tbsp	2.1	119
Corn oil, one tbsp	1.9	120
Olive oil, one tbsp	1.9	119
Spinach, cooked, 1/2 cup	1.9	21
Dandelion greens, cooked, 1/2 cup	1.8	18
Sardine, Atlantic, in oil, drained, 3 ounces	1.7	177
Blue crab, cooked/canned, 3 ounces	1.6	84
Brazil nuts, 1 ounce	1.6	186
Herring, Atlantic, pickled, 3 ounces	1.5	222

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

<sup>a</sup>Food sources of vitamin E ranked by milligrams of vitamin E per standard amount; also calories in the standard amount. (All provide  $\geq 10\%$  of RDA for vitamin E for adults, which is 15 mg  $\alpha$ -tocopherol [AT]/d).

which is best monitored through international normalized ratio (INR) where the timing level of 2–3 is desired. *AI is 120 mg for men and 90 mg for women. No UL has been established, but data are limited and one should not assume that high vitamin K consumption is harmless.*

**Functions.** Vitamin K is important for normal blood clotting, calcium metabolism, and bone mineralization. Low vitamin K intakes are associated with an increased incidence of hip fractures. Genetic loss of less critical vitamin K-dependent proteins, dietary vitamin K inadequacy, human polymorphisms or mutations, and vitamin K deficiency induced by chronic anticoagulant (warfarin/Coumadin) therapy are all linked to age-associated conditions: bone fragility after estrogen loss

(osteocalcin) and arterial calcification linked to cardiovascular disease (McCann and Ames, 2009). Vitamin K is also linked with sphingolipid metabolism in the brain.

**Sources.** Plant foods such as green leafy vegetables are better sources of vitamin K than animal foods. Fish, liver, meat, eggs, cereal, and some fruits contain smaller amounts (see Table A-14).

**Signs of Deficiency.** Hemorrhage with prolonged clotting time is the key sign of deficiency, which might even lead to a fatal anemia. Vitamin K deficiency can be found in lipid malabsorption, chronic antibiotic therapy, and liver disease where

**TABLE A-14 Food Sources of Vitamin K**

Food and Serving Size	Vitamin K ( $\mu$ g)
Kale, cooked 1/2 cup	531
Spinach, cooked 1/2 cup	444
Collard greens, cooked 1/2 cup	418
Beet greens, cooked 1/2 cup	348
Swiss chard, cooked 1/2 cup	286
Turnip greens, cooked, 1/2 cup	265
Mustard greens, cooked 1/2 cup	210
Spinach, raw one cup	145
Broccoli 1/2 cup	110 cooked, 45 raw
Brussels sprouts, cooked 1/2 cup	109
Scallions (including bulb and green tops), raw 1/2 cup	104
Cabbage, cooked 1/2 cup	81
Lettuce (green leaf), raw one cup	97
Prunes, stewed one cup	65
Okra, cooked one cup	64
Parsley one tablespoon	62
Cucumber, raw one large	49
Asparagus, cooked four spears	48
Tuna, canned 3 ounces	37
Celery, raw one cup	35
Black-eyed peas, cooked 1/2 cup	31
Kiwi one medium	30
Blackberries or blueberries, raw one cup	29
Artichoke, cooked one cup	25
Peas 1/2 cup	24
Grapes (red or green) one cup	23
Strawberries, sliced one cup	23
Green beans, cooked 1/2 cup	20
Soy beans or mung beans, cooked 1/2 cup	16–17
Oil, canola, or olive one tablespoon	8–10

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

bleeding and hypoprothrombinemia can result. Giving an injection of vitamin K upon birth prevents hemorrhagic disease of newborns. In addition, there are 16 known vitamin K-dependent (VKD) proteins; five of them have critical functions with preferential distribution of dietary vitamin K1 to the liver to preserve coagulation function when vitamin K1 is limiting (McCann and Ames, 2009).

**Vulnerable Populations.** Individuals who practice pica or have calcium disorders, use certain medications (anticoagulants, cholestyramine, mineral oil, phenytoin, neomycin or other antibiotics, or large doses of aspirin), hepatic biliary obstruction, hepatocellular disease, malabsorption syndromes, postmenopausal women at risk for hip fractures, prematurity, and small bowel disorders. Individuals who take large doses of vitamin A or E may also acquire a vitamin K deficiency.

**Signs of Excess.** Prolonged bleeding time. Menadione can be toxic if given in excessive dose; severe jaundice in infants or hemolytic anemia may result. Seek consistency in vitamin K intake while using warfarin; aim for 120 µg/d for men and 90 µg/d for women. Although dietary sources do not appear to be dangerous, excessive menadione can be toxic and may cause hemolytic anemia.

## REFERENCE

McCann JC, Ames B. Vitamin K, an example of triage theory: is micronutrient inadequacy linked to diseases of aging? *Am J Clin Nutr*. 90:889, 2009.

## Water-Soluble Vitamins

**Thiamin (Vitamin B<sub>1</sub>):** Known as the “morale” vitamin, thiamin is beneficial for nerve and heart function. Thiamin is absorbed by the proximal small intestine by active transport in low doses and passive diffusion in high doses. High-CHO intakes, pregnancy, lactation, increased basal metabolic rate, and antibiotic use will all increase needs. As energy intake from protein and fat increases, thiamin requirement decreases. The extent of absorption varies widely. Thiamin hydrochloride is the common supplemental form. The DRIs for thiamin include AIs for infants as found in human milk; RDAs are based on levels of energy intake. *RDA is 1.2 mg/d for men and 1.1 mg/d for women. No UL was established.*

**Functions.** Thiamin is mainly a coenzyme for decarboxylations of 2-keto acids and transketolations. It prevents beriberi and has a role in cell respiration, RNA and DNA formation, protein catabolism, growth, appetite, normal muscle tone in cardiac and digestive tissues, neurologic functioning. It is a coenzyme in the energy-producing Krebs’ cycle, with thiamin pyrophosphate (TPP) at the pyruvic acid step. Magnesium, manganese, riboflavin, and vitamin B<sub>6</sub> are synergists. Thiamin is essential for conversions derived from the amino acids methionine, threonine, leucine, isoleucine, and valine. Acetylcholine synthesis also requires thiamin.

**Sources.** Liver, fortified cereals, dried legumes such as split peas, brown rice, organ and lean meats, whole grains such as oats and whole wheat, nuts, cornmeal, enriched flour or bread, dried milk, wheat germ, dried egg yolk or whole egg, green peas, and seeds. Note: Two slices of bread or one slice

of bread and one serving of cereal will provide 15% of the daily RDA. Some nutrients are thiamin sparing; others destroy the nutrient. Thiamin is spared by fat, protein, sorbitol, and vitamin C; antagonists include raw fish, tea, coffee, blueberries, and red cabbage. Avoid cooking with excessive water and alkaline products such as baking soda; thiamin is lost readily.

**Signs of Deficiency.** Anorexia, calf muscle weakness, weight loss, cardiac and neurologic signs. Eventually, beriberi occurs with mental confusion, muscular wasting, edema, peripheral neuropathy, and tachycardia. Energy deprivation and inactivity are causes of dry (nonedematous) beriberi. Wernicke’s encephalopathy is due to thiamin deficiency and often associated with malnutrition and alcoholism. TPN without multivitamin use can lead to symptoms of Wernicke’s encephalopathy.

**Vulnerable Populations.** Individuals who have alcoholism, cancers, cardiomyopathies, CHO (high intakes), celiac disease, children with congenital heart disease before and after surgery, congestive heart failure, fever, high parenteral glucose loading, lactation and pregnancy, tropical sprue, and thymotoxicosis are at risk.

**Signs of Excess.** Respiratory failure and death with large doses (1000 times nutritional needs). With 100 times the normal dose, headache, convulsions, muscular weakness, cardiac arrhythmia, and allergic reactions have been noted. Massive doses greater than 1000 times the estimated needs suppress the respiratory center and lead to death.

**Riboflavin (Vitamin B<sub>2</sub>):** Riboflavin is important in CHO metabolism and maintenance of healthy mucous membranes.

Riboflavin is absorbed in the free form by a carrier-mediated process in the proximal small intestine. The DRIs for riboflavin include AIs for infants and RDAs based on the amount required to maintain normal tissue reserves based on urinary excretion, RBC riboflavin contents, and erythrocyte glutathione reductase activity. *RDA is 1.3 mg/d for men and 1.1 mg/d for women.* Requirements are higher during pregnancy and lactation. *No UL was established.*

**Functions.** It is the main coenzyme in redox reactions of fatty acids and the tricarboxylic acid (TCA) cycle. Cell respiration, oxidation reduction, conversion of tryptophan to niacin, component of retinal pigment, involvement in all metabolisms (especially fat), purine degradation, adrenocortical function, coenzyme in electron transport as flavin adenine dinucleotide (FAD) and flavin mononucleotide (FMN), healthy mucous membranes, skin and eyes, growth, and proper functioning of niacin and pyridoxine.

**Sources.** Milk, yogurt, cheese, egg whites, liver, beef, chicken, fish, legumes, peanuts, enriched grains and fortified cereals. Body size, growth, activity excesses, and fat metabolism affect daily requirements. Avoid excesses of niacin and methylxanthines. Light destroys riboflavin; buy milk in opaque cartons. As protein intake increases, the need for riboflavin decreases. Riboflavin is spared by dextrins and starch and is found in greater amounts in protein foods. Cheilosis causes a magenta-colored tongue.

**Signs of Deficiency.** Deficiencies are first evident in the tissues that have rapid cellular turnover such as the skin and epithelia. Seborrheic dermatitis of the nasolabial folds, ears, and/or eyelids; itchy and burning eyes or lips, mouth, and tongue; cheilosis (fissures and scaling of lips); angular stomatitis; glossitis with purplish-red, swollen tongue; peripheral neuropathy; dyssebacea (sharkskin); corneal vascularization; photophobia; lacrimation; normochromic normocytic anemia with erythroid hypoplasia; pancytopenia due to generalized marrow hypoplasia. Riboflavin deficiency is most commonly found in developing countries like India and can lead to deficiency of vitamins B<sub>6</sub> and B<sub>2</sub> and impairment of psychomotor function. Riboflavin metabolism is affected by infections, drugs, and hormones.

**Vulnerable Populations.** Alcoholism, cancers, chronic infections, drug use (broad-spectrum antibiotics and chloramphenicol), gastrectomy, and low oral intake during childhood, pregnancy, or lactation.

**Signs of Excess.** There is no known toxicity.

**Niacin (Nicotinic Acid, Nicotinamide):** Niacin is absorbed in the stomach and small intestine by carrier-mediated facilitated diffusion. Niacin requirements are related to protein and calorie intake. Intake for infants is established as AIs. *RDA is 16 mg/d for men and 14 mg/d for women. UL was established at 35 mg for men and women.*

**Functions.** Niacin serves as coenzyme for several dehydrogenases. It is part of nicotinamide adenine dinucleotide (NAD) and NADH in over 200 enzymes involved with metabolism of CHO, protein, and fat. It is involved with intracellular reactions and biosynthetic pathways; energy metabolism; growth; conversion of vitamin A to retinol; metabolism of fatty acids, serum cholesterol, and triglycerides. It has a role in DNA repair and gene stability, thus affecting cancer risk. It prevents pellagra (along with other B-complex vitamins). It is needed to treat tuberculosis as Isoniazid. Nicotinic acid is used as a vasodilator; nicotinamide is less vasodilating.

**Sources.** Beef and lean meats, organ meats, poultry, tuna and salt water fish, peanut butter, peanuts and legumes, enriched breads and fortified cereals. Diet supplies 31% of niacin intake as tryptophan. Milk and eggs are good sources of tryptophan but not niacin. Sixty milligrams of tryptophan are needed to equal 1 mg of niacin.

**Signs of Deficiency.** Signs start with beefy tongue, stomatitis with swelling and soreness of the oral mucosa; esophagitis with gastritis; diarrhea with proctitis; inflammation and erythema of the mucosal surfaces of the genitourinary tract; symmetric pigmented rash with scaling and hyperkeratosis; worsening of the skin rash in areas of sun exposure or trauma; headaches, insomnia, depression, anxiety; tremors or rigidity of limbs; loss of tendon reflexes; numbness and paresthesias in limbs. Severe deficiency leads to **pellagra** with Casal's collar, a rough, red dermatitis, **diarrhea**, **dementia** (the three Ds of pellagra).

**Vulnerable Populations.** Alcoholism, cancers, chronic diarrhea, cirrhosis, diabetes, and tuberculosis. Undernourished people in Africa.

**Signs of Excess.** Toxicity is generally low but may cause histamine release, flushing of skin (when using 1–2 g of nicotinic acid daily in an effort to lower cholesterol levels), or even liver toxicity. Megadoses should be avoided.

**Pantothenic Acid (Vitamin B-5):** Pantothenic acid is a coenzyme in fatty acid metabolism. Pantothenic acid is available "from everywhere." It is absorbed by passive diffusion and active transport in the jejunum. Fifty percent is bioavailable from diet. Needs increase by one-third in pregnancy and lactation. *AI for adult men and women is 5 mg/d. UL is not established.*

**Functions.** Coenzyme A is essential in the formation of acetyl CoA and energy production from the macronutrients. It also affects synthesis of cholesterol and fatty acids, adrenal gland activity, acetyl transfer, antibodies, normal serum glucose, electrolyte control and hydration, heme synthesis, and healthy RBCs. It changes choline to acetylcholine and prevents premature graying in some animals.

**Sources.** Pantothenic acid is present in all plant and animal tissues. The most important sources are meats, particularly heart and liver, but mushrooms, avocados, broccoli, egg yolks, yeast, skim milk, and sweet potatoes are also good sources.

**Signs of Deficiency.** Deficiency is rare but can impair lipid synthesis and energy production. Symptoms include paresthesia in the toes and soles of the feet, burning sensations in the feet, depression, fatigue, insomnia, and weakness.

**Vulnerable Populations.** Alcoholism, elderly women, liver disease, chronic ulcerative colitis, and pregnancy.

**Signs of Excess.** Rarely, excess causes mild intestinal distress or diarrhea.

**Vitamin B<sub>6</sub> (Pyridoxine):** This group includes numerous 2-methyl-3,5-dihydroxymethylpyridine derivatives exhibiting the biologic activity of PN, including pyridoxol, pyridoxal, and pyridoxamine. Vitamin B<sub>6</sub> is absorbed by passive diffusion of the dephosphorylated forms PN, PL, or PM, primarily in the jejunum and ileum. Pyridoxal phosphate (PLP) is the active form. Some studies suggest that a higher RDA is desirable for some individuals. About 96% of dietary vitamin B<sub>6</sub> is absorbed. High-protein intakes may deplete vitamin B<sub>6</sub> levels, thus needs increase with increased protein intake. Needs decrease with fatty acids or with other B-complex vitamins. The DRIs for vitamin B<sub>6</sub> include AIs for infants. Infants need three times as much vitamin B<sub>6</sub> as adults. *RDA is 1.3–1.7 mg/d for men and 1.3–1.5 mg/d for women. The UL was established at 100 mg/d for adult men and women.*

**Functions.** Vitamin B<sub>6</sub> is primarily known for its role in amino acid metabolism, histamine synthesis, gene expression, and hemoglobin synthesis. PLP is involved in practically all reactions in the metabolism of amino acids and in several aspects of the metabolism of neurotransmitters, glycogen, sphingolipids, heme, steroids, coenzymes (-ases), conversion of tryptophan to niacin, fat metabolism (changing linoleic to arachidonic acid), synthesis of folic acid, homocysteine metabolism, glandular and endocrine functions, antibodies, dopamine and serotonin metabolism, glycogen phosphorylase, and immunity.

**Sources.** Wheat and whole-grain cereals (such as oatmeal), legumes and nuts (garbanzo beans, soybeans, and peanuts) are the highest sources.

**Signs of Deficiency.** The vitamin is widely distributed throughout the diet; deficiency is rare but may present as convulsions in infants; depression, confusion, irritability; hypochromic, microcytic anemia. Peripheral neuropathies; glossitis, cheilosis, angular stomatitis; impaired immunity; seborrheic dermatitis involving the face and neck; blepharitis may also occur.

**Vulnerable Populations.** Alcoholism, use of certain medications (cycloserine, Dilantin, hydralazine, isoniazid, oral contraceptives, and penicillamine), elderly status, pregnancy, schizophrenia, isoniazid treatment and no vitamin replacement for tuberculosis.

**Signs of Excess.** Toxicity is relatively low. Sensory neuropathy with gait changes, peripheral sensations, and muscle incoordination.

**Biotin (Vitamin B-7):** Biotin is a coenzyme for carboxylations. *RDA is 30 mcg/d for adult men and women. UL is not established.*

**Functions.** Coenzyme in CO<sub>2</sub> fixation, deamination, decarboxylation, synthesis of fatty acids, CHO metabolism, oxidative phosphorylation, leucine catabolism, and carboxylation of pyruvic acid to oxaloacetate.

**Sources.** Liver, kidney, pork, milk, egg yolk, yeast, cereal, nuts, legumes, and chocolate. Note: Biotin can be synthesized by intestinal bacteria. Be wary of extended antibiotic use or prolonged unsupplemented TPN use. Probably, 50% of dietary biotin is absorbed from the small intestine. Biotin is called the “anti–raw egg white” factor; avidin in raw egg white decreases biotin availability.

**Signs of Deficiency.** Inflammation of the skin and lips. Other symptoms include dermatitis, alopecia, paralysis, depression, nausea, hepatic steatosis, hypercholesterolemia, and glossitis.

**Vulnerable Populations.** Individuals who consume excessive intake of avidin from raw egg whites. People with genetic conditions (beta-methylcrotonylglycinuria and propionic acidemia), or inadequate provision with long-term parenteral nutrition.

**Signs of Excess.** There are no known toxic effects.

**Folic Acid (Vitamin B-9):** Folate generally refers to pteroylmonoglutaminic acid and its derived compounds. Folate is found naturally in food; folic acid is the supplemental form. Pteroylglutamic acid is the pharmacological form. Folic acid works primarily as a coenzyme in single-carbon metabolism. Some folic acid can be made in the intestines with help from biotin, protein, and vitamin C. Synthetic folic acid increases serum levels more effectively than food sources of folate. Only 25–50% of dietary sources are bioavailable. Absorption occurs by active transport mainly in the jejunum, but can also be absorbed by passive diffusion when ingested in large amounts.

The DRIs express folate in “dietary folate equivalents or DFEs,” which account for the difference between food

sources and the more bioavailable supplemental sources. DFEs from fortified foods provide 1.7 times the micrograms of natural folic acid. Fortification of more commonly eaten foods has been implemented to provide adequate folic acid for vulnerable populations. About 90% of circulating folacin is bound to albumin. Drugs that interfere with utilization include aspirin, sulfasalazine (Azulfidine), methotrexate, antacids, anticonvulsants such as phenytoin (Dilantin), oral contraceptives, pyrimethamine, trimethoprim. *The DRI is described as AIs for infants. RDA is 400 mcg for adults. Pregnant women need 600 mcg and lactating women need 500 mcg. UL is 1000 mcg/d.*

**Functions.** Needed for growth; hemoglobin; amino acid metabolism. Prevents excessive buildup of homocysteine to protect against heart disease and some forms of cancer. Prevents megaloblastic and macrocytic anemias. Reduces the incidence of neural tube defects. Folate is required for synthesis of phospholipids, DNA, proteins, new cells, and neurotransmitters. Choline is used as a methyl donor (to convert homocysteine to methionine) when folate intake is low. Folic acid is needed during pregnancy to prevent spina bifida, cleft palate, some heart or other birth defects.

**Sources.** Foods with highest folate content include fortified cereals, pinto and navy beans (cooked), lentils, beets, asparagus, spinach, romaine lettuce, broccoli, and oranges. Analysis of foods for their folate content is complex and difficult. Folate exists in 150 different forms, and losses of 50–90% typically occur during storage, cooking, or processing at high temperatures (see Table A-15).

**Signs of Deficiency.** Decrease in total number of cells (pancytopenia) and large RBCs with a macrocytic or megaloblastic anemia. Deficiency is common, especially during pregnancy, with oral contraceptive use, in malabsorption syndromes, in alcoholics, in teens, and in elderly individuals. Neural tube defects such as spina bifida or anencephaly may result from impaired biosynthesis of DNA and RNA.

**Vulnerable Populations.** Alcoholics, cancer, medication use (aspirin, cycloserine, Dilantin, methotrexate, oral contraceptives, primidone, and pyrimethamine), hematological diseases (pernicious anemia, sickle cell anemia, and thalassemia), vitamin B<sub>12</sub> deficiency, malabsorption syndromes, and pregnancy.

**Signs of Excess.** No adverse effects of high oral doses of folate have been reported. Although parenteral administration of amounts some 1000 times the dietary requirement produce epileptiform seizures in the rat.

**Vitamin B<sub>12</sub> (Cobalamin, Cyanocobalamin):** Vitamin B<sub>12</sub> is known for its role as a coenzyme in metabolism of propionate, amino acids, and single-carbon fragments. It is known as a blood cell and nerve cell growth stimulator, along with folic acid. It is the “extrinsic factor” needed from diet to complement the “intrinsic factor” found in the stomach. Many people with achlorhydria or over age 50 lose the ability to absorb vitamin B<sub>12</sub> from foods and should consider using more fortified foods. *RDA is 2.4 mcg for adults. Pregnant women need 2.6 mcg and lactating women need 2.8 mcg. No UL was established.*

**TABLE A-15 Food Sources of Folic Acid**

Food	Folic Acid or Folate (μg)
Cereal, ready to eat, one cup	100–400
Cereal, cooked (oatmeal, farina, grits), one cup	75–300
Turkey giblets, cooked, one cup	486
Lentils or black-eyed peas, cooked, one cup	358
Pinto beans, cooked, one cup	294
Chickpeas (garbanzo beans), one cup	282
Okra, frozen, cooked, one cup	269
Spinach, cooked, one cup	263
Black beans, cooked, one cup	256
Enriched long-grain white rice, cooked, one cup	238
Beef liver, cooked, 3 ounces	221
Enriched egg noodles, cooked, one cup	221
Spinach, canned, one cup	210
Collards, cooked, one cup	177
Turnip greens, cooked, one cup	170
Broccoli, cooked, one cup	168
Enriched spaghetti, cooked, one cup	167
Brussels sprouts, cooked, one cup	157
Artichokes, cooked, one cup	150
Beets, cooked, one cup	136
Peas, cooked, one cup	127
Papaya, one whole	116
Cream-style corn, canned, one cup	115
Orange juice, one cup	110

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

**Functions.** Coenzymes, blood cell formation, nucleoproteins and genetic material, nutrient metabolism, growth, nerve tissue, thyroid functions, metabolism, transmethylation, myelin formation, homocysteine metabolism and prevention of heart disease.

**Sources.** Vitamin B<sub>12</sub> is not found in plant foods; monitor vegetarian diets. For best absorption, riboflavin, niacin, magnesium, and vitamin B<sub>6</sub> are also needed (see Table A-16).

**Signs of Deficiency.** Constipation, poor balance, loss of appetite, numbness and tingling in hands and feet, megaloblastic anemia. Some psychiatric disturbances such as depression, poor memory, dementia, or confusion. Biochemical deficiency such as serum cobalamin level <150–170 pg/mL or serum methylmalonic acid (MMA) <0.35 μg/dL; a return in MMA to normal after cobalamin therapy indicates prior deficiency.

**Vulnerable Populations.** Adolescents with poor diet with low intake of meat/fish/dairy products or strict vegetarian (vegan) diets are at risk. Senior citizens and those with severe,

chronic malnutrition are also at risk. Others at risk include those with pernicious anemia (autoimmune atrophic gastritis), disorders of the gastric mucosa, genetic defects (apoenzymes, absence of transcobalamin II, absence of ileal receptors), extensive disease affecting the stomach, intestinal infections, malabsorption (tropical sprue, celiac sprue, pancreatic insufficiency, Crohn's disease, fish tapeworm, HIV infection, or ileal resection), prolonged exposure to nitrous oxide or megadoses of folic acid. Monitor persons after total gastrectomy for megaloblastic anemia because intrinsic factor is not available. Some gastric bypass patients may also become deficient. Individuals who take zantac, pepcid, tagamet, metformin, omeprazole (Prilosec), lansoprazole (Prevacid) may also be at risk.

**Signs of Excess.** No toxicity is known.

**Choline:** Choline is a methyl-rich nutrient that is required for phospholipid synthesis and neurotransmitter function. Internal synthesis of phosphatidylcholine is insufficient to maintain choline status when intakes of folate and choline are low. *AI is set at 550 mg/d for adult men and 425 mg/d for adult women. UL level has been set at 3.5 g/d.*

**Functions.** Lipotropic agent, some role in muscle control and in short-term memory with the neurotransmitter acetylcholine, component of sphingomyelin, emulsifier in bile, and component of pulmonary surfactant (CO<sub>2</sub>/O<sub>2</sub> exchange). It helps the body absorb and use fats, especially for cell membranes. Choline is used as a methyl donor to convert homocysteine to

**TABLE A-16 Food Sources of Vitamin B<sub>12</sub>**

Food	Vitamin B <sub>12</sub> (μg)
Boneless lamb chop, cooked, 3 ounces	2.7
Fortified cereals, one cup	1–6 (varies)
Light tuna canned in water, drained, 3 ounces	2.5
Salmon, cooked, 3 ounces	2.4
Ground beef, 90% lean, cooked, 3 ounces	2.3
Eye round roast and steak, cooked, 3 ounces	1.4
Plain yogurt, low fat, one cup	1.4
Roast turkey, 3 ounces	1.3
Milk, skim, one cup	1.3
Beef hot dog, cooked	0.9
Cottage cheese, low-fat, 4 ounces	0.7
Boneless top loin pork roast, cooked, 3 ounces	0.6
Fortified soy milk or rice milk, one cup	0.6
Chicken breast, cooked, one cup	0.5
Dark meat chicken, cooked, one cup	0.4
Cheddar cheese, one slice	0.2
American cheese, one ounce	0.2

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods. Mixed dishes and multiple preparations of the same food item have been omitted from this table.

methionine when folate intake is low. Choline magnesium trisalicylate is used to relieve pain, inflammation and tenderness caused by arthritis as a form of nonsteroidal anti-inflammatory medications

**Sources.** Eggs, high-protein animal products such as liver, dairy foods, soybeans, peanuts, cauliflower, lettuce, and chocolate. Lecithin is a choline precursor, as is phosphatidylcholine. Liver can synthesize or resynthesize. Average daily intake is 400–900 mg. High-fat intake accelerates deficiency.

**Signs of Deficiency.** Insufficient phospholipid synthesis occurs; neurotransmitter function and liver damage might occur.

**Signs of Excess.** Anorexia, fishy body odor, upset stomach.

**Vitamin C (Ascorbic Acid, Dehydroascorbic Acid):** Vitamin C is needed via an exogenous source by all humans and is found in fruits and vegetables. About 90% of dietary intake is absorbed. Concentration of vitamin C in plasma and other body fluids does not increase in proportion to increasing daily doses of vitamin C. Saturation is complete at 200 mg. *RDA for vitamin C is 75 mg for women and teen boys. Pregnant women need 85 mg and lactating women need 120 mg. Teen girls need 65 mg; 80 if pregnant or 115 if lactating.*

Men need 90 mg. Smokers need an extra 35 mg daily. The UL for vitamin C is 2000 mg/d.

**Functions.** Hydroxylation (lysine and proline) in collagen formation and wound healing, norepinephrine metabolism, tryptophan to serotonin transformation, folic acid metabolism, antioxidant as a scavenger of superoxide radicals and to protect vitamins A and E, changing ferric iron to ferrous iron, healthy immunity and prevention of infection, intracellular respiration, tyrosine metabolism, intercellular structures of bone, teeth, and cartilage, prevention of scurvy. It may defer aging through the collagen turnover process. Vitamin C also serves as a reducing agent, elevates HDL cholesterol in the elderly, and lowers total serum cholesterol. It is also needed for biosynthesis of carnitine and for metabolism of drugs and steroids. Dietary antioxidants, including vitamins C and E, may protect against atherosclerotic disease and cognitive impairment.

**Sources.** For details see Table A-17. No more than 1 g/d is stored in liver tissue. An excretion of 50% of intake is normal. Men are found to have lower serum levels than women. Smoking decreases serum levels; increased intake removes greater amounts of nicotine. Avoid high levels of pectin, iron, copper, or zinc from the diet and do not cook fruits or vegetables in copper pans.

**Signs of Deficiency.** The first symptom of deficiency is fatigue; treatment with vitamin C results in quick recovery and alleviation of symptoms. Insufficient (depletion) is 11–28  $\mu\text{mol/L}$ , considered latent scurvy with mood changes; mild but distinct fatigue and irritability; vague, dull, aching pains. Deficient is  $<11 \mu\text{mol/L}$  with failure of wounds to heal, petechial hemorrhage, follicular hyperkeratosis, bleeding gums, eventual tooth loss, weak bones or cartilage and connective tissues, rheumatic pains in the legs, muscular atrophy, skin lesions, and psychological changes including depression and hypochondria. High blood lead levels will also deplete serum vitamin C.

**TABLE A-17 Food Sources of Vitamin C<sup>a</sup>**

Food, Standard Amount	Vitamin C (mg)
Guava, raw, 1/2 cup	188
Red sweet pepper, raw, 1/2 cup	142
Red sweet pepper, cooked, 1/2 cup	116
Kiwi fruit, one medium	70
Orange, raw, one medium	70
Orange juice, 3/4 cup	61–93
Green pepper, sweet, raw, 1/2 cup	60
Green pepper, sweet, cooked, 1/2 cup	51
Grapefruit juice, 3/4 cup	50–70
Vegetable juice cocktail, 3/4 cup	50
Strawberries, raw, 1/2 cup	49
Brussels sprouts, cooked, 1/2 cup	48
Cantaloupe, 1/4 medium	47
Papaya, raw, 1/4 medium	47
Kohlrabi, cooked, 1/2 cup	45
Broccoli, raw, 1/2 cup	39
Edible pod peas, cooked, 1/2 cup	38
Broccoli, cooked, 1/2 cup	37
Sweet potato, canned, 1/2 cup	34
Tomato juice, 3/4 cup	33
Cauliflower, cooked, 1/2 cup	28
Pineapple, raw, 1/2 cup	28
Kale, cooked, 1/2 cup	27
Mango, 1/2 cup	23

Source: Nutrient values from Agricultural Research Service (ARS) Nutrient Database for Standard Reference, Release 17. Foods are from ARS single nutrient reports, sorted in descending order by nutrient content in terms of common household measures. Food items and weights in the single nutrient reports are adapted from those in 2002 revision of USDA Home and Garden Bulletin No. 72, Nutritive Value of Foods.

<sup>a</sup>Food sources of vitamin C ranked by milligrams of vitamin C per standard amount; also calories in the standard amount. (All provide  $\geq 20\%$  of RDA for adult men, which is 90 mg/d).

**Vulnerable Populations.** Those with achlorhydria, Alzheimer's disease, burns, cancers, chronic diarrhea, nephrosis, pregnancy, severe trauma, surgical wounds, and tuberculosis. Older and very young are more likely to have weaker immune systems and need more vitamin C. Moderate-to-high alcohol intake reduces immune effectiveness; alcoholics are at risk of scurvy. High blood pressure and cholesterol can lead to immune problems and heart disease. Disease agents originating in the mouth may travel in addition to causing dental problems. Diabetes, high glucose, other abnormal labs can stress the immune system; pollutant exposure, steroid use, and radiation can deplete vitamin C levels. Individuals with gout, arthritis, bladder cancer, reflex pain after hip fracture, pneumonia, risk for stroke or macular degeneration or hip fracture, renal oxalate stones, pregnancy, *Helicobacter pylori* infection, or prolonged proton pump use should be evaluated closely.

**Signs of Excess.** GI distress and diarrhea are most common.

# Dietetic Process, Forms, and Counseling Tips

## INTRODUCTION TO THE PRACTICE OF DIETETICS

The American Dietetic Association (ADA) is responsible for establishing the expectations for required education, practice guidelines, and standards of professional performance for dietetic professionals. The Commission on Dietetic Registration maintains credentialing authority for the roles of Registered Dietitian (RD) and Dietetic Technician Registered (DTR). A scope of practice framework can be used to assist dietetic professionals in defining their responsibilities and refining practice according to professional job analyses that are conducted every few years.

Dietitians and dietetic technicians work in a variety of settings but tend to be **concentrated in healthcare settings**: acute care, long-term care, dialysis units, psychiatric facilities, community sites, and home health. They perform a variety of tasks including clinical services, food systems management, nutrition education, and public health functions. See Figure B-1.

There are over 59 core dietetics position descriptions including not only the roles of traditional clinical dietitian;

outpatient dietitian; or Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) nutritionist but also covering areas such as consulting, sales, and communications. Generally, dietetics professionals aim to improve the health of their clientele by influencing their food and nutrition decisions. Many dietetics practice groups have now established standards of practice that are specific to their area of expertise. The following guidelines are useful in consideration of an effective practice in dietetics.

1. **Standards** from The Joint Commission and other organizations set the expectation that quality care will lead to positive outcomes. Effective leadership and continuous performance improvement are critical for maintaining quality.
2. **Regulations**, such as those from the Centers for Medicare and Medicaid Services (CMS), have been written to protect vulnerable patients/residents from inadequate care. For example, in long-term care, the F325 tag related to **\$483.25 Nutrition** states that, based on a resident's comprehensive assessment, the facility must ensure that a resident (1) maintains acceptable parameters of nutritional status, such as body weight and protein levels, unless the resident's clinical condition demonstrates that this is not possible; and (2) receives a therapeutic diet when there is a nutritional problem. All of the guidelines and directives are to be followed by dietitians and their supporting staff members accordingly.
3. Most dietitians work in settings that are supportive of **interdisciplinary teamwork**. Dietitians must be proactive, take on new skills, and overcome traditional stereotypes. The roles are expanding, for example, in bariatric surgery, in functional medicine, and in home care.
4. Many dietetics positions now include **enhanced responsibilities** in nutritionally focused physical assessment, certification in cardiopulmonary resuscitation, assessment for the use of adaptive feeding equipment, worksite wellness, swallowing evaluations, exercise prescription and education, functional nutrition assessments, and home care services.
5. For **basic nutrition education**, advice can be provided by many healthcare professionals. However, **medical nutrition**

**Figure B-1** Employment sector of dietetics practitioners ( $n = 8115$ ) (Image courtesy of Compensation & Benefits Survey of the Dietetics Profession 2009.)

**therapy (MNT)** is an intensive approach to the nutritional management of chronic disease and requires significantly more education in food and nutrition science than is provided by other professional curricula. The RD is the single identifiable healthcare professional to have the most standardized education, supervised clinical training, and national credentialing, who meets the continuing education requirements for reimbursement as a direct provider of MNT.

6. **State licensure laws** protect the public from unscrupulous practices. Each licensure board establishes a relevant scope of practice for dietitians and nutritionists who practice in that state. Scopes of practice detail what can or cannot be performed by a person using the title of dietitian or nutritionist.
7. Application of the American Dietetic Association's **Nutrition Care Process** with **standardized terminology** enables dietitians to perform at a higher level of comprehensive care than in the past. See Figure B-2.
8. The best patient care emphasizes **coordinated, comprehensive care along the continuum of the healthcare delivery system**. Multidisciplinary teams are best suited to develop, lead, and implement evidence-based disease management programs. Evidence-based care integrates research into practice, regardless of the setting. Indeed, research is the basis of the profession (Pavlinac, 2010).
9. Dietitians must take an **evidence-based approach to care** based on their education, training, skill level, and work experiences. Science and evidence-based education can help to overcome dangerous perceptions of consumers or misunderstandings by members of the medical community (Krebs and Primak, 2006).
10. **Unique nutritional care guidelines** should be used in specialty areas such as cancer, diabetes, cardiology and

pulmonary, gastroenterology, geriatrics, HIV-AIDS, liver disease, nutrition support, pancreatic disease, renal failure, surgical or transplantation units, intensive care, and functional nutrition therapy. See Figure B-3 for the Functional Medicine Matrix Model™ that was used as part of a holistic assessment format.

11. **Medical classification systems** are used for a variety of purposes including statistical analyses, reimbursement, decision-support systems, and procedures.
12. **Diagnostic-related groups (DRGs)** classify hospital cases into similar categories for reimbursement, assuming a similar use of resources. In 2007, Medical Severity DRG (MS-DRG) codes were added to enhance payment for conditions that involve greater morbidity or risk for mortality. In 2008, Hospital Acquired Condition (HAC) was described, and some conditions were no longer considered to be complications if they were not present upon admission (POA).
13. Use correct **nutrition diagnosis nomenclature** for malnourished adults in clinical practice settings: "*starvation-related malnutrition*" when there is chronic starvation without inflammation; "*chronic disease-related malnutrition*" when a mild to moderate inflammation is chronic; and "*acute disease or injury-related malnutrition*" for acute, severe inflammation (Jensen et al, 2009).
14. For the **coding of malnutrition** in the medical record, use ICD-9 code 262.
15. **Sentinel events** are defined by The Joint Commission as unexpected occurrences leading to serious physical or psychological injury or death. The risk for a sentinel event requires an immediate investigation and response. Issues such as changes in functional status, the severity of a nutrition diagnosis, unintended weight changes (>10% in 6 months), and changes in body composition such as the loss of subcutaneous fat are risks that should be examined.
16. **Order-writing privileges** by dietitians allow orders for nutritional prescriptions for enteral and parenteral nutrition to be implemented quickly and effectively. Order-writing must be established by the local facility with medical staff approval.
17. **Age-specific competencies** are needed to serve various populations. For example, children and adolescents require different meal plans and interventions from those for adults (Stang et al, 2006). Residents in long-term care facilities may need extra time and attention (Simmons and Schnelle, 2006). Individuals on nutrition support require monitoring while using age-specific guidelines (Durfee et al, 2006).
18. **Evaluation of outcomes** is significant. Customer satisfaction must meet or exceed basic patient expectations. **Health-related quality of life (HRQL)** is another important outcome measure. For example, the quality of life and nutritional status of older residents in long-term care facilities may be enhanced by a liberalization of diet prescriptions and person-centered care. This care involves residents in decisions about schedules, menus, and dining locations; weight loss, undernutrition, and other effects of poor nutrition and hydration are then decreased (Neidert, 2005).

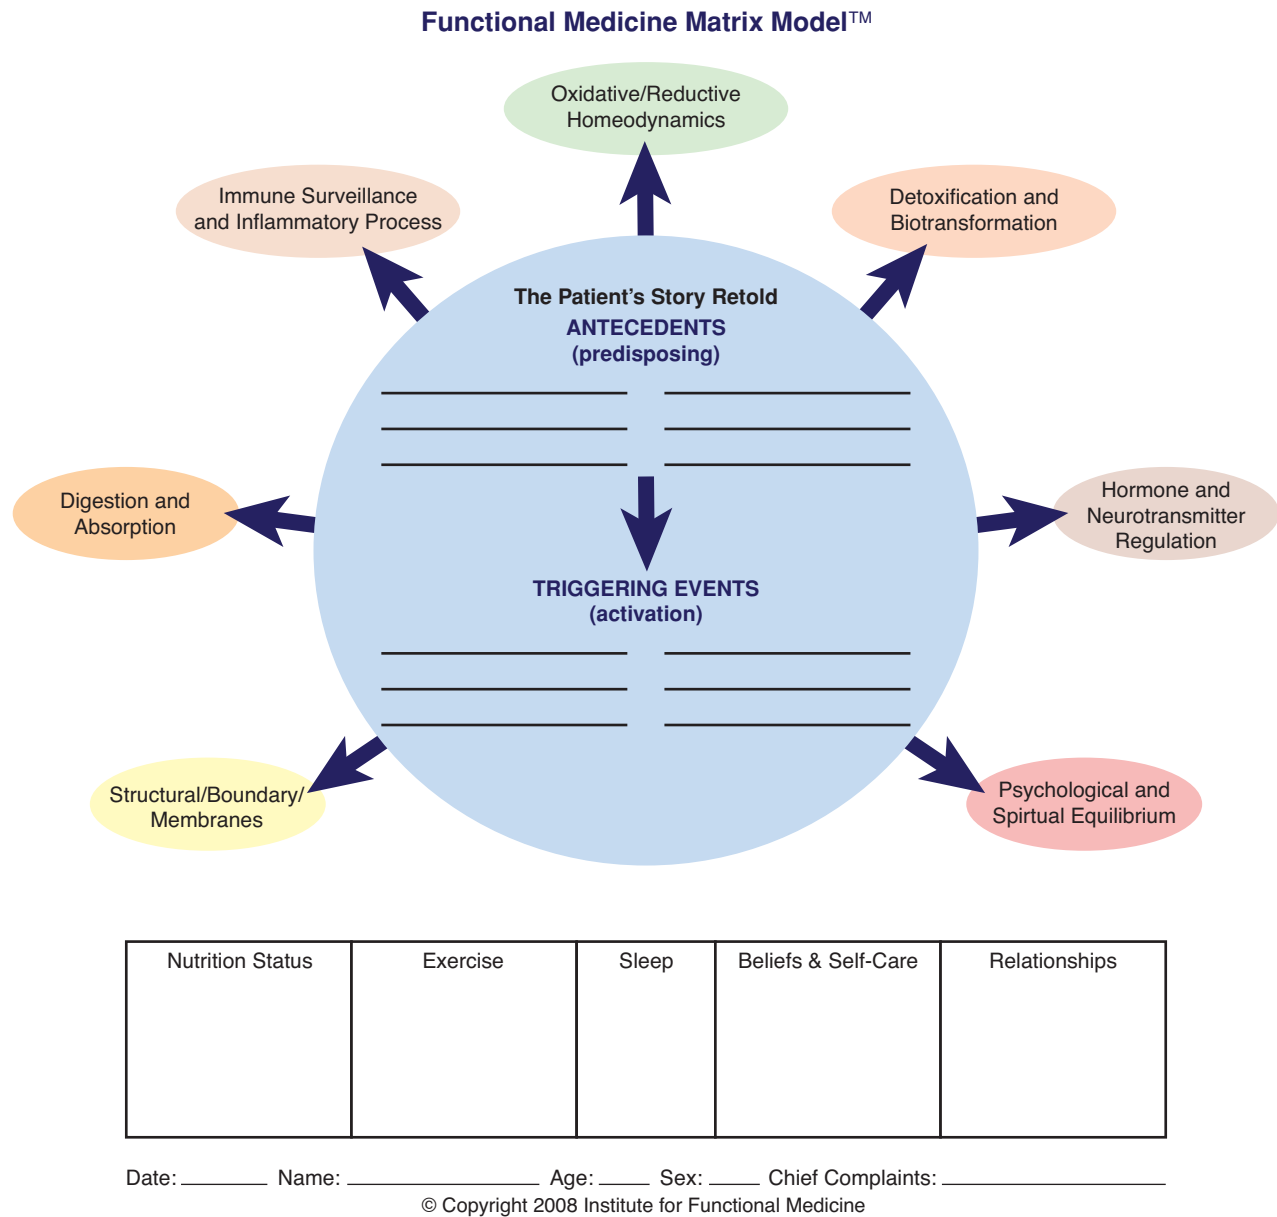

Figure B-2

**Figure B-3** Used with permission from The Institute for Functional Medicine.

19. **Ongoing review** is needed to monitor progress. Difficulty in obtaining current laboratory values makes it hard to follow patient outcomes after discharge. With electronic medical records and careful maintenance of confidentiality, monitoring can be more effective.
20. Dietetics professionals are likely to advance to **management positions**, such as food service director, consultant, or patient case manager, because they possess strong nutrition knowledge and management skills. Nearly half of all RDs and DTRs supervise other employees (Ward, 2010).
21. Having supervisory responsibility is strongly associated with higher wages (Ward, 2010). In addition, having a masters degree or PhD and one or more specialty certifications (e.g., CDE, CNSD, and the various Certified Specialist credentials offered by the Commission on Dietetic Registration) leads to an increased median wage (Ward, 2010).
22. **Food and nutrition managers** are in opportune positions to influence other managers, acquire resources, identify opportunities, and achieve desirable outcomes.
23. **Levels of responsibility** tend to increase with years of experience and with business skills such as leadership, marketing, and negotiation. Dietitians are encouraged to include management and leadership development as part of their continuing education portfolio.

## NUTRITION CARE PROCESS, FORMS, AND DOCUMENTATION TOOLS

The nutrition care process involves four steps and a comprehensive understanding of factors related to nutritional intake. Following a thorough **nutrition assessment** with patient history and current status, identify key problems (**nutrition diagnoses**). Use the latest edition of the nutrition diagnostic language from the American Dietetic Association, which is available to members at <http://www.eatright.org/Members/content.aspx?id=5477>. Write a PES statement (problem, etiology, and signs and symptoms) for each problem. Determine the plan of care, with **intervention** goals and actions, designed according to the etiology of the problem. Finally, plan how **monitoring and evaluation** will occur. The final

step should be measurable and should be related to the identified signs and symptoms. **Sample tools and forms** are provided here; all tools should be adapted for the facility and for the age and complexity of patients in the population.

Table B-13 describes various health promotion intervention models.

Table B-14 provides sample monitoring and evaluation audits for patient education.

**TABLE B-1** Sample Hospital Nutrition Department Scope of Services

### PURPOSE

In order to provide care consistent with the mission of the hospital system, the nutrition department has defined its scope of services and goals.

### POLICY

It is the policy of the hospital system for each department to provide care and/or services based on the defined scope of services and goals and to implement policies and procedures based on the scope of services and goals.

### DEPARTMENT MISSION

The nutrition department commits itself to enhancing the quality of life throughout the patient's life cycle and promoting and restoring health through the provision of quality nutritional care services in an environment that ensures dignity and respect for each person. The nutrition department has an obligation to ensure continuous quality improvement in the care and services it provides.

### PROCEDURE

#### Care/Services Provided

The department provides timely nutrition assessment, monitoring, counseling, education, discharge planning, and diet instruction, as defined in

department policies, to meet the needs of patients' various backgrounds, which affect nutritional preferences and habits. Administration evaluates the activities of the department with regard to the provision of quality dietary intervention, patient treatment and outcomes, and the quality of meal service.

#### Types of Patients/Customers Served

Nutrition services are available for all segments of the hospital population—newborn, infant, child, adolescent, adult, and geriatric—including outpatient services, cardiopulmonary rehabilitation, emergency department, corporate wellness, and community events.

#### Timeliness

Clinical dietitians are scheduled for Monday through Saturday, with shift availability at all meal periods. One dietitian is scheduled for weekend coverage; Sunday coverage is an on-call assignment. When appropriate, formula calculations, calorie counts or nutrient analyses, and basic nutrition assessments can be completed via the computer system and any telephone within the system to facilitate timely treatments.

#### STAFFING

The clinical nutrition manager sets a staffing plan to meet the needs of the patient population. A staffing assessment is completed every 2 years or when deemed necessary. Dietitian schedules are prepared in advance, including hours of duty and on-call schedules.

(continued)

**TABLE B-1 Sample Hospital Nutrition Department Scope of Services (continued)****STAFF CREDENTIALS AND REQUIREMENTS**

Dietitians are registered through the Commission on Dietetic Registration; each must maintain their registration through continuing education. The education requirement is 75 hours during each 5-year period. Competency standards are developed, updated, and reviewed regularly by the clinical nutrition manager to meet the specific, changing needs of the facility.

**ASSIGNMENTS**

Full-time equivalents of clinical dietitians are assigned to patient care and ambulatory clinics. One full-time equivalent of a clinical nutrition manager leads the clinical/outpatient staff. Staff are assigned to community education programs upon request and scheduling allows. Based on the daily census and acuity, clinical and outpatient dietitians may adjust the daily staffing pattern to meet needs according to changes in patient acuity.

**STANDARDS OF CARE**

Clinical dietitians apply the hospital-approved standards of nutrition care and the evidence-based guidelines of the American Dietetic Association.

**SCREENING**

All inpatients are screened by the nursing department within 24 hours of admission to determine the need for further nutrition assessment. Clinical dietitians develop the screening triggers, which are approved by the medical staff. Patients receive nutrition intervention based on the priority/acuity levels assigned by the dietitians. The clinical dietitians perform subsequent re-screening according to policy and regulatory guidelines.

Priority for Nutrition Services	High Priority	Moderate Priority	Low Priority
Definitions/Indications	Nutrition interventions that warrant frequent comprehensive patient reassessment to document the impact of the intervention on critical nutrition outcomes, medical status (i.e., labs, GI tolerance, etc.), and/or clinical progress.  Examples: New or modified EN/PN or use of medical food supplements. Comprehensive nutrition education or counseling.	Nutrition interventions that warrant early evaluation, which can be sufficiently tracked via brief f/u notes. Less frequent comprehensive patient reassessment is needed.  Examples: Stable EN or PN. Brief nutrition education for survival skills. Coordination of care.	Nutrition interventions that bring closure and/or immediately resolve a patient's nutrition diagnosis/problem OR when no nutrition intervention is needed. F/U is expected in the form of rescreening with reassessment as indicated by a change in status.  Examples: Brief nutrition education. No nutrition diagnosis. Palliative care only.
Plan of care review standard	Update POC when reassessing patient.	Within 5 days, based on a brief chart review, communication w/ other patient care providers as appropriate and patient contact. State the nutrition diagnosis, response to intervention, and the new or modified plan.	Per rescreening standards
Reassessment standard	Within 3 days	Within 7 days	Per rescreening standards

**ASSESSMENT AND NUTRITION DIAGNOSES**

The clinical dietitians assess patients using the guidelines in the standards of care approved by the medical staff. Following the profession's nutrition care process, a nutrition diagnosis is established as needed. The etiology of the diagnosis selected determines the type and extent of intervention that will be provided. The most common nutrition diagnoses in this facility are as follows:

- Inadequate oral food/beverage intake (NI-2.1)
- Inadequate protein-energy intake (NI-5.3)
- Increased nutrient needs (NI-5.1)
- Evident malnutrition (NI-5.2)
- Inadequate energy intake (NI-1.4)
- Swallowing difficulty (NC-1.1)
- Involuntary weight loss (NC-3.2)
- Inadequate intake from enteral/parenteral nutrition (NI-2.3)
- Food and nutrition-related knowledge deficit (NB-1.1)
- Underweight (NC-3.1)
- Overweight/obesity (NC-3.3)
- Excessive energy intake (NI-1.5)

**INTERVENTIONS: FOOD AND NUTRIENT DELIVERY**

According to the patient's ability to take in sufficient energy, protein, carbohydrate, fat, vitamins, minerals and water, the clinical dietitian will approve or recommend alterations in the nutrition prescription, the addition or discontinuation of enteral/parenteral nutrition, and the use of specific supplements or bioactive substances (e.g., fish oil, lycopene, lutein, ginger, and multivitamin-mineral supplements).

Most common food-nutrient delivery interventions in this facility are as follows:

- General/healthful diet (ND- 1.1)
- Commercial beverages (ND-3.1.1)
- Initiate EN or PN (ND-2.1)
- Modify rate, concentration, composition or schedule (ND-2.2)
- Modify distribution, type, or amount of food and nutrients within meals or at specified times (ND-1.2)
- Modified beverages (ND-3.1.3)
- Modified food (ND-3.1.4)
- Multivitamins/minerals (ND-3.2.1)
- Nutrition-related medication management (ND-6.1)

(continued)

**TABLE B-1 Sample Hospital Nutrition Department Scope of Services (continued)****INTERVENTIONS: EDUCATION**

The clinical dietitian performs a nutrition education needs assessment to determine patient/family knowledge and skill level. The patient's age, barriers to learning, assessed needs, abilities, readiness, and length of stay will determine the level of education to provide. Because lifestyle factors, financial concerns, patient/family expectations, and food preferences affect the individualized education plan, most patients will be referred to ambulatory clinics if extensive education is required to resolve a nutrition diagnosis. The most common education intervention in this facility is Nutrition Education—Survival Information (E-1.3).

**INTERVENTIONS: COUNSELING**

The clinical dietitian provides individualized guidance and nutritional advice to the patient and/or family members. Techniques to promote behavioral change are used, as appropriate, and documented accordingly. Readiness to change is noted. Follow-up counseling includes an evaluation of the effectiveness of counseling given and recommendations for additional follow-up. There are no specific counseling interventions most often noted for the in-patient setting; this type of intervention is handled in the ambulatory clinics.

**INTERVENTIONS: COORDINATION OF CARE**

The clinical dietitians participate in both weekly and patient care meetings on assigned units. Discharge planning needs are identified throughout the assessment, re-assessment, and education processes. These needs are referred to the social worker or case manager and communicated to the team during meetings. The dietitian communicates with the referring agency, facility, or next dietitian provider when a specialized care plan is needed. The most common coordination of care interventions in this facility are as follows:

- Team meeting (RC-1.1)
- Referral to an RD with different expertise (RC-1.2)
- Collaboration/referral to other providers (RC-1.3)

**MONITORING AND EVALUATION**

The clinical dietitian selects the appropriate measures to monitor and evaluate the effectiveness of interventions. The top nutrition monitors used in this facility are as follows:

- Total energy intake (FI-1.1)
- Enteral/Parenteral nutrition intake formula/solution (FI-3.1.2), initiation (FI-3.1.4), rate/schedule (FI-3.1.5)
- Nutrition physical exam findings: skin (S-3.1.6), gastrointestinal (S-3.1.3)
- Weight/weight change (S-1.1.4)

**DEPARTMENT GOALS**

In support of the hospital mission to provide high-quality healthcare through continuous improvement and to exceed the expectations of patients and customers, the clinical nutrition staff of the food and nutrition department have the following goals:

1. Staff qualified, progressive Registered Dietitians who exceed baseline knowledge proficiency standards set by the American Dietetic Association. To accomplish this, all Registered Dietitians must set annual professional development goals on their performance evaluations. These goals are supported by the clinical nutrition manager, funded by Food and Nutrition Services, and tracked through the professional development portfolio of the Commission on Dietetic Registration (CDR).

2. Provide timely nutrition therapy, which results in measurable improvements to patient health from the time of admission to the time of discharge from therapy. Dietitians will follow outcomes of therapy via objective measures (e.g., weight, verbalization of learning, and blood glucose improvements) and chart them in their documentation.
3. Ensure that outpatient medical nutrition therapy and diabetes education programs, combined, will break-even financially. Billing and accounts receivable will be monitored by the program coordinator. Two or three free community education nutrition programs will be offered yearly to local county residents.
4. Ensure that patients will indicate >90% satisfaction rating with their inpatient nutrition care and ambulatory services.
5. Review and administer the expanded dietitian scope of practice for those staff members who have demonstrated competency and have certification (where available) in their specialty area.

**EXPANDED SCOPE OF PRACTICE**

Because malnutrition is a key factor in determining the prognosis of a patient, protein, energy, vitamin and mineral deficiencies can be detected and corrected earlier through a better utilization of RD skills by assigning order-writing and prescribing privileges to the qualified dietitian specialists on staff. Prescribing authority boosts patient satisfaction by offering quicker interventions, reduces costs with shorter lengths of stays, improves nutrition outcomes, and promotes greater professional satisfaction by those qualified dietitians. Currently, there are three levels of prescriptive authority for dietitians, which are implemented in health-care facilities and defined as follows:

- **No prescriptive authority:** RDs recommend supplements, diets or diet changes, nutrition-related tests, or procedures to the physician. Recommendations may be written in the medical record or discussed with the physician, but a physician must write an order before recommendations are implemented.
- **Dependent prescriptive authority:** RDs have the authority to order diets, nutritional supplements, nutrition-related tests, or procedures according to protocols, algorithms, policies, or preapproved criteria that specify the type and magnitude of change. Physician approval of the nutritional treatment is not required as long as the orders and treatments provided fall within the guidelines of the protocol, algorithm, policy, or criteria approved in advance by the appropriate institutional authority (e.g., patient-care committee, medical executive committee). However, the RD can discuss the nutritional care provided with the physician and document the order appropriately in the medical record.
- **Independent prescriptive authority:** The RD may act autonomously to provide nutritional services that include ordering diets, nutrition-related tests, or procedures authorized by the clinical privileges granted to the practitioner by the appropriate institutional authority. Physician approval is not required; however, the RD can discuss the nutritional care provided with the physician and document the order appropriately in the medical record.

**Steps for Expanded Nutrition Scope of Practice with Dietitian Order-Writing Privileges:**

- Evaluate state licensure laws.
- Investigate the level of prescriptive authority permitted at the facility.
- Assure that current licensure and board certifications are accurate in the staff database.
- Discuss plans with each RD staff member with regard to credentialing, graduate study, fellowships, and other measures of basic and continuing competency.

(continued)

**TABLE B-1** Sample Hospital Nutrition Department Scope of Services (*continued*)

- When RDs are allowed to have complete order-writing privileges, patient care and outcome are better than they would be if a physician must first sign off on orders.
  - A literature review conducted on the clinical nutrition management list-serv noted that 42–57% of nutrition recommendations were actually put into action by the physician.
  - An average of 17 hours was required before orders were implemented by the MD.
  - Length of stay decreased by up to 5 days for patients who were given nutrition interventions earlier.
- Document success stories, cost savings, improved timeliness of care, shorter LOS than average related to early detection and intervention by the RD.
- Detail the desired scope of dietetics practice using the ADA evidence analysis library, the appropriate standards of professional practice, and other evidence-based guidelines.
- Draft new nutrition policies and procedures. Define the desirable steps for expanded scope of practice (e.g., ordering nutrition-related lab tests; prescribing basic diet orders; changing therapeutic diet orders according to measures such as weight loss or gain, decreased functional ability, significant appetite change; developing standing orders for common nutrition problems and interventions; and writing or updating enteral/parenteral infusion orders).
- Construct an **approval packet with letters of support** for the nutrition committee to establish medical review/consent. When approved by the nutrition committee, obtain signatures from the executive board, chief of medical staff, director of nursing, and hospital director. Include the time period for the scope and a date of review.

**TABLE B-2** Dietary Intake Assessment and Nutrition History

Methods for Assessing Dietary Intake	Advantages	Disadvantages
<p><b>24-Hour Recall:</b> An informal, qualitative method in which the patient recalls all of the foods and beverages that were consumed in the last 24 hours, including the quantities and methods of preparation.</p>	<p>Dietary information is easily obtained. It is also good during a first encounter with a new patient in which there are no other nutritional data. Patients should be able to recall all that they have consumed in the last 24 hours.</p>	<p>It is very limited and may not represent an adequate food intake for the patient. Data achieved using this method may not represent the long-term dietary habits of the patient. Estimating food quantities and food ingredients may be difficult, especially if the patient ate in restaurants.</p>
<p><b>Usual Intake/Diet History:</b> This method asks the patient to recall a typical daily intake pattern, including amount, frequencies, and methods of preparation. This intake history should include all meals, beverages, and snacks. Include discussion of usual intake and lifestyle recall. This consists of asking the patient to run through a typical day in chronological order, describing all food consumption as well as activities. This method is very helpful because it may reveal other factors that affect patient's nutritional and overall health.</p>	<p>This method evaluates long-term dietary habits and is quick and easy to do. Components usually include the following:</p> <ul style="list-style-type: none"> <li>Ability to secure and prepare food</li> <li>Activity pattern</li> <li>Alcohol or illicit drug use</li> <li>Appetite</li> <li>Bowel habits—diarrhea, constipation, steatorrhea</li> <li>Chewing/swallowing ability</li> <li>Diet history—usual meal pattern</li> <li>Disease(s) affecting use of nutrients</li> <li>Food allergies/intolerances</li> <li>Medications</li> <li>Nausea or vomiting</li> <li>NPO status or dietary restrictions</li> <li>Pain when eating</li> <li>Satiety level</li> <li>Surgical resection or disease of the GI tract</li> <li>Taste changes or aversions</li> <li>Vitamin/mineral or other nutritional supplements</li> <li>Weight changes</li> </ul>	<p>A limited amount of information on the actual quantities of food and beverages is obtained. Also, this method only works if a patient can actually describe a “typical” daily intake, which is difficult for those who vary their food intake greatly. In these patients, it is advisable to use the 24-hour recall method. Another disadvantage is that patients may not include foods that they know are unhealthy.</p>

*(continued)*

**TABLE B-2 Dietary Intake Assessment and Nutrition History (continued)**

Methods for Assessing Dietary Intake	Advantages	Disadvantages
<p><b>Food Frequency Questionnaire:</b> This method makes use of a standardized written checklist where patients check off the particular foods or type of foods they consume. It is used to determine trends in patients' consumption of certain foods. The checklist puts together foods with similar nutrient content, and frequencies are listed to identify daily, weekly, or monthly consumption.</p> <p>Dietary Food Log: Patient records all food, beverage, and snack consumption for a 1-week period. Specific foods and quantities should be recorded. The data from the food log may later be entered into a computer program, which will analyze the nutrient components of the foods eaten according to specific name brands or food types. Patients are asked to enter data into the food log immediately after food is consumed.</p>	<p>It is possible to identify inadequate intake of any food group so that dietary and nutrient deficiencies may be identified. The questionnaire can be geared to a patient's pre-existing medical conditions.</p> <p>A computer can objectively analyze data obtained. Data on calorie, fat, protein, and carbohydrate consumption can be obtained. Also, since patients are asked to enter data immediately after eating, the data are more accurate than other methods.</p>	<p>Patient error may occur in filling out how foods are prepared. Patients may over- or underestimate food quantities.</p> <p>Patients may err in entering accurate food quantities. In addition, it is possible that the week-long food log does not accurately represent a patient's normal eating habits since he or she knows that the foods eaten will be analyzed, and thus, he or she may eat healthier for that week.</p>

**TABLE B-3 Adult Nutrition History Questionnaire**

Patient Name \_\_\_\_\_ Date \_\_\_\_\_

- Height \_\_\_\_\_ feet \_\_\_\_\_ inches
- How much weight have you gained or lost in the past month? \_\_\_\_ 3 months? \_\_\_\_ 1 year? \_\_\_\_ Present weight \_\_\_\_ BMI \_\_\_\_  
Usual weight \_\_\_\_ Desirable weight for height \_\_\_\_
- Have you ever had problems with your weight? Overweight Underweight Comment: \_\_\_\_\_
- Describe your eating habits: Good Fair Poor
- How often do you skip meals? Daily Seldom Never
- Describe your appetite recently: Hearty Moderate Poor
- If you snack between meals, describe your typical snack \_\_\_\_\_ How often? \_\_\_\_
- When you chew your food, do you have problems or take a long time? Yes No
- Do you wear dentures at mealtime? Yes No. If yes, do they fit comfortably? Yes No
- List the vitamin/mineral supplements/herbs and botanicals you take: \_\_\_\_\_
- How many alcoholic drinks do you consume in a day? None 1-2 drinks More than 2 drinks
- Describe foods you **DO NOT** tolerate: \_\_\_\_\_ Why? \_\_\_\_\_
- List foods that you especially dislike: \_\_\_\_\_
- List your favorite foods: \_\_\_\_\_
- List foods that you are **ALLERGIC** to: \_\_\_\_\_ What symptoms do you experience? \_\_\_\_
- What type of modified diet do you follow? \_\_\_\_\_ What types in the past? \_\_\_\_\_ Who prescribed or suggested this diet for you? Doctor  
Friend Self-selected
- How many meals do you eat at home each week? \_\_\_\_ at school(s)? \_\_\_\_ in restaurants? \_\_\_\_
- What is your current occupation? \_\_\_\_\_
- How active are you on a daily basis? Sedentary \_\_\_\_ Moderate \_\_\_\_ Active \_\_\_\_

**TABLE B-4 Physical Assessment for Clinical Signs of Malnutrition**

Certain risk factors and signs of nutrient deficiency or excess can be identified during the physical examination. One sign is rarely diagnostic; the more signs present, the more likely it is that they reflect a malnourished individual.

Nutrient	Physical Signs of Deficiency	Nutrient	Physical Signs of Deficiency
Energy	Severe undernutrition, emaciation	Niacin	Dermatitis or skin eruptions
Protein	Dull, dry depigmented hair; easily pluckable		Tremors
	Edematous extremities		Sore tongue
	Poor wound healing; pressure ulcers		Skin that is exposed to sunlight develops cracks and a scaly form of pigmented dermatitis
	Pneumonia		May also show signs of riboflavin deficiency
Carbohydrate	Irritability, fatigue	Vitamin B <sub>6</sub>	Tongue inflammation
	Respiratory or neurological changes		Inflammation of the lining of the mouth
Fat	Skin rashes		Fissures in the corners of the mouth
	Dry, flaky skin	Folate	Weakness, fatigue, and depression
	Loss of subcutaneous fat		Pallor
Vitamin A	Hair follicle blockage with a permanent "goose-bump" appearance		Dermatologic lesions
	Dry, rough skin	Vitamin B <sub>12</sub>	Lemon-yellow tint to the skin and eyes
	Small, grayish, foamy deposits on the conjunctiva adjacent to the cornea		Smooth, red, thickened tongue
	Drying of the eyes and mucous membranes	Vitamin C	Impaired wound healing
Vitamin K	Small hemorrhages in the skin or mucous membranes		Edema
	Prolonged bleeding time		Swollen, bleeding, and/or retracted gums or tooth loss; mottled teeth; enamel erosion
Thiamin	Weight loss		Lethargy and fatigue
	Muscular wasting		Skin lesions
	Occasional edema (wet beriberi)		Small red or purplish pinpoint discolorations on the skin or mucous membranes (petechiae)
	Malaise		Darkened skin around the hair follicles
	Tense calf muscles		Corkscrew hair
	Distended neck veins	Chromium	Corneal lesions
	Jerky eye movement	Copper	Hair and skin depigmentation
	Staggering gait and difficulty walking		Pallor
	Infants may develop cyanosis	Iodine	Goiter
	Round, swollen (moon) face	Iron	Skin pallor
	Foot and wrist drop		Pale conjunctiva
Riboflavin	Tearing, burning, and itching of the eyes with fissuring in the corners of the eyes		Fatigue
	Soreness and burning of the lips, mouth, and tongue		Thin, concave nails with raised edges
	Cheilosis (fissuring and/or cracking of the lips and corners of the mouth)	Magnesium	Tremors, muscle spasms, tetany
	Purple swollen tongue		Personality changes
	Seborrhea of the skin in the nasolabial folds, scrotum, or vulva	Potassium	Severe hypertension
	Capillary overgrowth around the corneas		Arrhythmias
		Zinc	Delayed wound healing
			Hair loss
			Skin lesions
			Eye lesions
			Nasolabial seborrhea
			Pressure ulcers

**TABLE B-5 Calculation of Adult Energy Requirements**

For adults, body mass index is a useful guide.  $BMI = \text{Weight (kg)} / \text{Height}^2 \text{ (m)}$  [Where 1 kg = 2.2 lb; 1 in = 2.54 cm] or  $[\text{Weight (lb)} \times 705 / \text{Height (in)}]$ . Basal metabolic rate (BMR) or basal energy expenditure (BEE) is energy expenditure at rest. It involves energy required to maintain minimal physiological functioning (i.e., heart beating, breathing). Various methods are used to determine BEE and energy needs. Resting energy expenditure (REE) includes specific dynamic action for digestion and absorption (slightly above basal) and is considered relatively equivalent to BEE in a clinical context. Factors affecting energy requirements and BMR include the following:

1. **Age.** Infants need more energy per square meter of body surface than any other age group. BMR declines after maturity.
2. **Body Size.** Total BMR relates to body size; large persons require more energy for basal needs and for activity.
3. **Body Composition.** Lean tissue is more active than adipose tissue.
4. **Climate.** A damp or hot climate often decreases BMR, and a cold climate increases BMR slightly.
5. **Hormones.** Thyroxine increases BMR; sex hormones and adrenaline alter BMR mildly; low zinc intake may lower BMR.
6. **Fever.** BMR increases by 7% for each degree above normal in Fahrenheit; 10% for each degree Centigrade.
7. **Growth.** BMR increases during anabolism in pregnancy, childhood, teen years, and the anabolic phase of wound healing.

REE can be from normal to below normal in mild starvation, such as that which occurs in the hospital setting. **Unplanned weight loss** can affect morbidity and mortality. Problematic % weight change in adults is considered to be: >2% in 1 week, >5% in 1 month, >7.5% in 3 months, > 20% in any period of time. >40% is incompatible with life.

**Indirect calorimetry is useful for the critically ill** where the calculation of energy expenditure is measured by gas exchange ( $VO_2$  and  $VCO_2$  represent intracellular metabolism). However, note that the energy needs of critically ill or injured adults are lower than previously thought; estimates are based on body mass index (BMI) if indirect calorimetry is not available. Overfeeding can cause fluid overload, increased  $CO_2$  production, and hepatic aberrations. Defer weight repletion until a patient's critical episode subsides; needs generally normalize again in 3–6 weeks. Feeding programs should support a patient being within 10–15 pounds of desirable BMI range. Use these guidelines:

For Adults	Sedentary (kcal/kg)	Moderate	Active (kcal/kg)	Critically Ill (kcal/kg)
Overweight BMI >30	20–25	30	35	15–20
Normal weight BMI 20–29	30	35	40	20–25
Underweight BMI 15–19	30	40	45–50	30–35

**TABLE B-6** Calculations of Adult Protein Requirements

It requires 6.25 g of dietary protein to equal 1 g of nitrogen. Therefore, estimated nitrogen requirements  $\times 6.25$  = estimated protein needs in grams. If energy is not provided in adequate amounts, protein tissues become a substrate. Extra protein intake may be needed to compensate for excess protein loss in specific patient populations such as those with burn injuries, open wounds, and protein-losing enteropathy or nephropathy. Lower protein intake may be necessary in patients with chronic renal insufficiency who are not treated by dialysis and certain patients with hepatic encephalopathy. The following table provides an estimate for protein needs in adults.

Clinical Condition	Daily Protein Requirement (g/kg body weight)
Normal	0.8
Metabolic stress (illness/injury)	1.0–1.5
Acute renal failure (undialyzed)	0.8–1.0
Hemodialysis	1.2–1.4
Peritoneal dialysis	1.3–1.5

**TABLE B-8 Interpretation of Lab Values**

Many lab tests can provide useful information on patients' nutritional status along with information on their medical status. Age-specific criteria should be used to evaluate data. Common tests include the following.

#### *Allergy Antibody Assessment*

Allergy blood and skin testing

C-reactive protein

*Helicobacter pylori* Antibodies Test

Immunoglobulins: IgG, IgM, IgA, IgD, and IgE; specific IgE for molds, IgG for spices and herbs

Rheumatoid factor (RF)

#### *Blood Chemistry and Renal Tests*

Albumin

Blood urea nitrogen (BUN)

Creatinine clearance

Glomerular filtration rate (GFR)

Nitrogen balance

Serum creatinine

Serum proteins, total protein

#### *Cardiopulmonary System*

Arterial blood gases

Cardiac enzymes

Creatine kinase

Homocysteine

Lactate dehydrogenase, aspartate transaminase (AST)

Lipid profile: Cholesterol, lipoproteins, triglycerides

#### *Celiac Assessment*

IgA-antitissue transglutaminase (tTG)

IgA-antiendomysial antibodies (IgA-EMA)

IgA-antigliadin antibodies (IgA-AGA)

#### *Coagulation Tests*

Bleeding or coagulation time

International normalized ratio (INR)

Prothrombin time (PT)

#### *Endocrine System*

Aldosterone

Antidiuretic hormone

Blood glucose

C-peptide

Calcium

Calcitonin

Glucose tolerance test (GTT)

Insulin

Parathormone (PTH)

Phosphorus

Thyroxine (T4)

Thyroid-stimulating hormone (TSH)

Triiodothyronine (T3)

#### *Gastrointestinal System and Stool Tests*

Bacterial overgrowth of small intestine breath test

Comprehensive digestive stool analysis

Gastric analysis

Lactose intolerance breath test

Parasitology assessment

Serum gastrin

#### *Hepatic System*

Albumin, gamma-globulin, A-G ratio

Alanine aminotransferase (ALT)

Aspartate aminotransferase (AST)

Alkaline phosphatase (ALP)

Ammonia

Bilirubin

Gamma-glutamyl transpeptidase (GGT)

Hepatitis virus

Prothrombin time (PT)

Partial thromboplastin time (PTT)

Total protein

Urobilinogen

#### *Musculoskeletal System*

Alkaline phosphatase (ALP)

Acid phosphatase

Creatine phosphokinase (CPK)

Enzymes, isoenzymes

Lactate dehydrogenase (LDH)

#### *Pancreatic Tests*

Serum amylase

Serum lipase

#### *Red Cell Indices*

Carbon dioxide

Mean cell volume (MCV)

Mean cell hemoglobin (MCH)

MCH concentration

Reticulocyte cell count

Serum ferritin

Serum iron and total iron-binding capacity

Sodium, potassium, chlorine

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)***Vitamin and Mineral Assessment*

Calcium  
Zinc  
Vitamin A  
Vitamin C  
Vitamin B<sub>6</sub>  
Vitamin B<sub>12</sub>  
Folate

*Urinary System*

Physical observation: Color, clarity, odor  
Microscopic examination: Cells, casts, crystals, bacteria, yeast  
Urine volume  
Chemical tests: Specific gravity, pH, protein, glucose, ketones, blood, bilirubin, urobilinogen, nitrite, leukocyte esterase

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
<b>Hematology: Coagulation Tests and Bleeding Time</b>				
Prothrombin time (PT), international normalized ratio (INR)	11–16 seconds control; 70–110% of control value Patients on anticoagulant drugs should have an INR of 2.0–3.0 for basic “blood thinning” needs. For some patients who have a high risk of clot formation, the INR needs to be higher—about 2.5–3.5.	Since PT and INR evaluate the ability of blood to clot properly, they can be used to assess both bleeding and clotting tendencies. One common use is to monitor the effectiveness of blood thinning drugs such as warfarin (Coumadin). Anticoagulant drugs must be carefully monitored to maintain a balance between preventing clots and causing excessive bleeding.	A prolonged or increased prothrombin time means that blood is taking too long to form a clot.  Antibiotics, aspirin, and cimetidine can increase the PT/INR.	Too much anticoagulation (warfarin, for example). Barbiturates, oral contraceptives, hormone-replacement therapy (HRT), and vitamin K (either in a multivitamin or liquid nutrition supplement) can decrease PT.  Beef and pork liver, green tea, broccoli, chickpeas, kale, turnip greens, and soybean products contain large amounts of vitamin K and can alter PT results if consumed in large amounts.
<b>Hematology: Blood Cell Values</b>				
Erythrocyte count (red blood cells [RBC])	4.5–6.2 million/mm <sup>3</sup> in males; 4.2–5.4 million/mm <sup>3</sup> in females	Made in bone marrow; production controlled by erythropoietin.	Polycythemia, dehydration, severe diarrhea	Anemias such as vitamin B <sub>12</sub> , iron, folic acid, and protein; chronic infections; hemorrhage
Erythrocyte sedimentation rate	0–15 mm/hour in males; 0–25 mm/hour in females	Sedimentation rate measures how quickly RBCs (erythrocytes) settle in a test tube in 1 hour. Often used with C-reactive protein (CRP) for testing of inflammation.	Inflammation, pneumonia, appendicitis, pelvic inflammatory disease, lymphoma, multiple myeloma, lupus, rheumatoid arthritis (RA), osteomyelitis, temporal arteritis	
Ferritin	20–300 mg/mL in males; 20–120 mg/mL in females	Chief iron storage protein in the body. Reflects reticuloendothelial iron storage. Usually 23% of total iron stores.	Hemochromatosis, leukemias, anemias other than iron deficiency, Hodgkin's disease, liver diseases	Iron deficiency anemia
Folate, serum	0.3 µg/dL (7 nmol/L)	Important for DNA functioning	Blind loop syndrome	Pregnancy, lactation, macrocytic anemia, intestinal malabsorption syndrome, alcoholism, use of goat's milk in childhood, use of anticonvulsants, cycloserine, methotrexate, and oral contraceptives

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
Iron, serum	75–175 mg/dL in males; 65–165 mg/dL in females; 40–100+ mg/dL in children up to 2 years old; 50–120 mg/dL in children >2 years.	Iron found in blood, largely in hemoglobin	Hemochromatosis, acute or chronic liver disease, hemolytic anemia, leukemia, lead poisoning, thalassemia, vitamin B <sub>12</sub> or folate deficiency, dehydration, small bowel surgery	50 µg/dL (9 mmol/L) may indicate iron deficiency anemia or blood loss.  Chronic diseases, pregnancy, cancer, end-stage renal disease (ESRD) or chronic renal disease, malnutrition or poor dietary intake, sickle cell disease, viral hepatitis, thalassemia
Iron-binding capacity, total (TIBC)	240–450 mg/dL	Measure of the capacity of serum transferrin. 18–59% transferrin saturation is normal. As serum iron decreases, TIBC goes up, at least initially.	Iron deficiency, blood loss, later in pregnancy, oral contraceptive use, hepatitis, low serum iron, gastrectomy	High serum iron, renal disease, hemochromatosis, pernicious anemia, cancer, thalassemia, hemolytic diseases, small bowel surgery, sepsis, liver disease; may be low in malnutrition
Hematocrit (% packed cell volume)	40–54% in males; 37–47% in females; 33–35% in children; 37–49% in 12- to 18-year-old males; 36–46% in 12- to 18-year-old females	Cell volume % of RBCs in whole blood. Elevated when iron level is low.	Polycythemia	Anemias, prolonged dietary deficiency of protein and iron, sepsis, small bowel surgery, gastrectomy, renal or liver disease, blood loss
Hemoglobin, whole blood	14–17 g/dL in males; 12–15 g/dL in females; ≥10 g/dL in babies 6–23 months old; ≥11 in children 2–5 years old; 11.5–15.5 g/dL in children 6–12 years old; 13.0–16.0 g/dL in 12- to 18-year-old males; 12.0–16.0 g/dL in 12- to 18-year-old females	Oxygen carrier from lung to tissues. Binds CO <sub>2</sub> on return to the lung.	Polycythemia, dehydration, hemolysis, sickle cell anemia, recent blood transfusions, chronic obstructive pulmonary disease (COPD), heart failure, high altitude, burns, dehydration	Anemias, prolonged dietary deficiency of iron, excessive bleeding, cancer, lupus, overhydration, Hodgkin's disease, malnutrition, renal or liver disease, pregnancy, lead poisoning, sepsis, small bowel surgery, gastrectomy
Mean corpuscular hemoglobin (MCH)	26–32 pg; concentration is 32–36%	High concentration of individual RBCs (Hgb/RBC)	Macrocytic anemia	Hemoglobin deficiency, hypochromic anemia
Mean corpuscular volume (MCV)	80–94 cu/µm	Individual RBC size	<u>High MCV or macrocytosis:</u> folate, vitamin B <sub>12</sub> deficiency. Alcoholic or liver disease, blood loss, hypothyroidism, small bowel surgery	<u>Low MCV or microcytosis:</u> iron, copper, pyridoxine deficiency.  Thalassemia, anemia of chronic disease, cancer, blood loss
Transferrin (siderophilin)	170–370 mg/dL (1.7–3.7 g/L)	Glycoprotein in blood plasma that transports iron to liver and spleen for storage and to bone marrow for hemoglobin synthesis	Iron deficiency, acute hepatitis, oral contraceptive use, pregnancy, chronic blood loss, dehydration, gastrectomy	Acute or chronic inflammation, chronic liver disease, lupus, zinc deficiency, sickle cell anemia, pernicious anemia with vitamin B <sub>12</sub> or folate deficiency, chronic infection and inflammatory diseases, malnutrition, burns, iron overload, nephrotic syndrome, sepsis, small bowel surgery

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
White blood cells (WBC), leukocytes	4.8–11.8 thousand/mm <sup>3</sup>	Highly variable lab value; protect against disease or infection	Metabolic acidosis, acute hemorrhage, acute bacterial infections, leukemias, burns, gangrene, exercise, stress, eclampsia	Chemotherapy, ABT. Neutropenia is often seen in deficiency states. Some viral conditions, cachexia, anaphylactic shock, bone marrow suppression, pernicious or aplastic anemia, diuretic use
<b>Hematology and Lymphatic System: Differential</b>				
Lymphocytes	Total lymphocyte count (TLC) = normal, 12,000/mm <sup>3</sup> ; deficient, <900/mm <sup>3</sup> ; 24–44% total WBC count	Made in thymus and lymph nodes; produce antibodies	Infectious mononucleosis, mumps, German measles, convalescence from acute infections	Infections, malnutrition
Leukocytes: basophils	0–1.5% total WBC count	They release substances that cause smooth muscle contraction, vasoconstriction, and an increased permeability of small blood vessels. Basophils are stimulated by allergens.	Postsplenectomy, chronic myelogenous leukemia, polycythemia, Hodgkin's disease, chicken pox	Hyperthyroidism, acute infections, pregnancy, anaphylaxis
Leukocytes: eosinophils	0.5–4% total WBC count	Eosinophils are stimulated by parasites and some bacteria. They release substances that cause vasoconstriction, smooth muscle contraction, and an increased permeability of small blood vessels. Related to allergies.	Allergies, parasitic infections, pernicious anemia, ulcerative colitis, Hodgkin's disease	Use of $\beta$ -blockers, corticosteroids; stress, and bacterial and viral infections including trichinosis
Leukocytes: monocytes	4–8% total WBC count	Phagocytosis. Produced in bone marrow.	Monocytic leukemia, lipid storage disease, protozoan infection, chronic ulcerative colitis	
Leukocytes: neutrophils	60–65% total WBC count	Phagocytosis	Wound sepsis in burns, bacterial infections, inflammation, cancer, traumas, stress, diabetes, acute gout	Folate or vitamin B <sub>12</sub> deficiency, sickle cell anemia, steroid therapy, postsurgical status
Platelets (thrombocytes)	125,000–300,000 mm <sup>3</sup>	Largely polysaccharides and phospholipids. Role in coagulation.	Malignancy, polycythemia vera, splenectomy, iron deficiency anemia, cirrhosis, chronic pancreatitis	Thrombocytopenic purpura
<b>General Serum Values and Enzymes</b>				
Amylase	60–180 Somogyi units/dL	Pancreatic enzyme for hydrolysis of starch and glycogen	Increased in perforated peptic ulcer, acute pancreatitis, mumps, cholecystitis, renal insufficiency, alcohol poisoning, partial gastrectomy	Decreased in hepatitis, severe burns, pancreatic disease, advanced cystic fibrosis, toxemia of pregnancy, hepatitis
Bicarbonate	22–28 mEq/L	Acid–base balance	Metabolic alkalosis, large intake of sodium bicarbonate, excessive vomiting, potassium deficiency, respiratory acidosis, emphysema	Diabetic acidosis, starvation, chronic diarrhea, renal insufficiency, respiratory alkalosis (hyperventilation), fistula drainage

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
Bilirubin	Direct: $\leq 0.3$ mg/dL; total: $\leq 1$ mg/dL	Hemoglobin is converted to bilirubin when RBCs are destroyed.	Hepatitis, jaundice, biliary obstruction, drug toxicity, hemolytic disease, prolonged fasting	Seasonal affective disorder
Calcium	9–11 mg/dL (2.3–2.8 mmol/L); 3.9–5.4 mg/dL serum ionized	50% is protein bound, so protein intake affects serum calcium level more than dietary calcium. Regulated by parathormone (PTH) and thyrocalcitonin. Coma above 13 mg/dL; death below 7 mg/dL.	Hyperparathyroidism, renal calculi, vitamin D excess, osteolytic disease, milk-alkali syndrome, immobilization, tuberculosis, Addison's disease, antibiotic therapy, cancer	Steatorrhea, renal failure, malabsorption, vitamin D deficiency, hypoparathyroidism, sprue, celiac disease, overhydration, hypoalbumenia, hyperphosphatemia
Ceruloplasmin	27–37 mg/dL	Form of copper found in the bloodstream	Leukemias, anemias, cirrhosis of the liver, hypo/hyperthyroidism, collagen diseases, pregnancy	Wilson's disease, severe copper deficiency, nephrosis, leukemia remission, prolonged total parenteral nutrition (TPN) without copper, cystic fibrosis
Copper	70–140 $\mu$ g/dL in males; 80–155 $\mu$ g/dL in females	Found bound to albumin or as ceruloplasmin	Leukemias, anemias, cirrhosis of the liver, hypo/hyperthyroidism, collagen diseases, pregnancy	Wilson's disease, severe copper deficiency, nephrosis, leukemia remission, prolonged TPN without copper, cystic fibrosis
Creatine phosphokinase (CPK)	0–145 IU/L	Catalyst for phosphorylation of creatine by adenosine triphosphate (ATP). Mostly found in skeletal and cardiac muscle. Increases 2–4 hours after myocardial infarction (MI), returning to normal after 3 days.	Hepatic or uremic coma, striated muscle disease, muscular dystrophy, MI, cerebrovascular accident (CVA), trauma, alcoholic liver disease, encephalitis	
D-xylose, 25-g dose	30–40 mg/dL	This test measures the intestines' ability to absorb D-xylose—a simple sugar—as an indicator of whether nutrients are being properly absorbed.		Xylose malabsorption
Gamma-glutamyl transpeptidase (GGT)	5–40 IU/L	GGT participates in the transfer of amino acids across the cellular membrane and in glutathione metabolism.  Used to detect diseases of the liver, bile ducts, and kidney and to differentiate liver or bile duct (hepatobiliary) disorders from bone disease.	Coronary heart failure (CHF), MI, cholecystitis, liver disease, alcoholism, hepatic biliary disease, pancreatitis, nephritic syndrome	
Lactic acid dehydrogenase (LDH)	200–680 IU/mL	Catalyzes conversion between pyruvate and lactic acid in glycolytic cycle. Has 5 isoenzymes. Increases 8–10 hours after MI, returning to normal after 7–14 days.	Untreated pernicious anemia, acute MI, heart failure, malignancy, alcoholic liver damage, cardiovascular surgery, hepatitis, pulmonary embolus, leukemia, cancer, renal failure, hemolytic or megaloblastic anemia, muscular dystrophy, nephrotic syndrome	Radiation therapy
Lipase	0.2–1.5 IU/mL	Synthesized by the pancreas	Pancreatic disease, acute pancreatitis, perforated ulcer, pancreatic duct obstruction, biliary tract infection, renal insufficiency	

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
Phenylalanine, serum	<3 mg/dL	An amino acid of importance in phenylketonuria (PKU) patients	Levels might be high in PKU	Severe protein deficiency and malnutrition
Phosphatase, acid	0.5–2 Bodansky units	A blood test that measures prostatic acid phosphatase (an enzyme found primarily in men in the prostate gland and semen) to determine the health of the prostate gland	Prostate dysfunction results in the release of prostatic acid phosphatase into the blood.	
Phosphatase, alkaline (ALP)	2–4.5 Bodansky units (30–135 IU/L); children = 3× that of adults	ALP is an enzyme found in all tissues. Tissues with particularly high concentrations of ALP include the liver, bile ducts, placenta, and bone. Indirect test for calcium, phosphorus, vitamin D nutriture. Used to determine the presence of liver or bone cell disorders.	Anemia, Paget's disease, biliary obstruction, leukemia, hyperparathyroidism, rickets, bone disease, healing fracture	Malnutrition, protein deficiency
Sulfate, inorganic	0.5–1.5 mg/dL	Usual sulfur intake is 0.6–1.6 grams on a mixed diet containing 100 grams of protein.	Supplemental overdose; high sulfate intake from water supply	Protein deficiency; injury to the bones, cartilage, or tendons
Transaminase: aspartate aminotransferase (AST)	5–40 IU/mL	Found in the liver, muscle, and the brain. Functional measure of vitamin B <sub>6</sub> nutriture. Released in tissue injury. Formerly SGOT (serum glutamic oxaloacetic transaminase).	Hepatic cancer, shock/trauma, cirrhosis, neoplastic disease, MI	Uncontrolled diabetes mellitus; Beriberi
Transaminase: alanine aminotransferase (ALT)	4–36 IU/L	Found in the liver. Generally parallels AST levels. Functional measure of vitamin B <sub>6</sub> nutriture. Formerly SGPT (serum glutamic pyruvic transaminase).	Hepatitis, cirrhosis, trauma, hepatic cancer, shock, mononucleosis	Wilson's disease
<b>Glucose Control</b>				
Glucose, fasting serum	70–110 mg/dL (3.9–6.1 mmol/L)	Principle fuel for cellular function, particularly for the brain and RBCs.	DM, hyperthyroidism pancreatitis, MI, hyperfunction of endocrine, stress, CHF infection, surgery, CVA, hepatic dysfunction, cancer, Cushing's syndrome, burns, steroids, chromium deficiency	Postprandial hypoglycemia, sepsis, cancer, malnutrition, hypothyroid, gastrectomy, liver damage or disease, Addison's disease
Glucose tolerance test (GTT)	2-hour post load glucose <200 mg/dL	Test done when blood glucose levels are >120 mg/dL.	Diabetes, hyperthyroidism, pancreatic cancer, Cushing's syndrome, acromegaly, pheochromocytoma.	Hypoglycemia, hypothyroidism, malabsorption, malnutrition, insulinoma, hypopituitarism
Glycosylated hemoglobin–HbA1c	4–7% (nondiabetic); good, <9%; fair, 9–12%; poor, >12%	May reflect poor glucose control over the past 2–4 months	Poor blood sugar control, newly diagnosed diabetes, pregnancy	Low RBC (chronic blood loss, hemolytic anemia), chronic renal failure (CRF), sickle cell anemia
<b>Protein Factors</b>				
Albumin	3.5–5 g/dL (35–50 g/L); 3.2–5.1 g/dL in infants up to 1 year old; 3.2–5.7 in children aged 1–2 years; 3.5–5.8 for ages 2 years to adult. Albumin is usually 40% of proteins.	Nonspecific protein nutriture measure. Mostly synthesized in the liver. Transports fatty acids, thyroxine, bilirubin, and many drugs. Albumin–globulin ratio (A:G) is 1.2–1.9; low in renal or liver diseases.	Dehydration, multiple myeloma	Decreased with inflammation and severity of illness, acute stress, starvation, malabsorption of protein, cirrhosis, nephritis with edema, liver disease, malnutrition

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
C-reactive protein (CRP)	0	Elevated in inflammation	Systemic inflammation, obesity, diabetes, heart disease, arthritis, smoking	Vitamin C supplements may lower an elevated CRP. Marathon runners may have very low levels.
Creatinine	0.6–1.2 mg/dL	A basic creatine anhydride, nitrogenous end product of skeletal muscle metabolism. Indirect measure of renal filtration rate.	Hyperthyroidism, CHF, diabetic acidosis, dehydration, muscle disease, some cancers, nephritis, urinary obstruction	Overhydration, multiple sclerosis (MS), pregnancy, eclampsia, increased age, severe wasting
Creatinine–height index (CHI)	CHI = (measured 24-hour creatine excretion × 100)/predicted 24-hour creatine excretion	Estimates skeletal muscle mass. CHI values of 60–80% represent mild marasmus. CHIs of 40–59% represent moderate marasmus. CHIs of <40% represent severe marasmus.	High doses of creatine supplementation	Marasmus, malnutrition
Globulin	2.3–3.5 g/dL	5 fractions; transport antibodies	Infections, leukemia, dehydration, shock, tuberculosis (TB), chronic alcoholism, Hodgkin's disease	Malnutrition, immunological deficiency
Nitrogen balance	Goal of 1–4 g/24 hours urinary urea nitrogen (UUN)	Nitrogen balance is the result of nitrogen intake (from the diet) and nitrogen losses, which consist of nitrogen recovered in urine and feces and miscellaneous losses.	Severe liver disease	Nephrosis
Prealbumin (transthyretin)	16–35 mg/dL	Reflects the past 3 days of protein intake but is affected by inflammation	Renal failure, Hodgkin's disease, pregnancy, dehydration	Acute catabolic states, hepatic disease, stress infection, surgery, low protein intake, malnutrition, hyperthyroidism, nephritic syndrome, overhydration, inflammation
Proteins, total serum	6–8 g/dL; 5.6–7.2 in infants to 1 year; 5.4–7.5 in children 1–2 years old; 5.3–8.0 in ages 2 years to adult	Amount of protein in the bloodstream. Reflects depletion of tissue proteins. Act as buffers in acid–base balance. Plasma proteins equal approximately 7% of total plasma volume.	Dehydration, shock	Hepatic disease, leukemia, malnutrition, infection, pregnancy, malabsorption, severe burns
<b>Nutrient Values</b>				
Ascorbic acid (vitamin C)	0.2–2.0 mg/dL	Serum levels of vitamin C	Oxalate stones, diarrhea, high uric acid	Large doses of aspirin, barbiturates, stress, anemia, tetracycline, oral contraceptives, cigarette smoking, alcoholism, dialysis
Essential fatty acids (EFA) (triene to tetraene [T/T] ratio)	0.2 is normal; a ratio >0.4 in serum phospholipids indicates EFA deficiency in healthy people	Ratio 20:39/20:46 (T/T ratio) is measured. T/T ratios are assessed in RBCs, RBC phospholipids, and serum phospholipids.		EFA deficiency occurs in starvation, marasmus, and strict low-fat diets.
Niacin: <i>N</i> -methylnicotinamide	5.8 μmol/d	For niacin assessment. Usual dietary intake is 16–33 mg/d.	Large doses of nicotinic acid	Pregnancy, lactation, Hartnup disease, pellagra, schizophrenia
Riboflavin: glutathione reductase, erythrocyte	1.2 IU/g hemoglobin	Dietary intake is related to CHO and total energy intake.		Tetracycline or thiazide diuretic use, probenecid, oral contraceptives, sulfa drugs, pellagra, cheilosis, some forms of glossitis, vegetarians using no dairy products or supplements

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
Selenium: glutathione peroxidase	Serum enzyme levels	Works with vitamin E to protect RBCs as part of the enzyme.	Excessive lipid peroxidation	PCM, hypoproteinemia
Thiamin: transketolase activity, erythrocyte	1.20 $\mu\text{g/mL/hr}$	Dietary requirements increase when CHO intake is high.		Use of baking soda in cooking, high CHO intake, infantile beriberi, dry or edematous (cardiac) beriberi, excessive intake of caffeic or tannic acids, pellagra, chronic alcoholism, lactic acidosis in metabolic disorders such as maple syrup urine disease (MSUD)
Vitamin B <sub>6</sub> : pyridoxal 5'-phosphate, plasma	5 ng/mL (20 nmol/L)	Usual dietary intake is 2 milligrams, assuming 100 grams of protein is consumed.		Acute celiac disease, chronic alcoholism, pellagra, high protein intake, pregnancy, oral contraceptive use, isoniazid (INH) and other TB drug use, use of anticonvulsants, malarial drugs
Vitamin A: carotene; retinol, serum	48–200 mg/dL; 10–60 $\mu\text{g/dL}$	Serum levels of carotenoids	Excessive intake, such as from carrots; postprandial hyperlipidemia; diabetes; hypothyroidism	High fever, liver disease, malabsorption syndrome
Retinol-binding protein	2.6–7.6 mg/dL	Used less often to determine status of retinol	May be high in renal failure	Protein deficiency
Serum vitamin A	125–150 IU/dL or 20–80 mg/dL		Hypervitaminosis A	Cirrhosis, infectious hepatitis, myxedema, night blindness, malabsorption, starvation, infections such as measles
Vitamin B <sub>12</sub> : serum B <sub>12</sub>	24.4–100 ng/dL (180 pmol/L)	Vitamin B <sub>12</sub> is less well absorbed in the elderly and in persons who have less intrinsic factor or the ability to reabsorb in the intestines.	Leukemia such as acute myelogenous leukemia (AML) or CML, leukocytosis, polycythemia vera, liver metastasis, hepatitis, cirrhosis	Macrocytic anemia, iron or vitamin B <sub>6</sub> deficiency, gastritis, dialysis, congenital intrinsic factor deficiency, pernicious anemia, tapeworm, ileal resection, strict vegetarian diets, pregnancy
Vitamin D: 1,25-HCC, blood	0.7–3.3 IU/dL	Indirect measures are available from serum alkaline phosphatase, calcium levels, and serum phosphorus.	Hypervitaminosis D	Rickets; osteomalacia; steroid therapy; fracture; poorly calcified teeth; drug therapy such as anticonvulsants, cholestyramine, and barbiturates
Vitamin E: alpha-tocopherol; plasma vitamin E	<18 $\mu\text{mol/g}$ (41.8 $\mu\text{mol/L}$ ); 0.5–2.0 mg/dL	Usual dietary intake is 14 milligrams of d-alpha-tocopherol	High vitamin E intake (this affects coagulation because it works against vitamin K)	High polyunsaturated fatty acid (PUFA) intake, premature infants, cystic fibrosis, hemolytic anemia
Vitamin K: INR or PT	PT, 10–15 seconds	Combined low levels of prothrombin activity, serum calcium, and serum carotene may indicate abnormal fat and fat-soluble vitamin absorption.	Menadione use, intravenous (IV) administration of vitamin K, parenchymal liver disease	PT is prolonged in salicylates, sulfa, and tetracycline use. Liver disease, fat malabsorption, prematurity, small bowel disorders.
Zinc: serum zinc	0.75–1.4 mg/mL or up to 79 $\mu\text{g/dL}$ in plasma; 100–140 $\mu\text{g/dL}$ in serum	Large amounts are found in liver, skeletal muscle, and bone. Part of the insulin molecule. Usual intake is 10–15 mg/d.	Eating foods stored in galvanized containers. Excesses from supplements.	Wounds, geophagia, high-calcium or high-phytate diets, growth, stress, skin lesions, poor taste or olfactory acuity, upper respiratory infections, MI, oral contraceptive use, cancer, pregnancy, cirrhosis, sickle cell or pernicious anemias

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
<b>Electrolytes</b>				
Chloride	95–105 mEq/L	Acid–base balance. Major anion. Follows sodium passively in its transport.	Eclampsia, metabolic acidosis, dehydration, pancreatitis, anemia, renal insufficiency, Cushing's syndrome, head injury, hyperventilation, hyperlipidemia, hypoproteinemia	Diabetic acidosis, metabolic alkalosis, gastroenteritis, fever, potassium deficiency, excessive sweating, heart failure, hyponatremia, infection, diuretics, overhydration
Magnesium	1.8–3 mg/dL	Influences muscular activity. Coenzyme in CHO and protein metabolism.	Renal insufficiency, uncontrolled diabetes, Addison's disease, hypothyroidism, ingestion of magnesium-containing antacids or salts	Malnutrition, potassium-depleting diuretics, malabsorption, alcohol abuse, starvation, renal disease, acute pancreatitis, severe diarrhea, ulcerative colitis
Phosphorous phosphate (PO <sub>4</sub> )	2.3–4.7 mg/dL	Influenced by diet and absorption; regulated by kidneys.	Liver disease, bone tumors, hypervitaminosis D, end-stage renal disease, renal insufficiency, hypoparathyroidism, diabetic ketoacidosis (DKA), Addison's disease, childhood	Malnutrition, gout, hyperparathyroidism, osteomalacia, hyperinsulinism, hypovitaminosis D, alcoholism, overuse of phosphate-binding antacids, rapid refeeding after prolonged starvation
Potassium, serum	3.5–5.5 mEq/L (16–20 mg/dL)	Intracellular. Cellular metabolism; muscle protein synthesis. Enzymes.	Renal insufficiency or failure, overuse of potassium supplements, Addison's disease, dehydration, acidosis, cell damage, poorly controlled diabetes	Decreased potassium intake, renal disease, burns, trauma, diuretics, steroids, vomiting, stress, diarrhea, crash diet, overhydration, malnutrition, estrogen, steroid therapy, cirrhosis, hemolysis, fistula drainage
Sodium, serum	136–145 mEq/L	Absorbed almost 100% from gastrointestinal (GI) tract. Major cation; extracellular ion. Controls osmotic pressure. Acid–base balance.	Vitamin K deficiency, vomiting, heart failure, hypervitaminosis, dehydration, diabetes insipidus, Cushing's disease, primary aldosteronism, diarrhea, steroids	Decreased sodium intake, diuretic use, burns, diarrhea, vomiting, nephritis, diabetic acidosis, hyperglycemia, overhydration
<b>Lipids</b>				
Total serum cholesterol (TC)	<u>Adults:</u> Desirable: 120–199 mg/dL; borderline high: 200–239 mg/dL; high: ≥240 mg/dL <u>Child:</u> Desirable: 70–175 mg/dL; borderline: 170–199 mg/dL; high: ≥200 mg/dL	Fat-related compound; component of plaque. Need fasting sample. Usually 30% high-density lipoprotein (HDL) and 70% low-density lipoprotein (LDL).	High: >200 mg/dL. Hyperlipidemia, diabetes, MI, hypertension (HTN), high-cholesterol diet, nephrotic syndrome, hypothyroidism, pregnancy, cardiovascular disease (CVD)	Low: <160 mg/dL. Low dietary fat ingestion, malnutrition, malabsorption or starvation, fever, acute infections, liver damage, steatorrhea, hyperthyroidism, cancer, pernicious anemia
High-density lipoprotein (HDL)	Males: >45 mg/dL; females: >55 mg/dL	Usually higher in females. Low levels may indicate risk for heart disease.	Vigorous exercise, weight reduction, liver disease, alcoholism	Starvation, obesity, liver disease, DM, smoking, hyperthyroidism
Low-density lipoprotein (LDL)	Desirable: <130 mg/dL; borderline high: 130–159 mg/dL; high: ≥160 mg/dL	May indicate cardiac risk when elevated.	Familial hyperlipidemia, diet high in saturated fat and cholesterol, hypothyroidism, MI, DM, nephrotic syndrome, pregnancy, hepatic disease	Nephritic syndrome

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
Phospholipids	60–350 mg/dL	Measure of EFAs, indirect. Includes lecithin, sphingomyelins, cephalins, and plasmogens.		EFA deficiency
Triglycerides (TG)	Desirable: 10–190 mg/dL; borderline high: 200–400 mg/dL; high: 400–1000 mg/dL; very high: >1000 mg/dL	Neutral fats are the main transport form of fatty acids. Need fasting sample.	High-carbohydrate diet, alcohol abuse (secondary), hyperlipoproteinemias, nephrotic syndrome, CRF, MI, HTN, DM, respiratory distress, pancreatitis, hypothyroidism	Malnutrition, COPD, malabsorption, hyperthyroidism, hyperparathyroidism, brain infarct
<b>Osmolality and pH</b>				
pH, arterial, plasma	7.36–7.44	Hydrogen ion concentration. Enzymes work within narrow pH ranges.	Alkalosis (uncompensated), hyperventilation, pyloric obstruction, HCl losses, diuretic use	Acidosis (uncompensated), emphysema, diabetic acidosis, renal failure, vomiting, diarrhea, intestinal fistula
Osmolality, serum	270–280 mOsm/L	Maintaining normal serum level is desirable.	Elevated in dehydration	Low in overhydration
<b>Respiratory Factors</b>				
Respiratory quotient (RQ)	0.85 from mixed diet	1.0 from CHO; 0.80 from protein; 0.70 from fat	High-CHO diet	High-fat diet
Oxygen: partial pressure of oxygen (pO <sub>2</sub> )	80–100 mm Hg	Reflects hemoglobin concentration. Arterial blood is used.	Hyperoxia	Hypoxia (anemic, stagnant, chronic, anoxic)
Carbon dioxide: partial pressure of carbon dioxide (pCO <sub>2</sub> )	35–45 mm Hg; 24–30 mEq/L		Pulmonary problems, metabolic alkalosis due to ingestion of excess sodium bicarbonate, protracted vomiting with potassium deficiency, Cushing's syndrome, heart failure with edema	Diabetic ketosis or ketoacidosis, starvation, renal insufficiency, persistent diarrhea, lactic acidosis, respiratory alkalosis, diarrhea
<b>Renal Values</b>				
Glomerular filtration rate (GFR)	110–150 mL/min in males; 105–132 mL/min in females	GFR reflects kidney function		Renal failure: <90 mL/min/1.73 m <sup>2</sup> indicates renal decline
Urea clearance	40–65 mL/min standard; 60–100 mL/min maximum	Part of the assessment of renal status		Uremia
Blood urea nitrogen (BUN) to creatinine ratio	>10:1	Measure of impaired renal function.	Renal disease, excess protein intake, bleeding in small intestine, burns, high fever, steroid therapy, decreased renal blood flow, urinary tract obstruction	Low-protein intake, repeated dialysis without repletion, severe vomiting and diarrhea, hepatic insufficiency
BUN	8–18 mg/dL (3–6.5 mmol/L); slightly higher in males	Urea is the end product of protein metabolism. Varies directly with dietary intake. Formed in the liver from amino acids and other ammonia-containing compounds.	Renal failure, azotemia, DM, burns, dehydration, shock, heart failure, infection, chronic gout, excessive protein intake, catabolism, GI bleed, MI, urinary obstruction, starvation, steroid therapy, trauma	Hepatic failure, malnutrition, malabsorption, overhydration, pregnancy, acromegaly, low-protein diet

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
Uric acid	4.0–9.0 mg/dL in men; 2.8–8.8 mg/dL in women	Metabolite from purine metabolism. Excreted by kidney. Serum level reflects balance between production and excretion.	Higher in winter, stress, gout, leukemia, hypoparathyroidism, total fasting, toxemia of pregnancy, elevated triglycerides, DKA, hypertension, hemolytic or sickle cell anemia, renal disease, alcoholism, multiple myeloma, polycythemia, use of vincristine or mercaptopurine	Acute hepatitis, Wilson's disease, celiac disease, Fanconi's syndrome, Hodgkin's disease, use of allopurinol or large doses of Coumadin, folic acid anemia, burns, pregnancy, malabsorption, lead poisoning
<b>Hormones</b>				
Adrenocorticotrophic hormone (ACTH)	5–95 pg/mL at 9 AM; 0–35 pg/mL at midnight		Cushing's syndrome, secondary hypoadrenalism	Pituitary, Cushing's syndrome, primary adrenal insufficiency
Cortisol	5–25 µg/dL at 8 AM; 10 µg/dL at 8 PM	Lower in women	Extreme stress, elevated in patients with night-eating syndrome	
Gastrin	0–200 pg/mL		Zollinger–Ellison syndrome, pyloric obstruction, short bowel syndrome, pernicious anemia, atrophic gastritis	
Growth hormone (GH)	<6 ng/mL in men; <10 ng/mL in women	Being administered in some medical conditions		
Insulin	6–26 IU/mL, fasting	Serum levels are useful.	Untreated obese patients who have diabetes, metabolic syndrome, insulinoma	Severe diabetic acidosis with ketosis and weight loss
Iodine, total	8–15 mEq/L	Affects the activity of the thyroid gland; usual intake with 10 grams of NaCl is 1000 micrograms of iodine.	Hyperthyroidism	Cretinism, simple goiter, low-iodine diet or high-goitrogenic dietary intake
Protein-bound iodine (PBI)	3.6–8.8 mg/dL	Most iodine is protein-bound in the thyroid hormones.	Hyperthyroidism, thyroiditis, pregnancy, oral contraceptive use, hepatitis	Cretinism, simple goiter, low-iodine diet or high-goitrogenic dietary intake
Serotonin (5-HIAA)	0.05–0.20 µg/mL	Neurotransmitter		Depression
Thyroxine (T4); triiodothyronine (T3)	T4: 4–12 µg/100 mL; T3: 75–95 µg/100 mL	Tests of thyroid function	Myasthenia gravis, nephrosis, pregnancy, preeclampsia, Graves' disease, hyperthyroidism	Increased thyroid-stimulating hormone (TSH), decreased T4, T3 (hypothyroidism); malnutrition; hypothyroidism; nephrosis; cirrhosis; Simmonds' disease
Thyroid-stimulating hormone (TSH)	≤0.2 µU/L	Thyroid function tests (TSH, T4, T3)	Primary untreated hypothyroidism, post subtotal thyroidectomy	Hyperthyroidism
<b>Stool Values</b>				
Fat, fecal	<7 g/24 hr		Fat malabsorption	
Nitrogen	<2.5 g/d			
<b>Urinalysis</b>				
	Normal is pale golden yellow	Abnormal color changes: orange = high level of bile; red = blood, porphyria, urates, or bile or ingestion of beets, blackberries, or food dyes; brown = blood; melanin may turn black on standing.	Dehydration: dark golden color	Overhydration: clear color (diluted)

(continued)

**TABLE B-8 Interpretation of Lab Values (continued)**

Value	Normal Range	Purpose or Comment	Increased In	Decreased In
Acetone, ketones	0	Elevation indicates ketosis.	Diabetic ketoacidosis; starvation; fever; prolonged vomiting; high-protein, high-fat, or low-CHO diet; diarrhea; anorexia	
Aldosterone	6–16 mg/24 h			
Ammonia	20–70 mEq/L		Hepatic disease or coma, renal failure, severe heart failure, high-protein diet	Essential hypertension
Amylase	260–950 Somogyi units/24 h		Perforated peptic ulcer, acute pancreatitis, mumps, cholecystitis, renal insufficiency, alcohol poisoning	Hepatitis, pancreatic insufficiency, severe burns
Calcium, normal diet	<250 mg/24 h		Hyperparathyroidism, high calcium or vitamin D in diet, immobilization, metastatic bone disease, multiple myeloma, renal tubular acidosis	Decreased levels may reflect poor intake. Hypoparathyroidism, rickets, renal failure, steatorrhea, osteomalacia
Cortisol, urinary free	10–100 µg/dL		Elevated in stress	Adrenal insufficiency
Creatinine clearance	Males (20 years old): 90 mL/min/SA; females (20 years old): 84 mL/min/SA; decreases by 6 mL/min/SA per decade		Pregnancy, childhood, exercise.	Ascites, dehydration, renal failure, heart failure, shock, cirrhosis
Epinephrine, norepinephrine	Epinephrine: <10 µg/24 h; Norepinephrine <100 µg/24 h		Stress	
Estrogens	4–25 mg/24 h in males; 4–60 mg/24 h in females, higher in pregnancy			
Hemoglobin, myoglobin	0	Any amount	Blood loss, urinary tract injury	
5-Hydroxyindoleacetic acid (5-HIAA)	0	Serotonin excretion		
Oxalate pH	20–60 mg/24 h		Calcium oxalate stones	
	4.6–8; average of 6 (dependent on diet)	Depends on time of sampling and food ingested	Alkaline: metabolic alkalemia, proteus infection, aged specimen, large amount of fruits and vegetables eaten	Acidic: high-protein intake
Protein (albumin)	<30 mg/24 h (0 qualitative)	Amino acids in urine should be 0.4–1 g/L.	Nephrotic syndrome	
Specific gravity	1.003–1.030	Ability to concentrate urine	High in antidiuretic hormone deficiency	Low in renal tubular dysfunction
Sugar	0		Hyperglycemia, ketosis, DKA	
3-Methyl histidine, urine		Indicator of lean body mass turnover	Increased levels may reflect loss of lean body mass.	
Urea	20–35 g/L			
Uric acid	0.2–2.0 g/L			
Vanillylmandelic acid (VMA)	<6.8 mg/24 h	Metabolite of both epinephrine and norepinephrine		
Volume	1000–1500 mL	Varies slightly between individuals	Diabetes insipidus	Dehydration

The table provides estimated and sample normal values; normal ranges will vary by the techniques used by the laboratory completing the tests. Developed from: Pagana KD, Pagana TJ. *Mosby's manual of diagnostic and laboratory tests*. 4th ed. Philadelphia: Mosby, 2009.

**TABLE B-9 Quick Reference: Food–Drug Interactions**

Drugs	Effects and Precautions	Drugs	Effects and Precautions
<i>Antibiotics</i>		<i>Cholesterol-Lowering Drugs</i>	
Cephalosporins, penicillin	Take on an empty stomach to speed absorption of the drugs.	Cholestyramine	Increases the excretion of folate and vitamins A, D, E, and K.
Erythromycin	Do not take with fruit juice or wine, which decrease the drug's effectiveness.	Gemfibrozil	Avoid fatty foods, which decrease the drug's efficacy in lowering cholesterol.
Sulfa drugs	Increase the risk of vitamin B <sub>12</sub> deficiency.	<i>Heartburn and Ulcer Medications</i>	
Tetracycline	Dairy products reduce the drug's effectiveness. Lowers vitamin C absorption.	Antacids	Interfere with the absorption of many minerals; for maximum benefit, take medication 1 hour after eating.
<i>Anticonvulsants</i>		Cimetidine, famotidine, sucralfate	Avoid high-protein foods, caffeine, and other items that increase stomach acidity.
Dilantin, phenobarbital	Increases the risk of anemia and nerve problems due to a deficiency in folate and other B vitamins.	<i>Hormone Preparations</i>	
<i>Antidepressants</i>		Oral contraceptives	Salty foods increase fluid retention. Drugs reduce the absorption of folate, vitamin B <sub>6</sub> , and other nutrients; increase intake of foods high in these nutrients to avoid deficiencies.
Fluoxetine	Reduces appetite and can lead to excessive weight loss.	Steroids	Salty foods increase fluid retention. Increase intake of foods high in calcium, vitamin K, potassium, and protein to avoid deficiencies.
Lithium	A low-salt diet increases the risk of lithium toxicity; excessive salt reduces the drug's efficacy.	Thyroid drugs	Iodine-rich foods may lower the drug's efficacy.
Monoamine oxidase (MAO) inhibitors	Foods high in tyramine (e.g., aged cheeses, processed meats, legumes, wine, and beer) can bring on a hypertensive crisis.	<i>Laxatives</i>	
Tricyclics	Many foods, particularly legumes, meat, fish, and foods high in vitamin C, reduce absorption of the drugs.	Mineral oils	Overuse can cause a deficiency of vitamins A, D, E, and K.
<i>Antihypertensives, Heart Medications</i>		<i>Painkillers</i>	
Angiotensin-converting enzyme (ACE) inhibitors	Take on an empty stomach to improve the absorption of the drugs.	Aspirin and stronger nonsteroidal anti-inflammatory drugs	Always take with food to lower the risk of gastrointestinal irritation; avoid taking with alcohol, which increases the risk of bleeding. Frequent use of these drugs lowers the absorption of folate and vitamin C.
Alpha-blockers	Take with liquid or food to avoid excessive drop in blood pressure.	Codeine	Increase fiber and water intake to avoid constipation.
Antiarrhythmic drugs	Avoid caffeine, which increases the risk of an irregular heartbeat.	<i>Sleeping Pills, Tranquilizers</i>	
Beta-blockers	Take on an empty stomach; food, especially meat, increases the drug's effects and can cause dizziness and low blood pressure.	Benzodiazepines	Never take with alcohol. Caffeine increases anxiety and reduce drug's effectiveness.
Digitalis	Avoid taking with milk and high-fiber foods, which reduce absorption; increases potassium loss.	<i>Weight Loss–Inducing Drugs</i>	
Diuretics	Increases the risk of potassium deficiency.	Many drugs cause weight loss because of changes in appetite or other side effects.	
Potassium-sparing diuretics	Unless a doctor advises otherwise, do not take diuretics with potassium supplements or salt substitutes, which can cause potassium overload.		
Thiazide diuretics	Increases the reaction to MSG.		
<i>Asthma Drugs</i>			
Pseudoephedrine	Avoid caffeine, which increases feelings of anxiety and nervousness.		
Theophylline	Charbroiled foods and a high-protein diet reduce absorption. Caffeine increases the risk of drug toxicity.		

**TABLE B-10 Sample Worksheet for Using Standardized Nutrition Terminology**

**Nutrition Care Process**—Critical thinking worksheet to help determine the appropriate standardized language to document and support the NCP

**STEP ONE: NUTRITION ASSESSMENT**

Complete a comprehensive assessment of a patient using the established assessment standards/guidelines set by your facility or practice setting. Be sure to include “comparative standards:” anthropometrics, estimated needs, and nutrient intake as well as identify the reference standards used to analyze the calculated/numerical data such as the DRIs, BMI, and NCHS charts.

**STEP TWO: NUTRITION DIAGNOSIS**

- (1) List all of the patient’s problems/issues:
- (2) Cross off medical problems/medical diagnoses.
- (3) Cross off issues that do not have supporting evidence (of signs/symptoms).
- (4) Cross off issues where the root etiology (cause of) cannot be determined.
- (5) Place a “✓” by the issues you will be able to re-evaluate upon follow-up; be sure to have updated signs/symptoms data on the reassessment date.
- (6) Of the checked issues, circle those that are the most urgent nutrition problem(s) to resolve and the priority issue to start addressing.
- (7) Based on the problem(s) circled, choose the diagnosis that best suits the nutrition issue in its most detailed form.
- (8) Write P.E.S statement(s) with the appropriate “root” etiology and signs/symptoms:

**P:** \_\_\_\_\_ related to **E:** \_\_\_\_\_ as evidenced by  
**S/S:** \_\_\_\_\_ \*\*\*See examples

**STEP THREE: NUTRITION INTERVENTION** (Direct interventions at the **etiology**. If a dietitian cannot change the etiology, then direct the interventions at reducing the signs/symptoms of the nutrition diagnosis).

**Nutrition Prescription:** (Proper diet and regimen to meet the nutrient needs of what?) \_\_\_\_\_

Based upon scope of practice and clinical privilege established by your facility or practice setting, choose:

- |  |   |
|--|---|
| 1) <u>Recommended Interventions</u> (other practitioner must do) | 2) <u>Interventions you can/will do on your own</u> (actions) |
| • intervention term: _____                                       | • intervention term: _____                                    |
| goal of intervention: _____                                      | goal of intervention: _____                                   |
| • intervention term: _____                                       | • intervention term: _____                                    |
| goal of intervention: _____                                      | goal of intervention: _____                                   |
| • intervention term: _____                                       | • intervention term: _____                                    |
| goal of intervention: _____                                      | goal of intervention: _____                                   |

**Goal of intervention = why you chose that intervention/strategy – what the intervention is intended to do/accomplish**

**STEP FOUR: MONITORING & EVALUATION** (Directed at the **signs/symptoms** to monitor the success of intervention(s) and progress toward goal(s))

- 1) Indicate when/timeframe during which you plan to reassess: within \_\_\_\_\_ days/weeks/months
  - 2) List signs/symptoms from PES above and match to M&E Terms (unshaded) from Assess/M&E list (indicators)
  - 3) Establish criteria for each M&E indicator (pt goals)
    - Signs/Symptoms: \_\_\_\_\_  
 M&E term: \_\_\_\_\_  
 Criteria-Pt will: \_\_\_\_\_
    - Signs/Symptoms: \_\_\_\_\_  
 M&E term: \_\_\_\_\_  
 Criteria-Pt will: \_\_\_\_\_
    - Signs/Symptoms: \_\_\_\_\_  
 M&E term: \_\_\_\_\_  
 Criteria-Pt will: \_\_\_\_\_
- Reassessment or follow-up encounter
- 1) Do you have the info/data needed to compare previous signs/symptoms to the current time? If no, you need to address this as an intervention recommendation, and check it at the next encounter. If yes, evaluate progress toward the M&E criteria on the left (pt goals).  
☐ Pt met goal/criteria    ☐ Pt did not meet goal/criteria
  - 2) Based upon progress toward pt goals, evaluate progress toward the resolution of the nutrition problem from the PES:  
☐ Resolved (nutrition problem no longer exists)  
☐ Improvement shown (nutrition problem still exists)  
☐ Unresolved no improvement shown  
☐ No longer appropriate (change in condition)
  - 3) If no improvement is shown, you may need to change intervention(s).

**Criteria = measurable patient-centered goals**

(continued)

Evaluator: _____	Date: _____	Medical Record # _____		
<b>TOTAL POINTS:</b> _____				

**TABLE B-12 Tips for Adult Education and Counseling**

The adult as a learner	During the process of maturation, a person moves from dependency toward increasing self-directedness but at different rates for different people and in different dimensions of life. Teachers have a responsibility to encourage and nurture this movement. Adults have a deep psychological need to be generally self-directing, but they may be dependent in certain temporary situations.
The learner's experience	As people grow and develop, they accumulate an increasing reservoir of experience that becomes an increasingly rich resource for learning—for themselves and for others. Furthermore, people attach more meaning to lessons they gain from experience than those they acquire passively. Accordingly, the primary techniques in education are experiential ones—laboratory experiments, discussion, problem-solving cases, field experiences, case reports.
Readiness to learn	People become ready to learn something when they experience a need to learn it in order to cope more satisfyingly with real-life tasks and problems. The educator has a responsibility to create conditions and provide tools and procedures for helping learners discover their “need to know.” Learning programs should be organized around life-application categories and sequenced according to the learners’ readiness to learn. Key: Attend to learners’ developmental readiness.
Orientation to learning	Adult learners see education as a process of developing increased competence to achieve their full potential in life. They want to be able to apply whatever knowledge and skill they gain today to living more effectively tomorrow. Accordingly, learning experiences should be organized around competency-development categories. People are performance-centered in their orientation to learning.
Assumptions	<ol style="list-style-type: none"> <li>1. All learners can think; critical and creative thinking are goals.</li> <li>2. There needs to be a safe, risk-taking environment and sufficient time to learn.</li> <li>3. The environment for learning should be rich and responsive.</li> <li>4. Offer challenging problem-solving opportunities.</li> </ol>
Chief assessment factors for learning	<ol style="list-style-type: none"> <li>1. Socioeconomic factors</li> <li>2. Cultural/religious beliefs and background</li> <li>3. Age and sex of patient and significant others (SOs)</li> <li>4. Birth order of patient and family involvement</li> <li>5. Occupation</li> <li>6. Medical status and medical history</li> <li>7. Marital status; number and ages of children</li> <li>8. Cognitive status; educational level</li> <li>9. Readiness to learn and staging: precontemplation, contemplation, preparation, action, or maintenance</li> <li>10. Emotional status (stress, acceptance of illness, chronic disease, or condition)</li> </ol>
Health literacy and teaching tools	Low health literacy (the ability to read, understand, and act on health information) is a public health issue. One out of five American adults reads at the fifth-grade level or below, and the average American reads at the eighth to ninth grade level. Most consumers need help understanding healthcare information. Patients prefer medical information that is easy to read and understand. Easy-to-read healthcare materials are <i>essential</i> . Provide important information first.
Written materials	<p>Print very clearly and avoid handwritten messages. Use large print; font size should be a minimum of 12 points.</p> <p>Double space text to avoid crowding. Avoid using all capital letters. Use headings to introduce the upcoming topic.</p> <p>Avoid abbreviations, and use black ink on light-colored paper.</p> <p>Information must be current and accurate. Provide important information first.</p> <p>Highlight the “need to know” versus the “nice to know.”</p> <p>Present information in a “how to” manner.</p> <p>Use a conversational style.</p> <p>Spell out numbers below 10.</p> <p>Limit syllables to —one or two per word. Keep sentences short, and use bullets when possible.</p>
Educational tools	<p>Newsletters and bulletin boards</p> <p>Demonstrations or role-playing</p> <p>Laboratory reports, flip charts</p> <p>Food recall or intake records with feedback</p> <p>Educational games and fun quizzes</p> <p>Group classes or supermarket tours</p> <p>Educational video and audio tapes</p>

(continued)

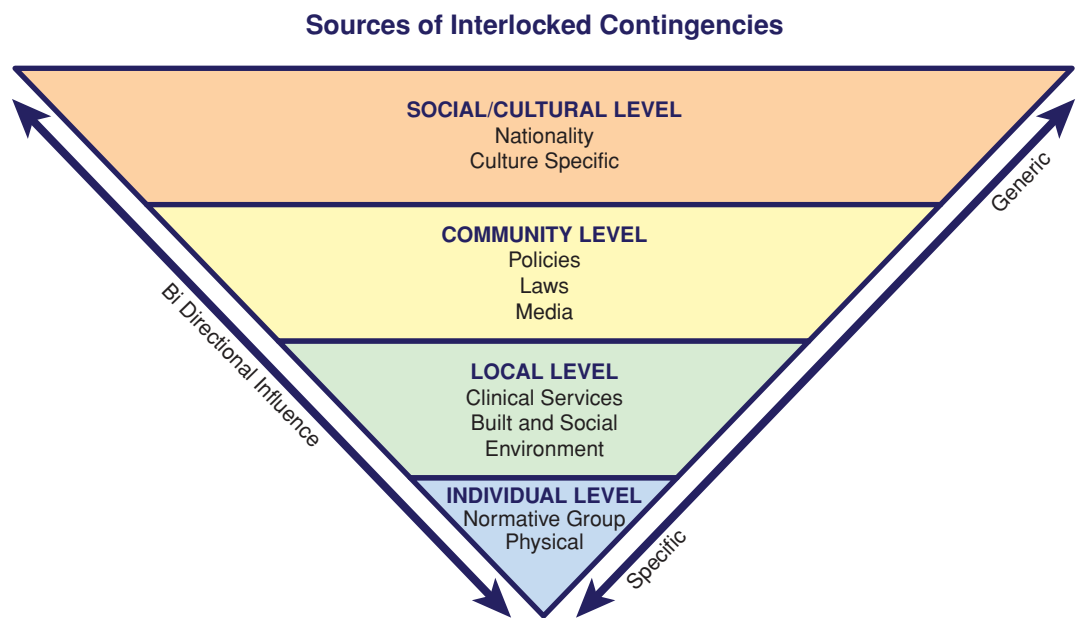

**TABLE B-12** Tips for Adult Education and Counseling (*continued*)

Visual aids	<p>Visuals should be able to stand alone, without words.</p> <p>Use photographs and realistic images.</p> <p>Use culturally appropriate food models, empty packages of real foods, and measuring cups and spoons.</p> <p>Work with restaurant menus where needed.</p> <p>Share simple recipes.</p>
Principles of learning	<p>The recipient must value the information.</p> <p>Pace should be adequate for learner; take small steps.</p> <p>Environment should be conducive to learning (free of distractions and stress), and patient should be ready to learn (free from pain).</p> <p>Information must be meaningful, relevant, and organized. Material should be logical in sequence.</p> <p>Counselor must be truly interested in sharing the information.</p> <p>Adequate follow-up should be available for the reinforcement of facts and principles.</p> <p>For adult learners, information that is useful in the present is more meaningful than facts learned for the “future.”</p> <p>Adults tend to prefer problem-solving information (survival skills) over learning facts.</p>
Principles of teaching	<p>The counselor must first listen to the patient. Involve the patient in setting mutual objectives.</p> <p>Small segments of information should be presented in understandable language in small, manageable “sound bytes.”</p> <p>An organized plan should be used to teach. Clear objectives should be established, with timelines and short- and long-term outcomes.</p> <p>Feedback should be used with each step. Be prepared to receive evaluation (peer review) from the patient; improve as needed.</p> <p>Good eye contact should be maintained with the patient. Be aware, however, that direct or prolonged eye contact can be seen as rude or threatening by some cultures; know your client.</p> <p>Appropriate teaching tools or audiovisual aids should be used as appropriate. Using a sixth- to eighth-grade reading level is suggested, preferably with an easy layout, visual appeal, and illustrations.</p> <p>Questions must be allowed for clarification.</p> <p>Praise and positive reinforcement should be offered to the learner. Carl Rogers emphasizes the use of “unconditional positive regard” for all persons.</p>
Counseling tips	<p>Knowledge does not automatically ensure compliance. Behavioral change takes time and encouragement.</p> <p>Trial and error will be common for the patient in learning new behaviors.</p> <p>An increase in self-esteem comes with an improvement in behavior.</p> <p>The counselor should appropriately foster independence.</p> <p>Empathy is an important part of humanistic care.</p> <p>The counselor serves as an intervention specialist. The “patient-centered” approach to counseling is effective.</p> <p>Assess the stage of change and motivation level of client. Evaluate past experiences with dietary changes and anticipated challenges.</p> <p>Goal-setting requires the patient to recognize the need for change, establish a goal, monitor goal-related activity, and use self-reward for goal attainment.</p> <p>Identify challenges, obstacles, coping strategies, and skills. Help the client to anticipate lapses and relapses.</p>
Patient assessment of chronic illness care (PACIC tool)	<p>Patient-centered model of behavioral counseling using the <b>5 As</b>:</p> <p><b>Assess:</b> Beliefs, behavior, and knowledge.</p> <p><b>Advise:</b> Provide specific information about health risks and benefits of change.</p> <p><b>Agree:</b> Collaboratively set goals based on the patient’s interest and confidence in their ability to change behavior.</p> <p><b>Assist:</b> Identify personal barriers, strategies, problem-solving techniques, and social/environmental support.</p> <p><b>Arrange:</b> Specify a plan for follow-up (e.g., visits, phone calls, mailed reminders).</p>
Counseling in hospice care	<p>Attempt to reduce fears related to eating.</p> <p>Recognize stages of terminal illness: fear of abandonment, finding a natural and realistic approach, building bridges, and ownership of the experience.</p> <p>Pain management is most important for quality of life.</p> <p>Respect the individual’s cultural beliefs and needs.</p> <p>Identify a patient advocate who will address concerns as care progresses.</p> <p>Help maintain self-esteem and dignity.</p> <p>Comfort foods can be important to patient satisfaction; address these needs on a meal-to-meal basis.</p> <p>Listen for hidden messages from the patient; communicate with other healthcare team members.</p>

**TABLE B-13**    Health-Promotion Intervention Models

Because increasing evidence suggests that health-promotion interventions that are based on social and behavioral science theories are more effective than those lacking a theoretical base, five models are described here (Glanz and Bishop, 2010.)

**Behavioral Ecological Model (BEM)**

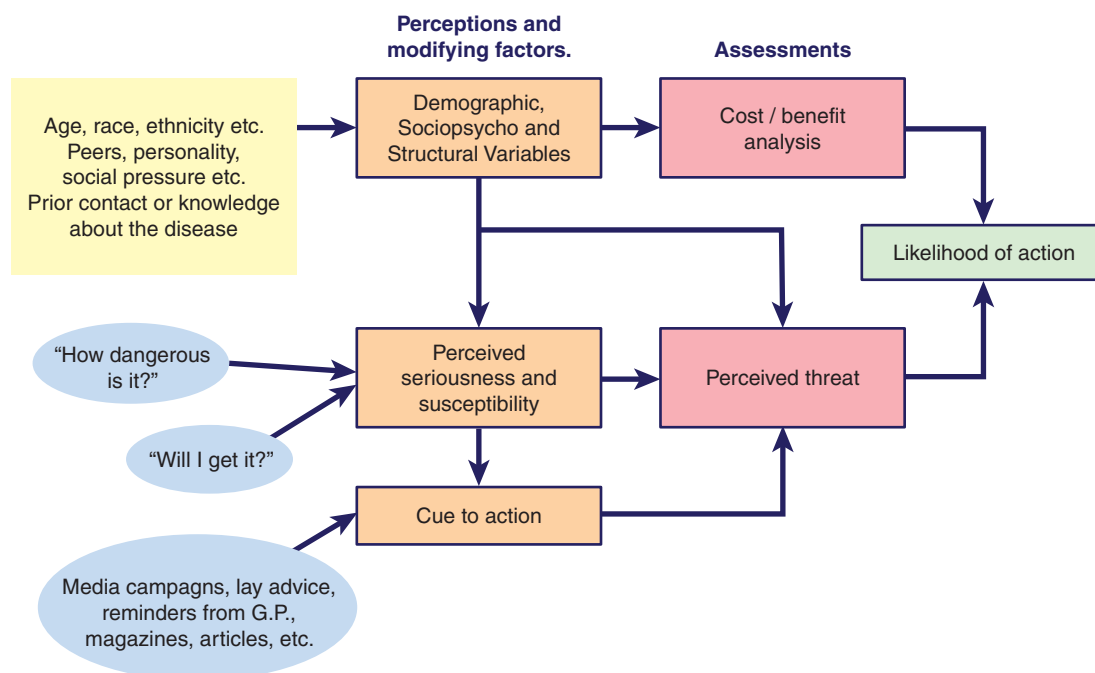

**Figure B-4**    Behavioral Ecological Model (BEM). (Image courtesy of Hovell et al [2002].)

Behavioral Ecological Model (BEM) Principle	Processes	Application
Environment influences behavior	Consequences are produced by the behavior	Control or change risky environment
Hierarchy of interacting reinforcement contingencies	Interaction is key	Interaction among both physical and social contingencies explain and ultimately control health behavior.

Hovell MF, Wahlgren DR, Gehrman C. The Behavioral Ecological Model: Integrating public health and behavioral science. In DiClemente RJ, Crosby R, Kegler M, (eds.). *New and Emerging Theories in Health Promotion Practice & Research*. Jossey-Bass Inc., San Francisco, California, 2002.

(continued)

**TABLE B-13 Health-Promotion Intervention Models (continued)****Health Belief Model****Figure B-5** Health Belief Model (HBM). (Image courtesy of Glanz et al (2002).)

Health Belief Model Concept	Definition	Application
Perceived susceptibility	One's opinion of chances of getting a condition.	Define population(s) at risk, risk levels. Personalize risk based on a person's features or behavior. Heighten perceived susceptibility if too low.
Perceived severity	One's opinion of how serious a condition and its sequelae are.	Specify consequences of the risk and the condition.
Perceived benefits	One's opinion of the efficacy of the advised action to reduce risk or the seriousness of impact.	Define action to take: how, where, when; clarify the positive effects to be expected.
Perceived barriers	One's opinion of the tangible and psychological costs of the advised action.	Identify and reduce barriers through reassurance, incentives, and assistance.
Cues to action	Strategies to activate readiness.	Provide how-to information; promote awareness, reminders.
Self-efficacy	Confidence in one's ability to take action.	Provide training, guidance in performing action.

Glanz K, Bishop DB. The role of behavioral science theory in development and implementation of public health interventions. *Annu Rev Public Health*. 31:399, 2010.  
 Glanz, K., Rimer, BK, Lewis, FM. *Health Behavior and Health Education. Theory, Research and Practice*. San Francisco: Wiley & Sons., 2002.

(continued)

TABLE B-13 Health-Promotion Intervention Models (continued)

Motivational Interviewing

Figure B-6 Key Words for Motivational Interviewing.

Motivational Interviewing (MI) Concept	Definition	Application
Motivation to change comes from the client, not the counselor	Direct persuasion is not an effective method for achieving change. Client must articulate and resolve his or her own ambivalence.	Counseling style is a quiet, eliciting one. Partnership is the goal, not an expert—recipient relationship.
Resolution of ambivalence	Directive, client-centered counseling style for eliciting behavior change by helping clients to explore and resolve ambivalence.	Compared with nondirective counseling, it is more focused and goal-directed. Readiness to change is a fluctuating product of personal interaction.

Rollnick S., & Miller, W.R. What is motivational interviewing? Behavioural and Cognitive Psychotherapy, 23: 325, 1995.

Social Cognitive Theory

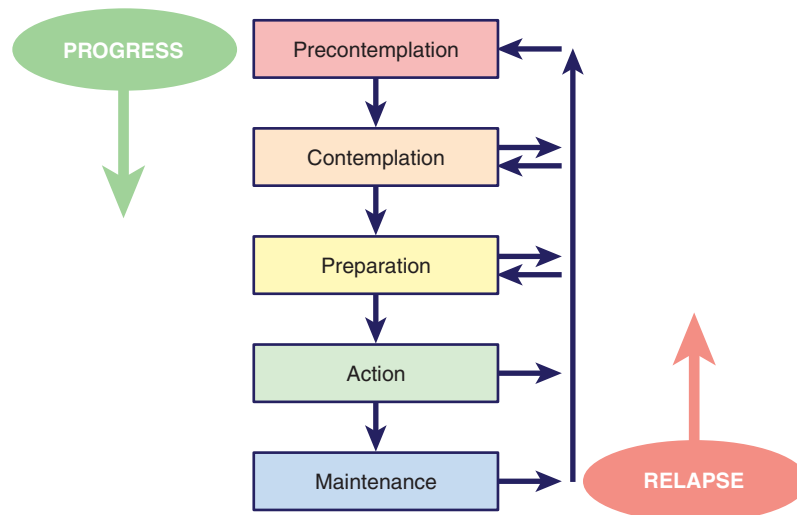

Figure B-7 Self-Efficacy as part of Social Cognitive Theory.

Social Cognitive Theory Principle	Processes	Application
Human functioning is self-regulated	Cognitive, vicarious, and self-reflective processes	Human adaptation to change
Dynamic interplay of personal, behavioral, and environmental influences	Self as organizing, proactive, self-reflective	People are not reactive organisms shepherded by environmental forces or concealed inner impulses
People watch and learn from others	Interactive learning	Confidence comes from practice
Self-efficacy is the belief in the ability to succeed in specific situations	Positive approaches to goals, tasks, and challenges.	Those who believe they can perform well are more likely to view difficult tasks as something to be mastered rather than something to be avoided.

Bandura, A. Social foundations of thought and action: A social cognitive theory. Englewood Cliffs, NJ: Prentice Hall, 1986.

(continued)

**TABLE B-13** Health-Promotion Intervention Models (*continued*)**Transtheoretical Model (TTM)****Figure B-8** Transtheoretical Model (TTM). (Image courtesy of Prochaska and DiClemente (1982).)

TTM Stage	Definition	Helping Processes
Precontemplation	Individual has the problem (whether he/she recognizes it or not) and has no intention of changing.	Consciousness raising (information and knowledge) Dramatic relief (role-playing) Environmental reevaluation (how problem affects physical environment)
Contemplation	Individual recognizes the problem and is seriously thinking about changing.	Self-reevaluation (assessing one's feelings regarding behavior)
Preparation for action	Individual recognizes the problem and intends to change the behavior within the next month. Some behavior change efforts may be reported but the defined behavior change criterion has not been reached consistently.	Self-liberation (commitment or belief in the ability to change)
Action	Individual has enacted consistent behavior change for less than six months.	Reinforcement management (overt and covert rewards) Helping relationships (social support, self-help groups) Counterconditioning (alternatives for behavior) Stimulus control (avoid high-risk cues)
Maintenance	Individual maintains new behavior for six months or more.	Support and encouragement

Prochaska JO, DiClemente CC. Trans-theoretical therapy – toward a more integrative model of change. *Psychotherapy: Theory, Research & Practice*. 19(3):276, 1982.

**TABLE B-14 Sample Monitoring and Evaluation Audits for Patient Education**

This patient education audit identifies the ability of the patient to demonstrate or verbalize how he or she will or has changed behaviors after nutritional instructions.

*Any Patient*

1. Patient is able to personalize the MyPyramid food guidance system.
2. Patient is able to explain the importance of his or her diet for his or her health.
3. Patient is able to plan \_\_\_\_ day's menus and snacks from his/her dietary pattern.
4. Patient is able to incorporate desirable economic/ethnic food choices into his/her prescribed diet.
5. Patient has been following \_\_\_\_ diet at home for a period of time and is able to describe the elements of this diet with accuracy.
6. Patient expresses recognition of a need to lose/gain weight.
7. Patient is able to describe specific food allergies and food ingredients to avoid.
8. Patient is able to describe the reasons for following \_\_\_\_ diet (e.g., improve appearance, increase energy, reduce chances for complications, improve quality of life).
9. Patient is able to describe the impact of appropriate activity or exercise on health and nutritional well-being.

*Cardiac Diet*

1. Patient is able to name three beverages that are high in caffeine.
2. Patient is able to describe modifications in his or her diet that will be needed to prevent further coronary complications: saturated versus poly- and monounsaturated fats, sodium and potassium, fiber, and use of the DASH diet.
3. Patient is able to categorize correctly into the proper food pyramid lists.
4. Patient is able to plan menus for home use that include appropriate modifications.
5. Patient is able to name snack foods that can be included in dietary plan.

*Diabetes Diet*

1. Patient is able to explain the relationship of diet with complications of diabetes.
2. Patient is able to name foods that contain CHO.
3. Patient is able to preplan meals for \_\_\_\_ weeks.
4. Patient is able to verbalize a simple definition of diabetes.
5. Patient is able to describe the role of medications related to food intake.
6. Patient is able to explain the rationale for following a prudent diet to prevent complications such as heart disease.
7. Patient is able to explain how proper spacing of meals affects his/her disorder.
8. Patient is able to describe symptoms of ketoacidosis and insulin shock and can name foods to take or avoid for each condition.
9. After looking at several food labels, patient is able to point out ingredients that mean carbohydrate.
10. Patient is able to describe techniques for managing special events (travel, parties, restaurants, holiday meals, weekends).
11. Patient is able to describe his or her personal exercise prescription as \_\_\_\_ minutes of activity \_\_\_\_ times per week.

12. Patient is able to describe 1–2 items to carry in case of episodes of low blood glucose.
13. Patient is able to define when to call his or her health provider (e.g., when glucose is above/below normal \_\_\_\_ times).
14. Patient is able to discuss proper foot care, the need for eye exams, and the need for foot exams.

*Dumping Syndrome Diet*

1. Patient is able to verbalize the effects of diet on dumping syndrome.
2. Patient is able to explain the guidelines to be followed to prevent dumping syndrome (e.g., beverages are served 30 minutes before or after meals; concentrated sweets are omitted or severely limited).

*Gliadin-Free/Gluten-Restricted Diet*

1. Patient is able to examine food labels and to name ingredients that must be avoided.
2. Patient is able to list products that must be avoided in diet.
3. Patient is able to plan menus that can be used at home.
4. Patient is able to adapt recipes for use at home.

*High-Fiber Diet*

1. Patient is able to verbalize foods that can be used to increase fiber in his or her diet, to desired level of \_\_\_\_ grams daily.
2. Patient is able to explain the role of fiber in his or her particular disorder.
3. Patient is able to describe the purpose of adequate fluids in the dietary regimen and is able to consume \_\_\_\_ milliliters daily.

*Lactose Intolerance Diet*

1. Patient is able to name foods or beverages that must be avoided.
2. Patient is able to plan menus that are nutritionally complete for calcium but are lactose restricted.
3. Patient demonstrates awareness that he or she can tolerate up to \_\_\_\_ milliliters of lactose per day at this time.
4. Patient is able to discuss the difference between lactose intolerance and milk allergy.

*Low-Cholesterol and Dyslipidemia Diets*

1. Patient is able to describe simple definitions for cholesterol and saturated, polyunsaturated, and monounsaturated fats.
2. Patient is able to identify foods that have high cholesterol content.
3. Patient is able to name vegetable oils that may be used in the diet.
4. Patient is able to describe three cooking methods that are acceptable for the dietary regimen.
5. Patient is able to name foods that are good sources of monounsaturated fats.

(continued)

**TABLE B-14 Sample Monitoring and Evaluation Audits for Patient Education (*continued*)***Low-Fat Diet*

1. Patient is able to name foods that he or she must omit for the low-fat diet.
2. Patient is able to explain the role of fat in his or her condition.
3. Patient is able to note grams of fat from a given food label.

*Mineral-Altered Diets (Iron, Potassium, Calcium, Sodium)*

1. Patient is able to name foods that are high/low in minerals.
2. Patient is able to accurately select menu choices for days that include/exclude foods that are high in mineral.
3. Patient is able to plan menus for home that are high/low in minerals.

*Pregnancy Diet*

1. Patient is able to describe nutritional changes to her diet in order to have a healthy baby.
2. Patient is able to describe why breastfeeding is an important consideration.

*Protein-Altered Diets*

1. Patient can identify foods that contain protein of high biological value.
2. Patient can name foods to include/omit in diet to increase/decrease the protein content of meals and snacks.

*Renal Diets*

1. Patient is able to describe restrictions that are needed in regard to protein, sodium, potassium, fluid, calories, and phosphorus.
2. Patient is able to plan menus that are balanced for the restricted nutrients.
3. Patient is able to name “free” foods that he or she can eat as desired.
4. Patient is able to discuss how foods, nutrients, and prescribed medications may interact.

*Sodium Restrictions*

1. Patient is able to name foods that are naturally high in sodium.
2. Patient is able to name foods that have been processed or prepared with an excess of sodium.
3. Patient is able to explain the difference between “salt” and “sodium” in foods.
4. Patient is able to list seasonings that can be used at home in place of salt and salt-containing seasonings.
5. Patient is able to plan menus for home that will be low in sodium.
6. Patient is able to identify salt substitutes that he or she can use for his or her condition.
7. Patient is able to discuss how other minerals (potassium, calcium, magnesium) play a role in the specific condition.

*Vegetarian Diet*

1. Patient is able to identify correctly two or more complementary protein foods.
2. Patient is able to plan menus that provide adequate protein and vitamin B<sub>12</sub>, zinc, and so on for age and gender.

*Weight Management Diet*

1. Patient is able to verbalize his or her primary motivation for losing weight and current readiness for a change in behaviors.
2. Patient is able to describe his or her realistic goal for weight loss—either short term or long term, including a timetable.
3. Patient is able to list foods that are low in energy and may be eaten as snacks.
4. Patient is able to categorize foods into the proper pyramid food categories.
5. Patient is able to demonstrate a proper technique for recording food intake at home.
6. Patient has demonstrated weight loss over a certain timeframe.

# Acuity Ranking for Dietitian Services and Concept Map

Over 100 dietitians, clinical nutrition managers, and specialists were surveyed for this acuity ranking for dietitian services, and a summary is given below. Levels of consensus on acuity are indicated for the medical diagnoses and conditions in this text. Where strong consensus was available, this table provides the acuity ranking for the nutritional involvement needed from a registered dietitian (RD). The survey asked the ques-

tions listed in Table C-1. Table C-2 summarizes the rankings given by participants to the nutrition acuity by condition or disease. Concept maps are useful for organizing data to prepare assessments or case reviews. Figure C-1 can be used or adapted as a teaching tool for skill development. Figure C-2 provides an example of a process chart for considering all aspects of data for a comprehensive functional nutrition plan.

**TABLE C-1 Nutrition Acuity and Medical Diagnosis–Related Survey Questions**

Rate your opinion about the level of dietitian involvement (over time, not just per visit) for the following diagnoses on a 1 to 5 rating scale where

1 = Little involvement; minimal, can be delegated to others	4 = Extensive involvement needed over time
2 = Some roles in oversight of nutrition care	5 = Unable to determine; no opinion or experience
3 = Moderate involvement needed over time	

**TABLE C-2 Acuity for Dietitian Roles in Medical Diagnoses**

Minimal Role of Dietitian–1	Some Roles of Dietitian–2	Moderate Role of Dietitian–3	Extended Role of Dietitian–4
<b>NORMAL LIFE-CYCLE CONDITIONS</b>			
Pregnancy, normal	Child, normal (1–2)	Pregnancy, high risk	
Lactation	Teenager, normal		
Infant, normal (birth up to 6 months)	Adult male, normal		
Infant, normal (6–12 months) (1–2)	Adult female, normal		
	Elderly male, normal		
	Elderly female, normal		
<b>DIETARY PRACTICES AND MISCELLANEOUS CONDITIONS</b>			
Periodontal disease (1–2)	Complementary medicine and herbal/botanical counseling	Pressure ulcer, stages 1 or 2 (2–3)	Pressure ulcer, stages 3 or 4 or multiple
Temporomandibular joint (TMJ) dysfunction	Cultural food pattern, advisement and planning	Vitamin deficiency prevention or counseling	
Skin disorders (acne, rosacea, eczema, psoriasis)	Vegetarian diet advisement or planning	Food allergy, multiple or complex (3–4)	
Ménière's syndrome	Religious dietary patterns, advisement/planning		
	Dental difficulties (caries, wired jaw, mouth pain, xerostomia) (2–3)		
	Vision and self-feeding problems (low vision or chewing problems) (1–2)		
	blindness, coordination		
	Food allergy, simple (2–3)		
	Foodborne illness, prevention or counseling		

(continued)

**TABLE C-2 Acuity for Dietitian Roles in Medical Diagnoses (continued)**

Minimal Role of Dietitian–1	Some Roles of Dietitian–2	Moderate Role of Dietitian–3	Extended Role of Dietitian–4
<b>PEDIATRICS: BIRTH DEFECTS, GENETIC, ACQUIRED DISORDERS</b>			
Attention deficit disorders	Abetalipoproteinemia (variable)	Bronchopulmonary dysplasia (3–4)	Failure to thrive, pediatric
Autism spectrum disorders (1–2)	Biliary atresia (2–3)	Cerebral palsy	Inborn errors of carbohydrate metabolism
Adrenoleukodystrophy (variable)	Congenital heart disease	Cleft palate	Hirschsprung's disease (congenital megacolon)
Leukodystrophies (variable)	Cystinosis and Fanconi's syndrome (variable)	Homocystinuria (3–4)	HIV infection and AIDS, pediatric
Otitis media	Down syndrome	Maple syrup urine disease (MSUD) (3–4)	Low birth weight or premature infant (3–4)
	Fetal alcohol syndrome (1–2)	Medium-chain acyl-CoA dehydrogenase deficiency (MCADD)	Necrotizing enterocolitis
	Large for gestational age infant (variable)	Myelomeningocele (variable)	Phenylketonuria (PKU)
		Obesity, childhood (prevention, treatment) (3–4)	Tyrosinemia (variable)
		Prader-Willi syndrome (3–4)	Urea cycle disorders (variable)
		Rickets, nutritional	
		Spina bifida and neural tube defects	
		Wilson's disease (hepatolenticular degeneration)	
<b>NEUROLOGICAL AND PSYCHIATRIC CONDITIONS</b>			
<b>Neurological Disorders</b>			
Migraine headache, prevention or counseling	Epilepsy or seizure disorders	Amyotrophic lateral sclerosis	Brain trauma
Trigeminal neuralgia (1–2)	Multiple sclerosis	Cerebral aneurysm	Coma
	Myasthenia gravis and neuromuscular junction disorders	Guillain-Barré syndrome	
	Parkinson's disease	Huntington's chorea (variable)	
	Tardive dyskinesia	Spinal cord injury	
<b>Eating Disorders</b>			
		Stroke (cerebrovascular accident)	
		Anorexia nervosa	
		Binge eating disorder (3–4)	
		Bulimia (3–4)	
		Other disordered eating patterns (3–4)	
<b>Psychiatric Disorders</b>			
Bipolar disorder (1–2)		Alzheimer's disease or other dementias	
Depression with numerous medications (1–2)			
Schizophrenia and psychoses (1–2)			
Substance use disorders			

(continued)

**TABLE C-2** Acuity for Dietitian Roles in Medical Diagnoses (*continued*)

Minimal Role of Dietitian–1	Some Roles of Dietitian–2	Moderate Role of Dietitian–3	Extended Role of Dietitian–4
<b>PULMONARY DISORDERS</b>			
Asthma	Cor pulmonale (variable)	Chronic obstructive pulmonary diseases (emphysema or chronic bronchitis)	Chylothorax
Bronchiectasis	Interstitial lung disease (1–2)	Cystic fibrosis	Respiratory failure and ventilator dependency
Bronchitis, acute	Sarcoidosis	Respiratory distress syndrome (3–4)	
Pneumonia (1–2)	Sleep apnea	Transplantation, lung (3–4)	
Pulmonary embolism (1–2)	Thoracic empyema		
	Tuberculosis		
<b>CARDIOVASCULAR DISORDERS</b>			
Angina pectoris	Peripheral artery disease	Atherosclerosis, coronary heart disease, and dyslipidemias	Cardiac cachexia
Arteritis		Cardiomyopathies	Heart transplantation or heart–lung transplantation
Pericarditis and cardiac tamponade		Heart failure	
Thrombophlebitis		Hypertension	
		Myocardial infarction	
<b>GASTROINTESTINAL DISORDERS</b>			
<b>Upper GI</b>			
Dyspepsia or indigestion (1–2)	Esophageal varices (2–3)	Dysphagia (3–4)	
	Hiatal hernia, esophagitis, and gastroesophageal reflux (GERD) (2–3)	Esophageal stricture or spasm, achalasia, or Zenker’s diverticulum	
	Gastric retention or gastroparesis (2–3)	Esophageal trauma (3–4)	
	Peptic ulcer	Gastritis and gastroenteritis	
		Giant hypertrophic gastritis (Ménétrier’s disease)	
		Gastrectomy and/or vagotomy (3–4)	
		Vomiting, pernicious	
<b>Lower GI</b>			
Lactose malabsorption (lactase deficiency) (variable)	Diarrhea, dysentery, and traveler’s diarrhea	Fat malabsorption syndrome	Tropical sprue
Constipation (1–2)	Diverticular diseases (2–3)	Megacolon, acquired	Celiac disease
Fecal incontinence	Peritonitis	Irritable bowel disease	Crohn’s disease (3–4)
Hemorrhoids, hemorrhoidectomy	Colostomy (2–3)	Carcinoid syndrome	Ulcerative colitis
Proctitis		Ileostomy	Short bowel syndrome
		Intestinal lymphangiectasia (variable)	Intestinal fistula
		Whipple’s disease (intestinal lipodystrophy) (3–4)	Intestinal transplantation

*(continued)*

**TABLE C-2 Acuity for Dietitian Roles in Medical Diagnoses (continued)**

Minimal Role of Dietitian–1	Some Roles of Dietitian–2	Moderate Role of Dietitian–3	Extended Role of Dietitian–4
<b>HEPATIC, PANCREATIC, AND BILIARY DISORDERS</b>			
Jaundice	Ascites and chylous ascites Hepatitis Pancreatic insufficiency (2–3) Gallbladder disease, surgical or nonsurgical Biliary cirrhosis Cholestatic liver disease (2–3)	Alcoholic liver disease Hepatic cirrhosis Hepatic encephalopathy, failure or coma (3–4) Pancreatitis, acute (3–4) Pancreatitis, chronic Zollinger–Ellison syndrome (variable)	Liver transplantation
<b>ENDOCRINE DISORDERS</b>			
Adrenocortical insufficiency, chronic	Pregnancy-induced Hypertension and preeclampsia	Metabolic syndrome (3–4) Prediabetes (3–4)	Type 1 diabetes Pancreatic transplantation
Addison's disease (variable)	Syndrome of inappropriate antidiuretic hormone (SIADH)	Diabetic gastroparesis (3–4)	Type 2 diabetes mellitus, adults
Cushing's syndrome (variable)		Diabetic ketoacidosis (3–4)	Type 2 diabetes mellitus, children and teens
Acromegaly (variable)	Parathyroid disorders	Hyperosmolar hyperglycemic state (3–4)	Gestational diabetes
Hyperaldosteronism (variable)	(altered calcium)	Hypoglycemia, iatrogenic	
Hypopituitarism (variable)		Hyperinsulinism and spontaneous hypoglycemia (3–4)	
Pheochromocytoma (variable)		Diabetes insipidus	
Hyperthyroidism			
Hypothyroidism			
<b>WEIGHT MANAGEMENT, UNDERNUTRITION, AND MALNUTRITION</b>		Underweight or unintentional weight loss (3–4) Protein–calorie malnutrition, mild (3–4)	Overweight or uncomplicated obesity Obesity, medical (with comorbidities) Protein–calorie malnutrition, moderate or severe Energy malnutrition Refeeding syndrome
<b>MUSCULOSKELETAL AND COLLAGEN DISORDERS</b>			
Ankylosing spondylitis (variable)	Immobilization, extended	Rhabdomyolysis (variable)	
Myofascial pain syndromes: fibromyalgia or polymyalgia rheumatica	Muscular dystrophy		
Osteomyelitis, acute (1–2)	Osteoarthritis and degenerative joint disease		
Paget's disease (osteitis deformans) (variable)	Osteopenia and osteomalacia		
Polyarteritis nodosa (variable)	Osteoporosis		
Rheumatoid arthritis	Systemic lupus erythematosus		
Ruptured intervertebral disc			
Scleroderma (systemic sclerosis) (1–2)			

(continued)

**TABLE C-2** Acuity for Dietitian Roles in Medical Diagnoses (*continued*)

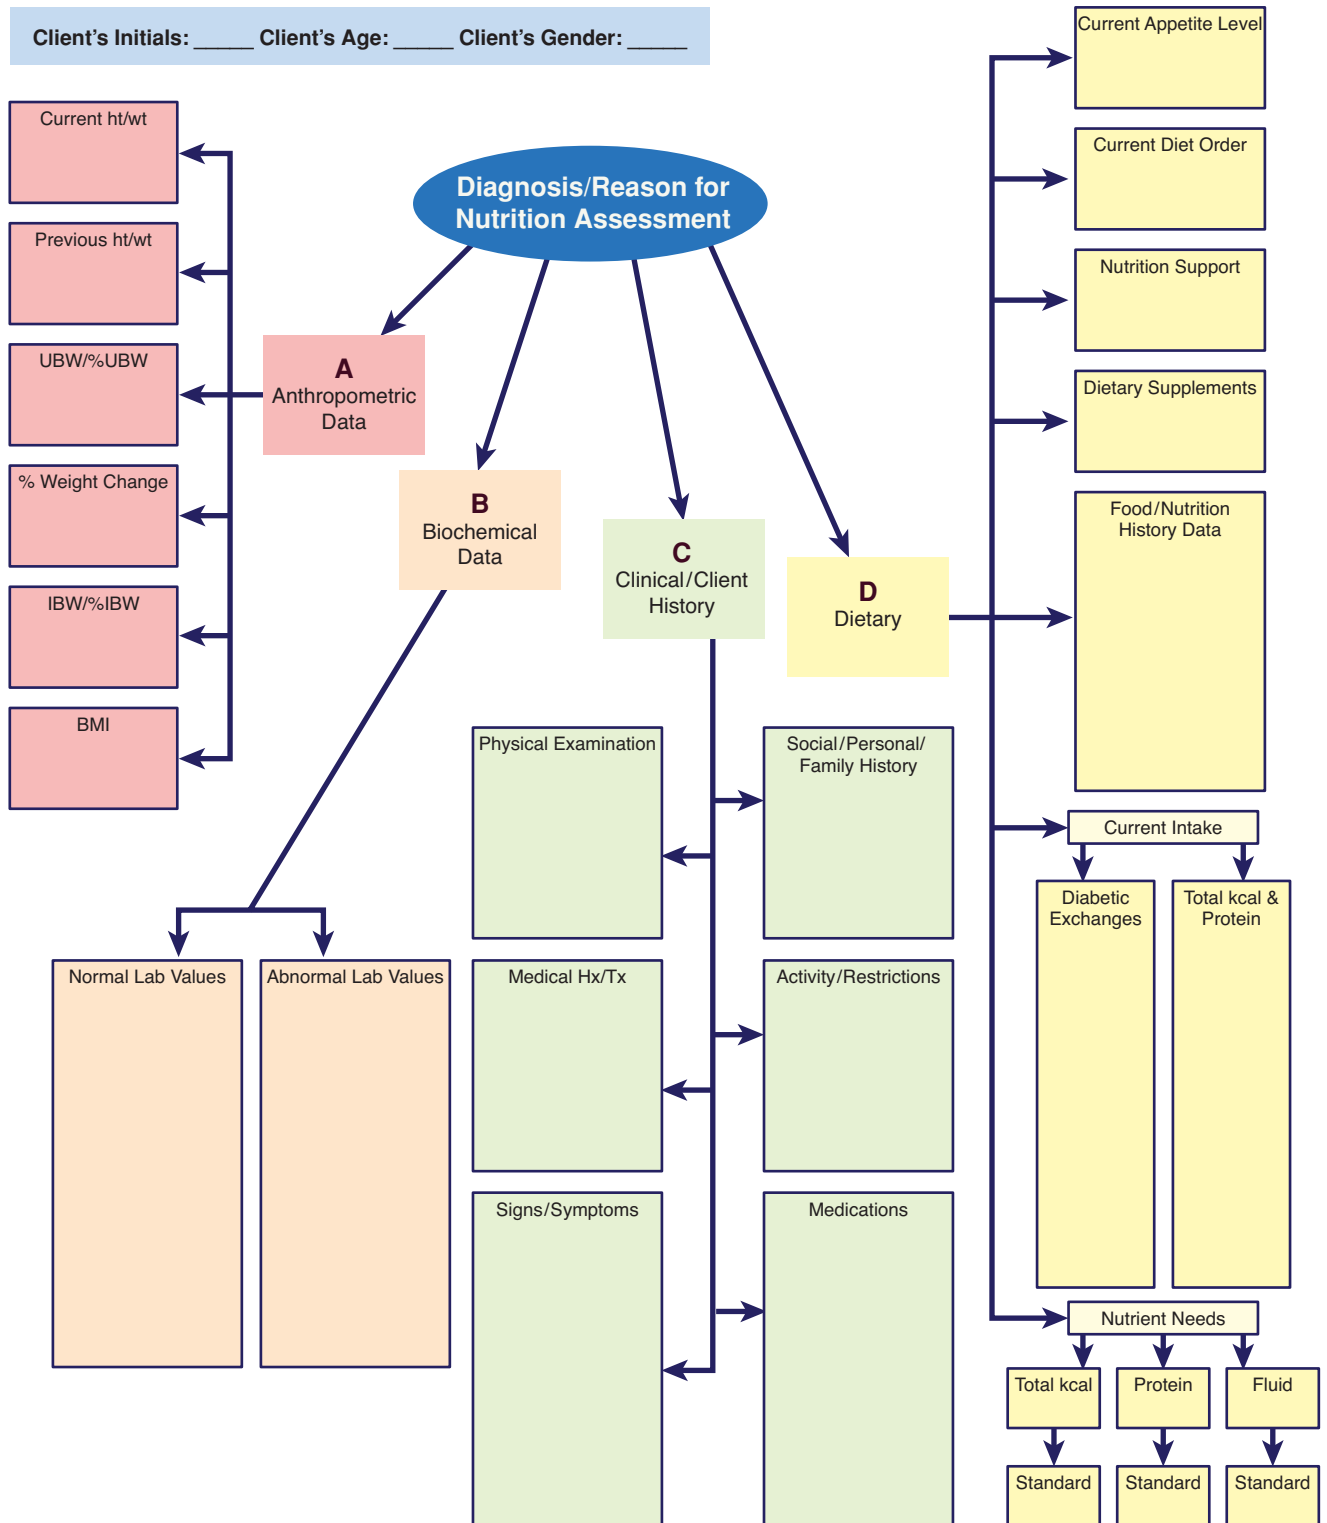

Minimal Role of Dietitian–1	Some Roles of Dietitian–2	Moderate Role of Dietitian–3	Extended Role of Dietitian–4
<b>HEMATOLOGY: ANEMIAS AND BLOOD DISORDERS</b>			
Aplastic anemia	Anemia, hemolytic from vitamin E deficiency (2–3)		
Anemia from parasitic infestation	Anemia, iron deficiency		
Anemia, sickle cell	Anemia, nutritional (folic acid, copper, etc.)		
Anemia, sideroblastic	Anemia, pernicious or vitamin B <sub>12</sub> deficiency		
Polycythemia vera (Osler's disease)	Hemochromatosis (iron overloading)		
Thalassemia (Cooley's anemia)	Hemorrhage, acute or chronic		
Thrombocytic purpura			
<b>CANCER</b>			
	Breast cancer	Brain tumor	Bone marrow transplantation
	Choriocarcinoma	Esophageal cancer (3–4)	
	Leukemia, chronic	Gastric carcinoma (3–4)	
	Lung cancer	Hepatic carcinoma	
	Myeloma (simple or multiple) (2–3)	Intestinal carcinoma (3–4)	
	Prostate cancer	Leukemia, acute	
		Lymphoma, Hodgkin's disease	
		Lymphoma, non-Hodgkin's	
		Oral cancer (3–4)	
		Osteosarcoma (2–3)	
		Pancreatic carcinoma	
		Radiation colitis or enteritis (3–4)	
		Wilms' tumor (embryoma of kidney)	
<b>SURGICAL DISORDERS</b>			
Appendectomy	Surgery, general	Bowel surgery	Gastric bypass surgery
Cesarean delivery	Sodium imbalances: hyponatremia or hypernatremia	Open heart surgery	
Hysterectomy, abdominal	Potassium imbalances: hypokalemia or hyperkalemia	Pancreatic surgery (3–4)	
Pelvic exenteration	Calcium imbalances: hypocalcemia or hypercalcemia		
Spinal surgery (1–2)	Magnesium imbalances: hypomagnesemia or hypermagnesemia		
Total hip arthroplasty	Phosphate imbalances: hypophosphatemia or hyperphosphatemia		
Tonsillectomy and adenoidectomy	Amputation, one or more limbs		
	Parathyroidectomy		

*(continued)*

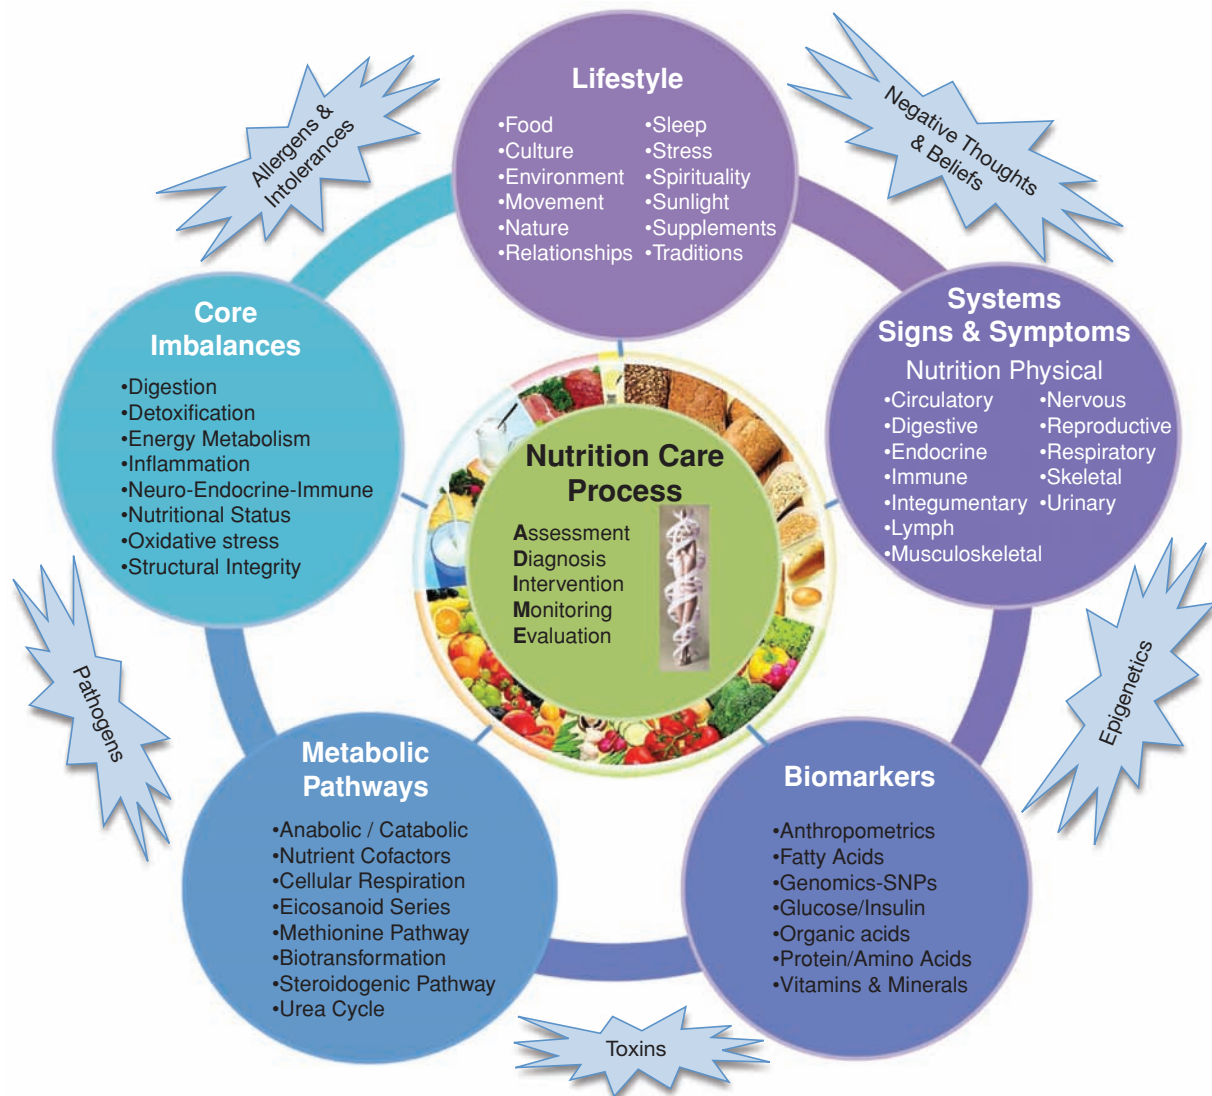

**TABLE C-2 Acuity for Dietitian Roles in Medical Diagnoses (continued)**

Minimal Role of Dietitian–1	Some Roles of Dietitian–2	Moderate Role of Dietitian–3	Extended Role of Dietitian–4
<b>AIDS, INFECTIONS, BURNS, IMMUNOLOGY, AND TRAUMA</b>			
Candidiasis	Bacterial endocarditis	AIDS and HIV infection, adult (3–4)	Burns, major thermal injury
Chronic fatigue syndrome (1–2)	Burns, minor thermal injury	Sepsis or septicemia	Multiple organ dysfunction
Fever >102°F	Encephalitis or Reye’s syndrome	Trauma, major	
Herpes simplex 1 or 2	Fracture, hip or long bone		
Herpes zoster (shingles)	Trauma, minor		
Infection, general			
Influenza (flu, respiratory)			
Intestinal parasites			
Meningitis			
Mononucleosis			
Pelvic inflammatory disease			
Poliomyelitis			
Rheumatic fever			
Toxic shock syndrome			
Trichinosis			
Typhoid fever			
<b>RENAL DISORDERS</b>			
Pyelonephritis	Inborn errors: polycystic kidney disease	Inborn errors: vitamin D-resistant rickets (3–4)	Chronic kidney disease
Urolithiasis (renal stones) (1–2)	Glomerulonephritis, acute	Inborn errors: Hartnup disease (variable)	Hemodialysis
	Glomerulonephritis, chronic	Nephrosclerosis (2–3)	Peritoneal renal dialysis
	Nephritis (Bright’s disease) (2–3)	Renal failure, acute	Renal transplantation
	Nephrotic syndrome (2–3)		
<b>ENTERAL–PARENTERAL NUTRITION</b>			Tube feeding, initiation, monitoring, or home
			Parenteral nutrition, initiation, monitoring, or home

Thanks to Matthew Dallas, MS, RD, for summarizing this table.

31–50 y	1,300	120	5*	19	90*	1.4	1.6	17	2.0	500	2.8	7*	35*	550*

**NOTE:** This table (taken from the DRI reports, see [www.nap.edu](http://www.nap.edu)) presents Recommended Dietary Allowances (RDAs) in **bold type** and Adequate Intakes (AIs) in ordinary type followed by an asterisk (\*). RDAs and AIs may both be used as goals for individual intake. RDAs are set to meet the needs of almost all (97 to 98 percent) individuals in a group. For healthy breastfed infants, the AI is the mean intake. The AI for other life stage and gender groups is believed to cover needs of all individuals in the group, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of individuals covered by this intake.

<sup>a</sup> As retinol activity equivalents (RAEs). 1 RAE = 1 µg retinol, 12 µg β-carotene, 24 µg α-carotene, or 24 µg β-cryptoxanthin. The RAE for dietary provitamin A carotenoids is twofold greater than retinol equivalents (RE), whereas the RAE for preformed vitamin A is the same as RE.

<sup>b</sup> As cholecalciferol. 1 µg cholecalciferol = 40 IU vitamin D.

<sup>c</sup> In the absence of adequate exposure to sunlight.

<sup>d</sup> As α-tocopherol. α-Tocopherol includes *RRR*-α-tocopherol, the only form of α-tocopherol that occurs naturally in foods, and the *2R*-stereoisomeric forms of α-tocopherol (*RRR*-, *RSR*-, and *RSS*-α-tocopherol) that occur in fortified foods and supplements. It does not include the *2S*-stereoisomeric forms of α-tocopherol (*SRR*-, *SSR*-, *SSR*-, and *SSS*-α-tocopherol), also found in fortified foods and supplements.

<sup>e</sup> As niacin equivalents (NE). 1 mg of niacin = 60 mg of tryptophan; 0–6 months = preformed niacin (not NE).

<sup>f</sup> As dietary folate equivalents (DFE). 1 DFE = 1 µg food folate = 0.6 µg of folic acid from fortified food or as a supplement consumed with food = 0.5 µg of a supplement taken on an empty stomach.

<sup>g</sup> Although AIs have been set for choline, there are few data to assess whether a dietary supply of choline is needed at all stages of the life cycle, and it may be that the choline requirement can be met by endogenous synthesis at some of these stages.

<sup>h</sup> Because 10 to 30 percent of older people may malabsorb food-bound B<sub>12</sub>, it is advisable for those older than 50 years to meet their RDA mainly by consuming foods fortified with B<sub>12</sub> or a supplement containing B<sub>12</sub>.

<sup>i</sup> In view of evidence linking folate intake with neural tube defects in the fetus, it is recommended that all women capable of becoming pregnant consume 400 µg from supplements or fortified foods in addition to intake of food folate from a varied diet.

<sup>j</sup> It is assumed that women will continue consuming 400 µg from supplements or fortified food until their pregnancy is confirmed and they enter prenatal care, which ordinarily occurs after the end of the preconceptional period—the critical time for formation of the neural tube.

**NOTE:** This table presents Recommended Dietary Allowances (RDAs) in **bold type** and Adequate Intakes (AIs) in ordinary type followed by an asterisk (\*). RDAs and AIs may both be used as goals for individual intake. RDAs are set to meet the needs of almost all (97 to 98 percent) individuals in a group. For healthy breastfed infants, the AI is the mean intake. The AI for other life stage and gender groups is believed to cover needs of all individuals in the group, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of individuals covered by this intake.

<sup>a</sup>UL = The maximum level of daily nutrient intake that is likely to pose no risk of adverse effects. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to lack of suitable data, ULs could not be established for vitamin K, thiamin, riboflavin, vitamin B<sub>12</sub>, pantothenic acid, biotin, carotenoids. In the absence of ULs, extra caution may be warranted in consuming levels above recommended intakes.

<sup>b</sup> As preformed vitamin A only.

<sup>c</sup> As α-tocopherol; applies to any form of supplemental α-tocopherol.

<sup>d</sup>The ULs for vitamin E, niacin, and folate apply to synthetic forms obtained from supplements, fortified foods, or a combination of the two.

<sup>e</sup> β-Carotene supplements are advised only to serve as a provitamin A source for individuals at risk of vitamin A deficiency.

<sup>f</sup>ND = Not determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.

**SOURCES:** *Dietary Reference Intakes for Calcium, Phosphorus, Magnesium, Vitamin D, and Fluoride* (1997); *Dietary Reference Intakes for Thiamin, Riboflavin, Niacin, Vitamin B<sub>6</sub>, Folate, Vitamin B<sub>12</sub>, Pantothenic Acid, Biotin, and Choline* (1998); *Dietary Reference Intakes for Vitamin C, Vitamin E, Selenium, and Carotenoids* (2000); and *Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicon, Vanadium, and Zinc* (2001). <sup>a</sup> UL = The maximum level of daily nutrient intake that is likely to pose no risk of adverse effects. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to lack of suitable data, ULs could not be established for arsenic, chromium, silicon, potassium, and sulfate. In the absence of ULs, extra caution may be warranted in consuming levels above recommended intakes.

<sup>b</sup> Although the UL was not determined for arsenic, there is no justification for adding arsenic to food or supplements.

<sup>c</sup> The ULs for magnesium represent intake from a pharmacological agent only and do not include intake from food and water.

<sup>d</sup> Although silicon has not been shown to cause adverse effects in humans, there is no justification for adding silicon to supplements.

<sup>e</sup> Although vanadium in food has not been shown to cause adverse effects in humans, there is no justification for adding vanadium to food and vanadium supplements should be used with caution. The UL is based on adverse effects in laboratory animals and this data could be used to set a UL for adults but not children and adolescents.

<sup>f</sup> ND = Not determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.

**Dietary Reference Intakes (DRIs): Estimated Energy Requirements (EER) for Men and Women  
30 Years of Age<sup>a</sup>**

Food and Nutrition Board, Institute of Medicine, National Academies

Height (m [in])	PAL <sup>b</sup>	Weight for BMI <sup>c</sup> of 18.5 kg/m <sup>2</sup> (kg [lb])	Weight for BMI of 24.99 kg/m <sup>2</sup> (kg [lb])	EER, Men <sup>d</sup> (kcal/day)		EER, Women <sup>d</sup> (kcal/day)	
				BMI of 18.5 kg/m <sup>2</sup>	BMI of 24.99 kg/m <sup>2</sup>	BMI of 18.5 kg/m <sup>2</sup>	BMI of 24.99 kg/m <sup>2</sup>
1.50 (59)	Sedentary	41.6 (92)	56.2 (124)	1,848	2,080	1,625	1,762
	Low active			2,009	2,267	1,803	1,956
	Active			2,215	2,506	2,025	2,198
	Very active			2,554	2,898	2,291	2,489
1.65 (65)	Sedentary	50.4 (111)	68.0 (150)	2,068	2,349	1,816	1,982
	Low active			2,254	2,566	2,016	2,202
	Active			2,490	2,842	2,267	2,477
	Very active			2,880	3,296	2,567	2,807
1.80 (71)	Sedentary	59.9 (132)	81.0 (178)	2,301	2,635	2,015	2,211
	Low active			2,513	2,884	2,239	2,459
	Active			2,782	3,200	2,519	2,769
	Very active			3,225	3,720	2,855	3,141

<sup>a</sup> For each year below 30, add 7 kcal/day for women and 10 kcal/day for men. For each year above 30, subtract 7 kcal/day for women and 10 kcal/day for men.

<sup>b</sup> PAL = physical activity level.

<sup>c</sup> BMI = body mass index.

<sup>d</sup> Derived from the following regression equations based on doubly labeled water data:

Adult man:  $EER = 662 - 9.53 \times \text{age (y)} + PA \times (15.91 \times \text{wt [kg]} + 539.6 \times \text{ht [m]})$

Adult woman:  $EER = 354 - 6.91 \times \text{age (y)} + PA \times (9.36 \times \text{wt [kg]} + 726 \times \text{ht [m]})$

Where PA refers to coefficient for PAL

**PAL = total energy expenditure ÷ basal energy expenditure**

PA = 1.0 if PAL ≥ 1.0 < 1.4 (sedentary)

PA = 1.12 if PAL ≥ 1.4 < 1.6 (low active)

PA = 1.27 if PAL ≥ 1.6 < 1.9 (active)

PA = 1.45 if PAL ≥ 1.9 < 2.5 (very active)

**Dietary Reference Intakes (DRIs): Acceptable Macronutrient Distribution Ranges**

Food and Nutrition Board, Institute of Medicine, National Academies

Macronutrient	Range (percent of energy)		
	Children, 1–3 y	Children, 4–18 y	Adults
Fat	30–40	25–35	20–35
<i>n</i> -6 polyunsaturated fatty acids <sup>a</sup> (linoleic acid)	5–10	5–10	5–10
<i>n</i> -3 polyunsaturated fatty acids <sup>a</sup> (α-linolenic acid)	0.6–1.2	0.6–1.2	0.6–1.2
Carbohydrate	45–65	45–65	45–65
Protein	5–20	10–30	10–35

<sup>a</sup> Approximately 10% of the total can come from longer-chain *n*-3 or *n*-6 fatty acids.

**NOTE:** This table presents Estimated Average Requirements (EARs), which serve two purposes: for assessing a adequacy of population intakes, and as the basis for calculating Recommended Dietary Allowances (RDAs) for individuals for those nutrients. EARs have not been established for vitamin D, vitamin K, pantothenic acid, biotin, choline, calcium, chromium, fluoride, manganese, or other nutrients not yet evaluated via the DRI process.

<sup>a</sup> As retinol activity equivalents (RAEs). 1 RAE = 1 µg retinol, 12 µg β-carotene, or 24 µg β-cryptoxanthin. The RAE for dietary provitamin A carotenoids is two-fold greater than retinol equivalents (RE), whereas the RAE for preformed vitamin A is the same as RE.

<sup>b</sup> As α-tocopherol. α-Tocopherol includes *RRR*-α-tocopherol, the only form of α-tocopherol that occurs naturally in foods, and the *2R*-stereoisomeric forms of α-tocopherol (*RRR*-, *RSR*-, *RSS*-, and *RSS*-α-tocopherol) that occur in fortified foods and supplements. It does not include the *2S*-stereoisomeric forms of α-tocopherol (*SRR*-, *SSR*-, *SRS*-, and *SSS*-α-tocopherol), also found in fortified foods and supplements.

<sup>c</sup> As niacin equivalents (NE). 1 mg of niacin = 60 mg of tryptophan.

<sup>d</sup> As dietary folate equivalents (DFE). 1 DFE = 1 µg food folate = 0.6 µg of folic acid from fortified food or as a supplement consumed with food = 0.5 µg of a supplement taken on an empty stomach.

**SOURCES:** *Dietary Reference Intakes for Calcium, Phosphorus, Magnesium, Vitamin D, and Fluoride* (1997); *Dietary Reference Intakes for Thiamin, Riboflavin, Niacin, Vitamin B<sub>6</sub>, Folate, Vitamin B<sub>12</sub>, Pantothenic Acid, Biotin, and Choline* (1998); *Dietary Reference Intakes for Vitamin E, Selenium, and Carotenoids* (2000); *Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicon, Vanadium, and Zinc* (2001), and *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids* (2002). These reports may be accessed via [www.nap.edu](http://www.nap.edu).
