Dietary cholesterol. Previous recommendations have been to decrease dietary cholesterol to decrease LDL cholesterol and reduce ASCVD risk. The ACC/AHA 2013 guidelines no longer make this recommendation, and they specifically state that dietary cholesterol does not raise LDLs (see Chapter 9). The 2015 U.S. Dietary Guidelines also eliminate the recommendation to restrict cholesterol. However it is important to remember that most high cholesterol foods are also high in saturated fats that do raise LDL cholesterol.

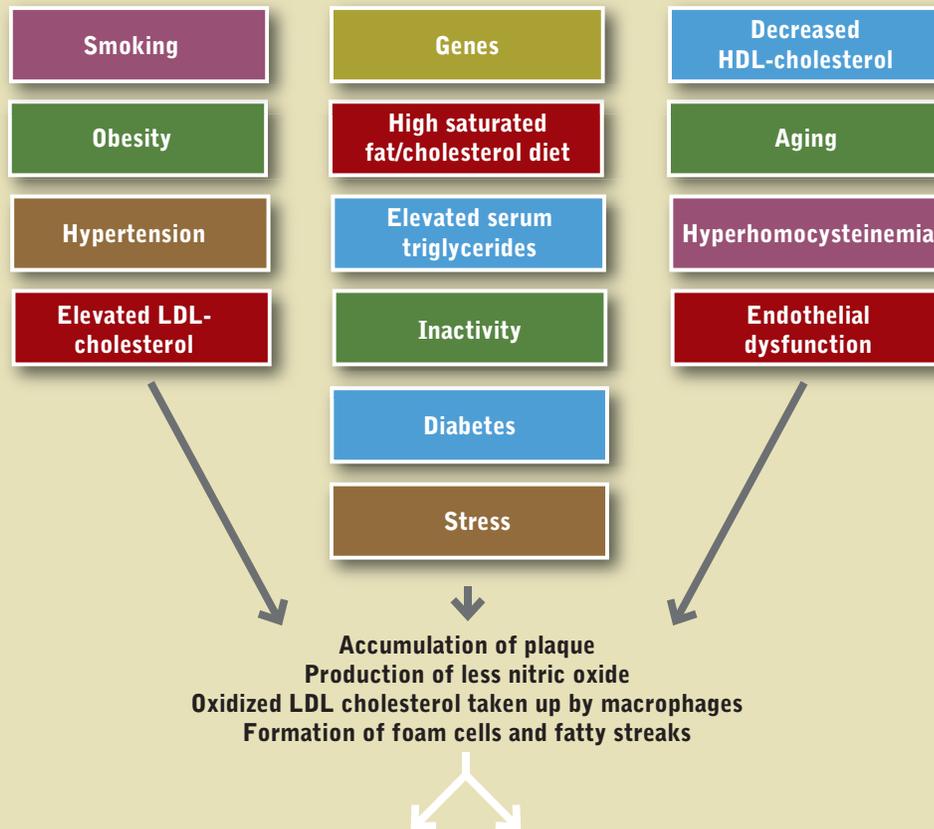

Fiber. High intake levels of dietary fiber are associated with significantly lower prevalence of ASCVD and stroke (Anderson et al, 2009). The USDA MyPlate, the DASH diet, and the MeD pattern emphasize fruits, vegetables, legumes, and whole grains, so they are innately high in fiber. This combination of foods provides a combination of soluble and insoluble fiber. Proposed mechanisms for the hypocholesterolemic effect of soluble fiber include the following: (1) the fiber binds bile acids, which lowers serum cholesterol and (2) bacteria in the colon ferment the fiber to produce acetate, propionate, and butyrate, which inhibit cholesterol synthesis. The role of fiber, if any, on inflammatory pathways is not well established. Minerals, vitamins,

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Atherosclerosis

ETIOLOGY

PATHOPHYSIOLOGY

Clinical Findings

- Elevated LDL cholesterol
- Elevated serum triglycerides
- Elevated C-reactive protein
- Low HDL-cholesterol

Nutrition Assessment

- BMI evaluation
- Waist circumference; waist to hip ratio (WHR)
- Dietary assessment for:
 - SFA, *trans*-fatty acids, ω -3 fatty acids, fiber, sodium, alcohol, sugar, and phytonutrients

MANAGEMENT

Medical Management

- Lifestyle change (increase physical activity and lower stress)
- HMG CoA reductase inhibitors (statins)
- Triglyceride-lowering medication
- Blood pressure—lowering medication
- Medication for glucose management
- Percutaneous coronary intervention (PCI)
 - Balloon
 - Stent
- Coronary artery bypass graft (CABG)
- Antiplatelet therapy

Nutrition Management

- DASH dietary pattern
- Mediterranean diet pattern
- Weight reduction if needed
- Increase dietary fiber to 25–30 g/day or more
- Add ω -3 fats from food sources
- Add fruits and vegetables
- CoQ₁₀ for those on statin drugs

MEDITERRANEAN DIET SCORE TOOL

A Mediterranean dietary pattern ('Med diet') is typically one based on whole or minimally processed foods. It's **rich in protective foods** (fruits, vegetables, legumes, wholegrains, fish and olive oil) and **low in adverse dietary factors** (fast food, sugar-sweetened beverages, refined grain products and processed or energy-dense foods) with moderate red meat and alcohol intake.

Evidence shows **overall dietary pattern** (reflected in TOTAL SCORE) as well as **individual components** reflect risk; a higher score is associated with lower risk of CVD and all-cause mortality (BMJ 2008;337:a1344). During rehabilitation patient scores should ideally rise in response to dietary advice and support.

This tool can be used by health professionals with appropriate nutritional knowledge and competencies, such as Registered Dietitians (NICE, 2007, 2013). It can be used as both an *audit tool* and *as part of a dietary assessment* at baseline, end of programme and 1 year follow-up, along with assessment and advice for weight management, salt intake and eating behaviours. For information on complete requirements for dietary assessments and advice, please refer to the latest NICE/Joint British Societies guidelines (BACPR, 2012. The BACPR Standards and Core Components for Cardiovascular Disease Prevention and Rehabilitation, 2nd Ed.).

	Question	Yes	No	Nutritional issue to discuss in response
1.	Is olive oil the main culinary fat used?			Choosing Healthier Fats Olive oil is high in monounsaturated fat. Using unsaturated fats instead of saturated fats in cooking and preparing food is advisable.
2.	Are ≥ 4 tablespoons of olive oil used each day?			Healthy fats are better than very low fat Med diet is more beneficial than a very low fat diet in prevention of CVD. So replacing saturated with unsaturated fat is better than replacing it with carbohydrates or protein.
3.	Are ≥ 2 servings (of 200g each) of vegetables eaten each day?			Eat plenty of fruits and vegetables Eating a wide variety of fruit and vegetables every day helps ensure adequate intake of many vitamins, minerals, phytochemicals and fibre. Studies have shown that eating plenty of these foods is protective for CVD and cancer.
4.	Are ≥ 3 servings of fruit (of 80g each) eaten each day?			
5.	Is < 1 serving (100-150g) of red meat/hamburgers/ other meat products eaten each day?			Choose lean meats and consider cooking methods Red and processed meats are high in saturated fat, can be high in salt and are best replaced with white meat or fish or vegetarian sources of protein. Grill or roast without fat, casserole or stir fry.
6.	Is < 1 serving (12g) of butter, margarine or cream eaten each day?			Keep saturated fat low These foods are high in saturated fat which can increase your blood cholesterol level. Choose plant-based or reduced-fat alternatives.
7.	Is < 1 serving (330ml) of sweet or sugar sweetened carbonated beverages consumed each day?			Excessive consumption of sugar-sweetened beverages can worsen many risk factors for CVD: keep consumption to < 1/day.
8.	Are ≥ 3 glasses (of 125ml) of wine consumed each week?			Moderate alcohol intake with meals While this does have some protective effect but there is no evidence that non-drinkers should take up drinking alcohol.
9.	Are ≥ 3 servings (of 150g) of legumes consumed each week?			Include soluble fibre These foods are high in soluble fibre and other useful nutrients. Regular consumption is advisable for raised cholesterol.
10.	Are ≥ 3 servings of fish (100-150g) or seafood (200g) eaten each week?			Eat more oily and white fish Oily fish is an excellent source of essential omega-3 fats. White fish is very low in saturated fat.
11.	Is < 3 servings of commercial sweets/pastries eaten each week?			Eat less processed food These foods are usually high in saturated fat, salt or sugar and often contain trans fats. Replacing these with healthy snacks such as fruit or unsalted nuts is beneficial.
12.	Is ≥ 1 serving (of 30g) of nuts consumed each week?			Snack on modest servings of unsalted nuts Nuts are rich in unsaturated fat, phytosterols, fibre, vitamin E and iron, e.g. walnuts, almonds, hazelnuts
13.	Is chicken, turkey or rabbit routinely eaten instead of veal, pork, hamburger or sausage?			'White meat' choices are lower in saturated fat. Remove the skin and consider your cooking method.
14.	Are pasta, vegetable or rice dishes flavoured with garlic, tomato, leek or onion eaten ≥ twice a week?			Using a tomato and garlic or onion or leek-based sauce regularly is a key feature of the Med diet.
TOTAL SCORE (total no. of 'yes' answers)				

26.09.13
Version 1

Alison Hornby, Katherine Paterson

and antioxidants that are components of a high-fiber diet further enrich the diet.

Insoluble fibers such as cellulose and lignin have no effect on serum cholesterol levels. For the purpose of heart disease prevention, most of the recommended 25 to 30 g of fiber a day should be soluble fiber.

Antioxidants. Two dietary components that affect the oxidation potential of LDL cholesterol are the level of LA in the particle and the availability of antioxidants. Vitamins C, E, and beta-carotene at physiologic levels have antioxidant roles in the body. Vitamin E is the most concentrated antioxidant carried on LDLs, the amount being 20 to 300 times greater than any other antioxidant. A major function of vitamin E is to prevent oxidation of PUFAs in the cell membrane. The AHA does not recommend vitamin E supplementation for CVD prevention. A dietary pattern that includes increased amounts of whole grains, nuts, and seeds (especially sunflower seeds) has increased amounts of vitamin E. Foods with concentrated amounts of antioxidants are found in phytochemicals known as catechins and have been found to improve vascular reactivity. Red grapes, red wine, tea (especially green tea), berries, and broad beans (fava beans) are part of the MeD (see Figs. 32.5 and 32.6).

Stanols and sterols. Since the early 1950s, plant stanols and sterols isolated from soybean oils or pine tree oil have been known to lower blood cholesterol by inhibiting absorption of dietary cholesterol. Stanols and sterols have been shown to lower LDL cholesterol in adults (Yanai et al, 2015). Because these esters also can affect the absorption of and cause lower beta-carotene, alpha-tocopherol, and lycopene levels, further safety studies are needed for use in normocholesterolemic individuals, children, and pregnant women.

Weight loss. According to the Centers for Disease Control and Prevention (CDC), in 2015 to 2016 39.8% of adults and 18.5% of children in the United States were classified as obese. Obesity raises the risk of hypertension, dyslipidemia, type 2 diabetes, ASCVD, and stroke. Obesity is associated with increased risk in all-cause and CVD mortality (Stone et al, 2014). Recommendations of the panel are summarized in Box 32.5.

Medical Management

Pharmacologic Management

Determination of drug therapy depends on risk category and attainment of the LDL cholesterol goal. The 2013 ACC/AHA Guidelines for

BOX 32.5 Recommendations from The Obesity Society (TOS) Obesity Guideline

1. Patient/provider encounter for obesity prevention and management: A patient encounter is defined as an interaction with a primary care provider who assesses weight status to determine need for further assessment and treatment.
2. Measure weight and height and calculate body mass index (BMI).
3. BMI 25<30 (overweight) or BMI 30<35 (class I obese) or BMI 35<40 class II obese or BMI >40 (class III obese): these BMI cutpoints define overweight and obese individuals who are at increased risk of cardiovascular disease (CVD). Within these categories, additional personal risk assessment is needed.
4. Assess and treat CVD risk factors and obesity-related comorbidities: A waist circumference measurement is recommended for individuals with BMI 25-35 to provide additional information on risk. It is not necessary to measure waist circumference in patients with BMI >35 because the waist circumference will likely be elevated and it will add no additional information. Increased cardiometabolic risk is defined as >88 cm or >35 in for women and >102 cm or >40 in for men.
5. Assess weight and lifestyle histories: Ask questions about history of weight gain and loss over time, details of previous weight loss attempts, dietary habits, physical activity, family history of obesity, and other medical conditions and medications that may affect weight.
6. Assess need to lose weight: Weight loss treatment is indicated for (1) obese and (2) overweight with one or more indicators of increased CVD risk.
7. Advise to avoid weight gain and address other risk factors.

Jensen, et al: 2013 AHA/ACC/TOS guideline for the management of overweight and obesity in adults. *Circulation*, 129:S102, 2014.

Treatment of Blood Cholesterol have updated recommendations for prescribing statin drugs to be more focused on overall patient risk than on specific serum cholesterol targets. The primary treatment for those at risk of ASCVD are the 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors, of which there are many (see Appendix 13). The classes of drugs include the following: (1) **bile acid sequestrants** such as cholestyramine (adsorbs bile acids); (2) nicotinic acid; (3) **statins**, or **3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA)** reductase inhibitors, which inhibit the rate-limiting enzyme in cholesterol synthesis; (4) fibric acid derivatives; and (5) probucol.

Medical Intervention

Medical interventions such as percutaneous coronary intervention (PCI) are now performed in patients with asymptomatic ischemia or

angina. PCI, previously known as percutaneous transluminal coronary angioplasty, is a procedure that uses a catheter with a balloon that, once inflated, breaks up plaque deposits in an occluded artery. Coronary stenting involves a wire mesh tube inserted to hold an artery open; it can release medication that prevents clotting (Thom et al, 2006).

PCI is often possible because of earlier detection of blockages. The most common problem with PCI is restenosis of the artery. A recent study examined more than 2200 patients, half of whom received intervention of medication and lifestyle changes such as quitting smoking, exercise, and nutrition, and half of whom received lifestyle changes as well as angioplasty. After 5 years it was observed that the number who had heart attacks, were hospitalized, or died because of their heart problems was virtually identical in both groups. Angioplasty did not appear to provide an additional benefit versus lifestyle changes combined with medication (Boden et al, 2007).

Because PCI is performed with the patient under local anesthesia in a cardiac catheterization laboratory, recovery is quicker than with **coronary artery bypass graft (CABG)** surgery. In CABG surgery, an artery from the chest is used to redirect blood flow around a diseased vessel. Candidates for CABG usually have more than two occluded arteries. CABG surgeries have decreased since 1995 because more PCI procedures are being done. These surgeries improve survival time, relieve symptoms, and markedly improve the quality of life for patients with ASCVD. However, CABG does not cure atherosclerosis; the new grafts are also susceptible to atherogenesis. Consequently, restenosis is common within 10 years of surgery.

HYPERTENSION

Hypertension is persistently high arterial blood pressure, the force exerted per unit area on the walls of arteries. The **systolic blood pressure (SBP)**, the upper reading in a blood pressure measurement, is the force exerted on the walls of blood vessels as the heart contracts and pushes blood out of its chambers. The lower reading, known as **diastolic blood pressure (DBP)**, measures the force as the heart relaxes between contractions. Blood pressure is measured in millimeters (mm) of mercury (Hg). Adult blood pressure is considered normal at 120/80 mm Hg. The blood pressure cutoffs for elevated blood pressure (formerly **prehypertension**), stage 1 and stage 2 hypertension are found in Table 32.1.

The clinical practice guidelines from the ACC/AHA Task Force for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults (Whelton et al, 2018) state that the combination of diet and lifestyle therapy is especially useful in adults for the prevention of hypertension and for the management of elevated blood

TABLE 32.1 Categories of Blood Pressure in Adults

	SBP (mm Hg)*		DBP (mm Hg)*
Normal	<120 mm Hg	and	<80 mm Hg
Elevated	120-129 mm Hg	and	<80 mm Hg
Hypertension			
Stage 1	130-139 mm Hg	or	80-89 mm Hg
Stage 2	>130-139 mm Hg	or	>90 mm Hg

SBP, Systolic blood pressure; DBP, Diastolic blood pressure.

*Individuals with SBP and DBP in 2 categories should be designated to the higher blood pressure category. Blood pressure is based on an average of ≥ 2 careful readings obtained on ≥ 2 occasions.

Whelton PK, et al: 2017 ACC/AHA/AAPA/ABC/ACPM/APH/AASH/ASPC/NMA/PCNA guideline for the prevention, detection, evaluation and management of high blood pressure in adults. *J Am Coll Cardiol* 71: e127-e240, 2018.

pressure and stage 1 hypertension without clinical ASCVD or estimated 10-year ASCVD risk of $\leq 10\%$ (see <http://tools.acc.org/ASCVD-Risk-Estimator-Plus/#/calculate/estimate/>). For adults with stage 1 hypertension with clinical ASCVD or estimated 10-year risk of ASCVD $\geq 10\%$ or stage 2 hypertension, the ACC/AHA guidelines recommends blood pressure–lowering medication in combination with nonpharmacotherapy for primary prevention of CVD. The guidelines also call for individuals with diabetes, HF, and chronic kidney disease to be treated with blood pressure–lowering medication when their blood pressure exceeds 130/80 mm Hg. The recommendations are based on clinical evidence showing that stricter guidelines for these patients may prevent acceleration of target organ damage (kidney, heart, and pancreas) and related comorbidities. Importantly, the guidelines emphasize that people with high blood pressure should follow a healthy diet and lifestyle along with medication management. Diet and lifestyle modifications are important parts of primary prevention of hypertension.

Hypertension is a common public health problem in developed countries. In the United States one in three adults has high blood pressure (CDC, 2017). Untreated hypertension leads to many degenerative diseases, including HF, end-stage renal disease, and peripheral vascular disease. It is often called a “silent killer” because people with hypertension can be asymptomatic for years and then have a fatal stroke or heart attack. Although no cure is available, hypertension is easily detected and usually controllable. Some of the decline in CVD mortality during the last two decades has been attributed to the increased detection and control of hypertension. The emphasis on lifestyle modifications has given diet a prominent role in the primary prevention and management of hypertension.

Of those persons with high blood pressure, 90% to 95% have **essential hypertension** (hypertension of unknown cause) or primary hypertension. The cause involves a complex interaction between poor lifestyle choices and gene expression. Lifestyle factors that have been implicated include poor diet (i.e., high sodium, low fruit and vegetable intake), smoking, physical inactivity, stress, and obesity. Vascular inflammation has also been implicated (De Miguel et al, 2015). Many genes play a role in hypertension; most relate to the renal or neuroendocrine control of blood pressure. Genome-wide association studies have revealed more than 100 variants associated with blood pressure, although cumulatively these explain only a small percent of blood

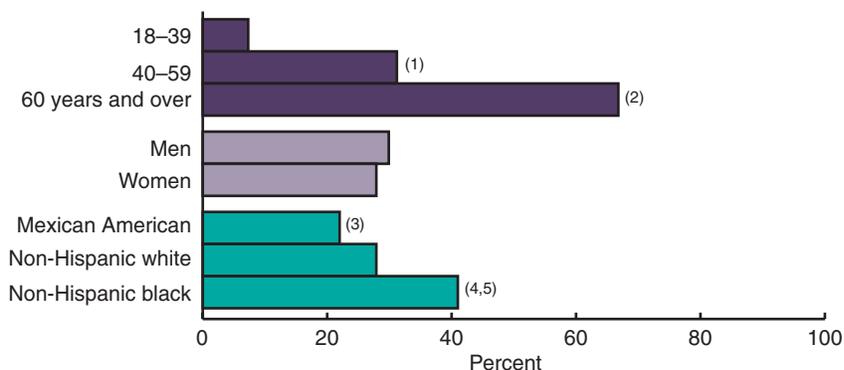

pressure variability (Seidel and Scholl, 2017). The majority of the genetic contributors to blood pressure regulation are currently unknown (see Chapter 6). Hypertension that arises as the result of another disease, usually endocrine, is referred to as **secondary hypertension**. Depending on the extent of the underlying disease, secondary hypertension can be cured.

Prevalence and Incidence

Approximately 85.7 million American adults age 20 and older have hypertension or are taking antihypertensive medication (Benjamin et al, 2018). Projections show that by 2030, prevalence of hypertension will increase by 8.4% from 2013 estimates. Non-Hispanic black adults have a higher age-adjusted prevalence of hypertension (45.0% of men; 46.3% of women) than non-Hispanic whites (34.5% of men; 32.3% of women) and Mexican Americans (30.1% of men; 28.8% of women) (Benjamin et al, 2018). The prevalence of high blood pressure in blacks is one of the highest rates seen anywhere in the world. Because blacks develop hypertension earlier in life and maintain higher blood pressure levels, their risk of fatal stroke, heart disease, or end-stage kidney disease is higher than whites (Benjamin et al, 2018).

A person of any age can have hypertension. Approximately 12.9% of boys and 6.5% of girls have elevated blood pressure (Ma et al, 2016; Xi et al, 2016). With aging, the prevalence of high blood pressure increases (Fig. 32.7). Before the age of 45 more men than women have high blood pressure, and after age 65 the rates of high blood pressure among women in each racial group surpass those of the men in their group (Go et al, 2014). Because the prevalence of hypertension rises with increasing age, more than half the older adult population (more than 65 years of age) in any racial group has hypertension. Although lifestyle interventions targeted to older persons may reduce the prevalence of hypertension, early intervention programs provide the greatest long-term potential for reducing overall blood pressure-related complications (Whelton et al, 2018).

The relationship between blood pressure and risk of CVD events is continuous and independent of other risk factors. The higher the blood pressure, the greater is the chance of target organ damage, including left ventricular hypertrophy (LVH), HF, stroke, chronic kidney disease, and retinopathy (Benjamin et al, 2018). As many as 13% of adults with hypertension have treatment-resistant hypertension, which means that their blood pressure remains high despite the

Fig. 32.7 Age-specific and age-adjusted prevalence of hypertension in adults: United States, 2005 to 2006. (Ostchega Y, et al: *Hypertension awareness, treatment, and control—continued disparities in adults: United States, 2005–2006*. NCHS data brief no. 3, Hyattsville, Md, 2008, National Center for Health Statistics.)

use of three or more antihypertensive drugs from different classes (Whelton et al, 2018). Treatment-resistant hypertension puts an individual at greater risk of target organ damage. Older age and obesity are two of the strongest risk factors associated with the condition. Identification and reversal of lifestyle factors contributing to treatment resistance, along with diagnosis and appropriate treatment of secondary causes and use of effective multidrug regimens, are essential treatment strategies.

The prevalence of hypertension among adults with diabetes is 80% and hypertension is at least twice as common among persons with type 2 diabetes as persons of the same age without diabetes (Whelton et al, 2018). Adults with diabetes have CVD death rates two to four times higher than adults without diabetes (Benjamin et al, 2018). Consequently, national health organizations, including the ACC/AHA, have set the target blood pressure goal for antihypertensive therapy for individuals with diabetes lower than that recommended for the general population, which is 140/90 mm Hg (Whelton et al, 2018). In adults with diabetes and hypertension, the ACC/AHA recommends antihypertensive drug treatment to be initiated at a blood pressure of 130/80 mm Hg or higher with a treatment goal of less than 130/80 mm Hg. Blood pressure control is often more difficult to achieve in patients with diabetes than in those without diabetes, necessitating use of a combination of blood pressure-lowering medications in the majority of patients (Whelton et al, 2018).

Although hypertensive patients are often asymptomatic, hypertension is not a benign disease. Cardiac, cerebrovascular, and renal systems are affected by chronically elevated blood pressure (Table 32.2). High blood pressure was the primary or a contributory cause in 427,631 of the 2.7 million U.S. deaths in 2009 (Benjamin et al, 2018). Between 2005 and 2015 the age-adjusted death rate from hypertension increased by 10.5%; overall deaths from hypertension increased by 37.5%. Death rates from hypertension are approximately three times higher in blacks than in whites (Benjamin et al, 2018). Hypertension is a major contributing factor to atherosclerosis, stroke, renal failure, and MI. Factors associated with a poor prognosis in hypertension are shown in Box 32.6.

Pathophysiology

Blood pressure is a function of cardiac output multiplied by peripheral resistance (the resistance in the blood vessels to the flow of blood). Thus the diameter of the blood vessel markedly affects blood flow. When the diameter is decreased (as in atherosclerosis) resistance and blood pressure increase. Conversely, when the diameter is increased (as with vasodilator drug therapy), resistance decreases and blood pressure is lowered.

Many systems maintain homeostatic control of blood pressure. The major regulators are the SNS for short-term control and the kidney for long-term control. In response to a fall in blood pressure, the SNS secretes norepinephrine, a vasoconstrictor, which acts on small arteries and arterioles to increase peripheral resistance and raise blood pressure. Conditions that result in overstimulation of the SNS (i.e., certain adrenal disorders or sleep apnea) result in increased blood pressure. The kidney regulates blood pressure by controlling the extracellular fluid volume and secreting renin, which activates the **renin-angiotensin system (RAS)** (Fig. 32.8). Abnormal blood pressure is usually multifactorial. In most cases of hypertension, peripheral resistance increases. This resistance forces the left ventricle of the heart to increase its effort in pumping blood through the system. With time, LVH and eventually HF can develop.

Common genetic variants of the RAS gene, including angiotensin-converting enzyme (ACE) and angiotensinogen, have shown relationships with hypertension (Heidari et al, 2017). An increased production

TABLE 32.2 Manifestations of Target Organ Disease from Hypertension

Organ System	Manifestations
Cardiac	Clinical, electrocardiographic, or radiologic evidence of arterial wall thickening left ventricular hypertrophy; left ventricular malfunction or cardiac failure
Cerebrovascular	Transient ischemic attack or stroke
Peripheral	Absence of one or more pulses in extremities (except for dorsalis pedis) Ankle-Brachial Index <0.9
Renal	Serum creatinine elevated: men 1.3-1.5 mg/dL, women 1.2-1.4 mg/dL Calculated GFR <60 mL/min/1.73 m ² Elevated albumin excretion
Retinopathy	Hemorrhages or exudates, with or without papilledema

GFR, Glomerular filtration rate.

of these proteins may increase production of angiotensin II, the primary mediator of the RAS, thus increasing blood pressure. Angiotensin II may also trigger low-grade inflammation within the blood vessel wall, a condition that predisposes to hypertension (McMaster et al, 2015).

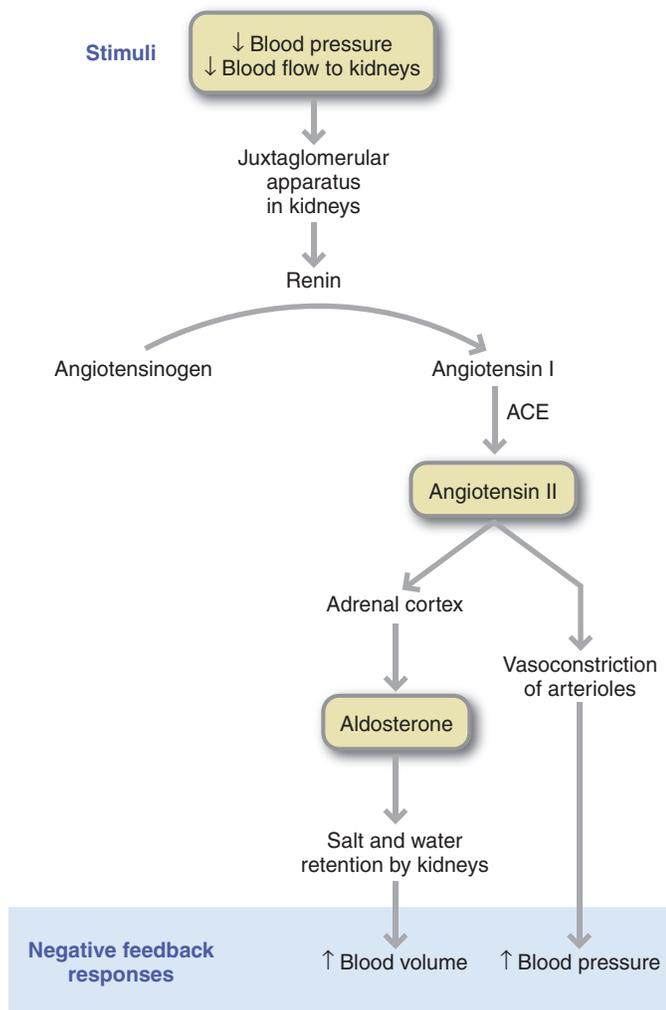

Fig. 32.8 Renin-angiotensin cascade. *ACE*, Angiotensin-converting enzyme. (Reprinted with permission from Fox SI: *Human physiology*, ed 6, New York, 1999, McGraw-Hill.)

Hypertension often occurs with other risk factors for CVD, including visceral (intraabdominal) obesity, insulin resistance, high triglycerides, and low HDL cholesterol levels. The coexistence of three or more of these risk factors leads to metabolic syndrome. It is unclear whether one or more of these risk factors precede the others or whether they occur simultaneously. Accumulation of visceral fat synthesizes increased amounts of angiotensinogen, which activates the RAS and increases blood pressure (Zhou et al, 2012). Also, angiotensin II, the primary mediator of the RAS, promotes the development of large dysfunctional adipocytes, which produce increased amounts of leptin and reduced quantities of adiponectin. Higher levels of leptin and lower amounts of circulating adiponectin activate the SNS, a key component of the hypertensive response (DeMarco et al, 2014).

Primary Prevention

Positive changes in hypertension awareness, treatment, and control have occurred during the last several years. Based on analysis of National Health and Nutrition Examination Survey (NHANES) data from 2011 to 2014, 84.1% of people with hypertension are aware that they have it (Benjamin et al, 2018), up from 81% in 2007 to 2010. Although current hypertension treatment and control rates have increased from 48.4% to 53.3%, during this same time period, additional

efforts are needed to meet the *Healthy People 2020* objective of 61.2%. In 2015 women, younger adults (aged 18 to 39 years), and Hispanic individuals had lower rates of blood pressure control compared with men, younger individuals, and non-Hispanic whites. Improving hypertension treatment through targeted intervention programs should have a positive effect on CVD outcomes. Blood pressure treatment guidelines highlight the importance of evaluating patients for the presence of multiple CVD risk factors and individualizing lifestyle modification and drug therapies accordingly.

Changing lifestyle factors have documented efficacy in the primary prevention and control of hypertension. These factors were systematically reviewed and categorized by the Academy of Nutrition and Dietetics (AND) in 2015 (Lennon et al, 2017) and more recently by the ACC and AHA in 2018 (Whelton et al, 2018). These guidelines made a strong recommendation (i.e., high benefit/risk ratio with supporting evidence) for reducing intake of dietary sodium in adults with elevated blood pressure and hypertension and for weight loss in adults with elevated blood pressure or hypertension who are overweight or obese. A strong recommendation was also made for a heart-healthy dietary pattern such as the DASH diet rich in fruits, vegetables, whole grains, and low-fat dairy to lower blood pressure. Combining a low-sodium DASH diet with weight reduction was recommended as the most efficacious approach to substantially lowering blood pressure in adults at high CVD risk. Additional strong recommendations from both the ACC/AHA and the AND were made for increasing physical activity with a structured exercise program and for moderating alcohol consumption, particularly among heavy drinkers. The ACC/AHA also included a strong recommendation for supplementation with potassium to lower blood pressure. Increased potassium intake should preferably be in the form of diet modification and may be contraindicated for some patients with CKD. A summary of recommendations and ratings from the ACC/AHA and the AND can be found in Table 32.3.

Fats

Systematic reviews of RCTs that examined the effects of replacing calories from one fatty acid class with another have generally shown no or only a small effect on blood pressure (Al-Khudairy et al, 2015; Maki et al, 2018). Supplementation with n-3 PUFAs (EPA + DHA) in doses higher than 2 g/day showed modest reductions in SBP and DBP, especially in untreated hypertensive adults (Miller et al, 2014).

Protein

Evidence from observational studies and RCTs suggests replacement of protein for fat or carbohydrate in an isocaloric diet results in lowered blood pressure (Bazzano et al, 2013). Protein supplementation in doses of 60 g/day reduced SBP by 4.9 mm Hg and DBP by 2.7 mm Hg compared with 60 g/day of carbohydrate in overweight individuals with elevated blood pressure and untreated stage 1 hypertension (Teunissen-Beekman and van Baak, 2013).

Dietary Patterns Emphasizing Fruits and Vegetables

Several dietary patterns have been shown to lower blood pressure. Plant-based dietary patterns have been associated with lower SBP in observational studies and clinical trials (Alexander et al, 2017). Average SBP reductions of 5 to 6 mm Hg have been reported. Specifically, the **Dietary Approaches to Stop Hypertension (DASH)** controlled feeding study showed that a dietary pattern emphasizing fruits, vegetables, low-fat dairy products, whole grains, lean meats, and nuts significantly decreased SBP in hypertensive and normotensive adults. The DASH diet (see Appendix 17) was found to be more effective than just adding fruits and vegetables to a low-fat dietary pattern and was equally effective in men and women of diverse racial and ethnic backgrounds

TABLE 32.3 Recommendations on Blood Pressure in Hypertensive Adults from Evidence Analysis Library (2015) and American College of Cardiology/American Heart Association (2018)

Food or Nutrient	EAL Recommendation	Rating	ACC/AHA Recommendation	Rating
Sodium	The RDN should counsel on reducing sodium intake for blood pressure reduction in adults with HTN. Lowering dietary sodium intake to 1500-2000 mg/day reduced SBP and DBP up to 12 and 6 mm Hg, respectively.	Strong	Lower sodium intake Consume no more than 2400 mg of sodium/day; further reduction of sodium to 1500 mg/day is desirable because it is associated with even greater reduction in blood pressure; reduce intake by at least 1000 mg/day because that will lower blood pressure, even if the desired daily sodium intake is not achieved.	Strong Moderate
Dietary patterns emphasizing fruits and vegetables	The RDN should counsel on a DASH dietary pattern plus reduced sodium intake for blood pressure reduction.	Consensus	Consume a dietary pattern that emphasizes intake of vegetables, fruits, and whole grains; includes low-fat dairy products, poultry, fish, legumes, nontropical vegetable oils and nuts; and limits intake of sweets, sugar-sweetened beverages, and red meat; adapt the pattern to appropriate calorie requirements; achieve this pattern by following plans such as DASH, USDA food pattern, or the AHA Diet; combine the DASH dietary pattern with lower sodium intake.	Strong
Fruits and vegetables	Fruits and vegetables should be recommended at a level of 5 to 10 servings per day for significant blood pressure reduction.	Strong		Not evaluated
Weight management	Optimal body weight should be achieved and maintained (BMI 18.5-24.9) to reduce blood pressure.	Strong	Counsel overweight and obese adults with high blood pressure that lifestyle changes that produce even modest, sustained weight loss of 3% to 5% produce clinically meaningful benefits (e.g., reduce TG, blood sugar, Hb A1C); >5% will reduce blood pressure and reduce the need for medications to control blood pressure.*	Strong
Physical activity	Individuals should be encouraged to engage in aerobic physical activity for at least 30 minutes per day on most days of the week, because it reduces SBP.	Consensus	Advise adults to engage in aerobic physical activity to lower blood pressure: three to four sessions a week, lasting on average 40 minutes per session, and involving moderate-to-vigorous-intensity physical activity.	Moderate
Alcohol	For individuals who can safely consume alcohol, consumption should be limited to no more than two drinks (24 oz beer, 10 oz wine, or 3 oz of 80-proof liquor) per day in most men and to no more than one drink per day in women.	Consensus		Not evaluated
Potassium	Studies support a modest relationship between increasing intake of potassium and a lower sodium-potassium ratio with lowered blood pressure.	Fair	Insufficient evidence	Low
Calcium	The effect of increasing calcium intake with lowered blood pressure is unclear; although some research indicates minimal benefit.	Fair		Not evaluated
Magnesium	The effect of increasing magnesium intake with lowered blood pressure is unknown; although some research indicates minimal benefit.	Fair		Not evaluated
Omega-3 fatty acids	Studies investigating increased consumption of omega-3 fatty acids have not demonstrated a beneficial effect on blood pressure.	Fair		Not evaluated

ACC, American College of Cardiology; AHA, American Heart Association; BMI, body mass index; DASH, Dietary Approaches to Stop Hypertension; DBP, diastolic blood pressure; Hb A1C, hemoglobin A1C; HTN, hypertension; RDN, registered dietitian nutritionist; SBP, systolic blood pressure; TG, triglyceride; USDA, U.S. Department of Agriculture.

Recommendations listed are for those rated by the Academy of Nutrition and Dietetics and the American Academy of Cardiology (ACC)/American Heart Association (AHA) as strong, fair/moderate, and consensus; for those with weak ratings consult the American Dietetic Association Evidence Analysis Library for Hypertension (2009) <http://www.adaevidencelibrary.com/topic.cfm?cat=3259> or the ACC/AHA data supplement at <http://circ.ahajournals.org/lookup/suppl/doi:10.1161/01.cir.0000437740.48606.d1/-DC1>

*Weight management guidelines are from Jensen MD, et al: 2013 AHA/ACC/TOS guideline for the management of overweight and obesity in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines, and the Obesity Society, *J Am Coll Cardiol* 63:2985, 2014.

(Appel et al, 2006). This dietary pattern serves as the core for the ACC/AHA dietary recommendations for lowering blood pressure (Whelton et al, 2018). Although the DASH diet is safe and currently advocated for preventing and treating hypertension, the diet is high in potassium, phosphorus, and protein, depending on how it is planned. For this reason the DASH diet may not be advisable for individuals with end-stage renal disease with high-normal or elevated serum potassium and phosphorus levels (Tyson et al, 2012).

Several versions of the DASH diet have been examined in regard to blood pressure–lowering potential. The OmniHeart trial compared the original DASH diet to a high-protein version of the DASH diet (25% of energy from protein, approximately half from plant sources), and a DASH diet high in unsaturated fat (31% of calories from unsaturated fat, mostly monounsaturated). Although each diet lowered SBP, substituting some of the carbohydrate (approximately 10% of total calories) in the DASH diet with either protein or monounsaturated fat achieved the best reduction in blood pressure and blood cholesterol (Miller et al, 2006). This could be achieved by substituting nuts for some of the fruit, bread, or cereal servings.

Because many hypertensive patients are overweight, hypocaloric versions of the DASH diet also have been tested for efficacy in promoting weight loss and blood pressure reduction. A hypocaloric DASH diet versus a low-calorie, low-fat diet produced a greater reduction in SBP and DBP. More recently, the ENCORE study showed that the addition of exercise and weight loss to the DASH diet resulted in greater blood pressure reductions, greater improvements in vascular function, and reduction in left ventricular mass compared with the DASH diet alone (Lee et al, 2018).

The MeD dietary pattern has many similarities to the DASH diet but is generally higher in fat, primarily MUFA from olive oil, nuts, and seeds. A traditional MeD diet also contains fatty fish rich in omega-3 fatty acids. A systematic review of the MeD diet and CVD risk factors, found that although limited, evidence from RCTs was suggestive of a blood pressure–lowering effect of this style dietary pattern in adults with hypertension (Rees et al, 2013). According to the ACC/AHA, more studies on diverse populations are warranted before recommendations can be made related to the MeD diet for use in blood pressure management (Whelton et al, 2018).

Weight Reduction

There is a strong association between BMI and hypertension among men and women in all race or ethnic groups and in most age groups. It is estimated that at least 75% of the incidence of hypertension is related directly to obesity (Benjamin et al, 2018). Weight gain during adult life is responsible for much of the rise in blood pressure seen with aging.

Some of the physiologic changes proposed to explain the relationship between excess body fat and blood pressure are overactivation of the SNS and RAS and vascular inflammation (Hall et al, 2015). Visceral fat in particular promotes vascular inflammation by inducing cytokine release, proinflammatory transcription factors, and adhesion molecules (Hall et al, 2015). Low-grade inflammation occurs in the vasculature of individuals with elevated blood pressure; whether it precedes the onset of hypertension is unclear. Weight loss, exercise, and a MeD-style diet are beneficial (see Appendix 23).

Virtually all clinical trials on weight reduction and blood pressure support the efficacy of weight loss on lowering blood pressure. Reductions in blood pressure can occur without attainment of desirable body weight in most participants. Larger blood pressure reductions are achieved in participants who lost more weight and were also taking antihypertensive medications. This latter finding suggests a possible synergistic effect between weight loss and drug therapy. Although

weight reduction and maintenance of a healthy body weight is a major effort, interventions to prevent weight gain are needed before midlife. In addition, BMI is recommended as a screening tool in adolescence for future health risk (Flynn et al, 2017).

Sodium

Evidence from a variety of studies supports lowering blood pressure and CVD risk by reducing dietary sodium. For example, in the Trials of Hypertension Prevention more than 2400 individuals with moderately elevated blood pressure were assigned randomly to either cut their sodium by 750 to 1000 mg per day or to follow general guidelines for healthy eating for 18 months to 4 years. In 10 to 15 years after the studies ended, individuals who cut their sodium experienced a 32% lower risk of heart attacks, strokes, or other cardiovascular events compared with the group that did not (Cook et al, 2014). A meta-analysis of 37 RCTs further supports the positive effects of sodium reduction on blood pressure and cardiovascular outcomes for normotensive and hypertensive individuals (Aburto et al, 2013).

The DASH sodium trials tested the effects of three different levels of sodium intake (1500 mg, 2400 mg, and 3300 mg/day) combined with either a typical U.S. diet or the DASH diet in persons with prehypertension or stage 1 hypertension (Appel et al, 2006). The lowest blood pressures were achieved by those eating the 1500-mg sodium level in the DASH diet. In the DASH diet and the typical American diet groups, the lower the sodium, the lower the blood pressure. Such data provide the basis for the 2018 ACC/AHA (Whelton et al, 2018) sodium guideline for most adults to aim for at least 1000 mg/day reduction in sodium and for adults with elevated blood pressure to reduce sodium to an optimal goal of <1500 mg/day. For those with normal blood pressure, the Dietary Guidelines for Americans recommend an intake of less than 2300 mg of sodium, the equivalent of 6 g of salt, each day (USDA, 2015). This goal is supported by the AND Practice Guidelines (Lennon et al, 2017) and other organizations.

There is agreement that some persons with hypertension show a greater decrease in their blood pressures in response to reduced sodium intake than others. The term salt-sensitive hypertension has been used to identify these individuals. Salt-resistant hypertension refers to individuals with hypertension whose blood pressures do not change significantly with lowered salt intakes. Salt sensitivity varies, with individuals having greater or lesser degrees of blood pressure reduction. In general, individuals who are more sensitive to the effects of salt and sodium tend to be individuals who are black, obese, and middle-aged or older, especially if they have diabetes, chronic kidney disease, or hypertension. Currently, there are no clinical tests methods for identifying the salt-sensitive individual from the salt-resistant individual.

Calcium and Vitamin D

Calcium potentiates vascular contraction and relaxation through modification of 1,25-dihydroxy vitamin D₃ and parathyroid hormone levels (Brozovich et al, 2016). Peptides derived from milk proteins, especially fermented milk products, may also function as ACEs, thereby lowering blood pressure (Fekete et al, 2016). The DASH trial found that 8-week consumption of a diet high in fruits, vegetables, and fiber; three servings of low-fat dairy products/day; and lower total and saturated fat could lower SBP by 5.5 mm Hg and DBP by 3 mm Hg further than the control diet. The fruit and vegetable diet without dairy foods resulted in blood pressure reductions approximately half that of the DASH diet. The AND practice guidelines recommend a diet rich in fruits, vegetables, and low-fat dairy products for the prevention and management of elevated blood pressure (Lennon et al, 2017). The DASH serving recommendation of 2 to 3 low-fat dairy foods per day would provide the minimum calcium intake (~ 800 mg) necessary to

achieve a SBP lowering of 4 mm Hg and DBP of 2 mm Hg in adults with hypertension (Lennon et al, 2017).

Cross-sectional studies suggest lower 25-hydroxy vitamin D (25[OH] D) levels are associated with higher blood pressure levels (Fraser et al, 2010) and higher rates of incident hypertension (Kunutsor et al, 2013). Mechanistically, vitamin D has been shown to improve endothelial function, reduce RAS activity, and lower parathyroid hormone (PTH) levels. However, recent evidence suggests that supplementation with vitamin D is not effective as a blood pressure–lowering agent on its own and therefore is not recommended as an antihypertension agent (Qi, 2017).

Magnesium

Magnesium is a potent inhibitor of vascular smooth-muscle contraction and may play a role in blood pressure regulation as a vasodilator. High dietary magnesium often is correlated with lower blood pressure (Schutten et al, 2018). Trials of magnesium supplementation have shown decreases in SBP of 3 to 4 mm Hg and DBP of 2 to 3 mm Hg with greater dose-dependent effects at supplementation of at least 370 mg/day (Zhang et al, 2016). The DASH dietary pattern emphasizes foods rich in magnesium, including green leafy vegetables, nuts, and whole-grain breads and cereals. Overall food sources of magnesium rather than supplemental doses of the nutrient are encouraged to prevent or control hypertension (Lennon et al, 2017).

Potassium

Supplemental doses of potassium in the range of 235 to 4700 mg/day lower blood pressure approximately 1 to 4 mm Hg DBP and 3 to 6 mm Hg SBP (Poorolajal et al, 2017). The effects of potassium are greater in those with higher initial blood pressure, in blacks compared with whites, and in those with higher intakes of sodium. Higher potassium intake also is associated with a lower risk of stroke (Aburto et al, 2013). Although the mechanism by which potassium lowers blood pressure is uncertain, several potential explanations have been offered, including decreased vascular smooth muscle contraction by altering membrane potential or restoring endothelium-dependent vasodilation (Bazzano et al, 2013). Failure of the kidney to adapt to a diet lower in potassium has been linked to sodium-sensitive hypertension.

The large number of fruits and vegetables recommended in the DASH diet makes it easy to meet the dietary potassium recommendations—approximately 4.7 g/day (Lennon et al, 2017). In individuals with medical conditions that could impair potassium excretion (e.g., chronic renal failure, diabetes, and congestive HF), a lower potassium intake (less than 4.7 g/day) is appropriate to prevent hyperkalemia (see Appendix 44).

Physical Activity

Less active persons are 30% to 50% more likely to develop hypertension than their active counterparts. Despite the benefits of activity and exercise in reducing disease, many Americans remain inactive. The prevalence of adults not meeting the Federal Physical Activity Guidelines for Americans (2008) is as follows: Hispanics (54.3% men, 59% women), blacks (49.7% men, 65% women), and whites (44.8% men, 49.1% women) all have a high prevalence of sedentary lifestyles (Benjamin et al, 2018). Exercise is beneficial to blood pressure. Increasing the amount of aerobic or dynamic resistance physical activity to a minimum of 90 to 150 minutes per week is an important adjunct to other blood pressure–lowering strategies (Whelton et al, 2018).

Alcohol Consumption

Excessive alcohol consumption is responsible for 5% to 7% of the hypertension in the population (Lennon et al, 2017). A three drink per day

amount (a total of 3 oz of alcohol) is the threshold for raising blood pressure and is associated with a 3-mm Hg rise in SBP. For preventing high blood pressure, alcohol intake should be limited to no more than two drinks per day (24 oz of beer, 10 oz of wine, or 2 oz of 80-proof whiskey) in men, and no more than one drink a day is recommended for lighter-weight men and for women.

Medical Management

The goal of hypertension management is to reduce morbidity and mortality from stroke, hypertension-associated heart disease, and renal disease. The three objectives for evaluating patients with hypertension are to (1) identify the possible causes, (2) assess the presence or absence of target organ disease and clinical CVD, and (3) identify other CVD risk factors that help guide treatment. The presence of risk factors and target organ damage determines treatment priority.

Lifestyle modifications are definitive therapy for some and adjunctive therapy for all persons with hypertension. Several months of compliant lifestyle modifications should be tried before drug therapy is initiated. An algorithm for treatment of hypertension is shown in Fig. 32.9. Even if lifestyle modifications cannot completely correct blood pressure, these approaches help increase the efficacy of pharmacologic agents and improve other CVD risk factors. Management of hypertension requires a lifelong commitment.

Pharmacologic therapy is necessary for many individuals with hypertension, especially if blood pressure remains elevated after 6 to 12 months of lifestyle changes. The blood pressure target for initiating pharmacologic treatment is 130/80 mm Hg in adults with diabetes or kidney disease. For adults with stage 1 hypertension with clinical ASCVD or estimated 10-year risk of ASCVD $\geq 10\%$ or stage 2 hypertension, the ACC/AHA guidelines recommends blood pressure–lowering medication in combination with nonpharmacotherapy for primary prevention of CVD. Recommended pharmacologic treatment includes thiazide-type diuretics, calcium channel blockers (CCBs), angiotensin-converting enzyme inhibitors (ACEIs), or angiotensin receptor blockers (ARBs). Thiazide-type diuretics and CCBs are recommended in black populations, including those with diabetes, because they have been shown to be more effective in improving CVD outcomes compared to other classes of medications (Whelton et al, 2018). All these drugs can affect nutrition status (see Appendix 13).

Diuretics lower blood pressure in some patients by promoting volume depletion and sodium loss. At high doses other water-soluble nutrients are also lost and may have to be supplemented. Thiazide diuretics increase urinary potassium excretion, especially in the presence of a high salt intake, thus leading to potassium loss and possible hypokalemia. Except in the case of a potassium-sparing diuretic such as spironolactone or triamterene, additional potassium usually is required. Grapefruits and grapefruit juice can affect the action of many CCBs and should not be consumed while taking the medication.

A number of medications either raise blood pressure or interfere with the effectiveness of antihypertensive drugs. These include oral contraceptives, steroids, nonsteroidal antiinflammatory drugs, nasal decongestants and other cold remedies, appetite suppressants, cyclosporine, tricyclic antidepressants, and monoamine-oxidase inhibitors (see Appendix 13).

In addition to standard, conventional medical care, more than 1/2 of Americans also use complementary approaches and this includes treatment of hypertension and other cardiovascular diseases. Table 32.4 lists some that are most common.

Medical Nutrition Therapy

The appropriate course of nutrition therapy for managing hypertension should be guided by data from a detailed nutrition assessment.

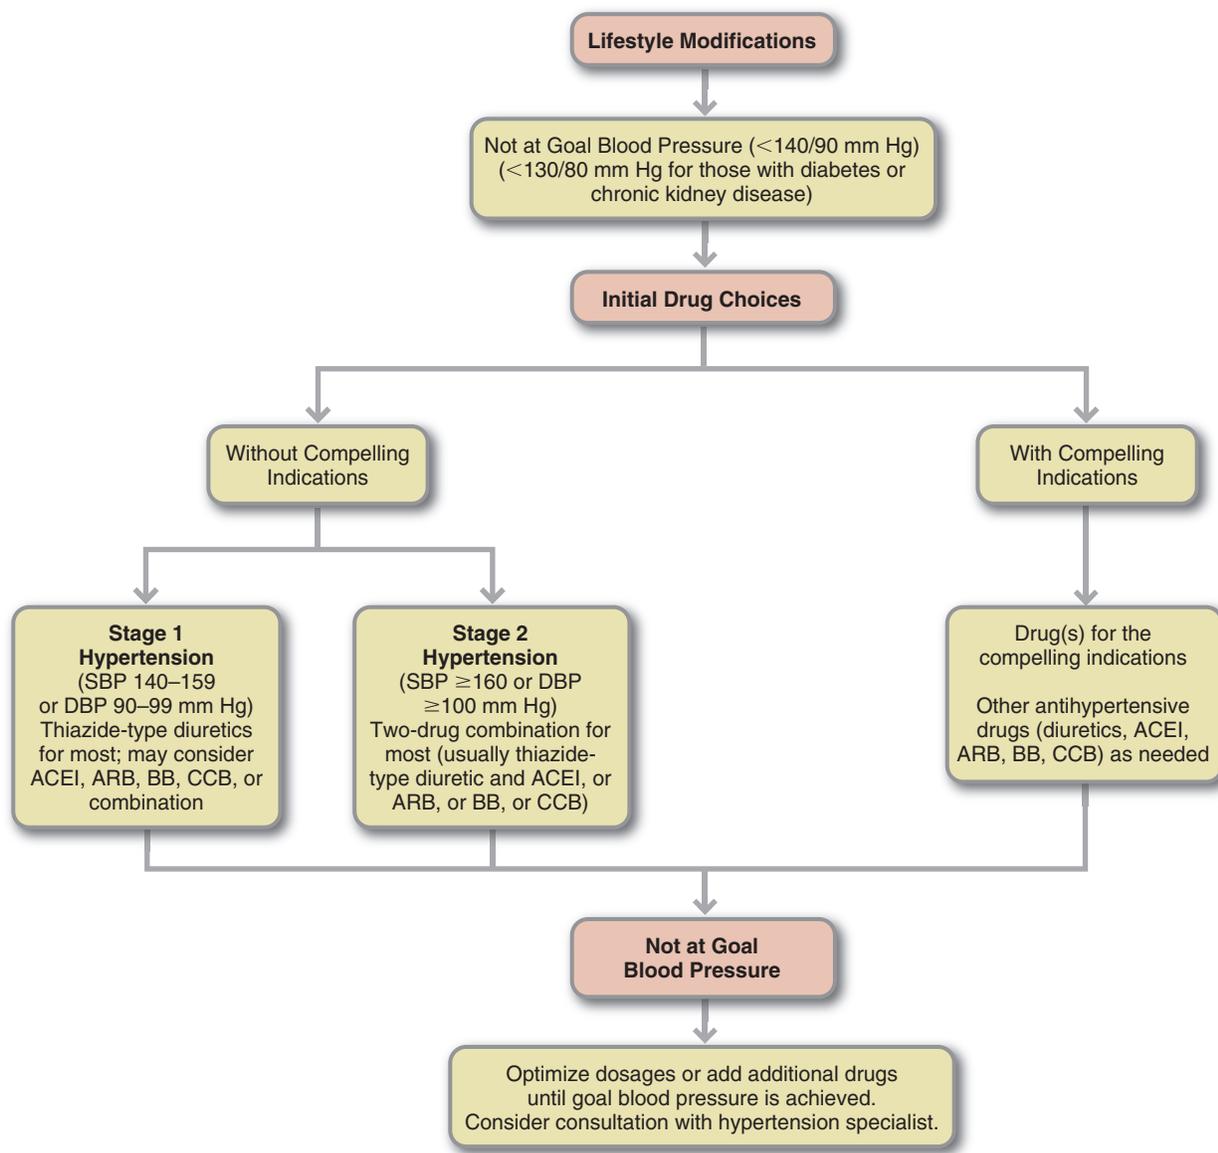

Fig. 32.9 Algorithm for treatment of hypertension. *ACEI*, Angiotensin-converting enzyme inhibitor; *ARB*, angiotensin-receptor blocker; *BB*, beta-blocker; *CCB*, calcium channel blocker; *DBP*, diastolic blood pressure; *SBP*, systolic blood pressure. (From National Institutes of Health, National Heart, Lung, and Blood Institute National High Blood Pressure Education Program: The seventh report of the Joint National Committee on prevention, detection, evaluation, and treatment of high blood pressure, NIH Publication No. 04-5230, August 2004.)

Weight history; leisure-time physical activity; and assessment of intake of sodium, alcohol, fat type (e.g., MUFA vs. SFA), and other dietary patterns (e.g., intake of fruits, vegetables, and low-fat dairy products) are essential components of the medical and diet history. Nutrition assessment should include evaluation of the individual in the following specific domains to determine nutrition problems and diagnoses: food and nutrient intake, knowledge, beliefs and attitudes, behavior, physical activity and function, and appropriate biochemical data. Following are the components of the current recommendations for managing elevated blood pressure.

Energy Intake

For each kilogram of weight lost, reductions in SBP and DBP of approximately 1 mm Hg are expected. Hypertensive patients who weigh

more than 115% of ideal body weight should be placed on an individualized weight-reduction program that focuses on hypocaloric dietary intake and exercise (see Chapter 20). A modest caloric reduction is associated with a significant lowering of SBP and DBP, and LDL cholesterol levels. Hypocaloric diets that include a low-sodium DASH dietary pattern have produced more significant blood pressure reductions than low-calorie diets emphasizing only low-fat foods. Another benefit of weight loss on blood pressure is the synergistic effect with drug therapy. Weight loss should be an adjunct to drug therapy because it may decrease the dose or number of drugs necessary to control blood pressure.

DASH Diet

The DASH diet is used for preventing and controlling high blood pressure. Successful adoption of this diet requires many behavioral

TABLE 32.4 Complementary and Integrative Approaches for Cardiovascular Health

Common Name	Scientific Name	Effect on Cardiac Health	Side Effects and Risks
Coenzyme Q ₁₀	Ubiquinone	Decreases SBP and DBP via a direct effect on the vascular endothelium and smooth muscle. May strengthen the heart muscle in heart failure.	May cause gastrointestinal discomfort, nausea, flatulence, and headaches
Vitamin C and vitamin E taken in combination as supplement	Ascorbic acid α-tocopherol	Decreases SBP and DBP, decreases arterial stiffness, and improves endothelial function by improving antioxidant status	Vitamin E may increase bleeding time with anticoagulants and reduce blood pressure. Vitamin C may cause diarrhea at high doses.
Vitamin D	1,25-dihydroxy vitamin D ₃	Decreases SBP via suppression of renin expression and vascular smooth muscle cell proliferation	Hypercalcemia may occur depending on level of supplementation
Fish oil	Omega-3 polyunsaturated fatty acid	Therapeutic doses (2-3g EPA/DHA) lowers triglycerides. Lowers blood pressure by increasing endothelial vasodilatory response and may increase NO	May cause gastrointestinal discomfort, belching, bad breath, and increased bleeding time above 3g EPA/DHA
Garlic	<i>Allium sativum</i>	Reduces SBP and DBP in individuals with hypertension via vasodilation resulting from activation of potassium channels; may also be due to activation of NOS. Significantly lowers serum cholesterol.	May cause bad breath and body odor may increase bleeding time with anticoagulants
Resveratrol	Trans-3,4',5-trihydroxystilbene	Reduces systolic blood pressure in animals via enhanced NOS expression in the aorta	Unknown
Beet Extract	<i>Beta vulgaris</i>	Increases NO production and effective in reducing blood pressure	May have an additive effect when taken with antihypertensive medication
Hawthorn berry	<i>Crataegus oxycantha</i> , <i>Crataegus monogyna</i>	Exerts a mild, gradual blood pressure lowering effect; protective to the endothelium, antioxidant	May have an additive effect when taken with antihypertensive medication
Vitamin B3	Niacin	Lowers total cholesterol and raises HDL at doses above 1,000 mg/d	Causes flushing, itching and may raise liver enzymes. Coordination of care with a physician is necessary.
Hibiscus	<i>Hibiscus sabdariffa</i>	Lowers SBP in pre- and mildly hypertensive adults via calcium channel activation	May have an additive effect when taken with antihypertensive medication
Red Yeast Rice	<i>Monascus purpureus</i>	Contains a compound called Monakolin K that is identical to lovastatin. Lowers cholesterol.	Banned by the FDA in standardized quantities. May cause myalgias.
Plant sterols and stanols	β-sitosterol, campesterol, sitostanol and campestanol	Have been shown to lower cholesterol	none known

DBP, diastolic blood pressure; NO, nitric oxide; NOS, nitric oxide synthase; SBP, systolic blood pressure.

Data from Fragakis AS, Thomson C: *The health professional's guide to popular dietary supplements*, ed 3, Chicago, 2007, American Dietetic Association. © American Dietetic Association. Available from: <https://naturalmedicines.therapeuticresearch.com>.

changes: eating twice the average number of daily servings of fruits, vegetables, and dairy products; limiting by one third the usual intake of beef, pork, and ham; eating half the typical amounts of fats, oils, and salad dressings; and eating one quarter the number of snacks and sweets. Lactose-intolerant persons may need to incorporate lactase enzyme or use other strategies to replace milk. Assessing patients' readiness to change and engaging patients in problem solving, decision making, and goal setting are behavioral strategies that may improve adherence.

The high number of fruits and vegetables consumed on the DASH diet is a marked change from typical patterns of Americans. To achieve the 8 to 10 servings, two to three fruits and vegetables should be consumed at each meal. Importantly, because the DASH diet is high in fiber, gradual increases in fruit, vegetables, and whole-grain foods should be made over time. Eight to 10 cups of fluids daily should be encouraged. Slow changes can reduce potential short-term gastrointestinal disturbances associated with a high-fiber diet, such as bloating and diarrhea. The DASH pattern is advocated in the 2017 ACC/AHA

nutrition guidelines on lifestyle management to reduce CVD risk (Whelton et al, 2018). Servings for different calorie levels are shown in Appendix 17.

Salt Restriction

The Dietary Guidelines for Americans recommend that young adults consume less than 2300 mg of sodium per day. This is also recommended for older people with hypertension (Whelton et al, 2018). Although further blood pressure improvements may be achieved by reducing sodium to 1500 mg/day (Appel et al, 2006), patients with HF should be cautioned against use of this dietary approach because adverse health effects of very-low-sodium diets in these patients have been reported (Institute of Medicine [IOM], 2013). Adherence to diets containing less than 2 g/day of sodium is very difficult to achieve.

In addition to advice on selection of minimally processed foods, dietary counseling should include instruction on reading food labels for sodium content, avoidance of discretionary salt in cooking or meal

preparation (1 tsp salt = 2400 mg sodium), and use of alternative flavorings to satisfy individual taste. The DASH eating plan is rich in fruits and vegetables, which are naturally lower in sodium than many other foods.

Because most dietary salt comes from processed foods and eating out, changes in food preparation and processing can help patients reach the sodium goal. Sensory studies show that commercial processing could develop and revise recipes using lower sodium concentrations and reduce added sodium without affecting consumer acceptance. The food industry has made strides in reducing sodium in the American diet (see *Focus On: Sodium and the Food Industry*).

FOCUS ON

Sodium and the Food Industry

Most foods sold in supermarkets and restaurants are high in salt. The dramatic differences in sodium from brand to brand suggest that many companies could easily achieve significant reductions without sacrificing taste. According to the Center for Science in the Public Interest (Liebman, 2014), processed foods and restaurant foods contribute approximately 80% of the sodium in Americans' diets: 10% comes from salt added during cooking at home or at the table and the remaining 10% is naturally occurring. Americans now consume approximately 3400 mg of sodium per day—1000 mg above the recommended amount. To help address this problem, in 2016, the Food and Drug Administration (FDA) issued draft guidance to the food industry on 2-year and 10-year voluntary sodium reduction targets for more than 150 foods, including snacks and frozen pizza. While not required, the proposed reduction targets would put significant public pressure on food manufacturers to reduce sodium in their products. The draft guidance triggered more than 200 written comments mostly from the leading food industry trade associations and food manufacturers. The majority of comments submitted to the FDA raised concerns about the challenges for the industry in reformulating food to lower sodium including consumer acceptance of reformulated products and concern with food safety and spoilage. In 2019 the FDA will issue the final guidance to food companies and restaurants on short-term sodium reduction targets. While some nutrition experts advocate for stronger action on the part of the FDA (mandatory sodium reduction), the guidelines still set a benchmark by which companies can be measured, something health advocates say is critical to lowering salt levels in the American diet.

Potassium-Calcium-Magnesium

Consuming a diet rich in potassium may lower blood pressure and blunt the effects of salt on blood pressure in some individuals (Appel et al, 2006). The recommended intake of potassium for adults is 4.7 g/day (IOM, 2004). Potassium-rich fruits and vegetables include leafy green vegetables, fruits, and root vegetables. Examples of such foods include oranges, beet greens, white beans, spinach, bananas, and sweet potatoes. Although meat, milk, and cereal products contain potassium, the potassium from these sources is not as well absorbed as that from fruits and vegetables (USDA, 2015).

Increased intakes of calcium and magnesium may have blood pressure benefits. Although there are not enough data to support a specific recommendation for increasing levels of magnesium intake, the AND EAL practice guidelines indicates that dietary calcium intakes of 800 mg or more may aid in blood pressure lowering (Lennon et al, 2017). The guidelines also recommend consideration of calcium supplementation of up to 1500 mg/day for adults with hypertension who are unable to achieve the dietary reference intake (DRI) of calcium with diet and

food alone. The DASH diet plan encourages foods that would be good sources of calcium and magnesium, including low-fat dairy products, dark green leafy vegetables, beans, and nuts (see Appendix 17).

Lipids

Current recommendations for lipid composition of the diet are recommended to help control weight and decrease the risk of CVD. Omega-3 fatty acids are not highlighted in blood pressure treatment guidelines (Lennon et al, 2017), although intakes of fish oils exceeding 2 g/day may have blood pressure benefits.

Alcohol

The diet history should contain information about alcohol consumption. Alcohol intake should be limited to no more than two drinks daily in men, which is equivalent to 2 oz of 80-proof whiskey, 10 oz of wine, or 24 oz of beer. Women or lighter-weight men should consume half this amount. Excessive alcohol consumption is associated with left ventricular function.

Exercise

Increasing the amount of aerobic or dynamic resistance physical activity to a minimum of 90 to 150 minutes per week is recommended as an adjunct therapy in hypertension management (Whelton et al, 2018). Because exercise is associated strongly with success in weight-reduction and weight-maintenance programs, any increase in activity level should be encouraged for those trying to lose weight. For substantial health benefits, the dietary guidelines recommends at least 150 minutes a week of moderate-intensity physical activity as well as muscle-strengthening activities that include all major muscle groups on 2 or more days for all Americans (USDA, 2015).

Treatment of Hypertension in Children and Adolescents

The prevalence of primary hypertension among children in the United States is increasing in concert with rising obesity rates and increased intakes of high-calorie, high-salt foods (Flynn et al, 2017). Hypertension tracks into adulthood and has been linked with carotid intimal-medial thickness, LVH, and fibrotic plaque formation. Secondary hypertension is more common in preadolescent children, mostly from renal disease; primary hypertension caused by obesity or a family history of hypertension is more common in adolescents (Miller and Joye Woodward, 2014). In addition, intrauterine growth retardation leads to hypertension in childhood (Longo et al, 2013).

High blood pressure in youth is based on a normative distribution of blood pressure in healthy children. Hypertension is defined as an SBP or DBP of greater than the 95th percentile for age, sex, and height. The designation for prehypertension in children is SBP or DBP of greater than the 90th percentile. Therapeutic lifestyle changes are recommended as an initial treatment strategy for children and adolescents with prehypertension or hypertension. These lifestyle modifications include regular physical activity, avoiding excess weight gain, limiting sodium, and consuming a DASH-type diet.

Weight reduction is considered the primary therapy for obesity-related hypertension in children and adolescents. Unfortunately, sustained weight loss is difficult to achieve in this age group. The Framingham Children's Study showed that children with higher intakes of fruits, vegetables (a combination of four or more servings per day), and dairy products (two or more servings per day) had lower SBP compared with those with lower intakes of these foods. Couch and colleagues (2008) showed that adolescents with prehypertension and hypertension could achieve a significant reduction in SBP in response to a behaviorally oriented nutrition intervention emphasizing the DASH diet. Because adherence to dietary interventions may be particularly challenging among children and teenagers, innovative

nutrition intervention approaches that address the unique needs and circumstances of this age group are important considerations in intervention design (see Chapters 16 and 17).

Treatment of Blood Pressure in Older Adults

More than half of the older population has hypertension; this is not a normal consequence of aging. The lifestyle modifications discussed previously are the first step in treatment of older adults, as with younger populations. The Trial of Nonpharmacologic Interventions in the Elderly study found that losing weight (8 to 10 lb) and reducing sodium intake (to 1.8 g/day) can lessen or eliminate the need for drugs in obese, hypertensive older adults. Although losing weight and decreasing sodium in older adults are very effective in lowering blood pressure, knowing how to facilitate these changes and promote adherence remains a challenge for health professionals.

Blood pressure should be controlled regardless of age, initial blood pressure level, or duration of hypertension. Severe sodium restrictions

are not adopted because these could lead to volume depletion in older patients with renal damage. Drug treatment in the older adult is supported by very strong data. Additionally, the benefits of treating hypertensive persons age 65 years and older to reach a blood pressure goal of less than 130/80 mm Hg are well supported in the literature. For older adults with hypertension and a high burden of comorbidity and limited life expectancy, a team-based approach is recommended to assess risk/benefit for decisions regarding intensity of blood pressure-lowering and choice of pharmacotherapy (Whelton et al, 2018).

HEART FAILURE

Normally the heart pumps adequate blood to perfuse tissues and meet metabolic needs (Fig. 32.10). In **heart failure (HF)**, formerly called congestive HF, the heart cannot provide adequate blood flow to the rest of the body, causing symptoms of fatigue, **dyspnea** (shortness of breath), and fluid retention. Diseases of the heart (valves, muscle,

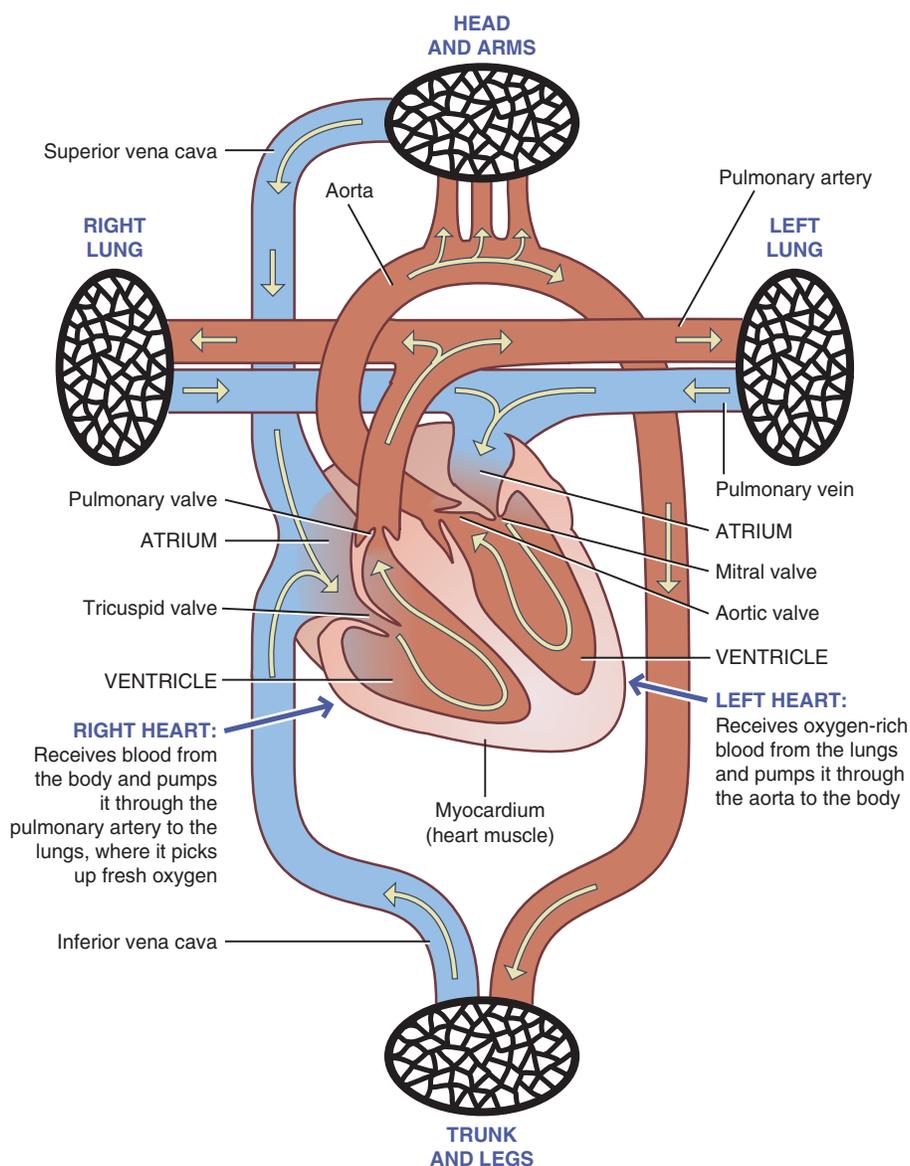

Fig. 32.10 Structure of the heart pump.

blood vessels) and vasculature can lead to HF (see *Pathophysiology and Care Management Algorithm: Heart Failure*). HF can be right-sided or left-sided or can affect both sides of the heart. It is further categorized as systolic failure when the heart cannot pump or eject blood efficiently out of the heart or diastolic failure, meaning the heart cannot fill with blood as it should.

The lifetime risk of developing HF is 20% for Americans age 40 or older. Approximately 5.1 million in the United States have HF. The incidence increases with age, rising from approximately 20 per 1000 individuals 65 to 69 years to greater than 80 per 1000 in those individuals 85 and older (Stone et al, 2014). Black men have been shown to be at the highest risk of HF; white women have the lowest. HF in non-Hispanic black males and females has a prevalence of 4.5% and 3.8% respectively, versus 2.7% and 1.8% in non-Hispanic white males and females, respectively (Stone et al, 2014).

Pathophysiology

The progression of HF is similar to that of atherosclerosis because there is an asymptomatic phase when damage is silently occurring (stages A and B) (Fig. 32.11). HF is initiated by damage or stress to the heart muscle either of acute MI or insidious (hemodynamic pressure or volume overloading) onset (see Table 32.5 for classifications of HF).

The progressive insult alters the function and shape of the left ventricle such that it hypertrophies in an effort to sustain blood flow, a process known as cardiac remodeling. Symptoms do not usually arise until months or years after cardiac remodeling begins. Many compensatory mechanisms from the SNS, RAS, and cytokine system are activated to restore homeostatic function. Proinflammatory cytokines, such as TNF- α , IL-1, and IL-6, are increased in blood and the myocardium and have been found to regulate cardiac remodeling.

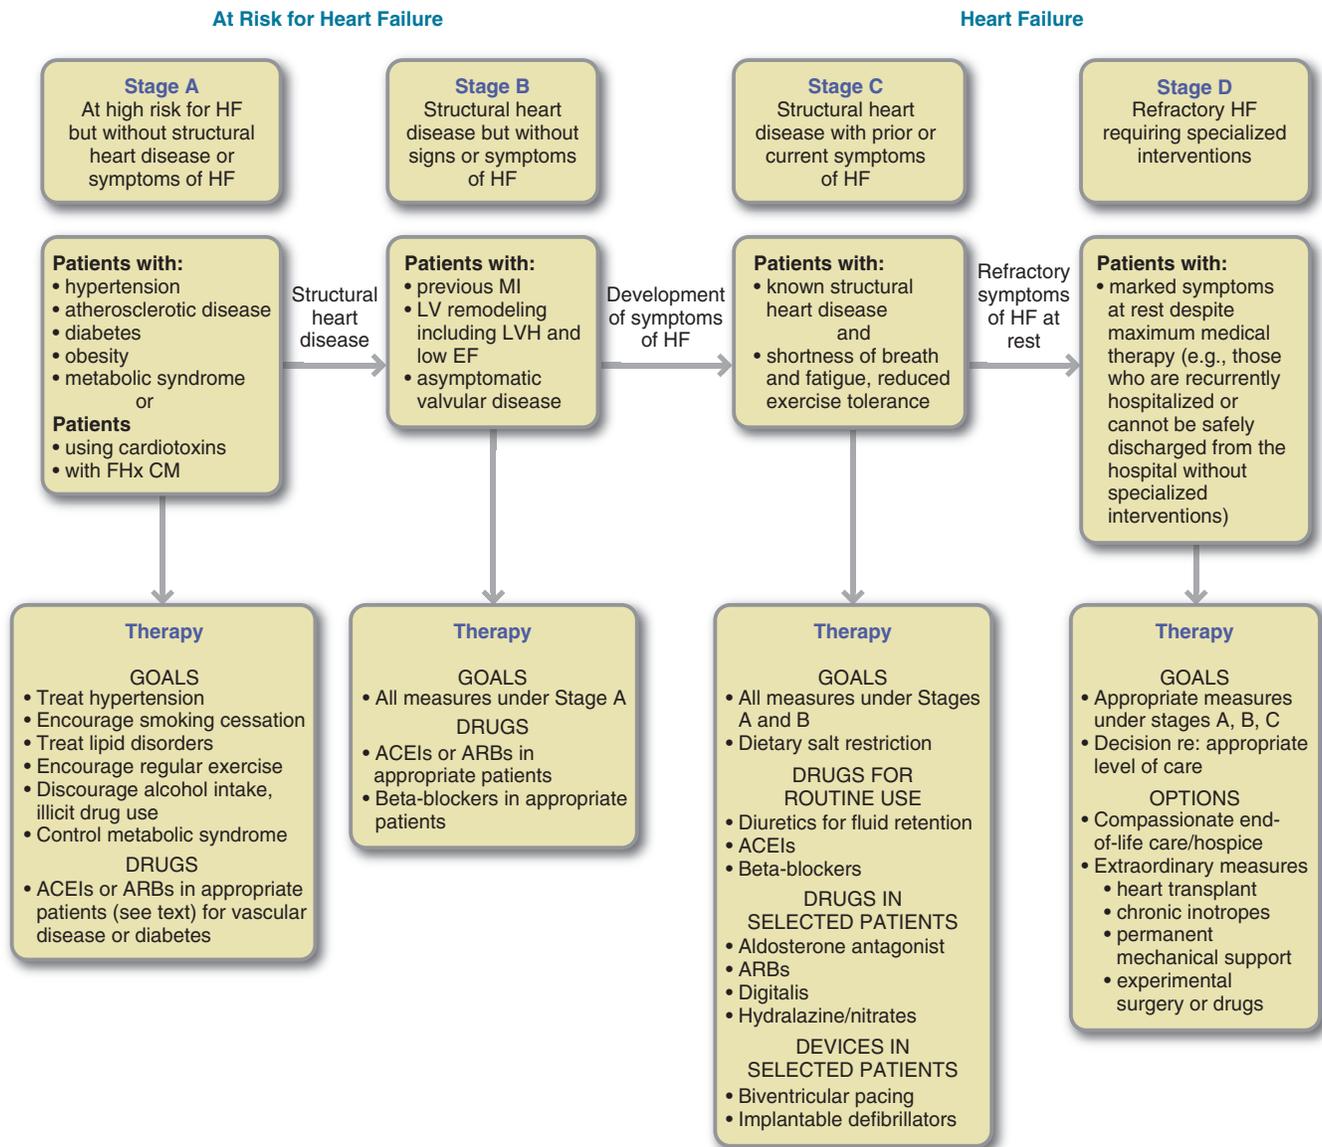

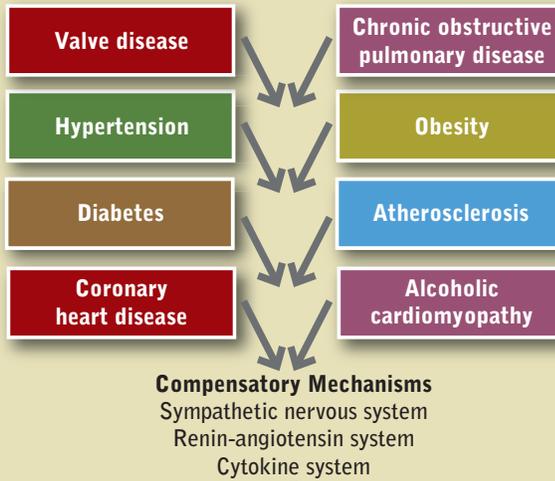

Fig. 32.11 Stages of heart failure and recommended therapy by stage. ACEI, Angiotensin-converting enzyme inhibitor; ARB, angiotensin receptor blocker; CM, cardiomyopathy; EF, ejection fraction; FHx, family history; HF, heart failure; IV, intravenous; LV, left ventricular; LVH, left ventricular hypertrophy; MI, myocardial infarction. (From Hunt SA, et al: ACC/AHA 2005 guideline update for the diagnosis and management of chronic heart failure in the adult: a report of the American College of Cardiology/American Heart Association Task Force, *J Am Coll Cardiol* 46:e1, 2005.)

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Heart Failure

ETIOLOGY

Left Ventricular Hypertrophy or Hemodynamic Stress on a Diseased Heart

- Dietary sodium excess
- Medication noncompliance
- Arrhythmias
- Pulmonary embolism
- Infection
- Anemia

Heart Failure

PATHOPHYSIOLOGY

Clinical Findings

- Shortness of breath
- Fatigue
- Fluid retention
- Peripheral vasoconstriction
- Elevated B-natriuretic peptide
- Mental confusion
- Memory loss
- Anxiety
- Insomnia
- Syncope and headache
- Dry cough

Nutrition Assessment

- Anorexia
- Nausea, abdominal pain, and feeling of fullness
- Constipation
- Malabsorption
- Malnutrition
- Cardiac cachexia
- Hypomagnesemia
- Hyponatremia

MANAGEMENT

Medical Management

- ACE inhibitors
- Angiotensin receptor blockers
- Aldosterone blockers
- β-blockers
- Digoxin
- Vasodilators
- Implantable defibrillator
- Heart transplant

Nutrition Management

- DASH diet
- Diet low in saturated fat, *trans* fat
- Restricted sodium diet—<3 gm/day
- Increased use of whole grains, fruits, vegetables
- Limit fluid to 2 L per day
- Lose to or maintain appropriate weight
- Magnesium supplementation
- Thiamin supplementation
- Increase physical activity as tolerated
- Avoid alcohol and tobacco

TABLE 32.5 Classifications of Heart Failure

Class I	No undue symptoms associated with ordinary activity and no limitation of physical activity
Class II	Slight limitation of physical activity; patient comfortable at rest
Class III	Marked limitation of physical activity; patient comfortable at rest
Class IV	Inability to carry out physical activity without discomfort; symptoms of cardiac insufficiency or chest pain at rest

Modified from Hunt SA, et al: ACC, AHA, 2005 guideline update for the diagnosis and management of chronic heart failure in the adult: a report of the American College of Cardiology/American Heart Association Task Force on practice guidelines, *J Am Coll Cardiol* 46:e1, 2005.

Another substance, **B-natriuretic peptide (BNP)**, is secreted by the ventricles in response to pressure and is predictive of the severity of HF and mortality at any level of BMI. BNP is often highly elevated in patients with HF (greater than 100 pg/mL is abnormal, and some patients have levels more than 3000 pg/mL). For every 100 pg/mL rise in BNP concentration, there is a corresponding 35% increase in the relative risk of death (Desai, 2013).

Eventually overuse of compensatory systems leads to further ventricle damage, remodeling, and worsening of symptoms (stage C). HF patients have elevated levels of norepinephrine, angiotensin II, aldosterone, endothelin, and vasopressin; all of these are neurohormonal factors that increase the hemodynamic stress on the ventricle by causing sodium retention and peripheral vasoconstriction. These neurohormones and the proinflammatory cytokines contribute to disease progression; hence, current studies focus on inhibition of these undesirable pathways and promotion of desirable ones.

For the final stages of HF, there is a subjective scale used to classify symptoms based on the degree of limitation in daily activities (Table 32.5). The severity of symptoms in this classification system is weakly related to the severity of left ventricular dysfunction; therefore treatment encompasses improving functional capacity and lessening progression of the underlying disease.

In HF the heart can compensate for poor cardiac output by (1) increasing the force of contraction, (2) increasing in size, (3) pumping more often, and (4) stimulating the kidneys to conserve sodium and water. For a time this compensation maintains near-normal circulation, but eventually the heart can no longer maintain a normal output (decompensation). Advanced symptoms can develop in weeks or months, and sudden death can occur at any time.

Three symptoms—fatigue, shortness of breath, and fluid retention—are the hallmarks of HF. Shortness of breath on exertion, or effort intolerance, is the earliest symptom. The shortness of breath known as orthopnea is breathlessness while lying down. Fluid retention can manifest as pulmonary congestion or peripheral edema. Evidence of hypoperfusion includes cool forearms and legs, sleepiness, declining serum sodium level caused by fluid overload, and worsening renal function.

Decreased cranial blood supply can lead to mental confusion, memory loss, anxiety, insomnia, **syncope** (loss of oxygen to the brain causing brief loss of consciousness), and headache. The latter symptoms are more common in older patients and often are the only symptoms; this can lead to a delay in diagnosis. Often the first

TABLE 32.6 Skeletal Muscle Changes in Heart Failure

Function loss	Weakness

Inactivity	TNF- α \neq \neq
Genetic factors	Myostatin, IGF

GH, Growth hormone; IGF, insulin-like growth factor; TNF- α , tumor necrosis factor alpha.

From Strassburg S, et al: Muscle wasting in cardiac cachexia, *Int J Biochem Cell Biol* 37:1938, 2005.

symptom in older adults is a dry cough with generalized weakness and anorexia.

Cardiac cachexia is the end result of HF in 10% to 15% of patients. It is defined as involuntary weight loss of at least 6% of nonedematous body weight during a 6-month period (Springer et al, 2006). Unlike normal starvation, which is characterized by adipose tissue loss, this cachexia is characterized by a significant loss of lean body mass. This decrease in lean body mass further exacerbates HF because of the loss of cardiac muscle and the development of a heart that is soft and flabby. In addition, there are structural, circulatory, metabolic, inflammatory, and neuroendocrine changes in the skeletal muscle of patients with HF (Delano and Moldawer, 2006) (Table 32.6). Some changes in cardiac function can be attributed to aging and are listed in Box 32.7.

Cardiac cachexia is a serious complication of HF with a poor prognosis and mortality rate of 50% in 18 months (Carlson and

BOX 32.7 Principal Effects of Aging on Cardiovascular Structure and Function

- Increased vascular stiffness
- Increased myocardial stiffness
- Decreased beta-adrenergic responsiveness
- Impaired mitochondrial ATP production
- Decreased baroreceptor responsiveness
- Impaired sinus node function
- Impaired endothelial function
- Net effect: Marked reduction in cardiovascular reserve

ATP, Adenosine triphosphate.

From Rich MW: Office management of heart failure in the elderly, *Am Med* 118:342, 2005.

Dahlin, 2014). Symptoms that reflect inadequate blood supply to the abdominal organs include anorexia, nausea, a feeling of fullness, constipation, abdominal pain, malabsorption, hepatomegaly, and liver tenderness. All of these contribute to the high prevalence of malnutrition observed in hospitalized patients with HF. Lack of blood flow to the gut leads to loss of bowel integrity; bacteria and other endotoxins may enter the bloodstream and cause cytokine activation. Proinflammatory cytokines such as TNF- α and adiponectin are highest in patients with cardiac cachexia. An increased level of TNF- α is associated with a lower BMI, smaller skinfold measurements, and decreased plasma total protein levels, indicative of a catabolic state.

Adiponectin levels are high in HF and are a marker for wasting and a predictor of mortality. As with TNF- α , adiponectin levels also are correlated inversely with BMI. Pharmacologic treatments for muscle wasting are being explored.

Risk Factors

The Framingham Heart Study (see *Focus On: Framingham Heart Study*) showed the risk factors for HF were hypertension, diabetes, ASCVD, and **left ventricular hypertrophy (LVH)** (enlargement of the left ventricle of the heart). Antecedent hypertension is present in about three fourths of HF patients. Individuals who have diabetes mellitus and ischemic heart disease more frequently develop HF compared with patients without diabetes (Rosano et al, 2006). Left ventricular dysfunction without ischemia is often related to excessive alcohol intake. Diabetes is an especially strong risk factor for HF in women. The prevalence of hypertension and diabetes increases with age, making the elderly particularly vulnerable to HF. Another large cohort study of older adults (70 to 79 years old) showed that waist circumference and percentage of body fat were the strongest predictors of who would develop HF (Nicklas et al, 2006). A recent study of elderly individuals with HF found a strong association between vitamin D deficiency and HF risk (Porto, 2018). Data from the Multi-ethnic Study of Atherosclerosis (also known as MESA) concluded that high EPA blood levels were significantly inversely correlated with risk of HF (Block, 2019). Numerous changes in cardiovascular structure and function also place the elderly at high risk for developing HF (see Box 32.7).

Prevention

Because long-term survival rates for persons with HF are low, prevention is critical. HF is categorized into four stages ranging from persons with risk factors (stage A—primary prevention) to persons with advanced HF (stage D—severe disease). For stages A and B the aggressive treatment of underlying risk factors and diseases such as dyslipidemia, hypertension, and diabetes is critical to prevent structural damage to the myocardium and the appearance of HF symptoms. Such prevention has been very effective. Even patients who experience an MI can reduce the risk of HF with antihypertensive therapy. Patients are often asymptomatic during these two stages.

For stages C and D, secondary prevention strategies to prevent further cardiac dysfunction are warranted. These strategies include the use of ACE inhibitors (first line of therapy), ARBs, aldosterone blockers, beta-blockers, and digoxin. Early detection, correction of asymptomatic left ventricular dysfunction, and aggressive management of risk factors are needed to lower the incidence and mortality of HF.

Medical Management

Therapy recommendations correspond to the stage of HF. For patients at high risk of developing HF (stage A), treatment of the underlying

conditions (hypertension, dyslipidemia, thyroid disorders, arrhythmias), avoidance of high-risk behaviors (tobacco, excessive alcohol, illicit drug use), and lifestyle changes (weight reduction, exercise, reduction of sodium intake, heart-healthy diet) are recommended. All these recommendations are carried through the other stages. In addition, an implantable defibrillator, which shocks the heart when it stops, can be placed in patients at risk of sudden death. Pharmacologic treatment of HF is the hallmark of therapy with progressive stages. The last stage also includes surgically implanted ventricular-assist devices, heart transplantation, and continual intravenous therapy.

The short-term goals for the treatment of HF are to relieve symptoms, improve the quality of life, and reduce depression if it is present. The long-term goal of treatment is to prolong life by lessening, stopping, or reversing left ventricular dysfunction. Medical management is tailored to clinical and hemodynamic profiles with evidence of hypoperfusion and congestion. In some cases, surgical procedures are needed to alleviate the HF caused by valvular disease; medical management is limited in these instances.

Standard fluid restrictions are to limit total fluid intake to 2 L (2000 mL) daily. When patients are severely decompensated, a more restrictive fluid intake (1000 to 1500 mL daily) may be warranted for adequate diuresis. A sodium-restricted diet should be maintained despite low-sodium blood levels because in this case the sodium has shifted from the blood to the tissues. Serum sodium appears low in a patient who is fluid overloaded because of dilution; diuresis improves the levels by decreasing the amount of water in the vascular space.

An ACE inhibitor is the first line of pharmacologic treatment for HF. As the stages progress, a beta-blocker or angiotensin receptor blocker may be added. In stages C and D selected patients also may take a diuretic, aldosterone antagonists, digitalis, and vasodilators (e.g., hydralazine). Basically these medications reduce excess fluid, dilate blood vessels, and increase the strength of the heart's contraction. Several of these medications have neurohormonal benefits along with their primary mechanism of action. For example, ACE inhibitors (e.g., captopril, enalapril) not only inhibit the RAS but also improve symptoms, quality of life, exercise tolerance, and survival. Similarly, spironolactone has diuretic and aldosterone-blocking functions that result in reduced morbidity and mortality in patients. Most of these medications can affect nutrition status (see Chapter 8).

Medical Nutrition Therapy

The RDN provides MNT, which includes assessment, a nutrition diagnosis, and interventions (education, counseling). As part of a multidisciplinary team (physician, pharmacist, psychologist, nurse, and social worker), the RDN positively affects patient outcomes. Reduced readmission to the hospital, fewer days in the hospital, improved compliance with restricted sodium and fluid intakes, and improved quality of life scores are the goals in HF patients.

Nutrition screening for HF in older adults can help prevent disease progression and improve disease management, overall health, and quality-of-life outcomes. The first step in screening is determination of body weight. Altered fluid balance complicates assessment of body weight in the patient with HF. Weights should be taken before eating and after voiding at the same time each day. A dry weight (weight without edema) should be determined on the scale at home. Patients should record daily weights and advise their care providers if weight gain exceeds more than 1 lb a day for patients with severe HF, more than 2 lb a day for patients with moderate HF, and more than 3 to 5 lb

with mild HF. Restricting sodium and fluids along with diuretic therapy is recommended to restore fluid balance.

Dietary assessments in HF patients reveal that more than half have malnutrition, usually related to the cardiac cachexia mentioned earlier. Negative energy balance and negative nitrogen balances can be noted. In overweight patients, caloric reduction must be monitored carefully to avoid excessive and rapid body protein catabolism. Nutrition education to promote behavior change is a critical component of MNT. The benefits of MNT should be communicated to patients.

The total diet must be addressed in patients with HF because underlying risk factors are often present; dietary changes to modify these risk factors are an important component of MNT. For dyslipidemia or atherosclerosis, a heart-healthy diet low in SFAs, trans fatty acids, and cholesterol and high in fiber, whole grains, fruits, and vegetables is recommended. For persons with hypertension, the DASH diet is recommended. Both of these dietary patterns emphasize lower-sodium foods and higher intake of potassium. Total energy expenditure is higher in HF patients because of the catabolic state; adequate protein and energy should be provided (*Academy of Nutrition and Dietetics, Evidence Analysis Library, 2017*).

Salt Restriction

Excessive sodium intake is associated with fluid retention and edema. A 2-g sodium restriction is regularly prescribed for patients with HF. The AND (2012) EAL recommends a 2-g sodium restriction but notes

that the evidence for this recommendation is only “fair.” The Heart Failure Society of America recommends 2 to 3 g of sodium daily unless severe symptoms are present, then the recommendation is for 2 g (*Gupta et al, 2012*). The updated AHA recommendation is for “moderate” sodium restriction. *Table 32.7* summarizes the recommendations from multiple organizations. The inconsistencies in the different organizations are due to the weak database of studies. Many have small sample sizes and many were not randomized trials. Three of the larger studies that were randomized had consistent results but showed that sodium restriction was associated with worse outcome (*Gupta et al, 2012*). It is hypothesized that this effect may be related to neurohormones including aldosterone, norepinephrine, and angiotensin II, all of which increased with dietary restriction. These hormones act to conserve fluid, thus trying to restore blood flow. Aldosterone promotes sodium reabsorption, and vasopressin promotes water conservation in the distal tubules of the nephron. This complex balance is further complicated by the medications used for HF.

Patient compliance with sodium restriction of 2 g/day has been shown to be poor. This can lead to generally inadequate nutritional intake that may be a contributing factor to poor outcomes associated with sodium restriction. A one-size-fits-all sodium restriction is not possible. The HF stage, amount of edema present, overall nutritional status, and medications must be taken into consideration. There is consensus that high sodium intake (above 3 g/day) is contraindicated for HF.

The degree of restriction depends on the individual (see *Focus On: Sodium and Salt Measurement Equivalents*).

TABLE 32.7 Dietary Sodium Intake in Heart Failure

Guideline	Year	Sodium/Fluid Restriction Recommendations	Level of Evidence
National Heart Foundation of Australia/Cardiac Society of Australia and New Zealand	2006	<3 g/day for NYHA class II without peripheral edema/ <2 g/day for NYHA class III and IV	C
		<2 L/day for all patients and <1.5 L/day during fluid retention episodes	
Heart Failure Society, India	2007	<2 g/day	Not stated
		<2 L/day	
European Society of Cardiology	2008	Moderate restriction 1.5-2 L/day in patients with severe symptoms and especially with hyponatremia	C
Canadian Cardiovascular Society	2008	<2 g/day	Not stated
		2 L/day	
American College of Cardiology/ American Heart Association	2009	Moderate restriction (≤ 2 g/day if volume overload, followed by fluid intake restriction to 2 L/day if fluid retention persists)	C
Royal College of Physicians	2010	Salt reduction Fluid restriction	Limited; further research required
Heart Failure Society of America	2010	2-3 g/day; <2 g/day may be considered in moderate to severe heart failure	C
		<2 L/day, if fluid retention persists and if severe hyponatremia (serum Na <130 mEq/L) is present	
Scottish Intercollegiate Guidelines Network	2010	<2.4 g/day tailored fluid restriction	1+
American Dietetic Association	2011	<2 g/day 1.4-1.9 L/day depending on clinical symptoms	Fair

Level of Evidence: C, Limited populations evaluated. Only consensus opinion of experts, case studies, or standard of care; Fair, Benefits exceed the harms but quality of evidence is not as strong; 1+, well-conducted meta-analysis, systemic reviews, or randomized controlled trials with low risk of bias.

FOCUS ON

Sodium and Salt Measurement Equivalents

Sodium chloride is approximately 40% (39.3%) sodium and 60% chloride. To convert a specified weight of sodium chloride to its sodium equivalent, multiply the weight by 0.393. Sodium also is measured in milliequivalents (mEq). To convert milligrams of sodium to mEq, divide by the atomic weight of 23. To convert sodium to sodium chloride (salt), multiply by 2.54. Millimoles (mmol) and milliequivalents (mEq) of sodium are the same. For example:

1 tsp of salt = approximately 6 g NaCl = 6096 mg NaCl
 $6096 \text{ mg NaCl} \times 0.393 = 2396 \text{ mg Na}$ (approximately 2400 mg)
 $2396 \text{ mg Na} / 23 = 104 \text{ mEq Na}$
 1 g Na = $1000 \text{ mg} / 23 = 43 \text{ mEq}$ or mmol
 1 tsp of salt = 2400 mg or 104 mEq Na

Adherence to sodium restrictions can be problematic for many individuals, and individualized instruction is recommended. Ethnic differences in sodium consumption must be considered. Some cultures have traditional diets that are very high in sodium such as Kosher and Asian diets. In some cases regional cooking, like in some areas in the southern United States, depends heavily on salt.

Positive outcomes (i.e., decreased urinary sodium excretion, less fatigue, less frequent edema) have been observed in HF patients receiving MNT. The type of sodium restriction prescribed should be the least restrictive diet that will achieve the desired results. The first step is to minimize or eliminate the use of table salt and high-sodium foods (Box 32.8) (see Appendix 46 for sodium content of foods).

Poor adherence to low-sodium diets occurs in part as a result of lack of knowledge about sodium and lower-sodium food choices by the patient, and perception that the diet interferes with the social aspects of eating. Lack of cooking skills or adequate cooking facilities is another obstacle because it leads patients to eat premade foods that tend to be high in salt. Memory loss, severe fatigue, and economic issues are all challenges to following a low-sodium diet. In addition, food labels, although informative, may be hard for many patients or their caregivers to comprehend (Box 32.9).

BOX 32.8 Top Ten Categories of High-Sodium Foods

1. Smoked, processed, or cured meats and fish (e.g., ham, bacon, corned beef, cold cuts, hot dogs, sausage, salt pork, chipped beef, pickled herring, anchovies, tuna, and sardines)
2. Tomato juices and tomato sauce, unless labeled otherwise
3. Meat extracts, bouillon cubes, meat sauces, MSG, and taco seasoning and other packaged seasonings
4. Salted snacks (potato chips, tortilla chips, corn chips, pretzels, salted nuts, popcorn, and crackers)
5. Prepared salad dressings, condiments, relishes, ketchup, Worcestershire sauce, barbecue sauce, cocktail sauce, teriyaki sauce, soy sauce, commercial salad dressings, salsa, pickles, olives, and sauerkraut
6. Packaged mixes for sauces, gravies, casseroles, and noodle, rice, or potato dishes; macaroni and cheese; stuffing mix
7. Cheeses (processed and cheese spreads)
8. Frozen entrees and pot pies
9. Canned soup
10. Foods eaten away from home

Note: Reading labels is most important; some brands are lower in sodium than others.
 MSG, Monosodium glutamate.

BOX 32.9 Food Labeling Guide for Sodium

Sodium-free	Less than 5 mg per standard serving; cannot contain any sodium chloride
Very low sodium	35 mg or less per standard serving
Low sodium	140 mg or less per standard serving
Reduced sodium	At least 25% less sodium per standard serving than in the regular food
Light in sodium	50% less sodium per standard serving than in the regular food
Unsalted, without added salt, or no salt added	No salt added during processing; the product it resembles is normally processed with salt
Lightly salted	50% less added sodium than is normally added; product must state "not a low-sodium food" if that criterion is not met

<https://www.labelcalc.com/nutrient-content-claims/low-sodium-nutrition-label-guidelines-for-your-food-product/>.

Alcohol

In excess, alcohol contributes to fluid intake and raises blood pressure. Many cardiologists recommend avoiding alcohol. Chronic alcohol ingestion may lead to cardiomyopathy and HF (Mirijello, 2017). Although heavy drinking should be discouraged, there is no evidence to support total abstinence from alcohol (AND, 2012). Quantity, drinking patterns, and genetic factors influence the relationship between alcohol consumption and HF (Djoussé and Gaziano, 2008). If alcohol is consumed, intake should not exceed one drink per day for women and two drinks per day for men. A drink is equivalent to 1 oz of alcohol (1 oz of distilled liquor), 5 oz of wine, or 12 oz of beer.

Caffeine

Until recently caffeine has been considered detrimental to patients with HF because it contributes to irregular heartbeats. However, a study in the Netherlands suggests that moderate intake of either tea or coffee reduces ASCVD risk; tea actually reduces ASCVD deaths (de Koning Gans et al, 2010). Researchers in the United States followed 130,054 men and women and found that those who reported drinking four or more cups of coffee each day had an 18% lower risk of hospitalization for heart rhythm disturbances. Those who reported drinking one to three cups each day had a 7% reduction in risk (Klatsky, 2010). The antioxidant effects of coffee and tea may be beneficial. A recently published randomized trial concluded that a high dose of caffeine did not induce arrhythmias in patients with systolic HF (Zuchinali, 2016).

Calcium

Patients with HF are at increased risk of developing osteoporosis because of low activity levels, impaired renal function, and prescription drugs that alter calcium metabolism (Zittermann et al, 2006). Cachectic HF patients have lower bone mineral density and lower calcium levels than HF patients without cachexia (Anker et al, 2006). Caution must be used with calcium supplements because they have been shown to be associated with adverse outcomes (Drozd et al, 2014).

L-Arginine

In patients with HF, decreased exercise capacity may be in part due to reduced peripheral blood flow related to impairment of endothelium-dependent vasodilation. L-Arginine is converted to NO, an endothelium-derived relaxing factor. At least four studies have shown some

benefit with supplementation. The studies were small, and more research is needed to establish clear recommendations.

Coenzyme Q₁₀

Some studies on the use of coenzyme Q₁₀ (CoQ₁₀) supplementation in HF patients showed positive outcome. Outcomes included significantly improved exercise tolerance, decreased symptoms, and improved quality of life. CoQ₁₀ levels are generally low in HF patients; it is postulated that repletion can prevent oxidative stress and further myocardial damage. A systematic review of 7 studies and over 900 patients on the use of CoQ₁₀ in HF patients concluded that the studies were too small and too diverse in study design to draw any useful conclusions (Madmani et al, 2014). Patients on statins (HMG-CoA reductase inhibitors) may have a different reason to consider supplementation. HMG-CoA reductase inhibitors are a class of cholesterol-lowering drugs that are known to interfere with synthesis of CoQ₁₀.

D-Ribose

D-ribose is a component of adenosine triphosphate (ATP) for cellular metabolism and energy production. Myocardial ischemia lowers cellular energy levels, integrity, and function. The failing heart is energy starved. D-ribose is being tested to correct this deficient cellular energy as a naturally occurring carbohydrate (Shectler et al, 2010). A recent prospective study that gave 6 weeks of D-ribose supplement was inconclusive in determining benefit (Bayram et al, 2015).

Energy

The energy needs of patients with HF depend on their current dry weight, activity restrictions, and the severity of the HF. Overweight patients with limited activity should be encouraged to maintain an appropriate weight that will not stress the myocardium. However, the nutrition status of the obese patient must be assessed to ensure that the patient is not malnourished. In patients with HF, energy needs are unclear. At least two studies found that standard energy equations used to determine calorie needs underestimated the needs of HF patients. Another study found lower calorie needs compared with healthy controls (AND, 2012). This area requires more research. Standard nutritional assessment should be employed with careful monitoring.

Fats

Fish consumption and fish oils rich in omega-3 fatty acids can lower elevated triglyceride levels and may prevent atrial fibrillation in HF patients (Roth and Harris, 2010). Intake of at least 1 g daily of omega-3 fatty acids from either oily fish or fish-oil supplements was used in the study. However, further studies are needed. Some evidence suggests that high saturated fat feeding in mild to moderate HF preserves contractile function and prevents the switch from fatty acid to glucose metabolism, thus serving a cardioprotective role (Chess et al, 2009; Christopher et al, 2010).

Meal Strategies

Patients with HF often tolerate small, frequent meals better than larger, infrequent meals because the latter are more tiring to consume, can contribute to abdominal distention, and markedly increase oxygen consumption. All these factors tax the already stressed heart. Caloric supplements can help to increase energy intake; however, this intervention may not reverse this form of malnutrition (Anker et al, 2006).

Folate, Vitamin B₆, and Vitamin B₁₂

High dietary intakes of folate and vitamin B₆ have been associated with reduced risk of mortality from HF and stroke in some populations

(Cui et al, 2010). However, deficiencies of vitamin B₁₂ and folate have been studied and found to be relatively rare in HF patients (van der Wal et al, 2015).

Magnesium

Magnesium deficiency is common in patients with HF as a result of poor dietary intake and the use of diuretics, including furosemide. As with potassium, the diuretics used to treat HF increase magnesium excretion. Magnesium deficiency aggravates changes in electrolyte concentration by causing a positive sodium and negative potassium balance. Because deficient magnesium status is associated with poorer prognosis, blood magnesium levels should be measured in HF patients and treated accordingly. Poor dietary intake of magnesium has been associated with elevated hs-CRP, a product of inflammation. Hypermagnesemia may be found in some cases of renal failure, HF, and high doses of furosemide.

Thiamin

Patients with HF are at risk for thiamin deficiency because of poor food intake; use of loop diuretics, which increases excretion; and advanced age. Thiamin is a required coenzyme in the energy-producing reactions that fuel myocardial contraction. Therefore thiamin deficiency can cause decreased energy and weaker heart contractions. Studies have shown thiamin deficiency to be associated with HF, in great part due to the effect of commonly used medications. Loop diuretics (e.g., furosemide) can deplete body thiamin and cause metabolic acidosis. Supplementation with thiamin has been shown to improve cardiac function, urine output, weight loss, and signs and symptoms of HF (DiNicolantonio et al, 2013). Thiamin deficiency is diagnosed using erythrocyte thiamin pyrophosphate. Thiamin status should be assessed in HF patients on loop diuretics and appropriate supplementation recommended if necessary. Thiamin supplementation (e.g., 100 mg/day) can improve left ventricular ejection fraction (fraction of blood pumped out of the ventricles with each heartbeat) and symptoms.

Vitamin D

Patients with a polymorphism of the vitamin D receptor gene have higher rates of bone loss than HF patients without this genotype. Vitamin D may improve inflammation in HF patients (Vieth and Kimball, 2006). In a double-blind, randomized, placebo-controlled trial, supplementation with vitamin D (50 mcg or 2000 international units of vitamin D₃ per day) for 9 months increased the antiinflammatory cytokine IL-10 and decreased the proinflammatory factors in HF patients (Schleithoff et al, 2006). As a steroid hormone, vitamin D regulates gene expression and inversely regulates renin secretion (Meems et al, 2011). With the recent study showing a relationship between vitamin D deficiency and the development of HF (Porto, 2018), the case for supplementation of vitamin D is now stronger.

CARDIAC TRANSPLANTATION

Cardiomyopathies represent a heterogeneous group of diseases that often lead to progressive HF; types include dilated cardiomyopathy, hypertrophic cardiomyopathy, restrictive cardiomyopathy, and arrhythmogenic right ventricular cardiomyopathy (Wexler et al, 2009). Cardiac transplantation is the only cure for refractory, end-stage HF. Because the number of donor hearts is limited, careful selection of recipients with consideration of the likelihood for adherence to lifelong therapeutic regimen and their quality of life is imperative. Nutrition support before and after transplantation is crucial to decrease morbidity and mortality. Thus the nutrition

care of the heart transplant patient can be divided into three phases: pretransplant, immediate posttransplant, and long-term posttransplant.

Pretransplant Medical Nutrition Therapy

A comprehensive nutrition assessment of the pretransplant patient should include a history, physical and anthropometric assessment, and biochemical testing. Recommended lifestyle changes before transplantation include restricting alcohol consumption, losing weight, exercising, quitting smoking, and eating a low-sodium diet (Wexler et al, 2009). Extremes in body weight (less than 80% or more than 140% of ideal body weight) increase the patient's risk for infection, diabetes, morbidity, and higher mortality. Pretransplant comorbidities such as hyperlipidemia and hypertension also reduce survival rates. If oral intake is inadequate, an enteral feeding should be tailored to the nutritional and comorbid conditions of the patient.

Immediate Posttransplant Nutrition Support

Nutrition guidelines are consistent for all types of organ transplants and not specific just to heart transplants (Table 32.8). The nutritional goals in the acute posttransplant patient are to (1) provide adequate protein and calories to treat catabolism and promote healing, (2) monitor and correct electrolyte abnormalities, and (3) achieve optimal blood glucose control (Hasse, 2015). In the immediate post-transplant period nutrient needs are increased, as is the case after any major surgery. Protein needs are increased because of steroid-induced catabolism, surgical stress, anabolism, and wound healing.

Patients progress from clear liquids to a soft diet given in small, frequent feedings. Enteral feeding may be appropriate in the short

term, especially if complications arise. Nutrient intake is often maintained by using liquid supplements and foods of high caloric density, especially in patients with poor appetite. Weight gain to an ideal weight is the nutritional goal for patients who were cachectic before transplant. The increase in cardiac function helps to halt the presurgical cachectic state. Hyperglycemia can be exacerbated by the stress of the surgery and the immunosuppressive drug regimen. Dietary adjustments can be made to aid in glucose control (see Table 32.8).

Long-Term Posttransplant Nutrition Support

Comorbid conditions that often occur after transplantation include hypertension, excessive weight gain, hyperlipidemia, osteoporosis, and infection. Hypertension is managed by diet, exercise, and medications. Minimizing excessive weight gain is important because patients who become obese after transplantation are at higher risk for rejection and lower rates of survival.

Increases in total LDL cholesterol and triglycerides are a consequence of immunosuppressive drug therapy and increase the risk of HF after transplantation. Along with a heart-healthy diet, patients also need a lipid-lowering drug regimen to normalize blood lipids. Statins are recommended in the early and long-term postoperative periods. Because of their LDL-lowering effect, stanols or sterols may be helpful to reduce statin dosages (Goldberg et al, 2006).

Before transplantation, patients are likely to have osteopenia because of their lack of activity and cardiac cachexia. After transplantation, patients are susceptible to steroid-induced osteoporosis. Patients require optimal calcium and vitamin D intake to slow bone loss; weight-bearing exercise and antiresorptive drug therapy are often necessary. Infection must be avoided because of the necessity of lifelong use of immunosuppressive drugs. Food safety should be discussed.

TABLE 32.8 Posttransplant Nutrient Recommendations

Nutrient	Short-Term Recommendations	Long-Term Recommendations
Calories	120%-140% of BEE (30-35 kcal/kg) or measure REE	Maintenance: 120%-130% BEE (20-30 kcal/kg) depending on activity level
Protein	1.3-2 g/kg/day	1 g/kg/day
Carbohydrate	~50% of calories Restrict simple sugars if glucose level elevated	~50% of calories Restrict simple sugars and encourage high-fiber complex carbohydrate choices
Fat	30% of calories (or higher with severe hyperglycemia)	≤30% of total calories <10% of calories as saturated fat
Calcium	1200 mg/day	1200-1500 mg/day (consider the need for estrogen or vitamin D supplements)
Sodium	2 g/day	2 g/day
Magnesium and phosphorus	Encourage intake of foods high in these nutrients Supplement as needed	Encourage intake of foods high in these nutrients Supplement as needed
Potassium	Supplement or restrict based on serum potassium levels	Supplement or restrict based on serum potassium levels
Other vitamins and minerals	Multivitamin/mineral—supplement to RDI levels May need additional supplements to replete suspected or confirmed deficiencies	Multivitamin/mineral—supplement to RDI levels May need additional supplements to replete suspected or confirmed deficiencies
Other	Avoid complementary or alternative products without proven safety and effectiveness in transplant patients	Avoid complementary or alternative products without proven safety and effectiveness in transplant patients

BEE, Basal energy expenditure; RDI, reference daily intake; REE, resting energy expenditure.

CLINICAL CASE STUDY

Tom is a 55-year-old single white man with hypertension (blood pressure 145/92 mmHg), high low-density lipoprotein cholesterol (241 mg/dL), and low high-density lipoprotein cholesterol (38 mg/dL) and a C-reactive protein (CRP) of 4mg/L. He has a strong family history of heart disease. He reports that he often eats in his car, so he frequents fast-food restaurants. He works long hours and, other than gardening on the weekends, he does not exercise. He is 5'10" and 220 lb with a BMI of 31.6. His breakfast is usually a cheese-egg biscuit, bacon, and coffee with milk or cream. Lunch is often a bean and cheese burrito and ice cream. His favorite dinner is fried chicken, mashed potatoes with gravy, collards sautéed with bacon fat, and pie.

Nutrition Diagnostic Statements

- Intake of types of fats inconsistent with needs (saturated fat) (NI-5.5.3) related to eating fast food on the run and busy schedule as evidenced by

unfavorable cholesterol profile (elevated LDL and low HDL) and regular consumption of fried foods, bacon and full fat dairy.

- Excessive mineral intake (sodium) (NI-5.10.7) related to frequent fast food consumption as evidenced by elevated blood pressure of 145.92 mmHg.
- Overweight/Obesity (NC-3.3) related to physical inactivity and consuming large portions of kcal dense foods as evidenced by BMI of 31.6 and frequent eating in fast food restaurants.

Nutrition Care Questions

1. What additional nutrition diagnoses would be appropriate for Tom?
2. What more would you want to know about Tom's diet and lifestyle to help him with health behavior change?
3. What is the significance of a CRP level of 4 mg/dL?
4. What nutrition and lifestyle interventions would be most helpful for Tom?

acinar	cor pulmonale	obstructive sleep apnea (OSA)
acinus	cyanosis	osteopenia
acute respiratory distress syndrome (ARDS)	cystic fibrosis (CF)	pancreatic enzyme replacement therapy (PERT)
adiponectin	cystic fibrosis related diabetes (CFRD)	pancreatic insufficiency (PI)
asthma	distal intestinal obstruction syndrome (DIOS)	pleural effusion
aspiration pneumonia	dyspnea	pneumonia
bronchiectasis	elastase	pulmonary cachexia
bronchogenic carcinomas	emphysema	pulmonary function tests
bronchopulmonary dysplasia (BPD)	ghrelin	pulmonary hypertension (PH)
cancer cachexia syndrome	hypercapnia	pulse oximetry
chronic bronchitis	hypopnea	resistin
chronic obstructive pulmonary disease (COPD)	idiopathic pulmonary fibrosis	resolvin
cilia	interstitial lung disease (ILD)	spirometry
chylothorax	interstitial pulmonary fibrosis	steatorrhea
clubbing	kyphosis	surfactant
continuous positive airway pressure (CPAP)	leptin	tachypnea
	obesity hypoventilation syndrome (OHS)	tuberculosis (TB)

Optimal nutrition supports the development, growth, and maintenance of the respiratory organs, supporting structures of the skeleton and muscles and related nervous, circulatory, and immunologic systems. A well-functioning pulmonary system enables the body to obtain the oxygen needed to meet its cellular demands for energy from macronutrients and to remove carbon dioxide as a byproduct of metabolism.

THE PULMONARY SYSTEM

The respiratory structures include the nose, pharynx, larynx, trachea, bronchi, bronchioles, alveolar ducts, and alveoli. Supporting structures include the skeleton and the muscles (e.g., the intercostal, abdominal, and diaphragm muscles). Within a month after conception, pulmonary structures are recognizable. The pulmonary system grows and

matures during gestation and childhood until it reaches full maturity and alveoli density at about 20 years of age. As aging occurs, the lungs lose elasticity and functional capacity declines.

The primary function of the respiratory system is gas exchange, and the anatomy and physiology is geared to fulfill this function (Fig. 33.1). The lungs enable the body to obtain the oxygen needed to meet its cellular metabolic demands and to remove the carbon dioxide (CO₂) produced. Healthy nerves, and efficient blood and lymph circulation are needed to supply oxygen and nutrients to all tissues. The lungs also filter, warm, and humidify inspired air.

The respiratory center is the name for structures involved in the generation of rhythmic respiratory movements and reflexes and is located in the medulla and pons (see Fig. 39.2 in Chapter 39). The electrical impulses generated by the respiratory center are carried by the phrenic nerves to the diaphragm and other respiratory muscles. Contraction of diaphragm and other muscles increases the intrathoracic volume, which creates negative intrathoracic pressure and allows air to be sucked in. The air traverses through the upper airways into the lower airways (see Fig. 33.1, A) and reaches the alveoli (see Fig. 33.1, B). The alveoli are surrounded by capillaries where gas exchange takes

Portions of this chapter were written by Sameera H. Kahn and Ashok M. Karnik.

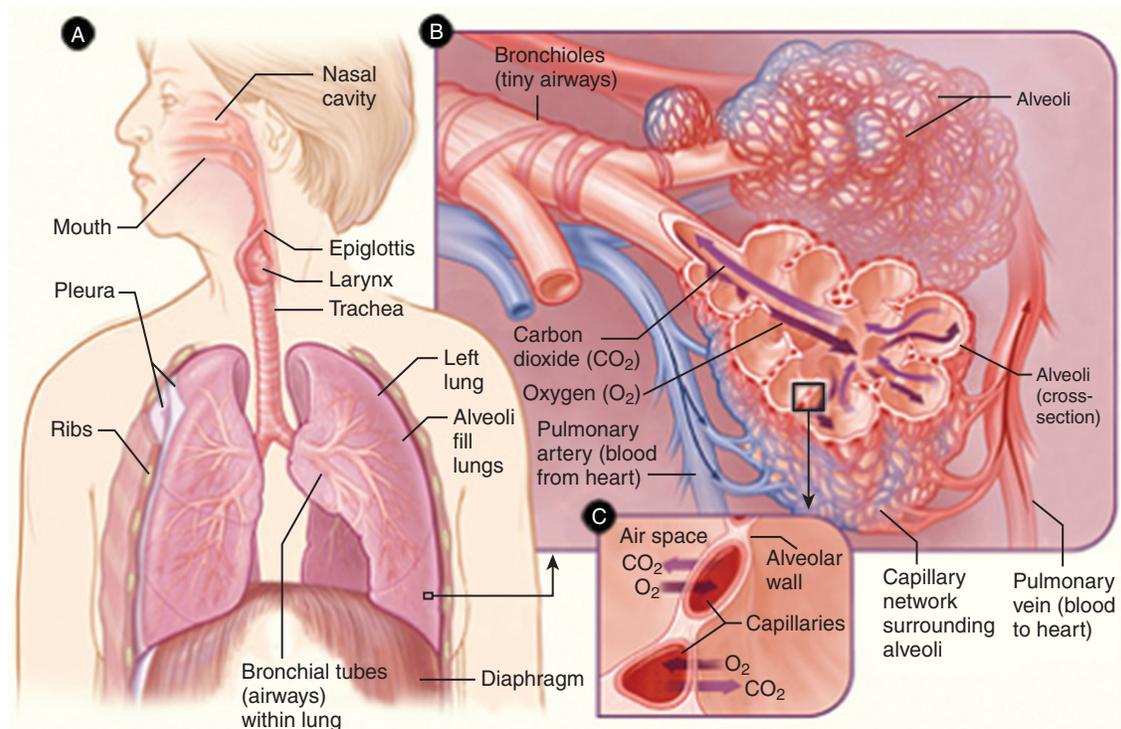

Fig. 33.1 Functional anatomy and physiology of the respiratory system. **A**, Various parts of respiratory system. **B**, Gas exchange unit. **C**, Alveolar-capillary interface. National Heart, Lung, and Blood Institute; National Institutes of Health; U.S. Department of Health and Human Services.

place (see Fig. 33.1, C). The pulmonary artery carries blood from the right ventricle of the heart into the small capillaries where gas exchange takes place with the alveoli; oxygenated blood returns back through the pulmonary veins into the left atrium of the heart to be delivered into the rest of the body. The large pulmonary blood vessels and the conducting airways are located in a well-defined connective tissue compartment—the pleural cavity.

The lungs are an important part of the body's immune system, because inspired air is laden with particles and microorganisms. Mucus keeps the airways moist and traps the particles and microorganisms from inspired air. The airways have 12 types of epithelial cells, and most cells that line the trachea, bronchi, and bronchioles have **cilia**. The cilia are “hair-like” structures that move the superficial liquid lining layer from deep within the lungs toward the pharynx to enter the gastrointestinal tract, thereby playing an important role as a lung defense mechanism by clearing bacteria and other foreign bodies. Each time a person swallows, microorganism-containing mucus passes into the digestive tract, in addition to the food. When inhaled bacteria or food particles are not cleared effectively, the patient is prone to develop recurrent chest infections that may eventually lead to bronchiectasis. The epithelial surface of the alveoli contains macrophages. By the process of phagocytosis, these alveolar macrophages engulf inhaled inert materials and microorganisms and digest them. The alveolar cells also secrete **surfactant**, a compound synthesized from proteins and phospholipids that maintains the stability of pulmonary tissue by reducing the surface tension of fluids that coat the lung.

The lungs have several metabolic functions. For example, they help regulate the body's acid-base balance (see Chapter 3). The body's pH is maintained partially by the proper balance of CO_2 and oxygen (O_2). The lungs also synthesize arachidonic acid that ultimately may be converted to prostaglandins or leukotrienes. These appear to play a role in

bronchoconstriction seen in asthma. The lungs convert angiotensin I to angiotensin II by the angiotensin-converting enzyme (ACE) found mainly in the numerous capillary beds of the lungs. Angiotensin II increases blood pressure. Because of the ultrastructure and the fact that they receive the total cardiac output, lungs are well suited to function as a chemical filter. They protect the systemic circulation from exposure to high levels of circulating vasoactive substances. Although serotonin, 5-hydroxytryptamine (5-HT), and norepinephrine are totally or partially eliminated or inactivated in the pulmonary circulation, epinephrine and histamines pass through the lungs unchanged.

Effect of Malnutrition on the Pulmonary System

The relationship between malnutrition and respiratory disease has long been recognized. Malnutrition adversely affects lung structure, elasticity, and function; respiratory muscle mass, strength, and endurance; lung immune defense mechanisms; and control of breathing. For example protein and iron deficiencies result in low hemoglobin levels that diminish the oxygen-carrying capacity of the blood. Low levels of calcium, magnesium, phosphorus, and potassium compromise respiratory muscle function at the cellular level. Hypoalbuminemia, as measured by serum albumin, contributes to the development of pulmonary edema by decreasing colloid osmotic pressure, allowing body fluids to move into the interstitial space. Decreased levels of surfactant contribute to the collapse of alveoli, thereby increasing the work of breathing. The supporting connective tissue of the lungs is composed of collagen, which requires ascorbic acid for its synthesis. Normal airway mucus is a substance consisting of water, glycoproteins, and electrolytes, and thus requires adequate nutritional intake.

Effect of Pulmonary Disease on Nutritional Status

Pulmonary disease substantially increases energy requirements. This factor explains the rationale for including body composition and

BOX 33.1 Adverse Effects of Lung Disease on Nutrition Status

Increased Energy Expenditure

Increased work of breathing
Chronic infection
Medical treatments (e.g., bronchodilators, chest physical therapy)

Reduced Intake

Fluid restriction
Shortness of breath
Decreased oxygen saturation while eating
Anorexia resulting from chronic disease
Gastrointestinal distress and vomiting

Additional Limitations

Difficulty preparing food because of fatigue
Impaired feeding skills (for infants and children)
Altered metabolism
Food-drug interactions

weight parameters in nutrition assessment. Weight loss from inadequate energy intake is significantly correlated with a poor prognosis in persons with pulmonary diseases. Malnutrition leading to impaired immunity places any patient at high risk for developing respiratory infections. Malnourished patients with pulmonary disease who are hospitalized are likely to have lengthy stays and are susceptible to increased morbidity and mortality compared with well-nourished patients.

The complications of pulmonary diseases or their treatments can make adequate food intake and digestion difficult. For example, patients who are unable to breathe well will find it tiring to prepare food or to eat. Absorption and metabolism of most nutrients are affected. As pulmonary disease progresses, several conditions may interfere with food intake and overall nutrition status. For example, abnormal production of sputum, vomiting, **tachypnea** (rapid breathing), hemoptysis, thoracic pain, nasal polyps, anemia, depression, and altered taste secondary to medications are often present. Weight loss, low body mass index (BMI), and other adverse effects are listed in [Box 33.1](#).

Medical Management

Pulmonary system disorders may be categorized as primary, such as tuberculosis (TB), asthma, and lung cancer; or secondary when associated with cardiovascular disease, obesity, infection, sickle cell disease, or scoliosis. Conditions also may be acute or chronic. Examples of acute conditions include aspiration pneumonia, airway obstruction from foods such as peanuts, and allergic anaphylaxis from consumption of shellfish. Examples of chronic conditions include cystic fibrosis (CF) and chronic obstructive pulmonary disease (COPD).

The assessment of the pulmonary status starts with obtaining a thorough history with a focus on the social history such as smoking and other inhalational toxins as well as exposure history. Typical symptoms of pulmonary disorders include **dyspnea** (shortness of breath), cough, sputum production, chest discomfort, fatigue, early satiety, and weight loss. The pulmonary assessment continues with percussion and auscultation. These bedside techniques provide important information on the patient's breathing.

Numerous diagnostic and monitoring tests such as imaging procedures, arterial blood gas determinations, sputum cultures, and

Fig. 33.2 Pulse oximeter.

biopsies also can be employed. **Pulmonary function tests** are used to diagnose or monitor the status of lung disease; they are designed to measure the ability of the respiratory system to exchange O_2 and CO_2 . **Pulse oximetry** is one such test. A small device called a pulse oximeter, which uses light waves to measure the O_2 saturation of arterial blood, is placed on the end of the finger ([Fig. 33.2](#)). Normal for a young, healthy person is 95% to 99%. **Spirometry** is another common pulmonary function test. This involves breathing into a spirometer that gives information on lung volume and the rate at which air can be inhaled and exhaled.

CHRONIC PULMONARY DISEASE

Cystic Fibrosis

Cystic fibrosis (CF) is a life-threatening autosomal recessive inherited disorder that is most commonly seen in white populations with a CF incidence of 1 out of 3000 babies born in the United States ([Cystic Fibrosis Foundation, 2016](#)). According to the Cystic Fibrosis Foundation 2016 Patient Registry, 29,497 persons have CF. CF is caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) protein, a complex chloride channel and regulatory protein found in all exocrine tissues. The function of CFTR is to regulate the passage of chloride, sodium, and bicarbonate in the epithelial cells. Due to absent or abnormal CFTR in CF, the decreased secretion of chloride and water and increased reabsorption of sodium result in the production of thick, viscous secretions in the lungs, pancreas, liver, intestines, and reproductive tract, and lead to increased salt content in the sweat gland secretions. Most of the clinical manifestations are related to the thick, viscous secretions ([Fig. 33.3](#)). Lung disease and malnutrition are predominant consequences of the disease.

In the past, most patients were diagnosed with CF because of symptoms related to various organ systems. All 50 states now provide newborn screening for CF in the first 2 to 3 days of life, with the majority of cases diagnosed by 1 month of age. Screening consists of using a neonatal blood spot to determine the concentration of immunoreactive trypsinogen; if it is elevated, then genetic analysis and sweat chloride tests are completed to confirm the diagnosis. The diagnosis of CF in persons other than neonates who have a clinical history consistent with the disease or have a sibling with CF, is determined by an abnormal sweat chloride test (chloride level in sweat >60 mmol/L). If the chloride sweat test is abnormal, genetic analysis is used to confirm the diagnosis and the CFTR mutation ([Katkin, 2014](#)). Abnormal sweat chloride tests can occur with malnutrition and adrenal insufficiency.

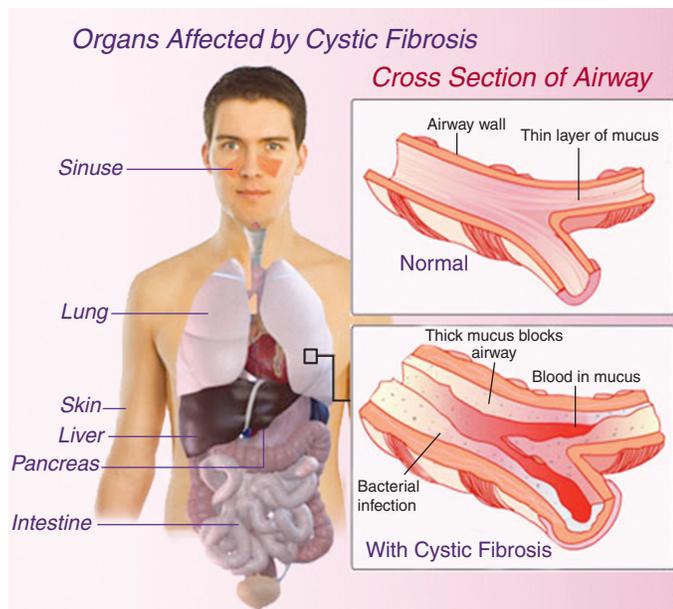

Fig. 33.3 Illustration showing multisystem involvement in cystic fibrosis (CF) and tenacious secretions.

Pathophysiology

Pulmonary and Sinus Disease

Due to the difficulty of expelling thick and viscous mucus in the respiratory tract, CF patients present with chronic persistent cough, dyspnea, and wheezing. Thick and viscous mucus is considered a rich environment for bacteria to grow, leading to a form of obstructive airway disease, **bronchiectasis**, a chronic condition of dilatation of the bronchi that develops as a result of recurrent lung infections. Examination of a patient with bronchiectasis may show presence of **clubbing**. Digital clubbing is characterized by increased digital tip mass and increased longitudinal and transverse nail plate curvature (Fig. 33.4), and lung auscultation reveals diffuse coarse crackles in the lungs and decreased breath sounds. Chest radiograph may show hyperinflation in advanced disease, and a computed tomography (CT) scan may show cystic and nodular densities, the classical picture of cystic bronchiectasis (Fig. 33.5). Pulmonary function testing shows

Fig. 33.4 Illustration of clubbing in a patient with “yellow nail syndrome.”

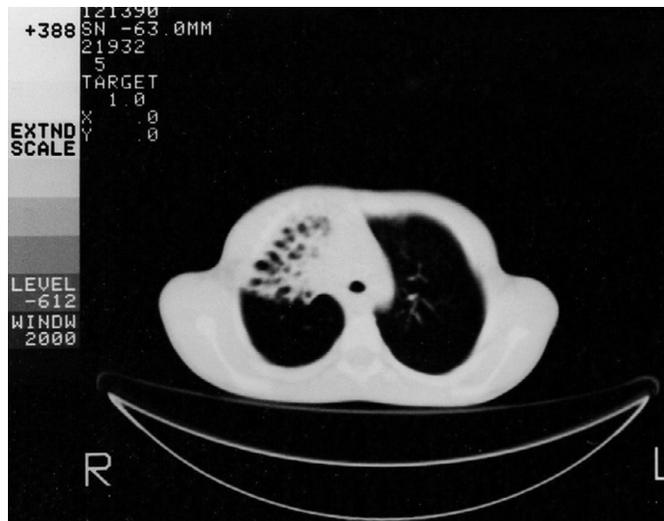

Fig. 33.5 Computed tomography (CT) scan of a patient showing cystic changes of bronchiectasis in right upper lobe.

airway obstruction. The spirogram shows reduced forced vital capacity (FVC), known as “restrictive pattern.” The reduced forced expiratory volume (FEV_1) and the reduced FEV_1/FVC ratio are suggestive of airway obstruction.

Sputum cultures are used to identify bacteria growing in the respiratory tract in CF patients. Most common bacteria in CF patients are *Staphylococcus aureus* and *Pseudomonas aeruginosa*, which colonize the airways frequently. Evidence exists that these bacteria play an important role in disease progression. Many children with CF develop chronic rhinosinusitis with nasal polyposis. Some questions remain unanswered as to the origin of polyps in CF patients.

Pancreatic Disease in Cystic Fibrosis

Several different types of pancreatic disease occur in CF patients.

Pancreatic insufficiency. **Pancreatic insufficiency (PI)**, in which the pancreas fails to make adequate enzymes to digest food in the small intestine, is the most common gastrointestinal complication of CF, affecting approximately 90% of patients at some time in their lives (Rogers, 2013).

Up to 90% of patients exhibit fat malabsorption by 1 year of age. The production of pancreatic enzymes is decreased, which leads to the malabsorption of fats and steatorrhea. **Steatorrhea** is characterized by foul smelling, bulky, oily stools and failure to thrive or poor weight gain. Such patients may also present with clinical features of deficiency of the fat-soluble vitamins A, D, E, and K. The CF population frequently presents with suboptimal vitamin D status. CF patients also suffer from vitamin K deficiencies and need routine supplementation.

Pancreatitis. The abnormal pancreatic secretions cause progressive pancreatic damage, so these patients can present with acute or recurrent pancreatitis.

CF-related diabetes. Patients with exocrine PI also may develop impaired function of the endocrine pancreas, leading to the development of **cystic fibrosis related diabetes (CFRD)**. It is the most common comorbidity in the CF population, occurring in 20% of the adolescents and 40% to 50% of the adults with CF. CFRD is associated with poor growth, clinical and nutritional deterioration, and early death. The American Diabetes Association and the Cystic Fibrosis Foundation recommend yearly CFRD screenings, starting at age 10

(see Chapter 29 for discussion of diabetes management), to be performed using a 2-hour 75 mg oral glucose tolerance test during a period of stable health. The use of hemoglobin A1C is not recommended for screening because it has low sensitivity in CFRD (Moran et al, 2010). Hemoglobin A1C is often normal in patients with CFRD regardless of the degree of hyperglycemia. However, if it is already measured and the value is >6.5 , this is still consistent with a diagnosis of CFRD.

Bone Disease

Due to vitamin D deficiency, bone disease is common in CF patients and is characterized by increased fracture rates, low bone density, and **kyphosis**, which is increased curvature of the upper back. Multiple risk factors contribute to developing bone disease—chronic corticosteroid use; multiple courses of antibiotics; failure to thrive; malabsorption of calcium, vitamin D, vitamin K, and magnesium; inadequate overall intake; and reduced weight-bearing activities. Obtaining and monitoring serum 25-hydroxy vitamin D level should be done yearly.

Other Conditions

Meconium ileus, rectal prolapse, biliary disease, infertility, musculoskeletal disorders, and recurrent venous thrombosis are other less common conditions that occur in patients with CF. Meconium ileus is an obstruction of the small intestine caused by thickened meconium (first feces) that can occur in neonates with CF. CF patients are susceptible to small intestine bacterial overgrowth due to decreased motility. This disorder interferes with fat absorption and appetite and can lead to multiple food intolerances and digestive disturbances (Baker et al, 2013) (see Chapter 27).

Medical Management

CF is a multisystem disease that requires a multidisciplinary approach to manage symptoms, correct deficiencies, and prevent complications and progression of the disease. The CF team usually includes medical and nursing staff; respiratory therapists, physical therapists, registered dietitian nutritionists; social workers; and genetic counselors. Impairment of the respiratory and gastrointestinal systems is responsible for significant mortality and morbidity. Sinus infection, glucose control, nutritional status, and psychosocial issues must be assessed and managed at regular intervals (Fig. 33.6).

CF management is usually separated into chronic maintenance therapy and acute exacerbation of the disease. Chronic therapy focuses on prevention and treatment of airway infections and obstructions as CF patients are prone to recurrent chest infections. Medical management consists of chest physiotherapy, nebulizer therapy, antiinflammatory agents, pulmonary hygiene, pneumococcal and influenza vaccinations, and, frequently, chronic prophylactic antibiotic use. A major step forward in the treatment of CF came in 2011 with the invention of a medication that targets the correction of the mutant CFTR function, Ivacaftor (VX-770). It is a small molecular weight oral drug that is designed specifically to treat patients who have a G551D mutation in at least one of their CFTR genes. Ivacaftor is the first approved CF therapy that restores the functioning of a mutant CF protein rather than trying to target one or more of its downstream consequences (Davis, 2011). In clinical trials, it was found to improve respiratory status, reduce pulmonary exacerbations, enhance quality of life, and promote weight gain. Currently, other drugs are coming onto the market that target the mutant CFTR function. If the CF patient continues to decline despite medical therapy, bilateral lung transplantation may be needed. The acute management of CF sometimes requires

hospitalization, usually to treat an infection with intravenous antibiotics and more frequent pulmonary hygiene.

Because of the PI, **pancreatic enzyme replacement therapy (PERT)** is an important component of the management for CF patients to adequately absorb carbohydrates, protein, and fat. The pancreatic ducts are obstructed in approximately 85% to 90% of CF individuals, and this prevents pancreatic enzymes such as lipase, amylase, and protease from secreting into the small intestine. The build-up of these enzymes in the pancreas leads to auto digestion of the pancreas and destruction of acinus. Pancreatic **acinus** is the secretory unit of exocrine pancreas, where pancreatic juice is produced. Destruction of pancreatic acinus, or **acinar** destruction, results in impaired secretion of pancreatic juice, which results in loose, oily, frequent stools and malabsorption. These individuals need PERT to combat the PI and maintain adequate absorption and digestion of nutrients (see *Focus On: PERT*).

FOCUS ON

PERT

Pancreatic enzyme replacement therapy (PERT) is the first step taken to correct maldigestion and malabsorption. The microspheres, designed to withstand the acidic environment of the stomach, release enzymes in the duodenum, where they digest protein, fat, and carbohydrate. Pharmaceutical advancements have improved the medications. The quantity of enzymes to be taken with food depends on the degree of pancreatic insufficiency; the quantity of food eaten; the fat, protein, and carbohydrate content of food consumed; and the type of enzymes used.

Enzyme dosage per meal or snack is adjusted empirically to control gastrointestinal symptoms, including steatorrhea, and to promote growth appropriate for age. Following the manufacturer's directions about storage and administration of a particular brand of enzyme is important to emphasize. If gastrointestinal symptoms cannot be controlled, enzyme dosage, patient adherence, and enzyme type should be reevaluated. Fecal **elastase** (protein-digesting enzyme secreted by the pancreas and involved in hydrolysis of peptide bonds), fecal fat, or nitrogen balance studies may help to evaluate the adequacy of enzyme supplementation.

The acidic environment of the stomach does not allow the enzymes of the enteric coated PERT to be degraded. This normally occurs once the pH is above 5.5, usually when the PERT reaches the duodenal jejunum. A common practice is placing cystic fibrosis (CF) patients on proton pump inhibitors in order to increase the duodenal pH by decreasing gastric acid secretion (Rogers, 2013).

Intestinal abnormalities such as gastroesophageal reflux disease (GERD), meconium ileus (MI), and **distal intestinal obstruction syndrome (DIOS)**, which is the blockage of intestines resulting from stool and intussusceptions (obstructions), are some of the complications seen in patients (Katkin, 2014).

Hepatobiliary problems are seen more commonly now in this population because of an increased survival rate. In the liver, the cystic fibrosis transmembrane conductance regulator (CFTR) is located in the biliary epithelium. Bile produced in patients with CF is thick and tenacious, causing blockage of the intrahepatic bile ducts. Blockage of these ducts eventually leads to cirrhosis. Use of ursodeoxycholic acid (UDCA) may delay the progression of liver disease (Kappler et al, 2012) (see Chapter 28); however, a recent Cochrane Review found little evidence to support routine use of UDCA, citing the small number of trials assessing its effectiveness (Cheng et al, 2017). At this time, there is little evidence-based research for the prevention and management of liver disease in persons with CF (Palanippan et al, 2017).

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Cystic Fibrosis

ETIOLOGY

Autosomal recessive inheritance

Cystic Fibrosis Gene
Cystic fibrosis transmembrane receptor (CFTR)

PATHOPHYSIOLOGY

Cystic Fibrosis (CF)

Obstruction of Glands and Ducts

- Secretion of abnormally thick, tenacious mucus by exocrine glands

Affected Organs

- Respiratory organs
- Pancreas; gallbladder, liver
- Reproductive organs
- Sweat glands
- Salivary glands
- Intestines

Physical Growth

- Short stature
- Low body weight (children and adults)
- Low muscle mass
- Malabsorption

MANAGEMENT

Medical Management

- Genotyping
- Oral or IV antibiotics
- Aerosol antibiotics
- Inhaled medications
- Chest and physical therapy

Nutrition Management

- Monitor ongoing nutrition status and support maintenance of lean body mass
- Supply pancreatic enzyme replacement therapy (PERT)
- Meet increased energy requirements
- Provide vitamin and mineral supplementation due to malabsorption

Fig. 33.6 Algorithm for diagnosis and management of cystic fibrosis.

Medical Nutrition Therapy

Medical nutrition therapy (MNT), critical to management of CF and all of its comorbidities, is vital in promoting longevity and positive outcomes. MNT begins with evaluation of the nutritional status of the patient (Baker et al, 2013) (see Chapters 4 and 5). CF patients frequently have growth failure, the cause of which is multifactorial: malabsorption, increased energy needs, and reduced appetite. Nutritional status is closely correlated to pulmonary function and survival in CF. As a result, close attention to growth status in children should be monitored; clinical care guidelines for infants and preschoolers have been published (Borowitz et al, 2009; Lahiri et al, 2016). All patients with CF should have regular nutritional assessments for early detection of nutritional status deterioration (see *Pathophysiology and Care Management Algorithm: Cystic Fibrosis*). Older children should be evaluated for bone density, using the dual-energy x-ray absorptiometry (DEXA) (see Chapter 23).

CF is typically associated with malnutrition; however, the number of overweight and obese patients has also increased in this population, raising concern for the effect of excess energy intake on lung function. Dietary recommendations should emphasize a balanced healthy diet with good exercise habits.

Major goals of nutritional therapy are increasing muscle strength, promoting optimal growth and weight maintenance, and enhancing the quality of life. To achieve these goals, the objectives of treatment are to correct maldigestion and malabsorption and to provide nutrients that are commonly deficient.

Energy. Evidenced-based nutrition goals for individuals with CF are based on the Cystic Fibrosis Foundation registry data analysis for age and sex:

- Newborn to 24 months: weight/length \geq 50th percentile, using Centers for Disease Control and Prevention (CDC) growth charts
- 2 to 20 years old: BMI 50th to 85th percentile, using CDC growth charts
- Adult females: BMI 22 to 27 kg/m²
- Adult males: BMI 23 to 27 mg/km²

These weight goals are associated with a desirable pulmonary function.

A broad range of energy requirements are reported in patients with CF, ranging from 120% to 150% of recommendations for the general population, depending on the CF mutation, the patient's age, degree of malabsorption, presence of pulmonary exacerbation, pulmonary function, sex, pubertal status, presence of additional medical complications (CFRD, CF liver disease), and the current state of health (Schindler et al, 2015).

A challenging issue is attaining an adequate energy intake with an energy dense diet. The determination to initiate enteral feedings is individualized for those who are unable to consume adequate calories and protein to meet growth/weight maintenance goals or those with moderate or severe malnutrition (Schwarzenberg, 2016). Tube feeding options include gastrostomy tube, nasogastric tube, and jejunostomy tube. The most common delivery option is the percutaneous endoscopic gastrostomy (PEG) tube (see Chapter 12). Appropriate PERT management should be maintained with general guidelines based on fat grams provided. If the patient is eating, PERT can be administered orally. For those who are not taking anything by mouth, PERT may be crushed (depending on the type of PERT), dissolved in a sodium bicarbonate solution, and then administered as an enteral medication. Recently a digestive enzyme cartridge became available that attaches to feeding tube sets, which simplifies PERT administration.

Vitamins and minerals. In CF patients, liver disease and pancreatic dysfunction lead to fat malabsorption, which predisposes these patients to deficiencies of fat-soluble vitamins A, D, E, and K and some minerals even with PERT use. Vitamin levels should be assessed at diagnosis (except the newborn) and supplemented as indicated. CF-specific vitamins contain fat and water-soluble vitamins as well as zinc to enhance absorption. Deficiencies of vitamins A, D, E, and K, which significantly affect CF patients, reduce their response to pulmonary infections.

Because bone disease is common in patients with CF and progresses with age (Rana et al, 2014), the Cystic Fibrosis Foundation recommends patients be treated with cholecalciferol (D₃). A daily vitamin D dosage of 1500 to 2000 IU is suggested by the Endocrine Society with dosages increasing to 10,000 IU daily for CF patients 18 or older (Rogers, 2013).

It is also recommended that the CF patient be supplemented with vitamin K. Taking at least 1000 mcg/day was found to achieve an optimal status of vitamin K (Rogers, 2013).

Fat-soluble vitamin testing is important in the identification of deficiencies in CF patients with PI. Fat-soluble vitamins are supplemented routinely and annually monitored. Patients may be noncompliant with vitamin supplementation or require higher dosages (Rana et al, 2014).

Salt. Excessive sodium loss in perspiration in patients with CF predisposes them to hyponatremic dehydration under conditions of heat stress. Most patients need supplementation of sodium chloride starting in infancy. The amount of salt supplementation should be increased under circumstances such as high temperature and humidity; a dry, desert climate; strenuous exercise in hot weather; excessive sweating; fever; and presence of diarrhea or vomiting.

Zinc. Additional zinc is recommended if a deficiency is suspected in patients with an unexplained decline in growth or appetite or those with prolonged diarrhea (Schindler et al, 2015).

ASTHMA

Asthma is a chronic disorder that affects the airways and is characterized by bronchial hyper-reactivity, reversible airflow obstruction, and airway remodeling. Asthmatic symptoms include periodic episodes of chest tightness, breathlessness, and wheezing. Asthma has become more prevalent and has been increasing at the rate of 25% to 75% every decade since 1960 in westernized countries (Allan and Devereux, 2011). It affects all age groups.

Pathophysiology

Asthma is the result of a complex interaction between environmental exposures and genetics. When people are genetically susceptible, environmental factors exacerbate airway hyper-responsiveness, airway inflammation, and atopy (tendency to develop allergic reaction), which eventually leads to asthma.

Environmental factors that are linked to the development of asthma include indoor allergies (dust mites, animal allergies) and outdoor allergies (pollen and fungi), exposure to tobacco smoke, air pollution, recurring respiratory infections, gastrointestinal esophageal reflux, sulfites in foods, and medication sensitivities (Fanta, 2017). A younger gestational age and a higher infant weight gain are associated with the development of asthma (Sonnenschein-van der Voort et al, 2014). Lower socioeconomic status may also be correlated with the incidence of asthma (Chen et al, 2016).

Clinicians identify three key areas when diagnosing asthma:

1. Airflow obstruction that is at least partially reversible
2. Airflow obstruction that recurs in response to a trigger
3. Symptoms consistent with asthma

Symptoms such as wheezing, coughing, shortness of breath, and chest tightness occur in most patients, and symptoms that worsen at night is a common feature. Although allergic asthma or “extrinsic asthma” is due to chronic allergic inflammation of the airways, “intrinsic asthma” is triggered by nonallergic factors such as exercise, certain chemicals, and extreme emotions (Chih–Hung Guo et al, 2012).

A life-threatening situation with markedly narrow airways, known as status asthmaticus, can result when asthma has not been treated properly. Corticosteroid therapy is often prescribed, but chronic use may place the individual at risk for **osteopenia** (precursor to osteoporosis), bone fractures, or steroid-induced hyperglycemia (see Appendix 13). Some evidence supports the effectiveness of sublingual immunotherapy in the treatment of asthma and rhinitis, but more studies are needed on optimal dosages (Lin et al, 2013).

Medical Management

The essential components of asthma therapy are routine monitoring of symptoms and lung function, patient education, control of environmental triggers, and pharmacotherapy.

Pharmacologic treatment must be tailored to the individual patient and is used in a stepwise manner. The medications and the regime chosen depend on the severity of the asthma, which can be classified as an acute attack, intermittent, mild persistent, moderate persistent, or severe persistent.

Quick-relief and long-term controller medications are used as therapy for asthma. Although quick-relief medications include short-acting beta agonists (bronchodilators) and steroid pills, long-term controller medications include inhaled corticosteroid, long-acting beta agonists, and leukotriene modifiers. Long-acting anticholinergics are now considered as additional therapy in those not controlled with inhaled corticosteroids (Sobieraj et al, 2018).

Inhaled corticosteroids are the cornerstone of pharmacologic management with persistent asthma. Some patients with refractory asthma need maintenance doses of systemic steroids. Because steroids change bone metabolism and the development of osteoporosis, these patients benefit from increased calcium intake. Therapies developed over the past decade for severe asthmatics focus on immunotherapy: anti-immunoglobulin E (anti-IgE), antiinterleukin-5 (anti-IL-5) antibodies, tumor necrosis factor-alpha (TNF- α) inhibitors, and macrolide antibiotics.

Antibiotics for exacerbation of asthma are not recommended by current clinical practice guidelines, because respiratory infection triggering asthma attacks are more often viral rather than bacterial.

Medical Nutrition Therapy

When treating asthma, the dietitian nutritionist addresses dietary triggers, corrects energy and nutrient deficiencies and excesses in the diet, educates the patient on a personalized diet that provides optimal levels of nutrients, monitors growth in children, and watches for food-drug interactions.

Modulation of antioxidant intake with nutritional supplementation has a beneficial effect on the severity and progression of asthma (Fabian et al, 2013). Although a slight inverse association was seen between a low vitamin E intake and wheezing symptoms, no association was found between vitamin E and asthma. Further studies are required to understand the mechanism of vitamin E on the inflammation of the immune system (Fabian et al, 2013). Low blood carotenoid levels also have been linked with asthma. A diet rich in

antioxidants and monounsaturated fats seems to have a protective effect on childhood asthma by counteracting oxidative stress (Garcia-Marcos et al, 2013). The relationship between selenium status and the incidence and severity of asthma has been inconsistent in humans so selenium supplementation is not recommended (Norton et al, 2012).

In the childhood asthma prevention study omega-3 polyunsaturated fatty acid (PUFA) fish oil was supplemented throughout childhood, and wheezing was reduced. This effect did not continue into later childhood. Supplementation of vitamin C and zinc also have been reported to improve asthma symptoms and lung function (Allan and Devereux, 2011).

Conflicting results on the efficacy of vitamin D supplementation have been reported. In one study an insufficient serum level of less than 30 ng/dL of vitamin D was associated with an increase in asthma exacerbation in the form of emergency room (ER) visits and hospitalizations (Brehm et al, 2010). In another, high doses of vitamin D supplementation were not shown to have any protective effect (Litonjua et al, 2014). Due to the conflicting results of these studies, it can be concluded that vitamin D supplementation should not be recommended at this time as therapy for asthma (Jiao and Castro, 2015).

Other nutritional interventions could potentially include use of probiotics, oral magnesium, and the Mediterranean diet. Reduced diversity or aberrant composition of the infant gut microbiota may be associated with the development of asthma in later life, so breastfeeding is recommended to ensure growth of healthy microbiota (Milani et al, 2017; Hendaus et al, 2016). A nutritionally healthy diet such as the Mediterranean diet may help prevent asthma during childhood (Hendaus et al, 2016). In a small study of 55 males and females with mild to moderate asthma, supplementing with 340 mg magnesium/day (in two divided doses of 170 mg) for 6 months reduced bronchial reactivity and improved pulmonary function tests (Kazaks et al, 2010).

A higher than desirable BMI during childhood is associated with a significant increase in the development of asthma. Institution of diets that help with weight loss in asthmatic obese children seem to show improvements with the control of asthma, static lung function, and improved quality of life (Gibson et al, 2013). However, a large study of adult obese asthmatics found that the degree of weight loss needed to improve cardiometabolic risk factors was not enough to enhance asthma control (Ma et al, 2015).

Gastroesophageal reflux disease (GERD) and food allergens are the two most common dietary triggers for asthma. GERD is highly prevalent in asthmatic patients. A critical component of MNT for asthmatic patients is a diet free of known irritants such as spicy foods, caffeine, chocolate, and acidic foods (see Chapter 26). Limiting the intake of high fat foods and portion control can prevent gastric secretions, which exacerbate GERD.

Food allergens and food additives are other potential dietary triggers for asthma. An IgE-mediated reaction to a food protein can lead to bronchoconstriction. Completely avoiding the allergenic food protein is the only dietary treatment currently available for food allergies. Some sulfites, such as potassium metabisulfite and sodium sulfide, used in the processing of foods have been found to be a trigger for asthmatics (Gaur et al, 2013)

Some asthma patients need maintenance oral steroids, and these patients are prone to develop drug-nutrient interaction problems. Due to risk of developing osteoporosis while on long-term steroids, intakes of 1000 mg calcium/day and 600 IU Vitamin D is suggested for children ages 4-17 (Buckley, 2017).

CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Chronic obstructive pulmonary disease (COPD) is now the third most common cause of death in the world and is predicted to be the fifth most common cause of disability by 2020 (Burney et al, 2014). Smoke from cigarettes is a major risk factor, along with that from biomass fuel used for cooking and heating in rural areas of developing countries. Occupational smoke or dust, air pollution, and genetic factors are also factors in the development of COPD (Table 33.1). Patients with COPD suffer from decreased food intake and malnutrition that causes respiratory muscle weakness, increased disability, increased susceptibility to infections, and hormonal alterations.

Pathophysiology

COPD is a term that encompasses **chronic bronchitis** (a long-term condition of COPD in which inflamed bronchi lead to mucus, cough, and difficulty breathing) and **emphysema** (a form of long-term lung disease characterized by the destruction of lung parenchyma with lack of elastic recoil). These conditions may coexist in varying degrees and are generally not reversible. Fig. 33.7 shows the overlap between these three conditions: asthma, chronic bronchitis, and emphysema. Asthma-COPD overlap syndrome (ACOS) is a new entity that entails those who have features of both COPD and asthma. ACOS was recognized in 2015 by the Global Initiative for Chronic Obstructive Lung Disease (GOLD) and Global Initiative for Asthma (GINA).

Patients with primary emphysema suffer from greater dyspnea and cachexia. On the other hand patients with bronchitis have hypoxia, **hypercapnia** (increased amount of CO₂), and complications such as pulmonary hypertension and right heart failure (Papaioannou et al, 2013).

Alpha-1 antitrypsin deficiency is present in 1% to 2% of COPD patients and is likely underrecognized. COPD exacerbations can be caused by *Haemophilus influenzae*, *Moraxella catarrhalis*, *Streptococcus pneumoniae*, rhinovirus, coronavirus, and to a lesser degree, organisms such as *P. aeruginosa*, *S. aureus*, *Mycoplasma* spp., and *Chlamydia pneumoniae*. Allergies, smoking, congestive heart failure, pulmonary embolism, pneumonia, and systemic infections are the reason for 20% to 40% of COPD exacerbations (Nakawah et al, 2013).

Prolonged tobacco use is associated with an increased risk of having COPD besides other respiratory disorders (Liu et al, 2015). Osteoporosis in COPD patients not only predisposes patients to painful vertebral fractures but also affects lung function by altering the configuration of the chest wall. Frequent acute exacerbations in COPD patients increase the severity of chronic system inflammation. This leads to bone loss by inhibiting bone metabolism. Lack of sun

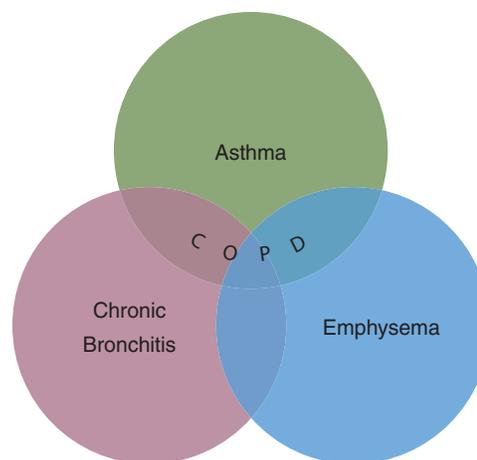

Fig. 33.7 The overlap of asthma, chronic bronchitis, and emphysema making up chronic obstructive pulmonary disease (COPD).

exposure and physical activity with COPD leads to a lack of 25-hydroxy vitamin D (25[OH]D), which regulates bone metabolism by promoting the absorption of calcium (Xiaomei et al, 2014).

Factors that influence the prognosis of COPD are the severity of disease, genetic predisposition, nutritional status, environmental exposures, and acute exacerbations.

Medical Management

In general, COPD therapies have a limited effect compared with therapies for asthma. With the exception of smoking cessation, no disease-modifying medications exist that can change the progression of airway obstruction in COPD. The airflow obstruction in COPD is irreversible.

Inhaled bronchodilators remain the mainstay of treatment for COPD patients. Usually these are given by metered dose inhalers (MDI), but for severe dyspnea or those unable to use inhalers (i.e., arthritis, cognitive dysfunction), they may be administered in a nebulized form. Anticholinergic medications such as ipratropium bromide or Spiriva (tiotropium bromide), a long-acting anticholinergic agent with specificity for muscarinic receptors, can be added to the treatment. Theophylline continues to be used but less often due to associated toxicity. Inhaled steroids and a trial of oral steroids may be required for some patients. Antibiotics often are prescribed when an exacerbation is considered to be due to bacterial infection.

Acute exacerbation of COPD is associated with adverse effects such as declining lung function, reduced quality of life, and increased mortality. In many institutions, reducing early (≤ 30 days) readmission for COPD has become a health care policy goal. Identifying reasons for readmissions are important. Some of these reasons include depression, smoking, anxiety, GERD, reduced functional status, unwillingness to use oxygen, and malnutrition.

Pulmonary hypertension is a risk factor that shortens life expectancy and is common in advanced COPD. The first step in treating pulmonary hypertension in patients with COPD is appropriate medical management of their obstructive lung disease, as mentioned earlier.

Patients with low oxygen levels (hypoxemic) need supplemental oxygen. Pulmonary rehabilitation may be helpful in advanced COPD. Patients with severe COPD may suffer respiratory failure related to complications such as pneumothorax, pneumonia, and congestive

TABLE 33.1 Risk Factors for Chronic Obstructive Pulmonary Disease (COPD)

Definite	Probable
Tobacco smoking	Pulmonary tuberculosis
Occupational exposure	Repeated lower respiratory infection during childhood
Exposure to biomass fuel smoke	Poorly treated asthma
Environmental tobacco smoke

Fig. 33.8 An intensive care unit (ICU) patient on ventilator.

heart failure, or due to uncontrolled administration of high-dose oxygen or narcotic sedatives. The patients in respiratory failure need mechanical ventilation (Fig. 33.8).

In addition to facing major physical impairment and chronic dyspnea, COPD patients are at an increased risk of developing depression that should be identified and treated.

Medical Nutrition Therapy

Malnutrition is a common problem associated with COPD, with prevalence rates of 30% to 60% due to the extra energy required by the work of breathing and frequent and recurrent respiratory infections. Breathing with normal lungs expends 36 to 72 kcal/day; it increases 10-fold in patients with COPD (Hill et al, 2013). Infection with fever increases metabolic rate even further (see Chapter 2). Malnourished patients, identified as those having decreased body weight, reduced fat-free body mass, or a BMI ≤ 20 kg/m², are likely to have more COPD exacerbations and a shorter survival time than those who are well-nourished (Itoh et al, 2013). Increasing energy intake can maintain or improve muscle strength and exercise tolerance in these patients (Itoh et al, 2013).

Low body weight is due to poor nutritional intake, an increased metabolic rate, or both. Inadequate food intake and poor appetite are the primary targets for intervention in patients with COPD. These two issues are the reasons COPD patients struggle to meet their nutritional needs. Depletion of protein and vital minerals such as calcium, magnesium, potassium, and phosphorus contribute to respiratory muscle function impairment. In severe malnutrition inadequate electrolyte repletion during aggressive nutrition repletion can lead to severe metabolic consequences related to refeeding syndrome (see Chapter 12).

There are two main goals in managing the hypermetabolism seen in stable COPD: (1) the prevention of weight loss and (2) the prevention of the loss of lean body mass (LBM). These goals can be achieved by ensuring the following:

- Small frequent meals that are nutritionally dense
- The patient eats the main meal when energy level is at its highest
- Adequate calories, protein, vitamins, and minerals to maintain a desirable weight—a BMI of 20 to 24 kg/m²
- Availability of foods that require less preparation and can be heated easily in a microwave oven if patients prepare their own food

- Limitation of alcohol to fewer than 2 drinks/day (30 g alcohol)
- A period of rest before mealtimes

People with COPD suffer a poor prognosis when they have malnutrition that predisposes them to infections. The ability to produce lung surfactant, exercise tolerance, and respiratory muscle force are reduced in the presence of infection. Weight loss leads to an increased load on the respiratory muscles, contributing to the onset of acute respiratory failure (Hill et al, 2013).

Many factors affect nutritional status during the progression of COPD. Although body weight and BMI should be followed because they are easily obtained markers of nutritional status in patients, they can underestimate the extent of nutritional impairment (Hill et al, 2013).

Current evidence suggests that a healthy diet pattern helps in protecting smokers against malnutrition. A combination of nutritional counseling and nicotine replacement seems to optimize success (Hill et al, 2013).

Studies have shown an inverse relationship between dietary iron and calcium intake and COPD risk. Iron deficiency anemia is seen in 10% to 30% of patients with COPD (Silverberg et al, 2014). It has been seen that correcting the anemia and iron deficiency by either blood transfusions or intravenous iron therapy improves dyspnea (shortness of breath) in COPD patients (Silverberg et al, 2014). COPD patients are also at higher risk of developing osteoporosis resulting from steroid usage, smoking, and vitamin D depletion. Maintaining adequate levels of 25(OH)D is important for COPD patients (Lee et al, 2013; see Appendix 38).

The primary goals of nutrition care for patients with COPD are to facilitate nutritional well-being, maintain an appropriate ratio of LBM to adipose tissue, correct fluid imbalance, manage drug-nutrient interactions (see Appendix 13), and prevent osteoporosis.

Nutritional depletion may be evidenced clinically by low body weight for height and decreased grip strength. Calculation of BMI may be insufficient to detect changes in fat and muscle mass. Instead, determination of body composition helps to differentiate lean muscle mass from adipose tissue and overhydration from dehydration. In patients with **cor pulmonale** (increased blood pressure that leads to enlargement and failure of the right ventricle of the heart) and the resultant fluid retention, weight maintenance, or gain from fluid may camouflage actual wasting of LBM. Thus for patients retaining fluids, careful interpretation of anthropometric measurements, biochemical indicators, and functional measures of nutrition status are necessary (see Chapter 5 and Appendices 11 and 12).

A combination of protein rich supplements and anabolic steroids can increase muscle mass and reverse any negative effects of weight loss. Exercise tolerance has been shown to improve with a dietary supplement that contains omega-3 PUFA, which has antiinflammatory effects (Berman, 2011) (see Chapter 7).

Adipokines is a generic term for the bioactive proteins that are secreted by adipocytes. They include adiponectin, leptin, IL-6, and TNF- α . They play a vital role in influencing the nutritional status and regulating the appetite. **Leptin** (satiety hormone) is secreted promptly in response to food intake and plays a role in suppressing appetite and enhancing energy expenditure. It has been suggested that measuring levels of leptin in the sputum can be useful in determining the severity of lung disease because it has been shown to increase during acute exacerbations (Itoh et al, 2013). **Adiponectin** (a protein involved in fatty acid breakdown and glucose regulation), like leptin, is secreted from adipocytes, but has an opposite effect. Adiponectin enhances appetite and has an antiinflammatory, anti-diabetic, and antiatherosclerotic effect and is considered beneficial.

TABLE 33.2 Blood Levels of Hormones and Adipokines in Patients with Chronic Obstructive Pulmonary Disease (COPD)

Hormone	Function	Changes in Blood Levels with COPD
Leptin	<ul style="list-style-type: none"> • Suppresses appetite • Promotes inflammation • Regulates hematopoiesis, angiogenesis, and wound healing 	Decreased in patients with a low BMI compared with patients with a normal and high BMI
Ghrelin	Stimulates appetite and release of growth hormone	Increased in underweight patients compared with normal weight patients
Adiponectin	<ul style="list-style-type: none"> • Stimulates fatty acid oxidation • Increases insulin sensitivity and inhibits inflammatory process 	Increased during acute exacerbation Decreased levels in current smokers
Resistin	Promotes inflammation and insulin resistance by the production of IL-6 and TNF- α	Inversely correlated with predicted FEV ₁ %
TNF- α	Antagonizes insulin signaling and promotes inflammation	Increased compared with healthy individuals
IL-6	<ul style="list-style-type: none"> • Loss of appetite • Promotes inflammation 	Increased compared with healthy individuals

BMI, Body mass index; FEV₁, forced expiratory volume; IL-6, interleukin-6; TNF- α , tumor necrosis factor alpha. Adapted from Itoh M, et al: Undernutrition in patients with COPD and its treatment, *Nutrients* 5:1316, 2013.

Resistin, another adipokine, induces inflammation and insulin resistance. In addition to being an appetite stimulant, **ghrelin** also stimulates growth hormone secretion, with antagonistic effects to leptin. [Table 33.2](#) summarizes the functions and change in the blood levels of these adipokines in COPD patients, and how they can influence management and recovery ([Itoh et al, 2013](#)).

Macronutrients

In stable COPD, requirements for water, protein, fat, and carbohydrate are determined by the underlying lung disease, oxygen therapy, medications, weight status, and any acute fluid fluctuations. Attention to the metabolic side effects of malnutrition and the role of individual amino acids is necessary. Determination of a specific patient's macronutrient needs is made on an individual basis, with close monitoring of outcomes.

Energy

Meeting energy needs can be difficult. For patients participating in pulmonary rehabilitation programs, energy requirements depend on the intensity and frequency of exercise therapy and can be increased or decreased. It is crucial to remember that energy balance and nitrogen balance are intertwined. Consequently, maintaining optimal energy balance is essential to preserving visceral and somatic proteins. Preferably, indirect calorimetry should be used to determine energy needs and to prescribe and monitor the provision of sufficient, but not excessive calories. When energy equations are used for prediction of needs, increases for physiologic stress must be included. Caloric needs may vary significantly from one person to the next and even in the same individual over time (see Chapter 2).

Fat

Omega-3 and omega-6 are PUFAs that are essential fatty acids. The simplest forms of these fatty acids are the omega-6 linoleic acid (LA) and alpha-linolenic acid (ALA). The body is unable to synthesize them, and they must be consumed in the human diet. These fatty acids are desaturated to form long-chain omega-3 PUFAs or omega-6 PUFAs. Docosahexaenoic acid (DHA), eicosapentaenoic acid (EPA), and ALA are the major omega-3 PUFAs, and the major long-chain omega-6 fatty acids are LA and arachidonic acid (AA). See Appendix 26 for the sources of these fatty acids in the diet. In theory, intake of long-chain omega-3 PUFAs, which reduces inflammation,

should improve the efficacy of COPD treatments. PUFA supplementation is beneficial in COPD, but various factors such as supplement adherence, comorbidities, and duration of the supplementation play vital roles ([Fulton et al, 2013](#)).

Dietary supplementation of DHA and AA has been shown to delay and reduce risk of upper respiratory infections and asthma, with lowering the incidence of bronchiolitis during the first year of life ([Shek et al, 2012](#)). Data from various studies have shown the positive impact of long-chain PUFAs in initiating and providing resolution of inflammation in respiratory diseases ([Shek et al, 2012](#)). It has been shown that aspirin helps to trigger resolvin, a molecule naturally made by the body from omega-3 fatty acids. **Resolvin** resolves or turns off the inflammation in underlying destructive conditions such as inflammatory lung diseases ([Dalli et al, 2013](#)). At this time, there are ongoing large studies evaluating the effectiveness of omega-3 PUFAs in the treatment of COPD.

Protein

Sufficient protein of 1.2 to 1.5 g/kg of dry body weight is necessary to maintain or restore lung and muscle strength, as well as to promote immune function. Other concurrent disease processes such as cardiovascular or renal disease, cancer, or diabetes affect the total amounts, ratios, and kinds of protein, fat, and carbohydrate prescribed.

Vitamins and Minerals

As with macronutrients, vitamin and mineral requirements for individuals with stable COPD depend on the underlying pathologic conditions of the lung, other concurrent diseases, medical treatments, weight status, and bone mineral density. For people continuing to smoke tobacco, additional vitamin C is necessary (see Appendix 35). One study indicated that vitamin C's role as an antioxidant improved plasma glutathione levels ([Pirabbasi et al, 2016](#)).

The role of minerals such as magnesium and calcium in muscle contraction and relaxation may be important for people with COPD. Intakes at least equivalent to the dietary reference intake (DRI) should be provided. Depending on bone mineral density test results, coupled with food intake history and glucocorticoid medications use, additional vitamins D and K also may be necessary (see Chapter 23).

Patients with cor pulmonale and subsequent fluid retention require sodium and fluid restriction. Depending on the diuretics prescribed, increased potassium supplementation may be required (Appendix 13).

BOX 33.2 Planning the Diet for the Patient with Pulmonary Cachexia

Energy requirements during healing = 30 kcal/kg of usual body weight or 13.7 cal/usual body weight (pounds)

Protein (g)/day during healing = [(1.2 g – 1.4 g) × body weight (kg) or 0.55 × usual body weight (pounds)]

Fluid requirements = body weight (lb)/2 = ounces per day or body weight (lb) × 9/16 = cups per day

Fluid requirements are increased because of fever, chemotherapy regimen, oxygen use, and presence of chronic obstructive pulmonary disease (COPD). Lack of energy or dehydration increases fatigue and constipation. Fluid deficits of 1% body weight lower metabolic function by 5%.

Levin RM: *Nutrition in the patient with lung cancer, caring ambassadors lung cancer choices* (website). http://lungcancer.org/wp-content/uploads/2014/10/Chapter_8_2014.pdf, 2012.

And other water-soluble vitamins, particularly thiamin, may need to be supplemented.

Patients are recommended to drink adequate fluids and stay hydrated to help sputum consistency and easier expectoration. The Parenteral and Enteral Nutrition Group (PENG) recommends a fluid intake of 35 mL/kg body weight daily for adults 18 to 60 years and 30 mL of fluid/kg body weight daily for adults over 60 years (PENG, 2011).

COPD patients report difficulties with eating because of low appetite, increased breathlessness when eating, difficulty shopping and preparing meals, dry mouth, early satiety and bloating, anxiety and depression, and fatigue. In addition to the above, inefficient and overworking respiratory muscles lead to increased nutritional requirements (Evans, 2012).

Patients in the Advanced Stage of COPD

Patients with advanced COPD are undernourished and in a state of **pulmonary cachexia**, which is defined as a BMI of less than 17 in men and less than 14 in women (Allen et al, 2017). The cause of cachexia in advanced COPD is poorly understood. The role for myostatin has been suggested. Myostatin is a member of the transforming growth factor-beta superfamily that functions as a negative regulator of muscle growth. This has been suggested by the significantly high levels of myostatin in patients with stable COPD compared with healthy individuals (Benedik et al, 2011).

These cachectic patients have anorexia as a typical symptom. Pulmonary cachexia is an independent risk factor and is common in the advanced stage of COPD. Pharmacotherapy and nonpharmacotherapeutic treatments such as respiratory rehabilitation and nutrition counseling are the mainstays of COPD treatment in such patients (Itoh et al, 2013). Sarcopenia and cachexia result from the accelerated loss of lean tissue (Raguso and Luthy, 2011). This muscle wasting has a detrimental effect on the respiratory function (Collins et al, 2012).

Osteoporosis exists as a significant problem in 24% to 69% of patients with advanced COPD (Evans and Morgan, 2014). Any sudden drop in height is a mark of developing osteoporosis. As COPD progresses, osteoporosis results because of immobility, which also leads to deconditioning and dyspnea. Smoking, low BMI, low skeletal muscle mass, and corticosteroid usage can lead to bone loss along with low serum vitamin D levels (Evans and Morgan, 2014) (Box 33.2).

PULMONARY HYPERTENSION

Pulmonary hypertension (PH) is defined as elevated pressure within the pulmonary circulation that includes the pulmonary artery,

capillaries, and pulmonary veins. The pulmonary artery takes deoxygenated blood from the right ventricle into the small capillaries, where gas exchange takes place, and oxygenated blood returns via the pulmonary vein into the left atrium.

Patients with PH usually complain of shortness of breath, mainly on exertion. As the disease advances, the shortness of breath becomes more prominent even at rest, and patients have symptoms related to hypoxia such as headache, dizziness, and chest pain. Upon evaluation by a pulmonologist or cardiologist, some of the important signs to look for would include cardiac murmur, right-sided ventricular heave (the heel of hand lifts off the chest with every beat, indicating an enlarged right ventricle), loud heart sound, and an elevated jugular vein pressure. **Cyanosis** can be evident with worsening hypoxia. Cyanosis occurs when hemoglobin is inadequately saturated with oxygen, and it is characterized by a bluish discoloration of the skin, nails, lips, or around the eyes.

An echocardiogram (ECHO) is usually the screening tool for PH. ECHO is used to measure the right ventricle function and to measure the right ventricle systolic pressure (RVSP), which can be used to estimate pulmonary artery systolic pressure. A RVSP >50 mm Hg suggests an elevated pulmonary systolic pressure and will need confirmation by direct measurements of the pulmonary artery pressure, using right heart catheterization.

Elevated pulmonary circulation pressure can occur due to primary pulmonary artery disease (primary PH) or secondary to pulmonary or extrapulmonary diseases. In 2013 the World Health Organization (WHO) classified PH into five categories (Hopkins and Rubin, 2018).

Category 1: Pulmonary arterial hypertension; PH due to autoimmune disorders, human immunodeficiency virus (HIV), toxins, drugs, sickle cell disease; porto-PH

Category 2: PH due to left heart disease

Category 3: PH due to underlying lung disease such as COPD, **interstitial pulmonary fibrosis** (scar tissue in the lungs)

Category 4: chronic thromboembolic PH

Category 5: multifactorial and unclear mechanisms leading to PH.

Examples include sarcoidosis (a condition that can lead to inflammation primarily in the lung and the lymph nodes)

Medical Management

Treatment of PH largely depends on the cause of the elevated pulmonary pressure. Those with category 1 can benefit from keeping oxygen above 90% and with medical therapy to reduce the pressure by acting directly on pulmonary circulation. Those with categories 2 and 3 will need to treat the underlying cause. Patients with category 4 require anticoagulation therapy and may benefit from mechanical or medical thrombolysis of their clots. Treatment for patients in category 5 depends on the underlying disorder.

Medical Nutrition Therapy

There is no evidence-based guidelines or research in this area. Nutrition interventions should be directed at the underlying cause of PH such as sodium and fluid restriction for those with left-sided heart failure or improving oral intake in persons with COPD. Persons with PH can have nutritional statuses ranging from malnutrition to overnutrition, so nutrition interventions should be designed to diagnose and correct these issues accordingly.

DIFFUSE PARENCHYMAL LUNG DISEASE

Diffuse parenchymal lung disease (DPLD) (also known as **interstitial lung diseases** [ILD]) is common and more recognized now with advances that have been made in imaging. DPLD comprises a long list of diseases and can be primary or secondary due to other systemic disorders or

medications. Patients typically complain of chronic shortness of breath, nonproductive cough, and fatigue. If the disease advances, patients become hypoxic, requiring oxygen, and are limited in their physical activity. The prognosis for these diseases vary due to the underlying cause and the response to treatment.

Idiopathic pulmonary fibrosis (IPF) is the most common ILD and is associated with the worst prognosis. IPF is a chronic progressive disease characterized by progressive lung scarring. The incidence of IPF is 0.22 to 8.8/100,000 in the United States. Men are affected more than women. Patients with IPF commonly present in the sixth and seventh decades of life. Typical symptoms are chronic shortness of breath that progresses and nonproductive cough. Pulmonary function tests show restrictive pattern with reduced volumes. The diagnosis of IPF includes the following:

1. Exclusion of known causes of ILD such as medication, environmental exposure, or systemic disorders
2. Symptoms that are consistent with IPF such as chronic progressive shortness of breath, nonproductive cough, and hypoxia
3. CT scan consistent with IPF pattern
4. If diagnosis remains uncertain, then open lung biopsy and histologic confirmation are necessary

Pathophysiology

Most cases of IPF are sporadic although some genetic component has been described. Risk factors for IPF include smoking and exposures to metals and some organic dusts. Gastroesophageal reflux may contribute to the progression of the disease (Lederer and Martinez, 2018).

Medical Management

The evaluation and management of IPF requires a pulmonologist, radiologist, and pathologist. Investigations need to rule out other diseases that could mimic IPF and to assess the severity of the disease. Lung biopsy is not always required if secondary causes were excluded and CT scan is consistent with all the radiographic features of IPF.

The medical management of IPF can be divided into acute and chronic courses. IPF slowly progresses over time without clear understanding. Patients are usually recommended to start treatment with antifibrotic medications early in the course with the goal to slow down progression of the disease. Currently, two antifibrotic medications are used in the United States (pirfenidone, nintedanib). Pirfenidone is associated with rash, photosensitivity, and possible gastrointestinal disturbances such as diarrhea, nausea, vomiting, or abdominal discomfort. Dose adjustment may help relieve some of these symptoms. Nintedanib is associated with more gastrointestinal side effects with diarrhea occurring in up to 60% of the patients; consequently, anti-diarrheal agents are usually prescribed at the same time. Other less common adverse effects include nausea, vomiting, and elevated liver enzymes.

Those with acute presentation usually are admitted to the intensive care unit (ICU) due to increased oxygen requirements. Their management is most often supportive care. High doses of steroids were used in the past with conflicting results and therefore are not always recommended. Patients who become more symptomatic and worsen quickly might benefit from an early referral to a lung transplant center.

Pulmonary Diagnostic Tests

Pulmonary Function Tests (PFT): includes spirometry, measuring lung volumes, and diffusion capacity. Used to diagnose asthma and COPD and to assess severity of lung disease such as ILD.
Chest Radiograph (chest x-ray)

Computed Tomography (CT) Scan: scans cross-section of chest. More accurate and higher sensitivity and specificity compared with chest x-ray. Greater radiation exposure than chest x-ray.

Bronchoscopy: Scope with a camera is inserted in the mouth or nose and goes through the upper airways and trachea. Used for airway examination, sampling fluid for infection workup, and biopsies to rule out malignancies or sarcoidosis.

Lung Biopsy: either by bronchoscopy or more invasive approach in the operating room by using video-assisted thoracoscopic surgery (VATS) and requiring general anesthesia.

Medical Nutrition Management

At this time, there are neither evidenced-based guidelines nor research studies specifically for patients with IPF. Patients with IPF can have weights varying from being underweight to obese, so nutrition interventions should be designed to diagnose and correct nutritional abnormalities. Pulmonary cachexia syndrome can occur similar to that seen in persons with COPD and is due to hypoxemia, low-grade inflammation, and corticosteroid use (Allen et al, 2017). As shortness of breath worsens, oral intake begins to decline so the suggestions for improving intake for persons with COPD may be appropriate for patients with IPF:

- small frequent meals
- consumption of main meal when energy level is at its highest
- adequate calories, protein, vitamins, and minerals to achieve appropriate weight
- use of foods that are easily prepared (i.e., microwave)
- use of protein and calorie dense liquid nutritional supplements, homemade or premade, if oral intake is poor

Sometimes, chewing becomes tiring for patients who are short of breath. Changing the diet to softer foods or relying more on nutritionally adequate liquid supplements to ensure adequate nutrition may be necessary nutrition interventions.

TUBERCULOSIS

Mycobacterium tuberculosis, the causative organism of **tuberculosis (TB)**, is an intracellular bacterial parasite, has a slow rate of growth, is an obligate aerobe, and induces a granulomatous response in the tissues of a normal host.

Even though TB is not as common in the United States as in some other countries, there has been a resurgence associated with HIV and drug-resistant forms of TB (see Chapter 36). In 2017 the WHO estimated approximately 10.4 million individuals became ill with TB and 1.7 million died. According to the WHO, multidrug resistant TB accounted for approximately 600,000 cases of TB worldwide.

Pathophysiology

When an infectious TB patient coughs, the cough droplets contain tuberculous bacilli. Small particles penetrate deep into the lungs. Each of these tiny droplets may carry 1 to 5 bacilli, which are enough to establish infection. This is the reason why cases of active TB must be isolated in an airborne infection isolation room (a room with a ventilation system that creates negative pressure by allowing air to enter the room but not leave it). This form of isolation should continue until patients become noninfectious. In about 5% of cases, the infection progresses and produces active TB. In 95% of cases when a host has an effective cell-mediated immune response, the infection is contained. When patients with active TB are left untreated, they can die as a result of progression and complications (Hood, 2013).

Although there may be minimal symptoms and the diagnosis is suspected because of an abnormal chest radiograph, most patients

with pulmonary TB present with chronic cough, prolonged fever, night sweats, anorexia, and weight loss.

Medical Management

An important component of management is to place these patients in respiratory isolation to prevent spread of infection until the smear for sputum acid fast bacillus (AFB) comes back negative. As soon as the diagnosis is established, treatment with four anti-TB medications—INH, rifampin, pyrazinamide, and ethambutol—is started. Each drug has food-nutrient interactions (see Appendix 13). These medications are continued for 2 months, and then only rifampin and INH are continued for an additional 4 months. Duration of treatment may be longer in some patients.

Medical Nutrition Therapy

Malnutrition is common in patients with pulmonary TB, and nutritional supplementation is necessary. Protein status can be assessed by looking at blood levels of acute phase reactants (inflammatory proteins) (see Table 5.4 in Chapter 5), anthropometric indices, and the micronutrient status of TB patients (Miyata et al, 2013).

TB leads to or worsens any preexisting condition of malnutrition and increases catabolism. The WHO guidelines suggest hospitalization of patients who are severely undernourished due to increased risk of death. Dietary supplementation is recommended until the patient achieves a BMI of 18.5 (Bhargava et al, 2013).

Active TB is associated with weight loss, cachexia, and low serum concentration of leptin. There is a synergistic interaction between malnutrition and infection. Recurrent infection leads to worsening nutritional status and loss of body nitrogen. The resulting malnutrition, in turn, creates a higher susceptibility to infection (Miyata et al, 2013).

In the short term, malnutrition increases the risk of infection and early progression of infection to produce active TB. In the long term, malnutrition increases the risk of reactivation of the TB disease. Malnutrition also can lower the effectiveness of the anti-TB drug regime, which patients have to be on for several months. The efficacy of Bacillus Calmette-Guerin (BCG) vaccine can also be impaired by malnutrition.

Upon correction of nutritional deficiencies, malnutrition-induced loss of certain immune processes can be reversed rapidly. Nutritional intervention in combination with appropriate medications does improve the outcome of malnourished TB patients.

Energy

Current energy recommendations are those for undernourished and catabolic patients, 35 to 40 kcal/kg of ideal body weight. For patients with any concomitant infections such as HIV, energy requirements increase by 20% to 30% to maintain body weight.

Protein

Protein is vital in preventing muscle wasting, and an intake of 15% of energy needs or 1.2 to 1.5 g/kg ideal body weight, approximately 75 to 100 g per day, is recommended.

Vitamins and Minerals

Poor nutritional intake associated with TB will likely promote micronutrient deficiencies (Kant et al, 2015). Providing supplemental zinc, vitamin D, vitamin E, and selenium will probably increase serum levels of these nutrients but the evidence has not demonstrated significant clinical benefit (Grobler et al, 2016). Supplementing these nutrients above the recommended daily amounts seems to be unnecessary due to the unreliable evidence (Grobler et al, 2016).

Isoniazid is an antagonist of vitamin B₆ (pyridoxine) and is frequently used in TB treatment. It may cause rare instances of peripheral neuropathy resulting from the nutritional depletion of vitamin B₆. A standard procedure is to supplement adults with 25 mg of vitamin B₆ per day to overcome this drug-nutrient interaction. Vitamin B₆ supplementation will be needed for exclusively breastfed infants, malnourished children, and HIV-infected children and adolescents (Rodà et al, 2016). Research indicates some healthy children could develop mild symptom-free pyridoxine deficiency (Rodà et al, 2016).

Studies have documented an increased prevalence of anemia in TB patients, which is associated with increased risk of death. To guide clinical decision making and provide treatment recommendations, factors that contribute to the TB-associated anemia have to be determined. Although other causes do coexist, iron deficiency anemia is the most important contributor in the development of anemia in TB patients (Isanaka et al, 2012).

Iron is an essential micronutrient not only for humans but also for bacteria such as *M. tuberculosis*; TB is dependent on the host's iron supply (Carver, 2018). Providing iron either as a supplement or blood transfusion could increase risk of infection but at this time this is controversial (Carver, 2018). The use of iron therapy is not universally recommended. However, if iron studies show iron deficiency, iron therapy is then initiated (see Chapter 31 for management of iron deficiency anemia).

LUNG CANCER

Lung cancer remains the leading cause of cancer deaths for males and females in the United States. In 2012 1.8 million patients worldwide were diagnosed with lung cancer (Mannino, 2014).

Neoplasms of the lower respiratory tract are a heterogeneous group of tumors. The group commonly called **bronchogenic carcinomas** comprises squamous cell carcinoma, adenocarcinoma, small cell undifferentiated carcinoma, and large cell undifferentiated carcinoma and account for 90% of all the neoplasms of the lower respiratory tract. Mortality is more common in males than females, although this difference is diminishing. While the female incidence rate is stabilizing, the male incidence rate seems to be decreasing (Baldini, 2014).

Pathophysiology

Often lung cancer is detected on a routine chest radiograph in an asymptomatic smoker. Other patients may present with symptoms related to the tumor itself, symptoms related to the local extension of the tumor or widespread metastases, or systemic symptoms such as anorexia, weight loss, weakness, and paraneoplastic syndromes.

Dyspnea is the most burdensome cancer symptom and occurs in 25% to 40% of lung cancer patients at diagnosis. In addition to the tumor, other factors contribute to the symptom of dyspnea—factors such as pericardial effusion, anemia, fatigue, depression, anxiety, metastatic involvement of other organs, aspiration, anorexia-cachexia syndrome, and pleural effusion.

Patients with lung cancer suffer from progressive weight loss with changes in body composition. Malnutrition impairs the contractility of the respiratory muscles, affecting endurance and respiratory mechanics.

Cough is present in 50% to 75% of lung cancer patients at presentation and occurs most frequently in squamous cell and small cell carcinoma because of their tendency to involve central airways (Kocher et al, 2015).

Pain and fatigue are common symptoms associated with lung cancer. The tumor may produce pleuritic pain because of tumor

extension into the pleura, or musculoskeletal type pain because of extension into the chest wall. Bone pain may occur as a result of metastases to the bones. Bone metastases in patients with lung cancer account for 30% to 40% of the pain. About 50% of early stage cancer and 75% to 100% of advanced stage cancer patients report fatigue (Kocher et al, 2015).

Pulmonary cachexia syndrome affects patients with advanced lung disease. In lung cancer, weight loss is associated with increasing mortality, and weight loss of even 5% indicates a poor prognosis. Although anorexia and cachexia are two different entities, they often are used interchangeably (Kocher et al, 2015) (see Chapter 35).

Medical Management

The choice of definitive management for a particular patient is determined by numerous factors, such as the tumor cell type, tumor stage, resectability of the tumor, and suitability of the patient for general anesthesia and surgery. Some patients need general palliative care in terms of psychological support, control of distressing symptoms, and palliative radiation. Nutritional support plays a very important role in the management of advanced lung cancer.

Medical Nutrition Therapy

The National Comprehensive Cancer Network (NCCN) guidelines include nutritional assessments, medications, and nonpharmacologic approaches to achieve the following:

1. Treat the reversible causes of anorexia such as early satiety
2. Evaluate the rate and severity of weight loss
3. Treat the symptoms interfering with food intake: nausea and vomiting, dyspnea, mucositis, constipation, and pain
4. Assess the use of appetite stimulants like megestrol acetate and Decadron (corticosteroids)
5. Provide nutritional support (enteral or parenteral) (Del Ferraro et al, 2012)

Cancer cachexia syndrome (CCS) is the presence of a metabolic state that leads to energy and muscle store depletion in lung cancer patients. When patients experience CCS, they lose adipose and skeletal muscle mass. Changes in hormone and cytokine levels, along with tumor byproducts, cause CCS. Weight loss seen with CCS, unlike starvation, is irreversible and continues to worsen despite increased nutritional intake (Huhmann and Camporeale, 2012) (see Chapter 35).

However, despite these findings, reversible causes of anorexia should be sought and treated. Although nutritional support does not improve spirometric values and arterial blood gas and does not stop weight loss, it does modestly improve clinical outcomes such as the 6-minute walk test, quality of life, and inspiratory and expiratory muscle strength (Bellini, 2013).

Nutrition repletion is problematic in advanced lung disease because fatigue and dyspnea tend to interfere with the preparation and consumption of food. Alterations in the taste of food because of chronic sputum production, early satiety resulting from flattening of the diaphragm, nausea and indigestion resulting from side effects of medications, and lack of motivation to eat because of depression make it difficult for the patient to take adequate nutrition by the oral route. However, accepted components of oral nutrition therapy are the following:

1. Small frequent meals that are calorie and protein dense
2. Provide calorie level that meets or exceeds the resting energy expenditure (REE)
3. Rest before meals
4. Meals that require minimal preparation
5. Oral nutritional supplements (homemade or preprepared)

With pulmonary CCS, patients are unable to gain weight with nutritional interventions alone. Prokinetic agents for delayed gastric emptying can be used with careful consideration of side effects. Megestrol acetate, an appetite stimulant, may result in increasing appetite and caloric intake. Ghrelin (a growth hormone releasing peptide) lowers fat use and stimulates feeding through growth hormone independent mechanisms, thereby inducing a positive energy balance. Studies have shown that repeated intravenous (IV) administration of ghrelin improves body composition, lowers muscle wasting, and increases functional capacity (Bellini, 2013).

One study suggests that whole body protein metabolism in pulmonary patients may benefit from branched-chain amino acid (BCAA) supplementation. This study was the first of its kind in assessing the clinical benefits of supplementing BCAA in a preoperative pulmonary rehabilitation center; 6.2 g of BCAA supplementation was the recommended daily dosage. However the effect of BCAA supplementation for lung cancer patients has not been clarified and requires further study before specific recommendations can be made. A comprehensive pulmonary rehabilitation protocol includes nutritional support and physical exercise (Harada et al, 2013).

OBESITY HYPOVENTILATION SYNDROME

Obesity hypoventilation syndrome (OHS) is defined as a BMI of more than 30 kg/m² and alveolar hypoventilation defined by arterial CO₂ (Paco₂) level of more than 45 mm Hg during wakefulness, which occurs in the absence of other conditions that cause hypoventilation (Piper and Grunstein, 2011).

Alveolar hypoventilation in OHS is related to the multiple physiologic abnormalities associated with obesity: obstructive sleep apnea (OSA), increased work of breathing, respiratory muscle impairment, a depressed central ventilator drive, and reduced effects of neurohumoral modulators (e.g., leptin) (Koenig, 2011; Piper and Grunstein, 2011).

Obstructive sleep apnea (OSA) is a common chronic disorder, which is characterized by loud snoring, excessive daytime sleepiness, and witnessed breathing interruptions or awakenings because of gasping or choking. The presence or absence of OSA and its severity usually is confirmed by a sleep study (polysomnography) before initiating treatment (Kapur et al, 2017). The polysomnography also serves as a baseline to establish the effectiveness of the subsequent treatment (Epstein et al, 2009).

Medical Management

Depending on the number of episodes of apnea or **hypopnea** (overly shallow breathing) per hour, OSA is graded as mild, moderate, or severe. Patients with OSA commonly are treated with a **continuous positive airway pressure (CPAP)** machine, which includes a mask worn over the nose, or nose and mouth that provides oxygen under pressure to aid in breathing. These primary treatment modalities for OSA must be used in addition to weight loss because of the low success and low cure rates by dietary approach alone.

Medical Nutrition Therapy

Weight reduction by MNT or by bariatric surgery remains an important component of management of these cases (see Chapter 20). A guideline from the American Thoracic Society recommends a lifestyle intervention consisting of reduced calorie intake, exercise or increased physical activity, and behavioral guidance, stating that weight loss is associated with improvements in respiratory function, cardiometabolic comorbidities, and quality of life (Hudgel et al, 2018). In a multicenter study of patients with OSA undergoing Roux-en-Y gastric bypass surgery, OSA was reduced from 71% to 44% one year later in

these patients; however, moderate to severe OSA remained in 20% of the patients (Peromaa-Haavisto et al, 2017).

PLEURAL EFFUSION

Pleural effusion is the accumulation of the fluid in the pleural space. The pleura, which is the layer that surrounds the lung, is divided into visceral and parietal layers and in between is a small space that contains about 10 to 20 mL fluid. If there is increased production or decreased drainage in the pleural space, fluid can accumulate. Pleural effusion can be either transudate or exudate (Feller-Kopman and Light, 2018). Transudate effusion is usually due to congestive heart failure, liver disease, or kidney disease, while exudate effusion may occur due to infection, malignancy, and autoimmune disorders.

Pleural effusion can be found incidentally on chest imaging in patients who are asymptomatic or can present with shortness of breath, chest pain, or symptoms related to the underlying cause such as pneumonia or congestive heart failure. Effusions can be unilateral or bilateral. Fig. 33.9 is a CT scan of a patient with bilateral pleural effusion.

Medical Management

The management of pleural effusion depends on numerous factors and usually involves drainage of the fluid either to make a diagnosis or to relieve symptoms in those with large effusions. Fluid can be drained by a procedure called thoracentesis, which can be done as an outpatient or inpatient at the bedside. Those who have recurrent effusion might benefit from a long-term therapy such as placement of an indwelling pleural catheter to drain the fluid as needed or through more invasive procedures such as injection of chemicals (talc or doxycycline) to achieve pleurodesis, which is an obliteration of the pleural space to prevent accumulation of fluid or recurrent pneumothorax.

Medical Nutrition Therapy

Neither evidence-based guidelines nor research exists for appropriate MNT for the patient with a pleural effusion. However, MNT

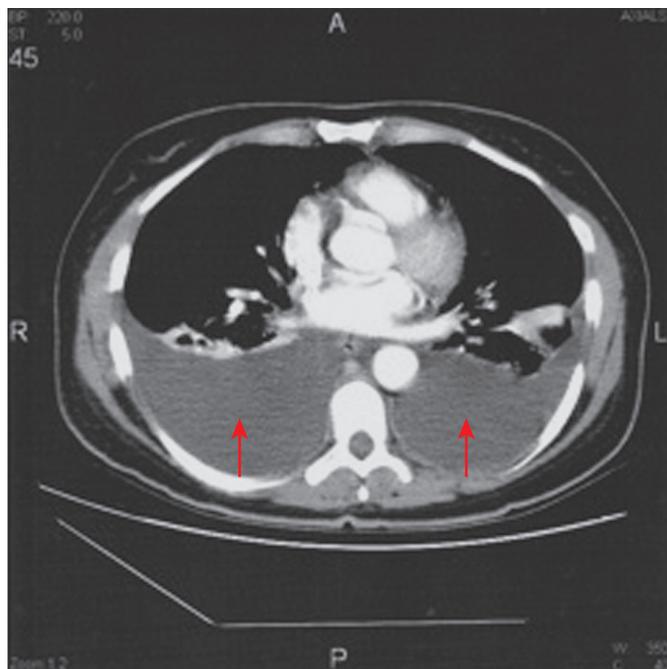

Fig. 33.9 Computed tomography (CT) scan showing bilateral pleural effusions.

interventions should be directed toward the underlying disorder causing the pleural effusion; for example, sodium and fluid restriction for the patient with congestive heart failure. Malnutrition may exist due to the primary disorder and should be appropriately diagnosed and treated.

CHYLOTHORAX

Chylothorax is a rare cause of pleural effusion. It is caused by the disruption or obstruction of the thoracic duct, which results in the leakage of chyle (lymphatic fluid of intestinal origin) into the pleural space. The fluid typically has a milky appearance. A pleural fluid triglyceride concentration of more than 110 mg/dL strongly supports the diagnosis of a chylothorax (Heffner, 2018).

Chylothorax can result from nontraumatic causes such as sarcoidosis or benign idiopathic chylothorax. It can occur because of surgical trauma such as postoperative chylothorax or postpneumonectomy chylothorax.

Medical Management

The principles of management of chylothorax are (1) treatment of the underlying condition such as sarcoidosis, infection, lymphoma, or metastatic carcinoma and (2) pleural drainage to relieve dyspnea. Those patients who do not improve by thoracentesis and dietary control measures may have to be treated by pleurodesis or thoracic duct ligation (Heffner, 2018).

Medical Nutrition Therapy

The goal of MNT is to reduce the flow of chyle, particularly in patients with low volume chylous drainage (less than one liter daily), by consuming a high-protein, low-fat (less than 10 grams) diet (Heffner, 2018). Decreasing fat intake will result in less fat to be absorbed in the gastrointestinal tract and therefore reduces chyle production. Long-chain triglycerides should be avoided. The restrictive very-low-fat diets may promote vitamin, particularly fat-soluble vitamin, and essential fatty acid deficiencies so intravenous vitamins and lipid emulsions may be needed. Very-low-fat enteral formulas are also available. If the pleural drainage decreases, medium-chain triglycerides (MCTs) could be added to the diet or enteral formula because MCTs, after absorption in the gastrointestinal tract, bypass the lymphatic system and are directly transported to the liver via the portal vein. MCTs are not very palatable and they have side effects such as gastrointestinal upset, steatorrhea, and hyperlipidemia. As the chylous drainage declines, fat intake can be gradually increased. It may take 7 to 10 days for the chylous drainage to clear. Patients with high volume chylous drainage (greater than one liter) will likely need surgery for correction. Parenteral nutrition may be needed for patients with high volume drainage and for those who do not respond to a very-low-fat intake.

ACUTE RESPIRATORY DISTRESS SYNDROME

Acute respiratory distress syndrome (ARDS) is a clinical state in which patients develop diffuse pulmonary infiltrates, severe hypoxia, and respiratory failure. Underlying clinical events such as sepsis or trauma that lead to the development of ARDS also result in a hypermetabolic state that markedly increases nutritional requirements (ARDS Definition Task Force et al, 2012).

Pathophysiology

For normal gas exchange, it is essential that dry, patent alveoli be in close proximity to capillaries. When an injury produces diffuse alveolar

TABLE 33.3 Common Clinical Conditions Associated with Acute Respiratory Distress Syndrome (ARDS)

Most Common	Less Common
Pneumonia	Drug toxicity
Sepsis	Aspiration
	Inhalation injury
	Near drowning
	Respiratory syncytial virus
	Transfusion related acute lung injury
	Trauma

Adapted from Saguil A, Fargo M: Acute respiratory distress syndrome: diagnosis and management, *Am Fam Phys* 85:352, 2012.

damage, proinflammatory cytokines are released. These cytokines promote migration of neutrophils to the lungs, where they become activated and release toxic mediators, which produce further damage to the alveolar epithelium and capillary endothelium. This damage allows protein to escape into the interstitium. Alveoli get filled with bloody, proteinaceous fluid which interferes with gas exchange, and severe, refractory hypoxemia results. Various clinical conditions can lead to the development of ARDS (Table 33.3).

Patients with ARDS present with acute onset of shortness of breath, tachypnea, and hypoxemia, which is refractory to oxygen supplementation.

Medical Management

The principles of ARDS management are the following (Siegel, 2013):

- Treatment of underlying cause such as sepsis, aspiration, or bacterial pneumonia
- Mechanical ventilatory support
- ICU including sedation with or without paralytic drug
- Ensuring hemodynamic stability
- Prevention of complications such as stress ulcers (gastrointestinal prophylaxis), hyperglycemia, deep venous thrombosis, and aspiration pneumonia
- Nutritional support
- Therapies with corticosteroids, exogenous surfactant, antioxidants, and inhaled nitric oxide have been used but have not shown consistent benefit.

Medical Nutrition Therapy

Malnutrition is common in these patients who require mechanical ventilation. Patients with severe respiratory disease have increased metabolic needs and require prompt initiation of supplemental nutrition. It is important to consider issues related to energy and protein use.

Nutrition support in ARDS patients is necessary for preventing cumulative caloric deficits, loss of LBM, malnutrition, and deterioration of respiratory muscle strength (Krzak et al, 2011). According to the 2016 Society of Critical Care Medicine and American Society for Parenteral and Enteral Nutrition (SCCM/ASPEN) guidelines, a standard enteral formula can be administered and a concentrated formula may be needed for those who are fluid-overloaded or have pulmonary edema (McClave et al, 2016).

Patients with ARDS are at high risk for complications as a result of underfeeding or overfeeding (Table 33.4). Reduction in respiratory

TABLE 33.4 Complications Resulting from Overfeeding and Underfeeding in Acute Respiratory Distress Syndrome (ARDS) Patients

Overfeeding	Underfeeding
Nosocomial infections	Nosocomial infections
Hypercapnia	Immunosuppression
Immunosuppression	Depressed respiratory muscle strength
Failure in weaning from mechanical ventilator	Failure in weaning from mechanical ventilator
Poor wound healing	Low ventilatory drive
Electrolyte imbalance	
Azotemia	

Adapted from Krzak A, et al: Nutrition therapy for ALI and ARDS, *Crit Care Clin* 27:647, 2011.

muscle strength is a negative consequence of underfeeding, which leads to problems in weaning from mechanical ventilation. In addition, poor wound healing, immunosuppression, and risk of nosocomial (hospital acquired) infections increase related to inadequate calories and protein. Overfeeding leads to undesirable outcomes such as stress hyperglycemia, delayed weaning from mechanical ventilation, and delayed wound healing (Krzak et al, 2011). Effective MNT requires careful assessment and monitoring. See Chapter 37 for further discussion on MNT for metabolically stressed patients.

PNEUMONIA

An inflammatory condition of the lungs that causes chest pain, fever, cough, and dyspnea is called **pneumonia**. In the clinical setting there are various kinds of pneumonias, such as community-acquired pneumonia, which may be viral or bacterial; hospital-acquired pneumonia; pneumonia in an immune compromised host; ventilator-associated pneumonia (VAP); and aspiration pneumonia, which will be discussed here. Aspiration is a common event even in healthy adults and usually causes no deleterious effects. At least one half of healthy adults aspirate during sleep. However, when this aspirate results in pulmonary infection, it results in **aspiration pneumonia** (Box 33.3).

Box 33.3 Conditions That Predispose a Patient to Aspiration Pneumonia

- Impaired level of consciousness, with compromised closure of glottis and impaired cough reflex
- Dysphagia from neurologic conditions (i.e., stroke)
- Gastric reflux, disorders of or surgery on the upper gastrointestinal tract
- Mechanical disruption of the glottis closure because of endotracheal tube, tracheostomy, bronchoscopy, and interference with the cardiac sphincter by gastroduodenal endoscopy or placement of a nasogastric tube
- Miscellaneous conditions such as protracted vomiting, feeding via gastrostomy at less than a 45-degree angle, and persistent recumbent position

Bartlett JG: Aspiration pneumonia in adults. In Baslow DS, editor: Wolters Kluwer: *UpToDate*, Waltham, Mass, 2012. Retrieved from <http://www.uptodate.com/contents/aspiration-pneumonia-in-adults>.

Pathophysiology

Two conditions must exist for aspiration pneumonia to develop. First, there is a breach in the normal defense mechanisms, such as failure of glottis closure or impaired cough reflex, and second, a large enough inoculum enters the lungs. The aspirate contains gastric acid, which has a direct toxic effect on the lungs, particulate matter that may cause airway obstruction and atelectasis, and oral bacteria, which can result in infection and pneumonia. Pathogens such as *S. pneumonia*, *Haemophilus influenzae*, gram-negative bacilli, and *S. aureus* are virulent, and only a small inoculum is needed to cause pneumonia. By convention, aspiration pneumonia is caused by less-virulent organisms such as anaerobes, which are part of the normal oral flora, with predisposing situations.

Medical Management

Three clinical syndromes exist within the category of aspiration pneumonia: (1) chemical pneumonitis resulting from aspiration of acid, (2) bacterial infection, and (3) airway obstruction. The clinical features depend on which of these predominates, but often there is an overlap. The details of the management of these syndromes is beyond the scope of this chapter but an understanding of pathophysiology and predisposing conditions helps in the effective treatment and prevention of aspiration pneumonia.

Patients who are observed to have aspirated should be cleared of the fluids or food with immediate tracheal suction. However, this maneuver will not necessarily protect the lungs from chemical injury, which occurs instantly (Bartlett, 2012). The main treatment in this situation is antibiotics and to support the pulmonary function. Use of glucocorticoids in chemical pneumonitis is controversial and not usually recommended.

Aspiration pneumonia usually presents with indolent symptoms. Many patients present with complications such as lung abscess, emphysema, and necrotizing pneumonia. Once a patient has been diagnosed with aspiration pneumonia, antibiotic therapy should include coverage for anaerobic pathogens because they may cause significant disease when present (Allen et al, 2013).

Medical Nutrition Therapy

Patients with aspiration pneumonia may have dysphagia so a swallow evaluation by a speech pathologist will be needed before allowing oral intake. Diet textures and liquid viscosities may need modification to prevent further aspiration. Dysphagia diets are described in Chapter 39 and Appendix 20.

If the patient has dysphagia and must have nothing by mouth, then enteral nutrition will be the preferred route of feeding. As per the 2016 SCCM/ASPEN and the American College of Gastroenterology guidelines (McClave et al, 2016), nutritional interventions for preventing aspiration pneumonia and managing it when it exists in the patient in the acute care setting are the following:

- Direct tube feedings into the small bowel rather than the stomach for those who are at high risk for aspiration
- Implement continuous feedings rather than bolus feedings
- Elevate the head of the patient's bed to 30 to 45 degrees
- Use prokinetic agents
- Minimize use of sedatives
- Optimize oral hygiene using chlorhexidine mouthwash

Gastric residuals volumes have been found not to correlate with incidences of aspiration. Also coloring agents, including blue food coloring, should not be used as markers of aspiration due to their potential toxicity.

LUNG TRANSPLANTATION

Lung transplantation was done for the first time in 1963 with good pulmonary results but the patient died 18 days after transplant due to comorbidities and malnutrition. Subsequently, multiple lung transplants were done without evaluating outcomes compared with other solid organ transplants. In the past, one of the main obstacles associated with lung transplantation was the type of immunosuppression required with the high dose of steroids that can affect airway anastomosis healing. Over the last 20 years, the number of lung transplants performed increased rapidly with 4122 lung transplants done in 2015. Outcomes have improved with better donor and recipient selection, surgical techniques, and medical therapy. The current median survival for lung transplant patients is about 5.5 years with chronic rejection being the most common complication.

Major indications for lung transplant are the following:

- COPD
- Idiopathic interstitial pneumonia (most commonly IPF)
- CF
- Pulmonary arterial hypertension
- Alpha-1 antitrypsin deficiency

Multiple factors are considered when a patient is being evaluated for lung transplantation; nutritional status is an important factor. Patients usually get referred to a registered dietitian nutritionist (RDN) before being listed for transplant. Nutritional status can adversely impact posttransplant outcomes. Patients with class I obesity (BMI: 30 to 34.9 kg/m²) are relatively contraindicated while those with class II obesity (BMI: >35 kg/m²) are absolutely contraindicated. A low BMI has not been a risk factor for mortality after lung transplantation (Weill et al, 2015). However, multiple studies have shown that malnutrition or a low BMI <18 kg/m² can be associated with worse outcomes (Christie et al, 2012; Lederer et al, 2009).

Medical Nutrition Therapy

As stated above, nutritional status plays a crucial role in a patient's hospital course and survival after lung transplantation. The pretransplant assessment by the RDN will determine the presence of malnutrition, and the nutrition interventions should include plans to correct the nutritional status. Postoperatively, the immediate concern is adequate nutrition for wound healing and recovery. Immunosuppressant medications have multiple adverse effects, some of which have nutritional implications that will need attention, including the need for education about food safety.

BRONCHOPULMONARY DYSPLASIA

Bronchopulmonary dysplasia (BPD) is a chronic lung disease most commonly seen in premature infants who require mechanical ventilation and oxygen therapy for acute respiratory distress. BPD occurs in 40% of preterm neonates less than or equal to 28 weeks gestational age (Davidson et al, 2017). BPD is a lung development disorder characterized by impairment of alveolarization. This leads to pulmonary and vascular hypoplasia with less interstitial cellularity and fibrosis (Jobe, 2011).

Common interventions have little impact on long-term outcomes, with respiratory care remaining supportive. Decreased lung compliance and increased need for respiratory support exists in these patients (Dani and Poggi, 2012).

Medical Management

Management should minimize any further injuries, while providing an optimal environment for growth and recovery (Adams and Stark, 2014).

Ongoing pulse oximetry is used to monitor oxygenation, whereas intermittent blood gas sampling monitors pH and Paco_2 . Periodic attempts are made to progressively wean infants from ventilator support. Prolonged ventilation is associated with laryngeal injury and subglottic stenosis, especially with infants who require multiple intubations. Suctioning should be limited to only when needed because it is associated with tracheal and bronchial injury (Adams and Stark, 2014).

The use of supplemental oxygen is challenging in patients with BPD because of the need to treat hypoxemia on one hand, and on the other, to avoid exposure to excess oxygen. Increasing the inhaled oxygen concentrations could have a negative affect by increasing the risk of retinopathy, pulmonary edema, or inflammation.

Most infants are managed with a modest fluid restriction of 140 to 150 mL/kg per day. Although diuretic therapy may improve short-term pulmonary status, there is no evidence that it improves clinical outcomes. Use of diuretics leads to serum electrolyte abnormalities such as hyponatremia and hypokalemia (Adams and Stark, 2014).

Medical Nutrition Therapy

Using the criteria in Box 33.4, assessment of the infant with BPD begins with MNT. Energy needs of infants with BPD are 15% to 20% higher than those of healthy infants, and they benefit from 140 to 150 kcal/kg/day during active stages of the disease (Dani and Poggi, 2012). Inadequate caloric intake leads to a catabolic state and muscle fatigue of the diaphragm. Adequate nutrition is essential for lung growth, alveolar development, surfactant production, and protection against infections.

Infants with BPD have decreased LBM, indicating an inadequate protein intake. Treatment with corticosteroids also increases body fat and lowers protein, thereby altering the composition of weight gain. Protein intakes of 3.5 to 4.0 g/kg body weight in infants with BPD help in meeting the growth and anabolic needs (Dani and Poggi, 2012). Amino acids are administered within the first 26 hours of life because they are well tolerated, improve glucose tolerance, and create positive nitrogen balance. An amino acid requirement of 1.5 to 2 g/kg/day is suggested for term infants, 2 to 3 g/kg/day for infants at 30 to 36 weeks, and 3.6 to 4.8 g/kg/day for infants at 24 to 30 weeks (Dani and Poggi, 2012) (see Chapter 41).

Although lipids remain a vital component in providing essential fatty acids and meeting energy goals, the role of lipid administration remains controversial. Lipids are held or administered in small quantities because they can cause hyperbilirubinemia and increase the risk of kernicterus (brain dysfunction due to hyperbilirubinemia) in these infants. Lipids result in less CO_2 production compared with carbohydrate, and although high-fat formulas do not show a significant change in respiration in adults, infants who receive high-fat formulas exhibit decreased CO_2 production and improved respiration (Dani and Poggi, 2012). Further investigation is required to determine the optimal lipid intake for infants with BPD. The European Society of Pediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN) recommends a reasonable range of 4.4 to 6.0 g of fat/100 kcal or 40% to 55% of caloric intake.

Sodium and potassium depletion are seen in infants with BPD who are treated with diuretics. Because sodium administration counteracts the action of diuretics, mild deficiencies in sodium and chloride are anticipated (Dani and Poggi, 2012).

Decreased bone mineralization is seen in infants with BPD. Urinary loss of calcium is increased with the administration of corticosteroids and diuretics. Osteopenia of prematurity is common in infants with BPD resulting from nutritional deficiencies of calcium and phosphorus. Enteral feeds are not useful in providing adequate amounts of calcium and phosphorus, whereas parenteral feeds restrict the intake because of limited solubility of calcium and phosphorus.

BOX 33.4 Components of Nutrition Assessment for Infants with Bronchopulmonary Dysplasia

History	Hemoglobin
Birthweight	Hematocrit
Gestational age	Serum electrolytes
Medical history	C-reactive protein
Nutrition history	
Previous growth pattern	Feeding History
	Volume of intake
	Frequency of feedings
Medical Status	Behavior during feedings
Respiratory status	Formula composition
Oxygen saturation	Use of solid foods
Use of medications	Developmental feeding milestones
Emesis	Swallowing difficulty
Stool pattern	Gastroesophageal reflux
Urine output	
Urine specific gravity	Environmental Concerns
Ventilator dependency	Parent-child interaction
	Home facilities
Nutrition-Biochemical Measures	Access to safe food supply
Anthropometrics	Community resources
Weight	Economic resources
Length	Access to adequate food and nutrients
Growth percentiles	
Head circumference	

Infants with BPD are monitored every 1 to 2 weeks for calcium and phosphorus and it is recommended to supplement with vitamin D (Dani and Poggi, 2012) and milk fortifiers (see Chapter 41).

The use of vitamin A, corticosteroids, and caffeine have been shown to reduce BPD at 36 weeks of age. 5000 IU of vitamin A was administered intramuscularly three times a week for a month to show a significant reduction in BPD and death in those infants receiving the supplementation (Ehrenkranz, 2014).

Parenteral nutrition is continued along with enteral feeds till the feeding volume reaches 100 mL/kg/day. Starting enteral feeds earlier induces gastric motility and promotes progression to full enteral feedings. Better neurologic development in preterm infants with BPD can be accomplished with early nutrition support, appropriate enteral feeds, and parenteral feed selection (Dani and Poggi, 2012). See Chapter 41 for further discussion on feeding the low birth weight infant.

Complementary and Integrative Approaches for Pulmonary Disease

Complementary and integrative approaches for pulmonary disease usually focus on providing support for the underlying pathology, whether it is inflammation and fibrosis or excess mucous production. It also focuses on exacerbating factors such as stress and environmental exposures (such as chemicals and pollution). Chapter 7 and appendix 22 provide a review of nutrition support for inflammation. Vitamin D and Omega-3 fatty acids have shown benefit for reducing inflammation, fibrosis and exacerbations in asthma and COPD and further study is underway on the long term benefit of these supplements (Gold, 2016). A recent review on diet and asthma concluded that study results are contradictory for single nutrient interventions and the authors recommend a whole diet approach (Han, 2015). Mind

body therapies such as meditation, yoga, tai chi, and mindfulness based stress reduction may be helpful for reducing stress and may reduce incidence of exacerbations in patients who are able and motivated to participate (McClafferty, 2014). N-acetyl cysteine (NAC), a derivative of the amino acid cysteine, has been used as a mucolytic for airway diseases such as COPD and chronic bronchitis. A recent Cochrane review concluded that while there is a small reduction in acute exacerbations and hospitalizations, there is not a significant improvement in overall lung function or reduction in mortality with the use of NAC. The authors stated that there was a high degree of heterogeneity in study participants and design, thus making the conclusions less certain (Poole, 2019). Contradictions in research on integrative approaches may come from the need for individualized assessment. For example, people who are not nutrient deficient will not respond to supplementation or dietary interventions to boost intake of that nutrient. Additionally, single nutrient interventions, including antioxidant vitamins, are typically inadequate for treating complex conditions. For this reason, integrative interventions are usually multi-modal, including whole diet, specific nutrient and mind body therapies, and work best when the patient is a willing and active participant.

CLINICAL CASE STUDY

Ray is a 75-year-old single white male who started smoking when he was in high school and quit several years ago because his breathing was becoming more difficult. His medical history includes chronic obstructive pulmonary disease (COPD), hypertension, hyperlipidemia, and coronary artery disease requiring a stent. He was admitted to the medical intensive care unit for a COPD exacerbation, his third exacerbation in the past 6 months. Significant findings are weight 120 lb, height 5'10", blood pressure 135/90 mm Hg, heart rate 82/minute, respiratory rate 28/minute, temperature 98.6° F, oxygen saturation 90% on 6L of O₂. Prescribed medications include an inhaled bronchodilator, antihypertensives, and a statin. Upon interviewing the patient, the registered dietitian nutritionist (RDN) learns the patient has not been eating well due to early satiety and shortness of breath, eating about 50% of usual intake in 2 meals, lost 50 lb in the past 6 months, and spends most of his day in a recliner as any physical activity leaves him breathless. His adult children bring in meals several times weekly, which he will reheat if he has the energy. Due to his limited income, he consumes no nutritional supplement, including herbal, vitamin, and mineral supplements.

Nutrition Diagnosis Statement

- Unintended weight loss related to decreased food intake due to COPD as evidenced by 50% of usual intake and weight loss of 50 lb/30% of body weight in 6 months.

Nutrition Care Questions

1. What are the interrelationships between COPD, food intake, and nutrient metabolism?
2. What are the goals of nutrition care for this patient? Keep in mind the frequency of the COPD exacerbations and their effect on the patient's prognosis.
3. What nutrition interventions can you suggest to increase intake of calories and protein? Why?
4. Due to his history of heart disease, the medical team ordered a low-fat, low-cholesterol, restricted-sodium diet for the patient. Is this diet appropriate? Why?
5. While hospitalized, what do you want to monitor to ensure the patient is making progress toward the agreed-upon nutrition goals?
6. The patient has a limited income and lives alone. Are there any food programs that may be beneficial? Also, if nutritional supplements are recommended, who will pay for them? Are there programs that will pay for them? If not, are there alternatives that are free or at a much lower price?

KEY TERMS

angiotensin-converting enzyme (ACE)	estimated glomerular filtration rate (eGFR)	nephrolithiasis
acute glomerulonephritis	erythropoietin (EPO)	nephrotic syndrome
acute kidney injury (AKI)	fistula	oliguria
adynamic (low turnover) bone disease	glomerular filtration rate (GFR)	osteitis fibrosa cystica
antidiuretic hormone (ADH)	graft	osteomalacia
angiotensin II receptor blocker (ARB)	hemodialysis (HD)	peritoneal dialysis (PD)
azotemia	hypercalciuria	phosphate binders
blood urea nitrogen (BUN)	hyperoxaluria	protein-nitrogen appearance (PNA) rate
calciphylaxis	idiopathic hypercalciuria (IH)	recombinant human EPO (rHuEPO)
chronic kidney disease (CKD)	intradialytic parenteral nutrition (IDPN)	renal failure
continuous renal replacement therapy (CRRT)	intra-peritoneal nutrition (IPN)	renal osteodystrophy
continuous venovenous hemodialysis (CVVHD)	Kidney Dialysis Outcome Quality Initiative (KDOQI)	renal replacement therapy (RRT)
continuous venovenous hemofiltration (CVVH)	Kidney Disease Improving Global Outcomes (KDIGO)	renal tubular acidosis (RTA)
creatinine	kinetic modeling	renin-angiotensin mechanism
dialysate	Kt/V	ultrafiltrate
end-stage renal disease (ESRD)	metastatic calcification	urea reduction ratio (URR)
		uremia
		vasopressin

PHYSIOLOGY AND FUNCTION OF THE KIDNEYS

The main function of the kidney is to maintain the balance of fluids, electrolytes, and organic solutes. The normal kidney performs this function over a wide range of fluctuations in sodium, water, and solutes. This task is accomplished by the continuous filtration of blood with alterations in secretion and reabsorption of this filtered fluid. The kidney receives 20% of cardiac output, filtering approximately 1600 L/day of blood and producing 180 L of fluid called **ultrafiltrate**. Through active processes of reabsorbing certain components and secreting others, composition of this ultrafiltrate is changed into the 1.5 L of urine excreted in an average day.

Each kidney consists of approximately 1 million functioning nephrons (Fig. 34.1), consisting of a glomerulus connected to a series of tubules. Tubules consist of different segments: the proximal convoluted tubule, loop of Henle, distal tubule, and collecting duct. Each nephron functions independently and contributes to the final urine, although all are under similar control and coordination. If one segment of a nephron is destroyed, that complete nephron is no longer functional.

The glomerulus is a spheric mass of capillaries surrounded by a membrane, Bowman's capsule. The glomerulus produces the ultrafiltrate, which then is modified by the next segments of the nephron.

Production of ultrafiltrate is mainly passive and relies on the perfusion pressure generated by the heart and supplied by the renal artery.

The tubules reabsorb the vast majority of components that compose the ultrafiltrate. Much of this process is active and requires a large expenditure of energy in the form of adenosine triphosphate (ATP). The tubule is a unique structure; differences in permeability between the various segments and hormonal responses allow the tubule to produce the final urine, which can vary widely in concentration of electrolytes, osmolality, pH, and volume. Ultimately, this urine is funneled into common collecting tubules and into the renal pelvis. The renal pelvis narrows into a single ureter per kidney, and each ureter carries urine into the bladder, where it accumulates before elimination.

The kidney has almost unlimited ability to regulate water homeostasis. Its ability to form a large concentration gradient between its inner medulla and outer cortex allows the kidney to excrete urine as dilute as 50 mOsm or as concentrated as 1200 mOsm. Given a daily fixed solute load of approximately 600 mOsm, the kidney can get rid of as little as 500 mL of concentrated urine or as much as 12 L of dilute urine. Control of water excretion is regulated by **vasopressin**, a small peptide hormone secreted by the posterior pituitary, which is also called **antidiuretic hormone (ADH)**. An excess of relative body water, indicated by a low osmolality, leads to prompt shut-off of all vasopressin secretion. Likewise, a small rise in osmolality brings about

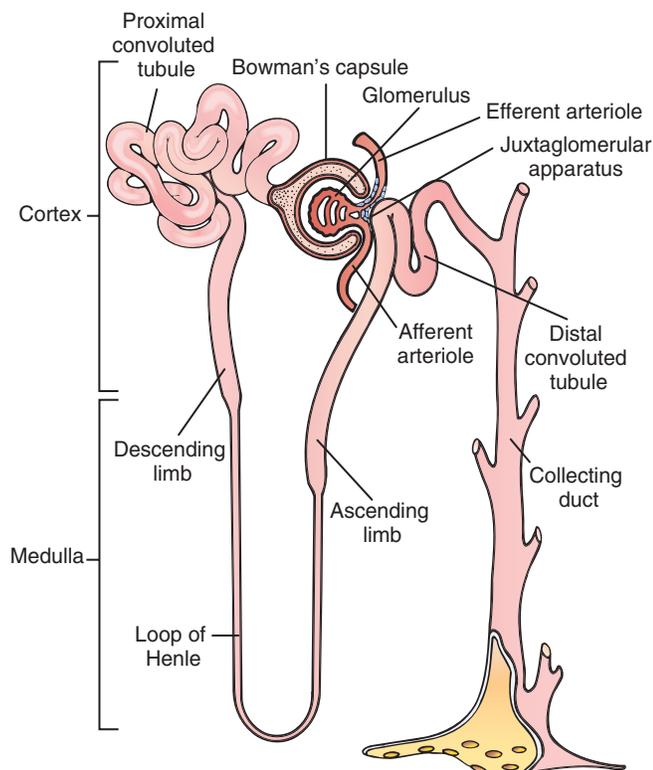

Fig. 34.1 The nephron. (Modified from Patton KT, Thibodeau GA: *The human body in health and disease*, ed 6, Maryland Heights, Mo, 2013, Mosby.)

marked vasopressin secretion and water retention. However, the need to conserve sodium sometimes leads to a sacrifice of the homeostatic control of water for the sake of volume.

The minimum urinary volume capable of eliminating a relatively fixed 600 mOsm of solute is 500 mL, assuming that the kidney is capable of maximum concentration. Urinary volume of less than 500 mL/day is called **oliguria**; it is impossible for such a small urine volume to eliminate all of the daily waste.

The majority of the solute load consists of nitrogenous wastes, primarily the end products of protein metabolism. Urea predominates in amount, depending on the protein content of the diet. Uric acid, **creatinine** (Cr), and ammonia are present in small amounts. If normal waste products are not eliminated appropriately, they collect in abnormal quantities in the blood, known as **azotemia**. The ability of the kidney to adequately eliminate nitrogenous waste products is defined as renal function. Thus **renal failure** is the inability to excrete the daily load of wastes.

The kidney also performs functions unrelated to excretion. One of these involves the **renin-angiotensin mechanism**, a major control of blood pressure. Decreased blood volume causes cells of the glomerulus (the juxtaglomerular apparatus) to react by secreting renin, a proteolytic enzyme. Renin acts on angiotensinogen in the plasma to form angiotensin I, which is converted to angiotensin II, a powerful vasoconstrictor and a potent stimulus of aldosterone secretion by the adrenal gland. As a consequence, sodium and fluid are reabsorbed, and blood pressure is returned to normal.

The kidney also produces the hormone **erythropoietin (EPO)**, a critical determinant of erythroid activity in the bone marrow. Deficiency of EPO is the primary cause of the severe anemia present in chronic renal disease.

Maintenance of calcium-phosphorus homeostasis involves the complex interactions of parathyroid hormone (PTH); calcitonin; active vitamin D; and three effector organs: the gut, kidney, and bone. The role of the kidney includes production of the active form of vitamin D—1,25-dihydroxycholecalciferol ($1,25[\text{OH}]_2\text{D}_3$)—as well as elimination of calcium and phosphorus. Active vitamin D promotes efficient absorption of calcium by the gut and is one of the substances necessary for bone remodeling and maintenance. Active vitamin D also suppresses PTH production, which is responsible for mobilization of calcium from bone (see Chapter 23).

RENAL DISEASES

The manifestations of renal disease are significant. They can be ordered by degree of severity: (1) kidney stones, (2) acute kidney injury (AKI), (3) chronic kidney disease (CKD), and (4) end-stage renal disease (ESRD) ([National Kidney Foundation, 2018](#)). Objectives of nutritional care depend on the abnormality being treated.

Kidney Stones (Nephrolithiasis)

Nephrolithiasis is a highly prevalent disease worldwide with rates ranging from 7% to 13% in North America, 5% to 9% in Europe, and 1% to 5% in Asia ([Sorokin et al, 2017](#)). National Health and Nutrition Examination Survey (NHANES) reveals a lower occurrence rate in black non-Hispanic and Hispanic individuals compared with white non-Hispanic individuals ([Scales et al, 2012](#)).

About one in 11 people has a kidney stone in their lifetime and more than 50% of these will have a recurrence within 5 to 10 years. A positive family history influences the clinical course of idiopathic calcium stones with significant gender related differences:

- Earlier onset in females and higher rate of recurrence.
- Men are one and a half times more likely than women to develop stones overall. ([Guerra et al, 2016](#)). Increased incidence of obesity, diabetes, hypertension, and metabolic syndrome have been linked to increasing rates of nephrolithiasis.

Health care cost of evaluation, hospitalization, and treatment of kidney stone disease in the United States exceeds 4.5 billion dollars per year. Preventing recurrence can have a significant cost-saving potential as a result of reduced stone burden. Medical nutrition therapy can play an important role in prevention and is economical compared with management with drugs. Medical evaluation and drug and diet therapy are underused. Only 7.4% of patients with visits to the emergency room (ER) with a stone submitted 24-hour urine collection for evaluation within 6 months ([Morgan and Pearle, 2016](#)). A low urine volume is the single most important risk factor for all types of nephrolithiasis. Body mass index (BMI), fluid intake, Dietary Approaches to Stop Hypertension (DASH)-style diet, dietary calcium intake, and sugar-sweetened beverage intake are the five modifiable risk factors that account for more than 50% of incident kidney stones ([Ferraro et al, 2017a](#)).

Pathophysiology

Kidney stone formation is a complex process that consists of saturation; supersaturation; nucleation; crystal growth or aggregation; crystal retention; and stone formation in the presence of substances that promote, inhibit, and precipitate stones in urine. A typical metabolic evaluation is described in [Table 34.1](#).

Calcium stones are the most common: 60% of stones are calcium oxalate, 10% calcium oxalate and calcium phosphate, and 10% calcium phosphate. Other stones are 5% to 10% uric acid, 5% to 10% struvite, and 1% cystine.

TABLE 34.1 Baseline Information and Metabolic Evaluation of Urolithiasis

Information	Description and Data
History of urolithiasis	History of onset, frequency Family history Spontaneous passage or removal Retrieval, analysis of stone Current status with radiologic examination
Medical history, investigation	Hyperparathyroidism Renal tubular acidosis Urinary tract infection Sarcoidosis Hypertension Osteoporosis Inflammatory bowel disease, malabsorption syndrome, intestinal bypass surgery for obesity (Roux-en-Y or gastric banding/sleeve gastrectomy) Metabolic syndrome or insulin resistance Diabetes mellitus Obesity
Blood tests	Serum—calcium, phosphorus, creatinine, uric acid, CO ₂ , albumin, parathyroid hormone, Hgb A1C
Urinalysis	Urine analysis with pH Urine culture
24-hr urine collection	Volume, calcium, oxalate, uric acid, sodium, citrate, magnesium, phosphorus Urea Creatinine Qualitative cystine
Medications and vitamins	Thiazide, allopurinol, vitamin C, vitamin B ₆ , vitamin D, cod liver oil, calcium carbonate, glucocorticoid therapy, potassium citrate, antacids
Occupation history and strenuous exercise	Dermal water losses Dehydration Low urine volume Type of job and activity level
Environment	Hard water area
Dietary evaluation	Intake of calcium, oxalate, animal protein, salt, purines, fructose, potassium Fruits and vegetables (related to urine pH) Herbal products, probiotics, fish oils Volume of fluid intake Type of fluids containing citrate, malate, caffeine, fructose, phosphoric acid; mineral water; sports drinks

CO₂, Carbon dioxide; Hgb A1C, hemoglobin A1C.

Stone formers with obesity excrete increased amounts of sodium, calcium, uric acid, and citrate, and have lower urine pH. Obesity is the strongest predictor of stone recurrence in first-time stone formers. As body weight increases, the excretion of calcium, oxalate, and uric acid also increases. Patients with a higher BMI have a decrease in ammonia excretion and impaired hydrogen ion buffering. With increasing BMI, uric acid stones become more dominant than calcium oxalate stones, especially in men.

Uric acid stones are common in the presence of type 2 diabetes. Hyperinsulinemia also may contribute to the development of calcium stones by increasing urinary calcium excretion. Uric acid stones are also associated with higher prevalence of CKD (Li et al, 2018).

TABLE 34.2 Causes and Composition of Renal Stones

Pathogenetic Causes	Composition of Stone
Hypercalciuria, hyperoxaluria, hyperuricosuria, or hypocitraturia	Calcium oxalate
Primary hyperparathyroidism	Calcium oxalate
Cystinuria	Cystine
Infection	Struvite
Acid urine pH	Uric acid
Hyperuricosuria	Uric acid
Renal tubular acidosis	Calcium phosphate
Alkaline urine pH	Calcium phosphate

Weight control may be considered one of the preventive modalities, and in stone formers a BMI of 18 to 25 kg/m² is recommended.

With malabsorptive bariatric procedures such as Roux-en-Y gastric bypass (RYGB), urolithiasis is higher than in obese controls, probably because of the increased prevalence of **hyperoxaluria** and hypocitraturia in RYGB patients. However, restrictive gastric surgery (i.e., gastric banding or sleeve gastrectomy) is not associated with increased risk of kidney stones (Semins et al, 2010).

Some oral antibiotics such as sulfa and broad-spectrum penicillins play a role in increasing stone risk in adults and children given the latter are prescribed antibiotics at a higher rate than adults (Tasian et al, 2018). Antibiotics alter the composition of human microbiome, and disruptions in the intestinal and urinary microbiome have been linked to the occurrence of kidney stones.

Agents added intentionally or unintentionally to food or drug products have led to the appearance of new types of stones containing melamine and indinavir (Zilberman et al, 2010) (Table 34.2).

Calcium Stones. Hypercalciuria is the most common abnormality identified in stone formers, occurring in 30% to 60% of patients. Ninety percent of patients with idiopathic hypercalciuria never form a stone. **Hypercalciuria** describes a value of calcium in excess of 300 mg (7.5 mmol) per day in men, 250 mg (6.25 mmol) per day in women, or 4 mg (0.1 mmol)/kg/day for either in random urine collections of outpatients on unrestricted diets.

Idiopathic hypercalciuria (IH) is a familial disorder characterized by abnormal serum calcium in the absence of known causes of hypercalciuria, such as primary hyperparathyroidism, sarcoidosis, excess vitamin D intake, hyperthyroidism, glucocorticoid use, or renal tubular acidosis (RTA).

The relationship between calcium intake and the risk of calcium stone formation is complex. Besides increased calcium intake raising urine calcium, other factors impact the risk of calcium stones. Higher calcium intake is associated with reduced risk of incident stone formation in all except men older than 60 years of age. The protective effect of dietary calcium has been attributed to the interaction between calcium and oxalate in the intestinal lumen to form an insoluble complex that is excreted in the stool. When calcium intake is low the formation of calcium oxalate complex declines and more oxalate is absorbed.

Low calcium intake in patients with IH increases bone loss associated with higher net acid excretion and greater risk of fractures. The loss of more calcium in urine than is in the diet indicates a total net loss of body calcium, its source being the skeleton. For decades low-calcium diets were recommended to reduce the hypercalciuria in stone formers. However, chronic prolonged calcium restriction, deficient calcium intake, and increased losses from hypercalciuria decrease bone

mineral density (BMD). The decreased BMD also correlates with an increase in markers of bone turnover as well as increased fractures (Krieger and Bushinsky, 2013). Vertebral fracture risk is four times higher in patients with urolithiasis than in the general population.

Negative calcium balance appears to be greater in stone formers than in non-stone formers. Patients with IH may also tend toward negative phosphorus balance even on normal intakes. The defective phosphate metabolism may lead to increased $1,25(\text{OH})_2\text{D}_3$ levels and increased intestinal calcium absorption. A high protein intake of non-dairy origin may enhance undesirable bone resorption. An inadequate calcium intake along with high protein intake induces metabolic acidosis, increases calcium excretion by inhibiting renal reabsorption of calcium secondary to the acid load, and lowers urinary pH. A reduction in nondairy animal protein, as well as potentially alkaline foods such as vegetables and fruit, is recommended (see *Clinical Insight: Acid and Alkaline Diets*).

Calcium supplementation is associated with an increased risk of stone formation compared with no supplementation as calcium supplements do not have the same protective effect against stone formation as dietary calcium. Widespread use of calcium supplements to prevent osteoporosis corresponds to an increase in kidney stones in women. A trial of combined calcium-vitamin D supplementation to prevent bone loss and fractures led to a 17% increase in new stone

formation in women who increased their calcium intake to 2000 mg a day by adding a 1000 mg calcium supplement to their baseline diet (Wallace et al, 2011).

If calcium is taken as a supplement, timing is important. Calcium supplements taken with meals increase urinary calcium and citrate but decrease urinary oxalate; thus the increase in citrate and decrease in oxalate counterbalance the effects of elevated urinary calcium. Therefore, if used by patients who cannot tolerate dairy products because of lactose intolerance, allergies, or preference, calcium supplements should be taken with meals. Urine calcium should be measured before starting the supplement and afterward to see the effect; if urine calcium increases, patients should increase fluid intake to dilute the urine concentration of calcium.

Higher dietary calcium from either nondairy or dairy foods is independently associated with a lower kidney stone risk (Taylor and Curhan, 2013). Therefore based on dietary reference intake (DRI) recommendations for age (1000 to 1200 mg/day) patients may select calcium from dairy or nondairy choices. Given recent concerns for increased risk for cardiovascular disease and kidney stones with increased use of calcium supplements, women should aim to meet DRI recommendations from a calcium-rich diet, taking calcium supplements only if needed to reach DRI goals. Calcium should be taken in divided doses, choosing a source with each meal to maximize oxalate

CLINICAL INSIGHT

Acid and Alkaline Diets

Dietary intake can influence the acidity or alkalinity of the urine (Berardi et al, 2008). It has been shown that excessive dietary protein (particularly high in sulfur-containing amino acids such as methionine and cysteine), and chloride, phosphorous, and organic acids are the main sources of dietary acid load. When these animal proteins, such as meat and cheese, are eaten with other acid-producing foods and not balanced with alkaline-producing foods, such as fruit and vegetables, there is an increased risk of chronic acidosis. Acidosis (which is not to be confused with acidemia) has been linked to inflammatory-related chronic diseases such as urolithiasis, hypertension, insulin resistance, low immune function, and osteoporosis (Adeva and Souto, 2011; Minich and Bland, 2007).

Consequently, when working with higher protein intakes it is important to provide a diet balanced with high alkaline foods. The most abundant alkaline foods are plant-based foods; particularly vegetables and fruit abundant in alkalizing micronutrients such as magnesium, calcium, sodium, and potassium. A more alkaline diet consisting of a higher fruit and vegetable intake and lower meat and refined carbohydrate intake is associated with a low potential renal acid load (PRAL) (Remer and Manz, 1995). Although acute acid loading may only temporarily disrupt acidbase equilibrium, a chronic perturbation occurs when metabolism of the diet repeatedly releases acids into the systemic circulation in amounts that exceed the amount of base released at the same time. To overcome the imbalance, the skeleton, which serves as the major reservoir of base, provides the buffer needed to main blood pH (Pizzorno et al, 2010).

Remer and Manz developed a physiologically based model to calculate the PRAL of selected, frequently consumed foods. By means of these PRAL data, the daily net acid excretion can be calculated, allowing for an accurate prediction of the effects of diet on acid load. This has been a reason to recommend animal protein limited diets, to control the dietary source of acids (Kiwull-Schone et al, 2008). The following food lists serve as a guide to influencing potential renal acid load (PRAL).

Potentially Acid Foods

Protein: meat, fish, fowl, shellfish, eggs, all types of cheese, peanut butter, peanuts

Fat: bacon, butternuts, walnuts, pumpkin seeds, sesame seeds, sunflower seeds, creamy salad dressings

Carbohydrate: all types of bread including cornbran, oats, macaroni, ricebran, rye, wheat, and especially wheat gluten, sugar (white)

Potentially Basic or Alkaline Foods

Fat: dried beechnuts, dried chestnuts, acorn

Vegetables: all types including legumes but especially beets, beet greens, Swiss chard, dandelion greens, kale, leeks, mustard greens, spinach, turnip greens

Fruit: all types, especially currants, dates, figs, bananas, dried apricots, apples, prunes, raisins

Spices/Herbs: all types, especially fresh dill weed and dried spices/herbs such as spearmint, basil, coriander, curry powder, oregano, parsley

Sweets: sorghum syrup, sugar (brown), molasses, cocoa (dry powder)

Beverages: coffee

Neutral Foods

Fats: butter, margarine, oils

Dairy: milk

Vegetables: corn

Sweets: sugar, maple syrup, honey

Beverages: water, tea

by Sheila Dean, DSc, RDN, LDN, CCN, IFMCP

binding. Calcium carbonate may be the best option. Low-fat dairy choices are good options for their lower saturated fat content.

Oxalate Stones. Hyperoxaluria (more than 40 mg of oxalate in urine per day) plays an important role in calcium stone formation and is observed in 10% to 50% of recurrent stone formers. Hyperoxaluria increases urinary saturation of calcium oxalate. Urinary oxalate levels are determined by calcium and oxalate in diet, functional integrity of gastrointestinal (GI) tract, presence of oxalate degrading bacteria in the gut, and genetic disorders. Primary hyperoxaluria is a feature of an autosomal-recessive genetic defect of a hepatic enzyme that results in overproduction of oxalate and a urinary oxalate concentration three to eight times normal. Multiple stones occur in these children, causing renal failure and early death.

GI malabsorptive conditions including inflammatory bowel diseases and gastric bypass often develop hyperoxaluria related to fat malabsorption. The bile acids produced during the digestive process normally are reabsorbed in the proximal GI tract, but when this fails to occur, bile salts and fatty acids increase colonic permeability to oxalate (see Chapter 27). The unabsorbed fatty acids also bind calcium to form soaps, decreasing availability of calcium in a soluble form. With less calcium available to bind oxalate in the gut and prevent its absorption, serum oxalate and thus urinary oxalate levels increase.

Urinary oxalate also comes from endogenous synthesis. Oxalate is generated in the liver from the metabolism of the amino acids hydroxyproline, glycine, phenylalanine, and tryptophan, and the dialdehyde glyoxal. GI oxalate absorption is not subject to regulation and its absorption is low and less than 15%. The oxalate absorbed is practically all excreted in the urine. Ascorbic acid accounts for 35% to 55%, and glyoxylic acid accounts for 50% to 70% of urinary oxalate. Pyridoxine acts as cofactor in the conversion of glyoxylate to glycine, and its deficiency could increase endogenous oxalate production (Holmes et al, 2016). In patients with CKD, excessive vitamin C intake may lead to stone formation. Dietary hyperoxaluria in patients on intensive, short time weight loss programs (Khneizer et al, 2017) or on high oxalate vegan diets (Hermann and Suarez, 2017) has been identified in case studies as a cause of acute or chronic kidney failure (oxalate nephropathy) due to oxalate crystal deposition in the tubules of the kidney.

The bioavailability of food oxalate and thus urine oxalate are affected by salt forms of oxalate, food processing and cooking methods, meal composition, and the presence of *Oxalobacter formigenes* in the GI tract. *O. formigenes* is part of the normal intestinal flora that degrades oxalate. Stone-forming patients who lack this bacterium have significantly higher urinary oxalate excretion secondary to reduced degradation and stone episodes compared with patients colonized with the bacteria. There is a strong inverse relationship between colonization and risk of recurrent calcium oxalate stone formation. In Western society 30% to 40% of the general population is colonized with *O. formigenes*. Stone formers are colonized at half this rate. Those not colonized are 70% more likely to develop a kidney stone (Holmes et al, 2016). Fecal samples from stone formers exhibit significantly lower bacterial representation of genes involved in oxalate degradation with inverse correlation with 24-hour urinary oxalate excretion (Ticinesi et al, 2018).

Administration of *O. formigenes* as enteric-coated capsules significantly reduces urine oxalate in patients with primary hyperoxaluria. Dietary advice for reducing urinary oxalate should include use of this probiotic and reduction of dietary oxalate, if needed, and simultaneous consumption of calcium-rich food or supplement to reduce oxalate absorption (Holmes et al, 2016; Box 34.1).

Uric Acid Stones. Uric acid is an end product of purine metabolism from food, de novo synthesis, and tissue catabolism. Approximately half

BOX 34.1 Foods to Avoid for a Low-Oxalate Diet

Rhubarb
Spinach
Strawberries
Chocolate
Wheat bran and whole-grain wheat products
Nuts (almonds, peanuts, or pecans)
Beets
Tea (green, black, iced, or instant)
High doses of the spice turmeric

Data from Siener R, et al: Oxalate content of cereals and cereal products, *J Agric Food Chem* 54:3008, 2006.

of the purine load is from endogenous sources and is constant. Exogenous dietary sources provide the other half, accounting for the variation in urinary uric acid. The solubility of uric acid depends on urine volume, the amount excreted, and urine pH (Table 34.3). Uric acid stones form when urine is supersaturated with undissociated uric acid, which occurs at urinary pH less than 5.5.

The most important feature in uric acid stone formers is low urine pH resulting from increased net acid excretion (NAE) and impaired buffering caused by reduced urinary ammonium excretion. The former can be a result of low intake of alkali-producing foods or increased consumption of acid-producing foods. Fruits, vegetables, and grains are alkali-producing foods while meat and dairy foods are acid-producing.

Inflammatory bowel disease results in chronically acidic urine, usually from dehydration. GI bicarbonate loss from diarrhea may predispose these patients to uric acid stones. Uric acid stones also are associated with lymphoproliferative and myeloproliferative disorders, with increased cellular breakdown that releases purines and thus increases uric acid load. Diabetes, obesity, and hypertension appear to be associated with nephrolithiasis; diabetes is a common factor in uric acid stone development (Scales et al, 2012). Besides diabetes management for patients with uric acid lithiasis and hyperuricosuric calcium oxalate stones, dietary purines also should be restricted (Morgan and Pearle, 2016).

Meat, fish, and poultry are rich in purines and acid ash and thus should be used in moderation to meet DRI for protein. Purines and metabolism of sulfur-rich amino acids, cystine, and methionine in animal protein confer an acid load to the kidney, thus lowering urine pH. Potential renal acid load (PRAL) value is assigned to groups of foods in terms of their positive or negative effect on acidic load (Trinchieri, 2012). Dietary factors that increase purines including fructose, excess animal protein, and alcohol should be minimized (see Chapter 38). Dietary noncompliance or persistence of hyperuricosuria warrants use of medication. Uric acid stones are the only stones amenable to dissolution therapy by urine alkalinization to a pH of 6 to 6.5. An alkali load can raise urine pH, prevent uric acid stone, and dissolve

TABLE 34.3 Effect of Urine pH on Stone Formation

pH	State of Urate	Likely Stone Development
<5.5	Undissociated urate	Uric acid stones
5.5-7.5	Dissociated urate	Calcium oxalate stones
>7.5	Dissociated urate	Calcium phosphate stones

them. Potassium citrate has been used as the first line of treatment. If this is not attainable or alkalization is not effective, allopurinol can be added. Sodium bicarbonate increases urinary monosodium urate and calcium and should not be used as a supplement.

Cystine Stones. Cystine stones represent 1% to 2% of urinary calculi and are caused by homozygous cystinuria. Cystine stones affect approximately 1 in 15,000 persons in the United States. Whereas normal individuals daily excrete 20 mg or less of cystine in their urine, stone-forming cystinuric patients excrete more than 250 mg/day. Cystine solubility increases when urine pH exceeds 7; therefore an alkaline urine pH must be maintained 24 hours per day, even while the patient sleeps. The primary goal of treatment is to reduce urinary cystine concentration to a level below the solubility limit of 250 mg/L. This is achieved almost always with the use of medication. Fluid intake of more than 4 L daily is recommended to prevent cystine crystallization and aim for urine volume of at least 3 to 4 L. Lower sodium intake (less than 100 mEq/day) may be useful in reducing cystine in the urine. Restriction of animal protein is associated with lower intake of cystine and methionine, a precursor of cystine. Ingestion of vegetables and fruit high in citrate and malate, such as melons, limes, oranges, and fresh tomato juice, may help alkalize the urine (Heilberg and Goldfarb, 2013). Potassium citrate can be used to raise urine pH of 7 to 7.5 (this may increase risk of calcium phosphate stones). Severe cystinuria requires the thiol drugs tiopronin, D-Penicillamine, and captopril, which form a complex with cysteine that is highly soluble. These drugs have significant side effects (Morgan and Pearle, 2016).

Melamine and Indinavir Stones. Kidney stones, acute renal failure (ARF), and death have been reported in young children who received melamine-contaminated infant formula. Melamine is an organic base synthesized from urea. When added as an adulterant to liquid milk or milk powder, it deceptively increases the protein content. Melamine precipitates in the distal renal tubules, forming crystals and sand-like stones. Hydration and urine alkalization help with stone passage.

The treatment of human immunodeficiency virus infection with protease inhibitors, such as indinavir, has led to the appearance of another previously unknown urinary calculus. Hypocitraturia is universal in all patients with indinavir stones as well as decreased solubility in a low urine volume with a low pH. These stones are soft, gelatinous, and radiolucent and are not amenable to basket removal or ureteroscopy. Intravenous (IV) hydration and temporary cessation of indinavir should be the first choice of treatment (Zilberman et al, 2010).

Struvite Stones. Struvite stones are composed of magnesium ammonium phosphate and carbonate apatite. They are also known as triple-phosphate or infection stones. Unlike most urinary stones, they occur more commonly in women than in men, at a ratio of 2:1. They form only in the presence of bacteria such as *Pseudomonas*, *Klebsiella*, *Proteus mirabilis*, and *Urealyticum*, which carry urease, a urea-splitting enzyme. Urea breakdown results in ammonia and carbon dioxide (CO₂) production, thus raising urine pH and the level of carbonate. Struvite stones grow rapidly to large staghorn calculi in the renal pelvic area. The mainstay of treatment is extracorporeal shockwave lithotripsy (ECSWL) with adjunctive culture-specific antimicrobial therapy that uses urease inhibitors. The goal is to eliminate or prevent urinary tract infections by regularly screening and monitoring urine cultures. Because of their infectious origin, diet has no definitive role except avoidance of urine alkalization. Acetohydroxamic acid is a potent urease inhibitor that prevents bacterial induced urease to alter the urinary milieu.

Medical Management

Uric acid stones are the only type amenable to dissolution therapy or dissolving of the stone by alkalization of the urine. This is done with consumption of a more vegetarian diet that is also lower in purines or

by the use of medication. Shockwave lithotripsy and endourologic techniques almost have replaced the open surgical procedures of stone removal of 20 years ago. Struvite stones also are treated with adjunctive culture-specific antimicrobial therapy that uses urease inhibitors. Management strategies are now aimed at kidney stone prevention.

Medical Nutrition Therapy

After corrective treatment, nutrition assessment is needed to determine risk factors for stone recurrence. The risk in men and women rises with increasing urine calcium and oxalate and decreases with increasing citrate and urine volume. There is a continuum of risk related to increasing urinary calcium and urinary oxalate. For patients with no metabolic abnormality there is a graded increase in stone risk that begins when the rate of urinary excretion of calcium, oxalate, and citrate is still within the normal range (Curhan and Taylor, 2008). Because urine chemistries change from day to day based on changes in the environment and diet, two 24-hour urine specimens are needed based on a usual diet, one during a weekday and one on the weekend. Specific medical nutrition therapy (MNT) is then based on comprehensive metabolic evaluations consisting of radiologic studies to assess stone burden, crystallographic stone analysis, and laboratory studies with standard serum chemistries and 24-hour urine collections. Nutrition counseling and metabolic monitoring can be effective (Table 34.4). Evaluation and management should be personalized according to risk

TABLE 34.4 Recommendations for Diet and 24-Hour Urine Monitoring in Kidney Stone Disease

Diet Component	Intake Recommendation	24-Hour Urine
Protein	Normal intake; avoid excess	Monitor urinary urea
Calcium	Normal intake: 1000 mg if age <50 years; 1200 mg if age >50 years Divide intake between three or more eating sessions. Choose from dairy or nondairy sources	Calcium <150 mg/L (<3.75 mmol/L)
Oxalate	Avoid moderate- to high-oxalate foods if urinary oxalate is high	Oxalate <20 mg/L (<220 μmol/L)
Fluid	2.5 L or more; assess type of fluids consumed; provide guidelines	Volume > 2 L/day
Purines	Avoid excessive protein intake; avoid specific high-purine foods	Uric acid <2 mmol/L (<336 mg/L)
Vitamin C	Avoid supplementation	Monitor urinary oxalate
Vitamin D	Meet DRI for vitamin D intake; use supplements to reach DRI	Serum 25(OH)D ₃ in acceptable range
Vitamin B ₆	No risk associated; no recommendation made except for primary hyperoxaluria	
Sodium	<100 mmol/day	Monitor urinary sodium

DRI, Dietary reference intake.

of recurrence, severity of stone disease, and presence of associated medical conditions (Shah and Calle, 2016).

When a patient passes a stone, it should be determined whether it is a new stone or a preexisting one and advisement given accordingly. The effectiveness of any MNT should be monitored with evaluation of subsequent 24-hour urine collections. This gives the dietitian and patient a measure of the effect of dietary changes. Once diet therapy is initiated, the goal is to prevent new stones from forming and preexisting stones from growing (see *Pathophysiology and Care Management Algorithm: Kidney Stones*).

Fluid and Urine Volume. A low urine volume is by far the most common abnormality noted in the metabolic evaluation of stone formers, and its correction with a high fluid intake should be the focus with all types of kidney stones. The objective is to maintain urinary solutes in the undersaturated zone to inhibit nucleation; this is accomplished by an increase in urine volume and reduction of solute load. The goal is the amount of urine flow rather than a specified fluid intake. High urine flow rate tends to wash out any formed crystals, and a urine volume of 2 to 2.5 L/day should prevent stone recurrence (Shah and Calle, 2016). Fluid intake should change based on different rates of extrarenal fluid loss that affect rate of urine flow. The concentration of urinary risk factors is important, not the absolute amount excreted, as the former will be high when the urine volume is low. The goal should be to maintain appropriate concentration of solutes per liter of urine.

Achieving a urine volume of 2 to 2.5 L/day usually requires an intake of 250 mL of fluid at each meal, between meals, at bedtime, and when arising to void at night. Hydration during sleep hours is important to break the cycle of the “most-concentrated” morning urine. Half of this daily 2.5 L should be taken as water. Even higher fluid intake, perhaps as much as 3 L/day, may be necessary to compensate for any GI fluid loss, excessive sweating from strenuous exercise, or an excessively hot or dry environment. Barriers to fluid intake success include lack of knowledge about the benefits of fluid or not remembering to drink, disliking the taste of water, lack of thirst, lack of availability of water, needing to void frequently, and not wanting workplace disruptions. Fluid intake behavior can be improved by specifically addressing barriers relevant to the individual patient.

Not all fluids are equally beneficial for reducing the risk of kidney stones. Cranberry juice acidifies urine and is useful in the treatment of struvite stones. Black currant juice increases urinary citrate and oxalate and, because of its urine alkalinizing effect, may prevent the occurrence of uric acid stones. Orange juice has citrate that delivers an alkali load.

Tea, coffee, decaffeinated coffee, orange juice, beer, and wine have been associated with reduced risk of stone formation. Coffee and tea induce moderate diuresis because of their caffeine content. Because decaffeinated coffee has no caffeine, it is suggested that other mechanisms may be involved, such as phytochemicals with antioxidant properties. Alcohol also helps because of diuresis. In a dose response meta-analysis each 500 mL increase in water intake was associated with a significantly reduced risk of kidney stone formation. Protective associations were found for an increasing intake of tea, coffee, and alcohol but no significant risk associated with an intake of juice, soda, or milk (Xu et al, 2015). Sugar-sweetened noncola soda and punch are associated with a 33% higher risk of kidney stones versus cola sodas with a 23% higher risk (Ferraro et al, 2013).

The oxalate content of tea brewed from regular black or green tea is 300 to 1500 $\mu\text{mol/L}$. Because of this high oxalate content of black tea, it should be taken with generous amounts of added milk; milk appears to reduce oxalate absorption by binding it in the gut lumen as calcium oxalate, making it less absorbable. Herbal teas have much lower oxalate content of 31 to 75 $\mu\text{mol/L}$ and are an acceptable alternative.

Animal Protein. Epidemiologic studies find a correlation between improved standard of living, high animal protein intake, and the rising incidence of kidney stones. Meat, fish, poultry, eggs, cheese, and grains are the primary contributors of acid; a load of acid to kidney evaluation (LAKE) score can be a simple and useful tool to evaluate dietary PRAL. Dietary modifications can be made to achieve LAKE reduction for the prevention of kidney stones. Fruits, juices, vegetables, potatoes, and legumes have negative PRAL values (Trinchieri, 2012) (see *Clinical Insight: Acid and Alkaline Diets*). An adequate-calcium (1200 mg/day), low-animal protein (52 g/day), low-salt diet (50 mmol/day) was associated with a lower incidence of stone recurrence compared with low calcium (400 mg/day) diet. Several multicomponent dietary interventions to study the effect of restricting animal protein have taken place but an independent evaluation of the effect of animal protein restriction has not been done. A protein moderation with a recommended intake of 0.8-1.0 g/kg/day is recommended (Shah and Calle, 2016; Morgan and Pearle, 2016) in calcium oxalate and uric acid stone formers who have relatively high levels of uric acid. Long-term consumption of protein supplements (whey protein and albumin) to increase muscle mass and improve performance may cause variable increase in urinary calcium, lower pH, and increase in urinary sodium (albumin). Caution and monitoring are warranted (Hattori et al, 2017).

Oxalate. Because much less oxalate than calcium exists in urine (the ratio is 1:5), changes in oxalate concentration have a greater effect than changes in urinary calcium. However, oxalate absorption, which is 3% to 8% of the amount in food, is affected by the amount of dietary calcium. Dietary calcium reduces oxalate absorption and appears to have more impact on urinary oxalate than the amount of dietary oxalate. The impact of dietary oxalate on urinary oxalate appears to be small. Absorption of soluble oxalate with varying amounts of daily calcium intake from 200 to 1800 mg/day showed a linear inverse relationship between daily calcium intake and oxalate absorption. Normal healthy people who consume oxalate at 100 to 750 mg/day can have an increase of 2 mg urinary oxalate per 100 mg of oxalate consumed. A difference of 5 mg increase in urinary oxalate can be associated with a 70% to 100% increase in stone risk in some groups (Holmes et al, 2016). Age is associated independently and inversely with urinary oxalate.

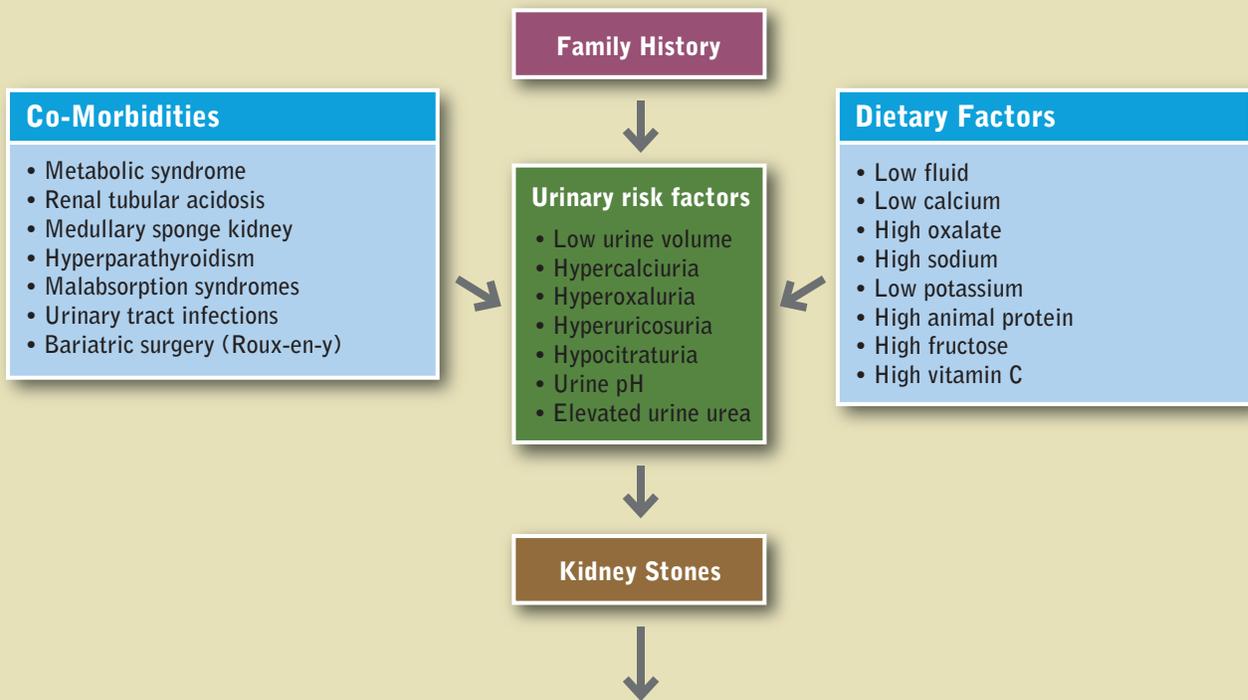

Dietary counseling to reduce oxalate absorption is beneficial for stone-forming individuals who have large intakes of high-oxalate foods and who excrete more than 30 mg (350 μmol) of oxalate per day. Based on the available evidence, severe oxalate restriction is not necessary. A low oxalate intake is considered at 80 to 100 mg/day (Holmes et al, 2016). Strategies to reduce urine oxalate excretion should be dually controlled with a reasonable reduction in oxalate intake (see Box 34.1 for foods high in oxalate) and maintenance of normal calcium consumption. The growth of kidney stones is not likely to be a constant process; it responds to transient sharp increases in oxalate concentration. It should be emphasized to patients that deviations in any meal or snack could potentially result in significant stone growth. Infrequent ingestion of high-oxalate and low-calcium foods (e.g., spinach) could risk rapid stone growth (Holmes et al, 2016). The patient is advised to add calcium to each meal to bind oxalate. The total calcium intake for the day can be divided between at least three meals or as many eating occasions as possible. Patients should include approximately 150 mg calcium in each meal, such as that found in $\frac{1}{2}$ cup milk, ice cream, pudding, yogurt, or $\frac{3}{4}$ oz cheese. In recurrent stone formers the DASH diet, which includes foods rich in oxalate compared with a low-oxalate diet, showed lower urinary saturation of calcium-oxalate, higher urine pH, and increased urinary magnesium and citrate excretion. A modified DASH diet with a reduced oxalate content may be more effective (Noori et al, 2014; Morgan and Pearle, 2016). Probiotics, specifically *Lactobacillus acidophilus*, have been shown to prevent

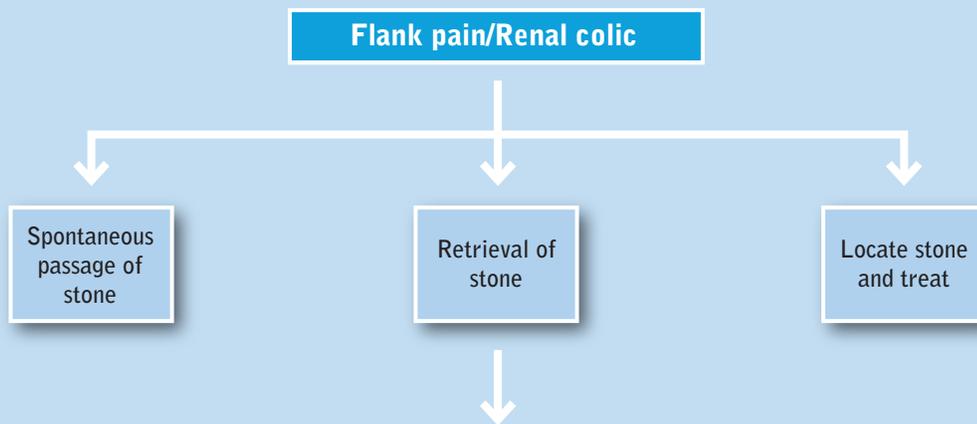

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Kidney Stones

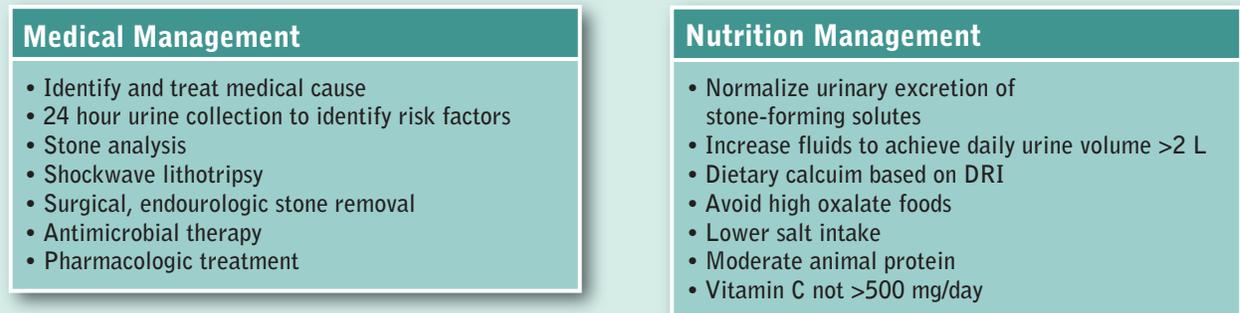

ETIOLOGY

PATHOPHYSIOLOGY

MANAGEMENT

intestinal oxalate absorption and therefore decrease its urinary excretion (Hermann and Suarez, 2017). New therapies include an oral formulation of the recombinant form of microbial enzyme that degrades dietary oxalate in the gut and decreases urinary oxalate excretion but needs more trials before it is accepted for use (Langman et al, 2016).

Potassium. Potassium intake is related inversely to the risk of kidney stones. Stone formers often have a low to normal potassium intake and high sodium intake that results in an adversely raised Na:K ratio. Estimation of fruit and vegetable intake should be included in the metabolic evaluation. Stone formers should be encouraged to consume diets high in potassium by choosing low-oxalate fruit and vegetables many times throughout the day (see Appendix 44 and Box 34.1). Foods high in potassium are replete with alkali, which stimulates urinary citrate excretion, raises pH and urine volume as shown in the study of dietary protein type (dairy, nondairy animal, and vegetable) and potassium, and animal protein to potassium ratio (an estimate of net acid load). Potassium intake is associated with lower risk of incident kidney stones. Greater risk is associated with higher animal protein to potassium ratio. Dairy protein was a better option compared with nondairy protein (Ferraro et al, 2016b).

Magnesium. Magnesium is a low-molecular-weight inhibitor that forms soluble complexes with oxalate. Like calcium, it inhibits oxalate absorption and may have a role to play in hyperoxaluric patients.

Phosphate. Excess urine phosphate contributes to calcium phosphate stone risk, but it is not as important a risk factor as urinary pH, which determines how much phosphate will be in the form of hydrogen phosphate (HPO_4). Calcium phosphate stones tend to occur in pregnant women in the second and third trimesters of pregnancy.

Sodium. The daily amount of sodium in modern diets reaches excessive levels that average 3500 mg/day in the United States. The amount of sodium in the urine and hypercalciuria are correlated directly because sodium and calcium are reabsorbed at common sites in the renal tubule. The risk for nephrolithiasis is significantly higher in hypertensive individuals compared with normotensive individuals. A low-sodium diet and water therapy lowered urine sodium, calcium, and oxalate in idiopathic hypercalciuric stone formers compared with controls on water therapy alone (Taylor et al, 2009). Urine sodium is associated positively with urine calcium and urine volume and negatively with urine calcium-oxalate supersaturation. Increased volume may confer a protective effect.

Sodium intake should be lowered to less than 2300 mg/day in patients with hypercalciuria. Consumption of a diet modeled on the DASH diet reduces the risk for kidney stones. Higher DASH scores are associated with higher intakes of calcium, potassium, magnesium, oxalate, and vitamin C and lower intakes of sodium as the diet is moderately high in low-fat dairy products, fruits and vegetables, and nuts and low in animal proteins (see Appendix 17).

Citrate. Citrate inhibits urinary stones by forming a complex with calcium in urine. Thus less calcium is available to bind urinary oxalate, which helps prevent the formation of calcium oxalate or calcium phosphate stones. Distal **renal tubular acidosis (RTA)** is an acidosis accompanied by hypokalemia. RTA, malabsorption syndrome with enteric hyperoxaluria, and excessive meat intake (lower urine pH) are associated with decreased urinary citrate levels.

Many citrate-containing beverages have been tested for their effect on urine. Several diet sodas contain moderate amounts of citrate and malate, bicarbonate precursors; malate increases the total alkali load delivered, which augments citraturia. One commercial sports drink tested in non-stone formers increased urine citrate as much as 170 mg/day, but many sports drinks also contain too much fructose and do not increase urinary citrate. Melon juice has citrate and malate and a PRAL value more negative than orange juice. Fresh tomato juice has citrate and malate and is low in sodium and oxalate.

Hypocitraturia is most commonly idiopathic but also may be caused by acidosis accompanied by hypokalemia, malabsorption syndrome with enteric hyperoxaluria, excessive meat intake, and acid ash. Half of recurrent calcium stone formers have hypocitraturia (urinary citrate of less than 300 mg/day). Normal daily urinary citrate level should be more than 640 mg/day. Long-term lemonade or lime or lemon juice therapy in hypocitraturic stone formers results in increased urinary citrate levels and decreased stone formation rate. Mineral water, with its magnesium and bicarbonate content, raises urine pH and stone inhibition.

Fructose. Fructose intake has increased approximately 2000% during the past 30 years from the widespread use of high-fructose corn syrup in foods. Fructose may increase urinary excretion of calcium and oxalate. It is the only carbohydrate known to increase the production of uric acid and its urinary excretion. Fructose also may increase insulin resistance, which is associated with low urine pH. Fructose intake has been positively associated with risk for all types of kidney stones. Increased fruit and vegetable consumption is recommended to increase potassium intake, but because of the fructose content of fruit, there should be more emphasis on vegetables.

Vitamins. Vitamin C can break down to oxalate in tissues as it performs its antioxidant function. Studies support vitamin C intake as a significant risk factor for the development of kidney stones. Men with an intake >218 mg/day had a 31% higher risk of forming stones than those consuming <105 mg/day. Supplemental vitamin C at 1000 mg/day was associated with twofold increased risk of kidney stones in men compared with less than 90 mg/day. Greater than 1000 mg/day results in 6.8 mg more oxalate in urine (Holmes et al, 2016). In another study, which included women, total vitamin C intake and supplemental vitamin C intake correlated with risk for stone formation in men but not women. In another study dietary vitamin C intake was not associated with stones among men or women although few participants had dietary intakes >700 mg/day (Ferraro et al, 2016a). Thus individuals with calcium oxalate stone disease and high levels of urine oxalate should avoid vitamin C supplementation and watch their intake of vitamin C-rich foods (Holmes et al, 2016).

Vitamin B_6 in the form of pyridoxal phosphate is a required cofactor in oxalate metabolism in promoting the activity of alanine glyoxylate aminotransferase, which diverts glyoxylate away from oxalate synthesis and may reduce urinary oxalate excretion. Conflicting results were found between intake of vitamin B_6 and risk of kidney stones in previous studies. Based on the result of a large cohort, no association was found between intake of vitamin B_6 and incident stones (Ferraro et al, 2018). Marginal B_6 status should be avoided. Pyridoxine supplementation, incrementally up to a dosage of 20 mg/kg/day in primary hyperoxaluria, has shown a 25% relative reduction in urinary oxalate, with benefit seen in 50% of patients (Morgan and Pearle, 2016; Holmes, et al 2016).

Patients with kidney stones have significantly higher vitamin D levels compared with controls (Wang et al, 2016). There is no statistically significant association between total vitamin D intake (<100 to $= > 1000$ IU/day) and supplemental vitamin D intake (0 to $= > 1000$ IU/day) and risk of incident stones. Use of vitamin D in typical amounts used appears safe (Ferraro et al, 2017b). Long-term vitamin D supplementation did not increase the risk of kidney stones (Malihi, 2016).

Omega-3 Fatty Acids. Elevated levels of arachidonic acid (AA) in cell membranes may promote hypercalciuria and hyperoxaluria. The intake of omega-3 fatty acids such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) may decrease the AA content of cell membranes and reduce urinary excretion of calcium and oxalate. EPA is an inhibitor of AA metabolism resulting in decreased synthesis of prostaglandin E2 (PGE2), a substance known to potentiate

urine calcium excretion. The use of fish oil (omega-3 fatty acids at 1200 mg/day) in the treatment of hypercalciuric stone formers combined with diet counseling resulted in a measurable decrease in urine calcium (24% became normocalciuric) and oxalate excretion, and an increase in urinary citrate. Calcium-oxalate supersaturation decreased in 38% of subjects. EPA at 1800 mg/day showed significant reduction in stone episodes (Yasui et al, 2008). Fish oil administration needs further exploration to confirm its effects and mode of action.

EDUCATION, ADHERENCE, AND COMPLIANCE

Based on current practice patterns more than half of the urologists provide dietary recommendations for greater than 75% of patients, time spent varying from less than 4 minutes to greater than or equal to 10 minutes. Although greater than 76% would like another provider to give recommendations, only 23% partner with a registered dietitian nutritionist (RDN) to do so (Wertheim et al, 2014). Multiple patient factors account for compliance and adherence with diet recommendations. Less than three recommendations are associated with higher patient recall. Most important dietary strategies to reduce stone risk should be prioritized, reserving those less important for follow-up (Penniston et al, 2016).

ACUTE KIDNEY INJURY (ACUTE RENAL FAILURE)

Pathophysiology

Acute kidney injury (AKI) is characterized by a sudden reduction in **glomerular filtration rate (GFR)**, the amount of filtrate per unit in the nephrons, and altered ability of the kidney to excrete the daily production of metabolic waste. AKI can occur in association with oliguria (decreased output of urine) or normal urine flow, but it typically occurs in previously healthy kidneys. Duration varies from a few days to several weeks. The causes of AKI are numerous and can occur simultaneously (Table 34.5). These causes are generally classified into three categories: (1) inadequate renal perfusion (prerenal), (2) diseases

within the renal parenchyma (intrinsic), and (3) urinary tract obstruction (postrenal).

A technique to help clinicians assess the severity and progression of AKI uses the acronym RIFLE (Risk, Injury, Failure, Loss, and ESRD), indicating the likelihood of a patient recovering or progressing to chronic renal failure. This, in turn, helps dietitians know whether to increase protein intake goals or be more moderate to preserve kidney function.

Medical Management

The ratio of **blood urea nitrogen (BUN)** to Cr can be used diagnostically to assess the location of damage to the kidney. Depending on where the insult occurs, BUN is increased because of poor filtration and is more actively reabsorbed. In this situation, with a BUN/Cr ratio greater than 20:1, damage is prerenal (before the kidney). Generally, if careful attention is directed at diagnosing and correcting the prerenal or obstructive causes, AKI is short lived and requires no particular nutritional intervention.

When damage is intrinsic (within the kidney), the BUN/Cr ratio decreases to less than 10:1. Intrinsic AKI can result from causes listed in Table 34.5; of these, a prolonged episode of ischemia leading to ischemic acute tubular necrosis is the most devastating. Typically patients develop this illness as a complication of an overwhelming infection, severe trauma, surgical accident, or cardiogenic shock. The clinical course and outcome depend mainly on the underlying cause. Patients with AKI caused by drug toxicity generally recover fully after they stop taking the drug. On the other hand, the mortality rate associated with ischemic acute tubular necrosis caused by shock is approximately 70%. Typically these patients are highly catabolic, and extensive tissue destruction occurs in the early stages. Hemodialysis (HD), which is discussed later, is used to reduce the acidosis, correct the uremia, and control hyperkalemia.

If recovery is to occur, it generally takes place within 2 to 3 weeks after the insult is corrected. The recovery (diuretic) phase is characterized first by an increase in urine output and later by a return of waste elimination. During this period dialysis may still be required, and careful attention must be paid to fluid and electrolyte balance and appropriate replacement.

Medical Nutrition Therapy

Nutritional care in AKI is particularly important because the patient not only has uremia, metabolic acidosis, and fluid and electrolyte imbalance but also usually suffers from physiologic stress (e.g., infection or tissue destruction) that increases protein needs. The problem of balancing protein and energy needs with treatment of acidosis and excessive nitrogenous waste is complicated and delicate. In the early stages of AKI the patient is often unable to eat. Early attention to nutritional support and early dialysis improves patient survival.

At the onset of AKI, depending on severity, some patients can be treated with medical management, and other patients require **renal replacement therapy (RRT)** with standard **hemodialysis (HD)** or **peritoneal dialysis (PD)** to remove wastes and fluids until kidney function returns. In significant AKI, a patient in the intensive care unit (ICU) may require continuous treatments, rather than periodic dialysis. **Continuous renal replacement therapy (CRRT)** is the broad category term that includes a whole host of modalities. Most often used are **continuous venovenous hemofiltration (CVVH)** and **continuous venovenous hemodialysis (CVVHD)**, which use a small ultrafiltration membrane to produce an ultrafiltrate that can be replaced by parenteral nutrition (PN) fluids. This treatment allows parenteral feeding without fluid overload.

Protein. The amount of protein recommended is influenced by the underlying cause of AKI and the presence of other conditions. A

TABLE 34.5 Some Causes of Acute Kidney Injury

Causes	Condition
Prerenal inadequate renal perfusion	Severe dehydration Circulatory collapse
Intrinsic diseases within the renal parenchyma	Acute tubular necrosis <ul style="list-style-type: none"> Trauma, surgery Septicemia Ischemic acute tubular necrosis Nephrotoxicity <ul style="list-style-type: none"> Antibiotics, contrast agents, and other drugs Local reaction to drugs Vascular disorders <ul style="list-style-type: none"> Bilateral renal infarction Acute glomerulonephritis of any cause <ul style="list-style-type: none"> Poststreptococcal infection Systemic lupus erythematosus
Postrenal urinary tract obstruction	Benign prostatic hypertrophy with urinary retention Carcinoma of the bladder or prostate Retroperitoneal or pelvic cancer Bilateral ureteral stones and obstruction Rhabdomyolysis

range of recommended levels can be found in the literature, from 0.5 to 0.8 g/kg for nondialysis patients to 1 to 2 g/kg for patients receiving dialysis. With CRRT protein losses are high, and estimated protein needs increase to 1.5 to 2.5 g/kg. As the patient's overall medical status stabilizes and improves, metabolic requirements decrease. During this stable period before renal function returns, a minimum protein intake of 0.8 to 1 g/kg of body weight should be given. This remains dependent on the patient's overall status and comorbidities and should be evaluated individually. In the past AKI patients were maintained in the hospital. Recent changes in Centers for Medicare and Medicaid Services (CMS) regulations have stable AKI patients moving to outpatient dialysis units. Questions may be posed to the nephrologist to clarify if the goal is lower protein for preserving or regaining kidney function versus a higher protein goal to address needs for healing and immune function.

Energy. Energy requirements are determined by the underlying cause of AKI and comorbidity. Energy needs can be measured at the bedside by indirect calorimetry in most ICUs (see Chapter 2). If this equipment is not available, calorie needs should be estimated at 25 to 40 kcal/kg/day of upper end ideal body weight (IBW). Excessive calorie intake can lead to excess CO₂ production, depressing respiration (see Chapter 33). With newer solutions available, glucose can be either absorbed or lost, depending on the concentration or type of solution used, and can be a source of calorie loss or gain. Large intakes of carbohydrate and fat are needed to prevent the use of protein for energy production. For patients who receive PN, high concentrations of carbohydrate and lipid can be administered to fulfill these needs as long as respiratory status is monitored.

A high-calorie, low-protein diet may be used in cases in which dialysis or hemofiltration is unavailable. In addition to the usual dietary sources of refined sweets and fats, special high-calorie, low-protein, and low-electrolyte formulas have been developed to augment the diet. However, care must be taken with these products because hyperglycemia is not uncommon as a result of glucose intolerance, and additional insulin often is needed.

Fluid and Sodium. During the early (often oliguric) phase of AKI, meticulous attention to fluid status is essential. Ideally fluid and electrolyte intake should balance the net output. With negligible urine output, significant contributions to total body water output include emesis and diarrhea, body cavity drains, and skin and respiratory losses. If fever is present, skin losses can be excessive, whereas if the patient is on humidified air, almost no losses occur. Because of the numerous IV drugs, blood, and blood products necessitated by the underlying disease, the challenge in managing patients at this point becomes how to cut fluid intake as much as possible while providing adequate protein and energy.

Sodium is restricted based on decreased urinary production. In the oliguric phase when the sodium output is very low, intake should be low as well, perhaps as low as 20 to 40 mEq/day. However, limiting sodium is often impossible because of the requirement for many IV solutions (including IV antibiotics, medications for blood pressure, and PN). The administration of these solutions in electrolyte-free water in the face of oliguria quickly leads to water intoxication (hyponatremia). For this reason, all fluid above the daily calculated water loss should be given in a balanced salt solution. Furthermore, aggressive fluid removal in AKI is generally discouraged. The risk of myocardial stunning, meaning damaging the heart by reducing left ventricular function from removing fluid too quickly, goes against the goals of returning the patient to prior stable health (Mahmoud, 2017).

Potassium. Most of the excretion of potassium and the control of potassium balance are normal functions of the kidney. When renal function is impaired, potassium balance should be scrutinized

TABLE 34.6 Summary of Medical Nutrition Therapy for Acute Kidney Injury

Nutrient	Amount
Protein	Adjust per MD. For goal of regain of function 0.8-1 g/kg IBW increasing as GFR returns to normal, but if the cause of AKI requires protein for healing, the goal should be closer to 1-1.2 g/kg IBW
Energy	30-40 kcal/kg of body weight
Potassium	30-50 mEq/day in oliguric phase (depending on urinary output, dialysis, and serum K ⁺ level); replace losses in diuretic phase
Sodium	20-40 mEq/day in oliguric phase (depending on urinary output, edema, dialysis, and serum Na ⁺ level); replace losses in diuretic phase
Fluid	Replace output from the previous day (vomitus, diarrhea, urine) plus 500 mL
Phosphorus	Limit as necessary

AKI, Acute kidney injury; GFR, glomerular filtration rate; IBW, ideal body weight; K⁺, potassium; MD, medical doctor; Na⁺, sodium.

carefully. In addition to dietary sources, all body tissues contain large amounts of potassium; thus tissue destruction can lead to potassium overload. Potassium levels can shift abruptly and have to be monitored frequently. Potassium intake must be individualized according to serum levels (see Appendix 44). The primary mechanism of potassium removal during AKI is dialysis. Control of serum potassium levels between dialysis administrations relies mainly on IV infusions of glucose, insulin, and bicarbonate, all of which drive potassium into cells. Exchange resins, such as sodium polystyrene sulfonate (Kayexalate), which exchange potassium for sodium in the GI tract, can be used to treat high potassium concentrations; however, for many reasons these resins are less than ideal. Table 34.6 summarizes MNT for AKI.

CHRONIC KIDNEY DISEASE

Many forms of kidney disease, two of which are described earlier, are characterized by a slow, steady decline in renal function and lead to renal failure in some patients, whereas other patients have a benign course without loss of renal function. It is unclear why some patients remain stable with **chronic kidney disease (CKD)** for many months to years, whereas others progress rapidly to renal failure and dialysis. The nature of this progressive loss of function has been the subject of an enormous amount of basic and clinical research during the past several decades and the subject of several excellent reviews (National Kidney Foundation, 2018; Yang et al, 2014). MNT begins when the patient is diagnosed, with the goal of preventing the progression of the disease as well as mitigating symptoms.

Pathophysiology

Diabetes is the leading risk factor for CKD followed by hypertension and glomerulonephritis. The National Kidney Foundation divides CKD into five stages related to the **estimated glomerular filtration rate (eGFR)**, the rate at which the kidneys are filtering wastes (Table 34.7). Stages 1 and 2 are early stages with markers such as proteinuria, hematuria, or anatomic issues. Stages 3 and 4 are considered advanced stages. Stage 5 results in death unless dialysis or transplantation is initiated. See Box 34.2 for additional causes of CKD.

TABLE 34.7 Stages of Chronic Kidney Disease

				Albuminuria Categories		
				A1	A2	A3
				Normal to mildly increased	Moderately increased	Severely increased
				<30 mg/g <3 mg/mmol	30–299 mg/g 3–29 mg/mmol	≥300 mg/g ≥30 mg/mmol
GFR stages	G1	Normal or high	≥90			
	G2	Mildly decreased	60–90			
	G3a	Mildly to moderately decreased	45–59			
	G3b	Moderately to severely decreased	30–44			
	G4	Severely decreased	15–29			
	G5	Kidney failure	<15			
<p>Key to Figure: Colors: Represents the risk for progression, morbidity and mortality by color from best to worst.</p> <p>Green: Low risk (if no other markers of kidney disease, no CKD) Yellow: Moderately increased risk Orange: High risk Red: Very high risk Deep red: Highest risk</p>						

From National Kidney Foundation. *Estimated Glomerular Filtration Rate* (website). <https://www.kidney.org/atoz/content/gfr>.

BOX 34.2 Causes of Chronic Kidney Disease (CKD)

	Examples of systemic diseases affecting the kidney	Examples of primary kidney diseases (absence of systemic diseases affecting the kidney)
Glomerular diseases	Diabetes, systemic autoimmune diseases, systemic infections, drugs, neoplasia (including amyloidosis)	Diffuse, focal or crescentic proliferative glomerulonephritis; focal and segmental glomerulosclerosis; membranous nephropathy, minimal change disease
Tubulointerstitial diseases	Systemic infections, autoimmune, sarcoidosis, drugs, urate, environmental toxins (lead, aristolochic acid), neoplasia (myeloma)	Urinary-tract infections, stones, obstruction
Vascular diseases	Atherosclerosis, hypertension, ischemia, cholesterol emboli, systemic vasculitis, thrombotic microangiopathy, systemic sclerosis	ANCA-associated renal limited vasculitis; fibromuscular dysplasia
Cystic and congenital diseases	Polycystic kidney disease, Alport's syndrome, Fabry's disease	Renal dysplasia, medullary cystic disease, podocytopathies
Genetic diseases are not considered separately because some diseases in each category are now recognized as having genetic determinants.		

National Kidney Foundation. *How to Classify CKD* (website). <https://www.kidney.org/professionals/explore-your-knowledge/how-to-classify-ckd>.

Medical Management

The prevalence of CKD is now estimated at approximately 15% of adults in the United States, or greater than 30 million Americans. This estimated prevalence of CKD shows that 1 in 3 people with diabetes and 1 in 5 people with hypertension have CKD ([Centers for Disease Control and Prevention \[CDC\], 2019](#)). Many states have legislated

clinical laboratories reporting serum Cr also to report the patient's eGFR. Patients with a low calculated eGFR do not necessarily have CKD. They must have several blood samples drawn 3 months apart that are consistently low (showing eGFR of less than 60) (see Table 34.7). The National Kidney Foundation and the American Society for Clinical Pathology and many other laboratories have standardized

testing, so that doctors can easily identify and diagnose patients. Evidenced-based clinical practice guidelines recommend two tests for CKD assessment: eGFR and urine albumin-Cr ratio. These tests come paired on most laboratory profiles. This streamlining of tests helps doctors easily monitor all patients for the presence of kidney disease.

An online eGFR calculator can be found at the National Kidney Foundation website. With screening tools such as the calculated eGFR and a greater awareness of the progressive nature of CKD, more attention has focused on its social, medical, and financial effects. For example, CKD is strongly linked with cardiovascular disease (see *Clinical Insight: Chronic Kidney Disease and Heart Disease—A Deadly Union*).

CLINICAL INSIGHT

Chronic Kidney Disease and Heart Disease—A Deadly Union

The presence of chronic kidney disease (CKD) increases the risk category for those with cardiovascular disease (CVD), and exacerbates existing CVD. An alarming fact is that most patients with CKD die of heart disease before they develop end-stage renal disease. Recommendations are that CKD patients should decrease their cardiovascular risks: quit smoking, increase exercise, choose healthy fats, increase intake of fruits and vegetables, and reach and maintain a healthy body weight. Fortunately, intervention makes a difference. The United States Renal Data System Dialysis M/M Study included 2264 patients with CKD. More than half had not seen a nephrologist in the year before needing dialysis, and a third had their first nephrologist encounter less than 4 months before starting dialysis. This late referral to nephrologists resulted in low serum albumin and hematocrit levels. Patients who had seen a nephrologist at least 2 years before dialysis had a decrease in mortality. Thus patients who have CKD and receive early nutrition counseling may postpone the need for dialysis, or come to dialysis better nourished. The expertise of the renal dietitian has been recognized by the Center for Medicare Services, allowing for physician-ordered medical nutrition therapy by registered dietitian nutritionist (RDN) providers for Americans with CKD who are not on dialysis.

Medical Nutrition Therapy

With each level of CKD, a different nutritional therapy may be proposed. The primary objectives of MNT are to manage the symptoms associated with the syndrome by treating the primary cause of the disease and then the secondary symptoms (edema, hypoalbuminemia, and metabolic acidosis), decrease the risk of progression to renal failure, decrease inflammation, and maintain nutritional stores. Patients are treated primarily with sodium bicarbonate, blood pressure medicines such as **angiotensin-converting enzyme (ACE)** inhibitors and **angiotensin II receptor blockers (ARBs)**, low-sodium diets, and diuretics. Research has shown that starting with diet modification, specifically increasing fruits and vegetables, can be as effective alone or paired with these treatments (Goraya et al, 2013). Research further shows that use of ACEs and ARBs work poorly when not in the setting of a low-sodium diet (Garofalo et al, 2018). The DASH and Mediterranean diet are being utilized more and more for MNT in CKD to support patients (Gallieni and Cupisti, 2016).

Protein. Patients with an established severe protein deficiency who continue to lose protein may require an extended time of carefully supervised nutritional care. The diet should attempt to provide sufficient protein and energy to maintain a positive nitrogen balance

and to support tissue synthesis while not overtaxing the kidneys. In most cases, sufficient intake from carbohydrate and fats is needed to spare protein for anabolism. Providing adequate protein remains the same goal with **Nephrotic Syndrome**. With this diagnosis, giving excess protein tends to cause more protein to spill into the urine further damaging the kidneys, with little impact on improving nutritional status.

The recommended dietary protein level for CKD patients has changed over time. Historically, these patients received diets low in protein to prevent symptoms of uremia prior to the development of dialysis. Studies have shown that a reduction of protein intake to 0.8 g/kg/day may decrease proteinuria without adversely affecting serum albumin. Multiple studies comparing protein intake in this population have had inconsistent results. It seems prudent to encourage adequate protein targeted to their overall nutrition needs.

A large multicenter trial, Modification of Diet in Renal Disease (MDRD), attempted to determine the role of protein, phosphorus restriction, and blood pressure control in the progression of renal disease. Thus the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDKD) developed recommendations for the management of patients with progressive renal disease or pre-ESRD. Those recommendations for dietary protein intake in progressive renal failure are 0.8 g/kg/day with 60% high biologic value (HBV) for patients whose GFR is greater than 55 mL/min, and 0.6 g/kg/day with 60% HBV for patients whose GFR is 25 to 55 mL/min.

The National Kidney Foundation's **Kidney Dialysis Outcome Quality Initiative (KDOQI)** panel who establish national renal guidelines and **Kidney Disease Improving Global Outcomes (KDIGO)** who establish international guidelines, suggests that patients whose GFR is less than 25 mL/min and who have not yet begun dialysis should be maintained on 0.6 g/kg/day of protein and 35 kcal/kg/day. If patients cannot maintain an adequate caloric intake on this protein recommendation, their protein intake should be increased to 0.75 g/kg/day. In both cases approximately 50% of the protein should be of HBV.

The potential benefits of protein restriction in the patient with moderate renal insufficiency must be weighed against the potential hazards of such treatment (i.e., protein malnutrition). If protein is restricted, careful monitoring and anthropometric studies should be carried out periodically as directed by the KDOQI guidelines.

Systemic hypertension, which aggravates the progressive loss of renal function, must be well controlled to produce benefits from protein restriction. Also important in the control of the progression of renal failure in people with diabetes is good blood glucose control. In a national multicenter trial, the Diabetes Control and Complications Trial (DCCT) showed that blood glucose control was more important than protein restriction in delaying the onset of renal failure in individuals who have diabetes (see Chapter 29).

Research continues about the use of more plant-based proteins in CKD, including tofu and legumes. Some benefits can be assessed looking at inflammation and improvement in mortality rates, but it is not yet conclusive that this is related to the plant-based proteins, or a result of the nutrition and lifestyle changes associated with a more plant-based diet (Sparks, 2018).

Energy. Energy intake should be approximately 35 kcal/kg/day for adults to spare protein for tissue repair and maintenance. In patients who are significantly overweight, some adjustment should be made to normalize requirements (see Box 2.1 in Chapter 2).

Sodium. Edema, the most clinically apparent manifestation, indicates total body sodium overload. In addition, because of low oncotic pressure from hypoalbuminemia, the volume of circulating blood

may be reduced because of migration of fluid to interstitial space. Attempts to severely limit sodium intake or to use diuretics may cause marked hypotension, exacerbation of coagulopathy, and deterioration of renal function. Therefore control of edema in this group of diseases should be with dietary intake of 1500mg of sodium daily (Whelton et al, 2012).

Potassium. Potassium management is possible through use of medications such as diuretics, individualized diet prescription, and rate of progression of CKD. Many patients in early-stage CKD take potassium-wasting diuretics (e.g., furosemide) that require supplementation of potassium. When urine output drops below 1 L/day, these same patients may require a change to potassium restriction as the kidney is no longer able to excrete all the potassium ingested. This typically occurs rather late in stage 4 CKD.

Phosphorus. The importance of controlling phosphate in patients with early-stage disease often is overlooked. Serum phosphorous levels elevate at the same rate as eGFR decreases. Early initiation of phosphate reduction therapies is advantageous for delaying hyperparathyroidism and bone disease. Unfortunately, patients are often asymptomatic during the early phase of hyperparathyroidism and hyperphosphatemia; they may not attend to their modified diets or understand the need to take **phosphate binders** with meals.

Those with an eGFR of less than 60 should be evaluated for renal bone disease and benefit from phosphorus restriction. Ongoing monitoring of a patient's phosphorus and use of phosphate binders is recommended. The diet typically is modified to allow no more than 1000 mg of phosphates daily, a limit that allows approximately one to two dairy foods per day. Because of the recommended decrease in protein intake, the control of phosphorus is somewhat easier to manage. Patients who are in later stages of CKD and intolerant of red meats because of uremic taste alterations often are able to substitute milk foods for meat and still maintain a limited phosphate intake.

Lipids. The important consequence of dyslipidemia is cardiovascular disease. Pediatric patients with frequently relapsing or resistant nephrotic syndrome are at particular risk for premature atherosclerosis. Certain lipid-lowering agents in combination with a cholesterol-lowering diet can reduce total cholesterol, low-density lipoprotein cholesterol, and triglycerides in these patients (see Chapter 32). KDIGO, a global nonprofit organization that develops guidelines for the treatment of CKD, recently made the recommendation not to use statins in CKD patients as they do not improve cardiovascular outcomes despite lowering cholesterol (KDIGO, 2013). Standard diet recommendations for lowering cholesterol remain appropriate, with the understanding of protein goals.

Vitamins and Probiotics. CKD patients routinely are recommended a water-soluble renal customized vitamin supplement, because restrictions of fruits, vegetables, and dairy foods may cause the diet to be inadequate. Significant research is being done at this time linking the gut microbiome to progression of CKD paired with research to see if probiotics are both safe and effective in the treatment of this dysbiosis (Lau, 2017; Borges et al, 2018). Further research will continue to try to unlock the answers to the balance of gut repair paired with safety and efficacy of probiotics use in this immunocompromised population.

END-STAGE RENAL DISEASE

End-stage renal disease (ESRD) reflects the kidney's inability to excrete waste products, maintain fluid and electrolyte balance, and

produce certain hormones. As renal failure slowly progresses, the level of circulating waste products eventually leads to symptoms of uremia (see *Pathophysiology and Care Management Algorithm: Chronic Kidney Disease and End-Stage Renal Disease*). **Uremia** is a clinical syndrome of malaise, weakness, nausea and vomiting, muscle cramps, itching, metallic taste in the mouth, and neurologic impairment that is brought about by an unacceptable level of nitrogenous wastes in the body.

Pathophysiology

ESRD can result from a wide variety of different kidney diseases. Currently 90% of patients reaching ESRD have chronic (1) diabetes mellitus, (2) hypertension, or (3) glomerulonephritis. The manifestations are somewhat nonspecific and vary by patient. No reliable laboratory parameter corresponds directly with the beginning of symptoms. However, as a rule of thumb, BUN of more than 100 mg/dL and Cr of 10 to 12 mg/dL are usually close to this threshold.

Medical Treatment

Once the patient progresses from stage 4 to stage 5 CKD, options for treatment for ESRD include dialysis, transplantation, or medical management progressing to death.

Dialysis

Patients may choose to dialyze in an outpatient dialysis facility, or they may prefer hemodialysis (HD) at home using either conventional daily or nocturnal dialysis. They may choose peritoneal dialysis (PD) and have a choice of continuous ambulatory peritoneal dialysis (CAPD) or automated peritoneal dialysis (APD, formerly called continuous cyclic peritoneal dialysis, or CCPD), or combinations of the two. Patients, families, and their physicians together evaluate the therapy that best meets the patient's needs (Table 34.8).

HD requires permanent access to the bloodstream through a **fistula** created by surgery to connect an artery and a vein (Fig. 34.2). If the patient's blood vessels are fragile, an artificial vessel called a **graft** may be implanted surgically. Large needles are inserted into the fistula or graft before each dialysis and removed when dialysis is complete. Temporary access through subclavian catheter is common until the patient's permanent access can be created or can mature; however, problems with infection make these catheters undesirable. In 2003 the CMS paired with the national oversight groups called the Renal Network to establish a quality improvement project called Fistulas First to encourage fistula placement and catheter removal to work toward better patient outcomes.

The HD dialysate fluid and electrolyte content is similar to that of normal plasma. Waste products and electrolytes move by diffusion, ultrafiltration, and osmosis from the blood into the dialysate and are removed (Fig. 34.3). Outpatient HD usually requires treatment of 3 to 5 hours three times per week in a dialysis unit (Fig. 34.4). Newer therapies can shorten the duration of treatment by increasing its frequency. Patients on these more frequent dialysis therapies have lower mortality rates, approaching that of transplantation. Patients on daily dialysis at home typically have treatments lasting from 2 to 3.5 hours 5 to 6 days a week, whereas some home dialysis patients receive nocturnal dialysis three to six times a week for 8 hours, while they sleep.

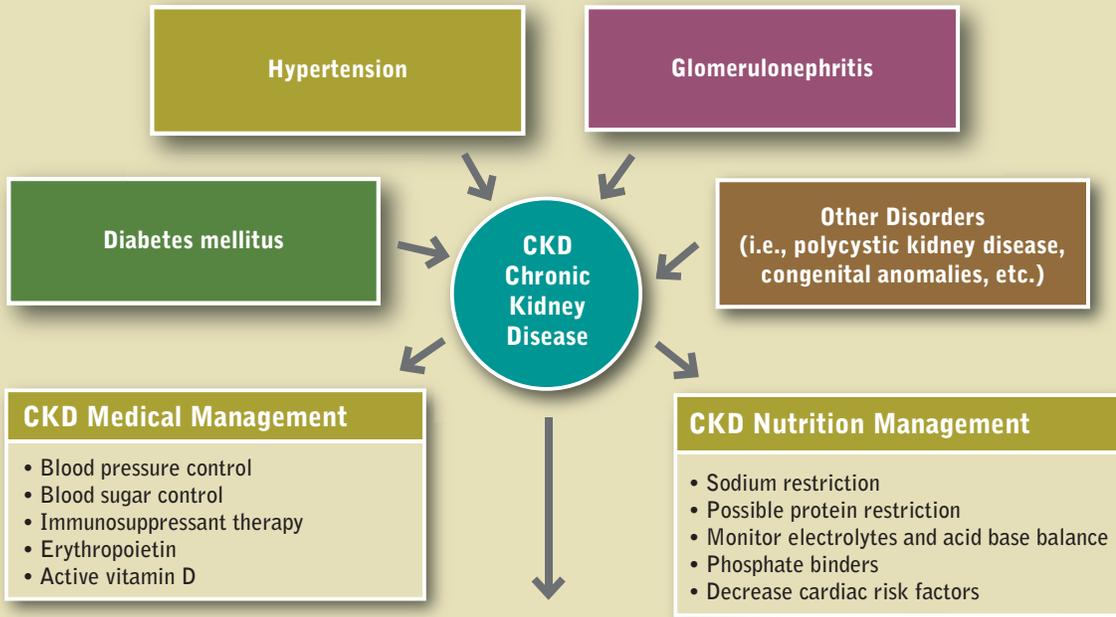

PD makes use of the body's own semipermeable membrane, the peritoneum. A catheter is implanted surgically through the abdomen

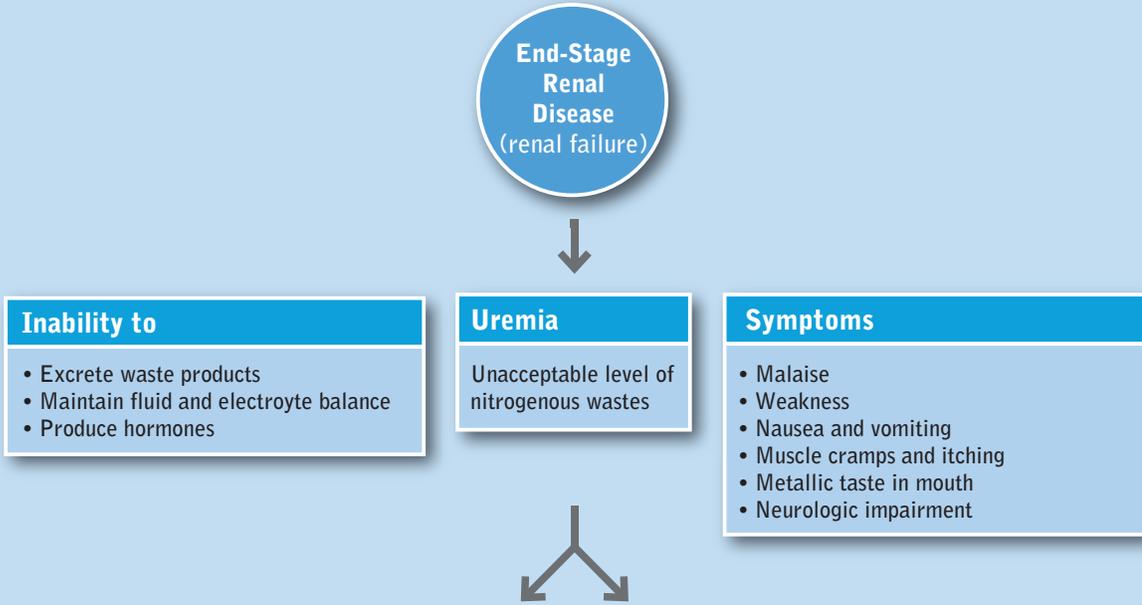

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Chronic Kidney Disease and End-Stage Renal Disease

ETIOLOGY

PATHOPHYSIOLOGY

MANAGEMENT

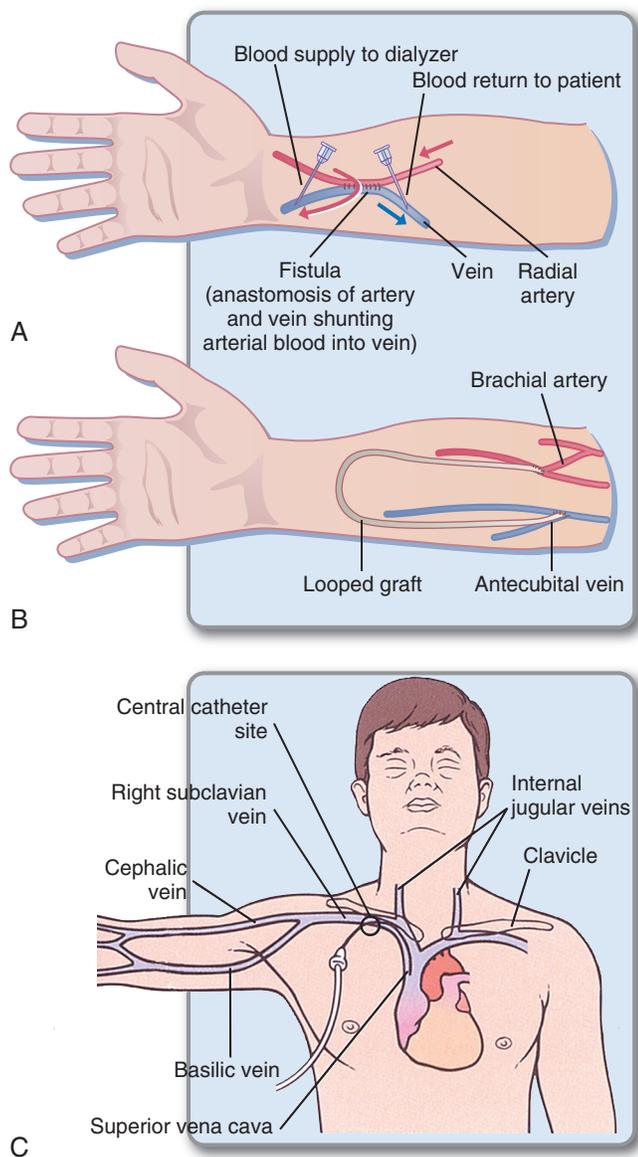

Fig. 34.2 Types of access for hemodialysis. **A**, Arteriovenous fistula. **B**, Artificial loop graft. **C**, Subclavian catheter (usually temporary). (From Lewis SL, et al: *Medical-surgical nursing: assessment and management of clinical problems*, ed 9, St Louis, 2013, Elsevier Mosby.)

and into the peritoneal cavity. **Dialysate** containing a dextrose concentration is instilled into the peritoneum, where diffusion carries waste products from the blood through the peritoneal membrane and into the dialysate; water moves by osmosis. This fluid then is withdrawn and discarded, and new solution is added multiple times each day providing 24 hours per day dialysis and is more similar to normal kidney function.

Several types of PD exist. In CAPD, the dialysate is left in the peritoneum and exchanged manually by gravity. Exchanges of dialysis fluid are done four to five times daily (Fig. 34.5). In APD, patient treatments are done at night by a machine that mechanically performs the exchanges. During the day these patients sometimes keep a single dialysate exchange in the peritoneal cavity for extended periods of time, perhaps the entire day. Different combinations of CAPD and APD are possible and are referred to here as PD.

Advantages of PD are avoidance of large fluctuations in blood chemistry, maintaining residual renal function, and achievement of a more normal lifestyle. Complications include peritonitis, challenges

managing blood sugars, and weight gain. Tissue weight gain is experienced by most patients as a result of absorbing 400 to 800 calories per day from the dextrose in the dialysate. The amount depends on the concentration of the dialysate solution and how many exchanges are done daily. This may be desirable in patients who are underweight, but eventually dietary intake or activity must be modified to account for the calories absorbed from dialysate.

Evaluation of Dialysis Efficacy

Kinetic modeling is a method for evaluating the efficacy of dialysis that measures the removal of urea from the patient's blood over a given period. This formula, often called Kt/V (where K is the urea clearance of the dialyzer, t is the length of time of dialysis, and V is the patient's total body water volume), should ideally produce a result higher than 1.4 per HD, or 3.2 per week. These calculations are somewhat complex and are typically calculated using a computer program. A more accurate method for determining adequacy of HD is eKt/V , in which e stands for equilibrated and takes into account the amount of time it takes for urea to equilibrate across cell membranes after dialysis has stopped. An acceptable eKt/V is 1.2 or greater.

Another method to determine effective dialysis treatment is the **urea reduction ratio (URR)**, which looks at the reduction in urea before and after dialysis. The patient is considered well dialyzed when a 65% or greater reduction in the serum urea occurs during dialysis. Unlike Kt/V , this calculation can be done quickly at the patient's bedside by the practitioner. The method for calculating the efficacy of PD is somewhat different, but a weekly Kt/V of 2 is the goal. The Kt/V can be altered by several patient- and dialysis-associated variables. The calculations for Kt/V can also be used to determine the patient's **protein-nitrogen appearance (PNA) rate**, which compares to a simplified nitrogen balance study in the dialysis patient. The PNA values should be between 0.8 and 1.4. Patients on short daily HD and nocturnal HD require different calculations to estimate their Kt/V .

Medical Nutrition Therapy

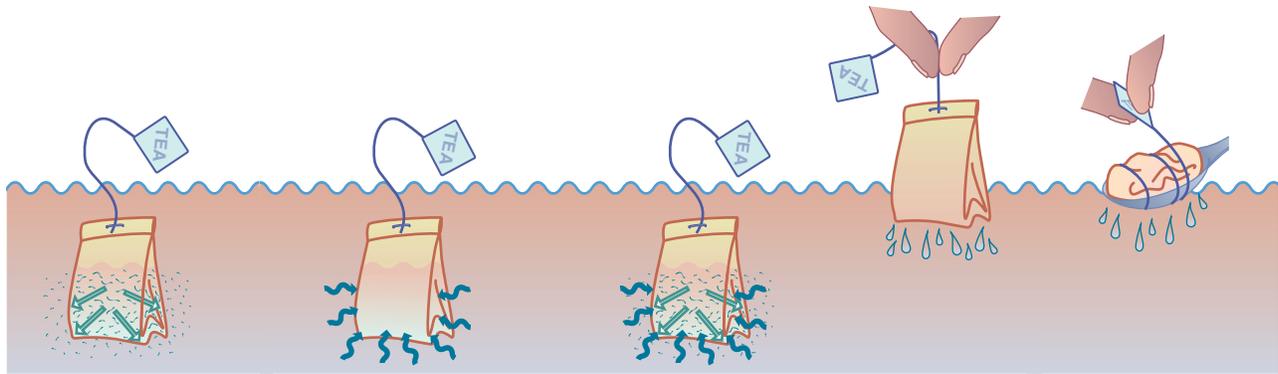

Goals of MNT in the management of ESRD are intended to do the following:

1. Prevent deficiency and maintain good nutrition status (and, in the case of children, growth) through adequate protein, energy, vitamin, and mineral intake (Table 34.9).
2. Control edema and electrolyte imbalance by controlling sodium, potassium, and fluid intake.
3. Prevent or slow the development of renal osteodystrophy by balancing calcium, phosphorus, vitamin D, and PTH.
4. Enable patients to eat a palatable, attractive diet that fits their lifestyle as much as possible.
5. Coordinate patient care with families, dietitian nutritionists, nurses, and physicians in acute care, outpatient, or skilled nursing facilities.
6. Provide initial nutrition education, periodic counseling, and long-term monitoring of patients, with the goal of patients receiving enough education to direct their own care and diet.

Table 34.10 presents a guide for teaching patients about their blood values and control of their disease. Because dialysis is done at home or in an outpatient unit, most patients with ESRD assume responsibility for their own diets. Most long-term patients know their diets very well (Fig. 34.6), having been instructed many times by renal dietitian nutritionists at their dialysis units.

Protein

Dialysis is a drain on body protein, so protein intake must be increased. In addition, exposure of patients' blood to an artificial membrane three

Diffusion

is the passage of particles through a semipermeable membrane. Tea, for example, diffuses from a tea bag into the surrounding water.

Osmosis

is the movement of fluid across a semipermeable membrane from a lower concentration of solutes to a higher concentration of solutes. (The water moves into the teabag.)

Diffusion and Osmosis

can occur at the same time. (Particles move out and fluid moves in at the same time.)

Filtration

is the passage of fluids through a membrane.

Ultrafiltration

provides additional pressure to squeeze extra fluid through the membrane.

Fig. 34.3 Dialysis: how it works. (Modified from Core curriculum for the dialysis technician: a comprehensive review of hemodialysis, 2001, AMGEN, Inc.)

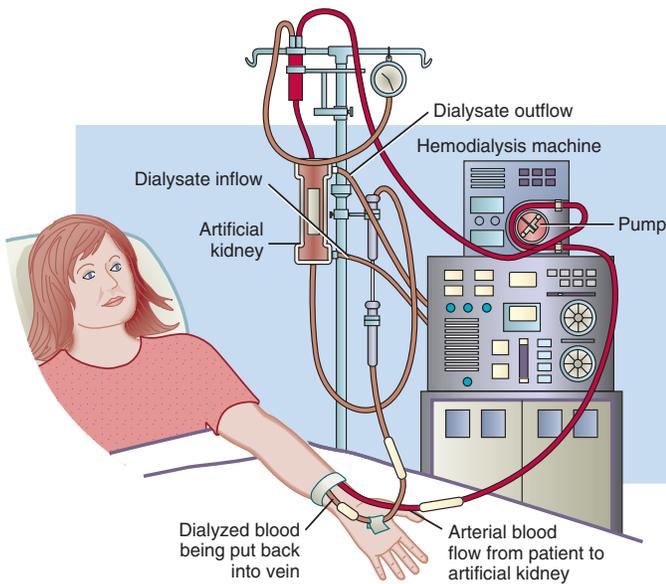

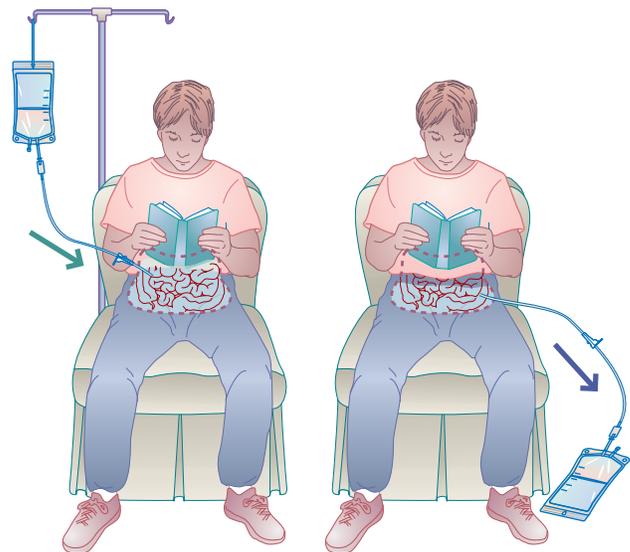

Fig. 34.4 Hemodialysis. Treatment is usually for 3 to 5 hours, three times per week.

The peritoneal cavity is filled with dialysate, using gravity.

At the end of the exchange, the dialysate is drained into the bag, again using gravity.

Fig. 34.5 Continuous ambulatory peritoneal dialysis; 20-minute exchanges are given four to five times daily every day.

or more times a week induces a state of chronic inflammation and distorts protein metabolism. Patients who receive HD three times per week can lose about 15 g of protein per dialysis treatment and require a daily protein intake of 1.2 g/kg of body weight. Protein losses of 20 to 30 g can occur during a 24-hour PD, with an average of 1 g/hr. Those receiving PD need a daily protein intake of 1.2 to 1.5 g/kg of body weight. At least 50% should be HBV protein. Serum BUN and serum Cr levels, uremic symptoms, and weight should be monitored, and the diet should be adjusted accordingly.

In renal failure, prealbumin, which is metabolized by the kidney, is not a good nutritional marker, because values are routinely elevated. Albumin is not recommended by the Academy of Nutrition and Dietetics

to be used as an indicator of protein but continues to be routinely used in evaluating ESRD patients based on KDQOI goals. However, because of the complexity of either acute or chronic inflammation, albumin remains predictive more of poor survival in ESRD and less of nutritional status. Current international research cites Subjective Global Assessment as being even more predictive of clinical outcomes (Lu et al, 2017). Hypoalbuminemia is multifactorial and may be related to fluid status, inflammation, or comorbid disease. When interpreting albumin values, it is important to know the laboratory's methodology for measuring serum albumin, because different laboratory techniques give

TABLE 34.8 Options for Treatment in ESRD

	Hemodialysis	Peritoneal Dialysis	Short Daily Hemodialysis or Nocturnal Dialysis	Transplant
Primary treatment responsibility	Health care personnel	Patient and/or family member	Patient and/or family member	Patient
Diet	Low K, low PO ₄ , low Na, moderate protein, fluid restriction	High K, low PO ₄ , low Na, high protein, moderate fluid restriction	High K, low PO ₄ , low Na, high protein, moderate fluid restriction	High and moderate protein, no K or PO ₄ restrictions, no fluid restriction.
Location	Clinical dialysis unit	Home, office, vacation	Home, vacation	No limitations
Risks	Bleeding, sepsis, infection	Peritonitis, hernia, constipation, exit site infections, poorly controlled diabetes, weight gain, early satiety	Unattended dialysis, rare user error bleeding	Immuno-compromised, diabetes, cancer
Contraindications	Poor cardiac status, poor blood vessels for access creation	Multiple abdominal surgeries, lack of a clean home, altered mental status	Dementia, illiteracy, inability to communicate, lack of a clean home	High body mass index, noncompliance with medications, less than 5-year hx of cancer

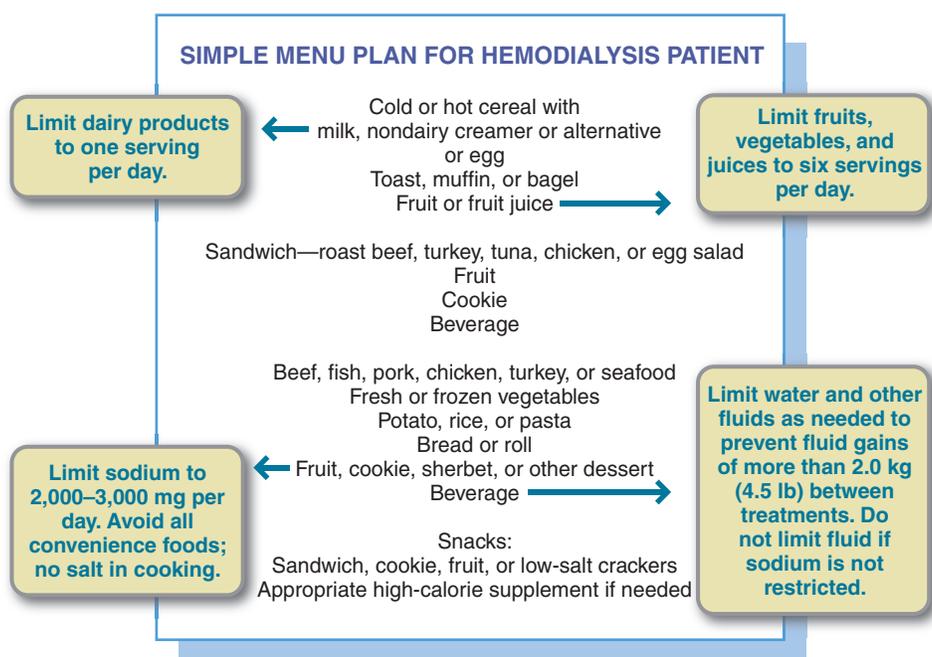

Fig. 34.6 A simple menu plan for a patient on hemodialysis. The diet should allow for less than 4% fluid weight gain between dialyses.

different results in renal failure (see Table 34.10). Federal mandates require some nutrition intervention at levels below 4 g/dL to attempt to improve albumin to this level despite the evidence that low albumin is not a function of nutritional intake.

Most patients find it challenging to consume adequate protein because uremia itself causes taste aberrations, notably to red meats. Some patients cannot tolerate even the smell of meat cooking. Often this protein aversion makes it difficult to achieve recommended HBV protein intake. Patients may prefer eggs, tofu, and “white” meats. Spices can be used to alter the taste of meats, and serving animal proteins cold, minimizes the urea taste. Nutritional supplements may be helpful in some patients, and occasionally the phosphate restriction may have to be lifted to allow the consumption of dairy products to meet protein

needs. Vegetarian protein sources are able to meet protein goals for HD, and the diet can be safely recommended (Sparks, 2018). As with all the nutritional parameters, meeting patient needs must be individualized.

Energy

Energy intake should be adequate to spare protein for tissue protein synthesis and to prevent its metabolism for energy. Depending on the patient’s nutrition status and degree of stress, between 25 and 40 kcal/kg of body weight should be provided, with the lower amount for transplantation and PD patients and the higher level for the nutritionally depleted patient (see Chapter 5 and Appendix 8 for determining BMI and appropriate body weight). Tools have been developed to allow the renal

TABLE 34.9 Nutrient Requirements of Adults with Renal Disease Based on Type of Therapy

Therapy	Energy	Protein	Fluid	Sodium	Potassium	Phosphorus
Impaired renal function	30-35 kcal/kg IBW	0.6-1.0 g/kg IBW	Ad libitum	Variable, 1.5-2 g/day	Variable, usually ad libitum or increased to cover losses from diuretics	0.8-1.2 g/day or 8-12 mg/kg IBW
Hemodialysis	35 kcal/kg IBW	1.2 g/kg IBW	750-1000 mL/day plus urine output	1.5-2 g/day	2-3 g/day or 40 mg/kg IBW	0.8-1.2 g/day or <17 mg/kg IBW
Peritoneal dialysis (CAPD)(CCPD)	30-35 kcal/kg IBW	1.2-1.5 g/kg IBW	Ad libitum (minimum of 1000 mL/day from urine plus output)	1.5-4 g/day	3-4 g/day	0.8-1.2 g/day
Transplant, 4-6 weeks after transplant	30-35 kcal/kg IBW	1.3-2 g/kg IBW	Ad libitum	1.5-2 g/day	Variable; may require restriction with cyclosporine-induced hyperkalemia	Calcium 1.2 g/day No need to limit phosphorus
6 weeks or longer after transplant	Kcal/kg to achieve/maintain IBW Limit simple CHO Fat <35% cal CHO <400 mg/day PUFA/SFA ratio >1	1 g/kg IBW	Ad libitum	1.5-2 g/day	Variable	Calcium 1.2 g/day No need to limit phosphorus

CAPD, Continuous ambulatory peritoneal dialysis; CCPD, continuous cyclical peritoneal dialysis; CHO, cholesterol; IBW, ideal body weight; PUFA, polyunsaturated fat; SFA, saturated fat.

Modified from National Kidney Foundation: KDOQI clinical practice guidelines for nutrition in chronic renal failure, *Am J Kidney Dis* 35(suppl 2):S1, 2000; Wiggins K: Guidelines for nutrition care of renal patients, ed 3, Chicago, 2002, American Dietetic Association.

TABLE 34.10 Guide to Blood Values in End-Stage Renal Disease Patients

This guide is to help in understanding laboratory reports. In the following table, the normal values are for people with good kidney function. Acceptable values for dialysis patients are also given. Many things affect blood values. Diet is only one of these. Underlying disease, adequacy of treatment, medications, and complications all may affect laboratory values.

Substance	Normal Values	Normal for People on Dialysis	Function	Diet Changes
Sodium	135-145 mEq/L	135-145 mEq/L	Found in salt and many preserved foods. A diet high in sodium causes thirst. When patients drink too much fluid, it may actually dilute their sodium, and serum levels will appear low. If patients eat too much sodium and do not drink water, sodium may be high. Too much sodium and water raise blood pressure and can cause fluid overload, pulmonary edema, and congestive heart failure.	High: Check fluid status. If high fluid gains, tell patient to eat fewer salty foods. If low fluid gains, make sure patient is gaining about 1.5 kg between dialyses (or <4% body weight) and is not dehydrated (this is rare). Low: If high fluid gains, tell patient to eat less salt and fluid. Check fluid status—patient is probably drinking too much fluid. Limit weight gains to less than 4% of body weight between runs and ask patient to eat fewer salty foods and limit fluid to 3 C plus urine output.
Potassium	3.5-5.5 mEq/L	3.5-5.5 mEq/L	Found in most high-protein foods, milk, fruits, and vegetables. Affects muscle action, especially the heart. High levels can cause the heart to stop. Low levels can cause symptoms such as muscle weakness and atrial fibrillation.	High: Ascertain that no other causes, such as gastrointestinal bleeding, trauma, or medications are creating high potassium values. Tell patient to avoid foods with more than 250 mg/serving and limit daily intake to 2000 mg. Consider lowering potassium in dialysate bath. Recheck blood level next treatment. Low: Add one high-potassium food/day and recheck blood level. Use salt substitutes or potassium supplements. Consider raising potassium in dialysate bath if diet changes are not working.
Urea nitrogen (BUN)	7-23 mg/dL	50-100 mg/dL	Waste product of protein breakdown. Unlike creatinine, this is affected by the amount of protein in the diet. Dialysis removes urea nitrogen.	High: Patient is probably underdialyzed. Check eKt/V. Check nPNA. Low: Underdialysis is also a cause. BUN may decrease if patient is not eating because of uremic symptoms. Also decreases with loss of muscle.

Continued

TABLE 34.10 Guide to Blood Values in End-Stage Renal Disease Patients—cont'd

Substance	Normal Values	Normal for People on Dialysis	Function	Diet Changes
Creatinine	0.6-1.5 mg/dL	Less than 15 mg/dL	A normal waste product of muscle breakdown. This value is controlled by dialysis. Patients have a higher amount because they are not dialyzing 24 hours a day, 7 days a week, as they would with normal kidney function.	Dialysis normally controls creatinine. Low creatinine may indicate good dialysis or low body muscle. Check the clearance of urea during dialysis (Kt/V) to assess dialysis adequacy. If patient is losing weight, will break down more muscle, so creatinine may be higher. Patient may need to eat more protein and calories to stop weight loss.
URR	N/A	Above 65% (or 0.65)	A measure of reduction of urea that occurs during a dialysis treatment. Postdialysis BUN is subtracted and divided by predialysis BUN to give a percentage.	No diet changes, but catabolism or anabolism will affect values, as with Kt/V and equilibrated clearance of urea during dialysis (eKt/V).
eKt/V	N/A	Above 1.2	A mathematic formula that attempts to quantify how well a patient is dialyzed. Represents the clearance of urea by the dialyzer, multiplied by the minutes of treatment, and divided by the volume of water the patient's body holds.	No diet changes. Low: Values below 1.2 are associated with increased morbidity and mortality. High: Higher values are associated with better outcomes.
Kt/V		Above 1.2 for hemodialysis Above 2 for peritoneal dialysis	Not adjusted for urea equilibration. See above.	No diet changes. See above.
nPNA	N/A	0.8-1.4	A calculation used to look at the rate of protein turnover in the body. Assumes patient is not catabolic because of infection, fever, surgery, or trauma. A good indicator of stable patient's protein intake, when combined with dietary history and albumin. The term <i>normalized</i> means that values have been adjusted to the patient's normal or ideal weight.	High: Patient may need to decrease protein intake. Patient may be catabolic or may be eating large amounts of protein. Low: Patient may need to increase protein intake. If patient is putting out urine, a small urine volume can make a big difference in results. Have patient keep a 48-hour urine collection.
Albumin	3.5-5 g/dL (bromocresol green) 3-4.5 g/dL (bromocresol purple)	3.5-5 g/dL Above 4 g/dL	Protein is lost with all dialysis. If albumin is below 2.9, fluid will leak from blood vessels into the tissue, thus causing edema. When fluid is in the tissue, it is more difficult to remove with dialysis. Low albumin is closely associated with increased risk of death in dialysis patients.	Low: Increase intake of protein-rich foods: meat, fish, chicken, eggs. A protein supplement may be needed. Intravenous albumin corrects short-term problems with oncotic pressure but does not change serum albumin levels.
Calcium	8.5-10.2 mg/dL	8.5-10.2 mg/dL	Found in dairy products. Dialysis patients' intakes are usually low. Active vitamin D is needed for absorption. The calcium value multiplied by the phosphorus value should not exceed 59, or patient will get calcium deposits in soft tissue. Because it is bound to albumin, calcium can be falsely lower if albumin is low. Ionized calcium is a more accurate test in this case.	High: Check if patient is taking calcium supplement or a form of active vitamin D. These should be temporarily stopped. Low: If albumin is low, suggest an ionized calcium be drawn. Patient may need a calcium supplement between meals and active vitamin D. Check with physician.
Phosphorus	2.5-4.8 mg/dL	3-6 mg/dL	Found in milk products, dried beans, nuts, and meats. Used to build bones and helps the body produce energy. Acceptable levels depend on variety of factors, including calcium, PTH levels, and the level of phosphorus in diet. If calcium and PTH levels are normal, a slightly higher-than-normal level of phosphorus is acceptable.	High: Limit milk and milk products to 1 serving/day. Remind patient to take phosphate binders as ordered with meals and snacks. Noncompliance with binders is the most common cause of high phosphorus. Low: Add 1 serving milk product or other high-phosphorus food per day or decrease phosphate binders.

TABLE 34.10 Guide to Blood Values in End-Stage Renal Disease Patients—cont'd

Substance	Normal Values	Normal for People on Dialysis	Function	Diet Changes
PTH intact (I-PTH)	10-65 pg/mL	150-600 pg/mL	A high level of PTH indicates that calcium is being pulled out of bone to maintain serum calcium levels. This syndrome is called secondary hyperparathyroidism. Leads to osteodystrophy. Pulsed doses of oral or IV vitamin D usually lower PTH.	High: Check whether patient taking oral or IV active vitamin D. Contact patient's physician regarding therapy. If patient has no symptoms (high phosphorus, bone pain, fractures), treat less aggressively. Low: No treatment available.
Aluminum	0-10 mcg/L	Less than 40 mcg/L	Patients taking aluminum hydroxide phosphate binders may develop aluminum toxicity, which can cause bone disease and dementia. Value should be checked every 6 months.	High: Discontinue aluminum hydroxide treatment.
Magnesium	1.5-2.4 mg/dL	1.5-2.4 mg/dL	Magnesium normally is excreted in the urine and can become toxic to dialysis patient. High levels may be caused by antacids or laxatives that contain magnesium such as Milk of Magnesia or Maalox.	No dietary changes, except to use nontoxic methods such as fiber to aid in relief of constipation. If magnesium is used as a phosphate binder, levels will have to be checked more often.
Ferritin	Male: 20-350 mcg/L Female: 6-350 mcg/L	300-800 mcg/L with EPO; 50 mcg/L without EPO	This is the way iron is stored in the liver. If iron stores are low, red blood cell production is decreased.	Low: Iron in food is not well absorbed. Most patients need an IV iron supplement. Patients should not take oral iron at same time as phosphate binders.
CO ₂	22-25 mEq/L	22-25 mEq/L	Dialysis patients are often acidotic because they do not excrete metabolic acids in their urine. Acidosis may increase the rate of muscle and bone catabolism.	Low: Review eKt/V, BUN, nPNA. Oral sodium bicarbonate may be given to raise CO ₂ , but it presents a significant sodium load to patient.
Glucose	65-114 mg/dL	Same for nondiabetic patients Less than 300 mg/dL (patients with diabetes)	Because the kidney metabolizes insulin, low blood sugar levels caused by a longer half-life of insulin are possible. For patients with diabetes: a high blood sugar may increase thirst.	Most people need 6-11 servings of breads and starches or cereals per day and 2-4 servings of fruit per day to provide energy. Patients with diabetes should avoid concentrated sweets, unless blood sugar level is low.

BUN, Blood urea nitrogen; CO₂, carbon dioxide; DHT, dihydrotachysterol; EPO, erythropoietin; IV, intravenous; N/A, not applicable; nPNA, normalized protein nitrogen appearance; PTH, parathyroid hormone; URR, urea reduction ratio.

Developed by Katy G. Wilkens, MS, RDN, Northwest Kidney Centers, Seattle, Washington.

dietitian to assess the quality of the patient's nutrition status (see Chapter 5 and Appendices 12 and 21). Indirect calorimetry remains a valid tool (Morrow et al, 2017) but is rarely available in outpatient practices.

Fluid and Sodium Balance

The kidney's ability to handle sodium and water in ESRD must be assessed frequently through measurement of blood pressure, edema, fluid weight gain, serum sodium level, and dietary intake. The vast majority of dialysis patients need to restrict sodium and fluid intakes. Excessive sodium intake is responsible for increased thirst, increased fluid gain, and resultant hypertension. Even those patients who do not experience these symptoms but produce minimal amounts of urine benefit from a reduced sodium intake to limit their thirst and prevent large intradialytic fluid gains.

In the patient who is maintained on HD, sodium and fluid intake are regulated to allow for a weight gain of 4 to 5 lb (2 to 3 kg) from increased fluid in the vasculature between dialyses. The goal is a fluid gain of less than 4% of body weight. A sodium intake of 65 to 87 mEq

(1500 to 2000 mg) daily and a limit on fluid intake (usually about 750 mL/day plus the amount equal to the urine output) is usually sufficient to meet these guidelines. Only fluids that are liquid at room temperature are included in this calculation. The fluid contained in solid foods is not included in the 750 mL limit. Solid foods in the average diet contribute approximately 500 to 800 mL/day of fluid. This fluid in solid food is calculated to approximately replace the 500 mL/day net insensible water loss.

A 65 to 87 mEq (1500 to 2000 mg) sodium diet requires no salt in cooking; no salt at the table; no salted, smoked, enhanced, or cured meat or fish; no cheese except Swiss or cream cheese; and no salted snack foods, canned soups, packaged bread products, or high-sodium convenience foods. In today's marketplace, increased intake of convenience foods is the norm and it is estimated that 75% to 90% of sodium intake is consumed in convenience foods, with only 10% to 25% added to foods in cooking or at the table.

The most effective way to reduce the renal patient's thirst and fluid intake is to decrease sodium intake. It is salt intake that drives fluid

consumption. Appendix 21 gives the details of a low-sodium meal plan. Attempts to restrict fluid in patients who are not on a restricted sodium diet are futile, because feelings of thirst become overwhelming to the patient with a high sodium intake.

When educating about fluid balance, the health care provider must teach the patient how to deal with thirst without drinking. Sucking on a few ice chips, cold sliced fruit, or sour candies or using artificial saliva are good suggestions. In approximately 15% to 20% of patients, hypertension is not alleviated even after meticulous attention to fluid and water balance. In these patients hypertension usually is perpetuated by a high level of renin secretion and requires medication for control.

Although the majority of patients with ESRD retain sodium, a small number may lose it. Examples of conditions with a salt-losing tendency are polycystic disease of the kidney, medullary kidney disease, chronic obstructive uropathy, chronic pyelonephritis, ostomy losses, and analgesic nephropathy. To prevent hypotension, hypovolemia, cramps, and further deterioration of renal function, extra sodium may be required. A diet for these types of patients may contain 130 mEq (3 g) or more of sodium per day. Not limiting sodium in the diet can satisfy the need for extra sodium. The number of patients who require this level of sodium intake is small, but these patients exemplify the need for individual consideration of the diet prescription and a thorough understanding of the patient's underlying disease and present diet.

Potassium

Potassium usually requires restriction, depending on the serum potassium level, urine output, medications, and the frequency of HD. The daily intake of potassium for most Americans is 75 to 100 mEq (3 to 4 g). This usually is reduced in ESRD to 60 to 80 mEq (2.3 to 3.1 g) per day and is reduced for the anuric patient on dialysis to 51 mEq (2 g) per day. Some patients (i.e., those on high-flux dialysis or with increased dialysis times or frequencies such as PD, short daily or nocturnal) require higher intakes. Again, a close monitoring of the patient's laboratory values, potassium content of the dialysate, and dietary intake is essential.

The potassium content of foods is listed in Appendix 44. When counseling HD patients on a low-potassium diet, clinicians should take care to point out that some low-sodium foods contain potassium chloride as a salt substitute rather than sodium chloride. Nutrition labels for products such as salt substitutes and low-sodium herb mixtures must be checked carefully to be sure they do not contain dangerous levels of potassium. Low-sodium soy sauces, low-sodium soups, and other low-sodium products may require particular review by a trained professional (see Chapter 10 for labeling definitions). Reviewing food preparation techniques should include anyone who may be cooking for the patient, such as restaurants, family members, friends, or neighbors.

When a thorough diet history does not reveal the reason for elevated serum potassium, other nondietetic sources for the elevated potassium should be researched. Examples include incomplete dialysis or missed dialysis treatments, too high a concentration of potassium in the dialysate bath, defective HD access or recirculation of blood within the access, very elevated blood sugar, acidosis, constipation, significant GI bleeding, some medications, blood transfusions, major trauma, chemotherapy, or radiation therapy. Occasionally blood samples are handled improperly, resulting in hemolysis and falsely elevated potassium levels.

Phosphorus

More than 99% of excess phosphate is excreted in the urine. However, as GFR decreases, phosphorus is retained in the plasma. Phosphorus is

not easily removed by dialysis, and patients experience net gain of about one half of the phosphate they consume daily. Phosphate intake is lowered by restricting dietary sources to 1200 mg/day or less. The difficulty in implementing the phosphorus restriction comes from the necessity for a high-protein diet. High-protein foods, such as meats and dairy, contain high levels of phosphorus in the form of ATP. In addition, other sources of protein—nuts and legumes (including soy)—are also high in phosphorus. Thus high-phosphorus foods cannot be eliminated without restricting protein, creating a challenge to balance intake with dietary intervention alone.

The American diet, which contains highly processed foods, has resulted in increases in the types and amounts of phosphorus available for absorption, making compliance with a phosphorus restriction more difficult. Naturally occurring phosphate in food is only approximately 60% absorbed. Commonly used phosphate additives such as trisodium phosphate, disodium phosphate, and dicalcium phosphate are nearly 100% absorbed, making the processed diet a contributor to elevated phosphorus levels (Chang and Anderson, 2017). Dietary intervention should focus on a balance of limiting dairy, nuts, beans, and processed foods while still encouraging enough proteins of HBV to meet dietary needs. Phosphorus management through diet has the added challenge of not being included in the values on the standard nutrition label. Phosphate additives are becoming more prevalent throughout our food system (León et al, 2013) and dietitian nutritionists are crucial to helping patient find foods that are better choices.

Because dietary restrictions alone are not adequate to control serum phosphorus, nearly all patients who undergo dialysis require phosphate-binding medications. Phosphate binders such as calcium carbonate, calcium acetate, sevelamer carbonate, sucroferric oxyhydroxide, ferric citrate, and lanthanum carbonate are used routinely with each meal and snack to bind to phosphorus. These medications bind excess dietary phosphate and transport it through the GI tract for elimination, thus preventing its absorption into the blood. Side effects of taking these medications over long periods are common. Some may cause GI distress, diarrhea, or gas. Severe constipation, leading to intestinal impaction, is a potential risk of excessive use of some types of phosphate binders; occasionally this may lead to perforation of the intestine resulting in peritonitis or death. Common medications are listed in Table 34.11 (see *Clinical Insight: Why Don't Clients Take Their Phosphate Binders?*).

CLINICAL INSIGHT

Why Don't Clients Take Their Phosphate Binders?

Phosphate binders are prescribed to be taken with all meals and snacks, whether the client eats at home, at work, or in a restaurant. Reasons clients give for not taking their phosphate binders are that they:

- cause gastrointestinal discomfort and acid reflux
- cause severe constipation and can lead to bowel impaction
- may be difficult to chew or swallow
- may need to take an average of 2 to 5 pills each meal
- forget to take them
- do not like to be reminded of being "sick"
- cannot feel a difference when taking them
- may be expensive and not always covered by insurance

Calcium and Parathyroid Hormone

In ESRD, the body's ability to maintain phosphorus-calcium balance is complicated by calcium and PTH controls. As GFR decreases, the

TABLE 34.11 Common Medications and Nutritional Supplements for Patients with End-Stage Renal Disease

Phosphate Binders		EPO	
Taken with meals and snacks to prevent dietary phosphorus absorption		Stimulates bone marrow to produce red blood cells	
Calcium carbonate	TUMS, Os-Cal, Calci-Chew, Calci-Mix	IV or IM	Erythropoietin Stimulating Agents
Calcium acetate	PhosLo	Activated Vitamin D	
Mg/Ca ⁺⁺ carbonate	MagneBind	Used for the management of hyperparathyroidism	
Sevelamer carbonate	Renvela	Oral	Calcitriol (Rocaltrol), doxercalciferol (Hectorol)
Lanthanum carbonate	Fosrenol	IV	Calcitriol (Calcijex), paricalcitol (Zemplar)
Aluminum hydroxide	AlternaGEL	Bisphosphonates	
Iron-based binders	Velphoro, Auryxia	Inhibit bone resorption by blocking osteoclast activity	
Vitamins		Oral	Alendronate (Fosamax)
Increased need for water-soluble vitamins because of losses during dialysis		IV	Pamidronate (Aredia)
Fat-soluble vitamins A, E, and K are not supplemented		Calcium Supplements	
Dialysis Recommendations		TUMS, Os-Cal, Calci-Chew	
Vitamin C	60 mg (not to exceed 200 mg daily)	Phosphorus Supplements	
Folic acid	1 mg	Kphos neutral, NutraPhos, NutraPhos K	
Thiamin	1.5 mg	Calcimimetics	
Riboflavin	1.7 mg	Mimic calcium and bind to parathyroid gland	
Niacin	20 mg	Cinacalcet (Sensipar) and Etelcalcetide (Parsabiv)	
Vitamin B ₆	10 mg	Potassium Lowering Agents	
Vitamin B ₁₂	6 mcg	For the treatment of hyperkalemia	
Pantothenic acid	10 mg	Oral or rectal	SPS (Kayexalate) Patiromer (Veltassa) Sodium Zirconium Cyclocilate (Lokelma)
Biotin	0.3 mg		
Brand names include Nephrocap, Nephron FA, Nephplex, Nephro-Vites, and Dia-tx			
Iron			
Iron needs are increased because of EPO therapy and oral iron is not adequate			
IV iron	Iron dextran (Infed), Iron gluconate (Ferrlecit), Iron sucrose (Venofer)		

Ca⁺⁺, Calcium; CHO, cholesterol; EPO, epoetin; ESRD, end-stage renal disease; IV, intravenous; IM, intramuscular; MVI, multiple vitamin injection; SPS, sodium polystyrene sulfonate.

Developed by Fiona Wolf, RDN, and Thomas Montemayor, RPh, Northwest Kidney Centers, Seattle, Washington, 2015.

serum calcium level declines for several reasons. First, decreased ability of the kidney to convert inactive vitamin D to its active form, 1,25(OH)₂D₃, leads to poor GI absorption of calcium. Second, the need for serum calcium increases as serum phosphate levels increase. Both of these causes lead to hypertrophy of the parathyroid gland, which is responsible for calcium homeostasis. The resultant oversecretion of PTH increases resorption of bone to provide a calcium source. Because calcium is bound to albumin in the blood serum calcium will appear low when albumin is low (see Chapter 3).

The resulting metabolic bone disease, **renal osteodystrophy**, is essentially one of four types: (1) **osteomalacia**, (2) **osteitis fibrosa cystica**, (3) **metastatic calcification**, or (4) **adynamic (low turnover) bone disease**. With a deficit of calcium available from dietary absorption due to lack of vitamin D, the low calcium level triggers the release of PTH from the parathyroid glands. PTH acts to increase release of calcium from the bones by stimulating osteoclast activity. This can lead to osteomalacia or bone demineralization, as a result of lack of osteoblast stimulation to replace lost calcium in the bones.

Ongoing low calcium causes the parathyroid glands to continue producing PTH in an attempt to elevate serum calcium levels. In time this leads to secondary hyperparathyroidism, in which even the baseline production of PTH by these enlarged glands is enough to cause severe bone demineralization (osteitis fibrosa cystica), which is characterized by dull, aching bone pain.

Even though the serum calcium level is elevated in response to PTH, serum phosphate concentration remains high as the GFR falls lower. If the product of serum calcium multiplied by the serum phosphate level is greater than 70, metastatic calcification is imminent. Metastatic calcification occurs when calcium phosphate is deposited in nonbone cells. This extraskeletal calcification may develop in joints, soft tissue, and vessels.

Calciphylaxis occurs when calcium phosphate is deposited in wound tissues with resultant vascular calcification, thrombosis, nonhealing wounds, and gangrene. It is closely linked with use of blood thinners, so bone mineral management paired with coagulation management are the primary treatments. It is frequently fatal. Newer treatments pair calcium and phosphorus control with increased dialysis, antibiotic therapy, sodium thiosulfate, and hyperbaric chamber treatments (Nigwekar et al, 2015).

Many patients on dialysis suffer from hypocalcemia, despite calcium supplementation. Because of this, the routine drug of choice is active vitamin D, 1,25(OH)₂D₃, available as calcitriol (Rocaltrol and Calcijex). Analogs such as doxercalciferol (Hectorol) and paricalcitol (Zemlar) are also effective in lowering PTH and raising calcium levels, but with less enhancement of gut absorption of calcium than the 1,25 forms.

Other mechanisms for controlling PTH include the oral medication cinacalcet (Sensipar) or IV medication etelcalcetide (Parsabiv), and calcimimetic or calcium-imitating drugs. They bind to sites on the parathyroid gland, simulating acceptable calcium levels. The drugs are effective in suppressing PTH production and also may lower calcium levels dramatically, with significant benefit. Known complications of low calcium means that overall, close monitoring is essential.

In more extreme cases of hyperparathyroidism, use of surgical excision of portions of the parathyroid glands can be used in an attempt to restore balance. This creates the risk of low PTH and can lead to adynamic (low turnover) bone disease, characterized by decreased levels of bone turnover and suppression of both osteoclasts and osteoblasts. This condition is unique to ESRD, in which oversuppression of the parathyroid gland and too much active vitamin D lead to decreased bone formation and fragile bones with very little matrix. Usually diagnosed by a low PTH level, this disease results in a high risk of nonhealing fractures. Oversuppression of the parathyroid gland by use of vitamin D or its analogs can mimic this as well.

Overall the dietary balance of phosphorus, the use of phosphate binders, vitamin D analogs, calcium mimetics (drugs that mimics the action of calcium on tissue), the removal of phosphate by dialysis, and intense monitoring of laboratory values contribute to complex bone management in ESRD.

Lipid

Atherosclerotic cardiovascular disease (AHD) is a common cause of death among patients maintained on long-term dialysis (Sarnak *et al.* 2019). This appears to be a function of underlying disease (e.g., diabetes mellitus, hypertension, nephrotic syndrome) and a lipid abnormality common among patients with ESRD. As stated earlier in the chapter the use of statins is no longer recommended in CKD based on KDIGO 2013 guidelines. Low-fat diet recommendations for AHD have been replaced with recommendations to replace unhealthy fats with healthier ones (see Chapter 32). General diet education for cardiac health is advised, with consideration for the higher protein recommendations and the need to limit potassium.

Iron and Erythropoietin

The anemia of chronic renal disease is caused by an inability of the kidney to produce erythropoietin (EPO), the hormone that stimulates the bone marrow to produce red blood cells; an increased destruction of red blood cells secondary to circulating uremic waste products; and blood loss with dialysis or blood sampling. A synthetic form of EPO, **recombinant human EPO (rHuEPO)**, is used to treat this form of anemia. Clinical trials have demonstrated a dramatic improvement in correcting anemia and restoring a general sense of well-being. Recent studies have indicated that higher dosages of EPO pose increased risk of stroke, adverse cardiac events, and death, so close monitoring and balancing the needs of the patient are essential.

Use of EPO increases red blood cell production 2.5-fold. Almost always accompanying the rise in hematocrit is an increased need for iron that requires IV supplementation. While many things can be managed by diet, the increased need for iron to increase red blood cells formed with use of EPO outweighs what can be accomplished from food. Oral supplementation of iron is also not effective in maintaining

adequate iron stores in patients on EPO. Unless a documented allergic reaction exists, almost all patients taking EPO require periodic IV or intramuscular iron. For patients who are allergic to IV iron, several better-tolerated forms are now available as iron dextran (Infed), iron gluconate (Ferrlecit), and iron sucrose (Venofer).

Serum ferritin is an accurate indicator of iron status in renal failure. Patients who have received several transfusions and who are storing extra iron may have high serum ferritin levels of 800 to 5000 ng/mL (a normal level is 68 ng/mL for women and 150 ng/mL for men; see Appendix 12). In patients who are receiving EPO, ferritin should be kept above 300 ng/mL but below 800 ng/mL. When ferritin values fall below 100 ng/mL, IV iron is usually given. The percent of transferrin saturation is another useful indicator of iron status in these patients and should be between 25% to 30%.

Vitamins

Water-soluble vitamins are rapidly lost during dialysis. In general, ascorbic acid and most B vitamins are lost through dialysate at approximately the same rate they would have been lost in the urine (depending on the type and duration of treatment), with the exception of folate, which is highly dialyzable. Patients who still produce urine may be at increased risk of loss of water-soluble vitamins. Folate is recommended to be supplemented at 1 mg/day based on extra losses. Because vitamin B₁₂ is protein-bound, losses of this B vitamin during dialysis are minimal. Altered metabolism and excretory function, as well as drug administration, also may affect vitamin levels. Little is known about GI absorption of vitamins in uremia, but it may be significantly decreased. Uremic toxins may interfere with the activity of some vitamins, such as inhibition of phosphorylation of pyridoxine and its analogs.

Another cause of decreased vitamin intake in uremia is the restriction of dietary phosphorus and potassium. Water-soluble vitamins are usually abundant in high-potassium foods such as citrus fruits, vegetables, and high-phosphorus foods such as milk. Diets for patients on dialysis tend to be low in folate, niacin, riboflavin, and vitamin B₆. With frequent episodes of anorexia or illness, vitamin intake is decreased further. Whereas levels of water-soluble vitamins decrease as a result of dialysis, replacement of fat-soluble vitamins usually is not required in renal disease.

Several vitamin supplements that fit the needs of the uremic patient or the dialysis patient are now available by prescription: Nephro-caps, Renavite, Diallyvite, Folbee Plus, and Renal Caps or Virt-Caps. An over-the-counter supplement containing the vitamin B complex and vitamin C often is used and can be less expensive than a prescription, but additional supplements of folic acid and pyridoxine may be needed.

Niacin has been found to be helpful in lowering phosphate levels in ESRD patients. It interferes with the sodium-phosphate pump in the GI lumen, causing decreased transport of phosphate, and thus works with a different mechanism than phosphate binders (Cheng *et al.* 2008; Edalat-Nejad *et al.* 2012). It has shown benefit in improving outcomes in patients that struggle with a serum phosphorus of more than 6.0 when used in conjunction with phosphate binders as a once-daily pill. Potential side effects such as GI bleeding, liver disease, and flushing must be carefully considered.

Nutrition Support in End-Stage Renal Disease

Enteral Tube Feeding

Patients with ESRD who require enteral tube feeding generally can use standard formulas used for most tube-fed patients (see Chapter 12) and do not require a specialty or renal formula. Formulas marketed as renal products are more calorie-dense, higher in protein, and lower in specific nutrients such as potassium and phosphorus. If patients are

receiving renal products only, they may develop problems with low phosphorus or potassium levels as these products are designed to be used in conjunction with oral intake.

Oral Protein Supplementation During Dialysis

Recent research has focused on use of oral protein supplements while a patient is receiving dialysis treatments. The theory is that muscle protein will be replaced, offsetting catabolism, which occurs during dialysis. This is thought to be similar to what an athlete might experience using a protein supplement immediately after exercise. Study results show possible links to reduction in mortality from use during dialysis treatments, not related to serum albumin levels (Lacson et al, 2012). Another study by Beddhu et al (2015) measured midarm muscle circumference, albumin and C-reactive protein (hs-CRP) in response to intradialytic protein supplementation and found no change.

Parenteral Nutrition

PN in ESRD is similar to PN used for other malnourished patients with respect to protein, carbohydrates, and fat, but differs in use of vitamins and minerals. Most researchers agree that vitamin needs for ESRD during PN differ from normal requirements; however, they do not agree on recommendations for individual nutrients. Folate, pyridoxine, and biotin should be supplemented. Vitamin A should not be provided parenterally unless retinol-binding protein is monitored during each HD treatment because it is elevated in patients with ESRD. Because there is currently no parenteral vitamin that is specifically designed for patients with renal failure, a standard vitamin preparation usually is administered. Little information related to parenteral trace mineral supplementation is available. Because most trace minerals, including zinc, chromium, and magnesium, are excreted in the urine, a close monitoring of these minerals in the serum seems to be appropriate.

Intradialytic Parenteral Nutrition

Malnourished patients with chronic renal failure who are on HD have easy access to PN because of the direct blood access required by the dialysis therapy itself. **Intradialytic parenteral nutrition (IDPN)** can be administered to support a patient's nutritional status. IDPN is administered typically through a connection to the venous side of the extracorporeal circuit during dialysis. Because of the high blood flow rate achieved through use of the surgically created fistula and the high blood pump speeds that are attained, glucose protein and lipids can be administered without requiring a separate port.

Another method of nutrition support in PD patients is called **intra-peritoneal nutrition (IPN)** using a peritoneal dialysate solution that contains amino acids instead of dextrose. Typically one bag of this solution is used per day.

End-Stage Renal Disease in Patients with Diabetes

Because renal failure is a complication of diabetes, approximately 45% of all new patients starting dialysis have diabetes (United States Renal Data System, 2017). The need to control blood sugar in these patients requires specialized diet therapy. The diet for diabetes management (see Chapter 29) can be modified for the patient on dialysis. In addition, the diabetic patient on dialysis often has other complications such as retinopathy, neuropathy, gastroparesis, and amputation, all of which can place this patient at high nutritional risk.

Chronic Kidney Disease and End-Stage Renal Disease in Children

Although CKD may occur in children at any age, from the newborn infant to the adolescent, it is a relatively uncommon diagnosis. Causal

factors in children include congenital defects, anatomic defects (urologic malformations or dysplastic kidneys), inherited disease (autosomal-recessive polycystic kidney disease), metabolic disorders that eventually result in renal failure (cystinosis or methylmalonic aciduria), or acquired conditions or illnesses (untreated kidney infections, physical trauma to kidneys, exposure to nephrotoxic chemicals or medications, hemolytic anemia resulting from *Escherichia coli* 0157 ingestion, or glomerular nephritis).

As with all children, the major concern is to promote normal growth and development. Without aggressive monitoring and encouragement, children with renal failure rarely meet their nutritional requirements. If the renal disease is present from birth, nutrition support needs to begin immediately to avoid losing the growth potential of the first few months of life. Growth in children with CKD usually is delayed. Although no specific therapy ensures normal growth, factors capable of responding to therapy include metabolic acidosis, electrolyte depletion, osteodystrophy, chronic infection, and protein-calorie malnutrition. Energy and protein needs for children with chronic renal disease are at least equivalent to the DRIs for normal children of the same height and age. If nutrition status is poor, energy needs may be even higher to promote weight gain and linear growth.

Feeding by tube is required in the presence of poor intake, particularly in the critical growth period of the first 2 years of life. Gastrostomy tubes almost always are placed in these children to enhance nutritional intake and facilitate growth. PN rarely is initiated unless the GI tract is nonfunctional. For the nutritional requirements of children with renal failure see the National Kidney Foundation website.

Control of calcium and phosphorus balance is especially important for maintaining good growth. The goal is to restrict phosphorus intake while promoting calcium absorption with the aid of $1,25(\text{OH})_2\text{D}_3$. This helps prevent renal osteodystrophy, which can cause severe growth retardation. Use of calcium carbonate formulations to supplement the dietary intake enhances calcium intake while binding excess phosphorus. Persistent metabolic acidosis is often associated with growth failure in infancy. In chronic acidosis the titration of acid by the bone causes calcium loss and contributes to bone demineralization. Bicarbonate may be added to the infant formula to counteract this effect.

Restriction of protein in pediatric diets is controversial. The so-called protective effect on kidney function must be weighed against the clearly negative effect of possible protein malnutrition on growth. The recommended dietary allowance for protein for age is usually the minimum amount given.

Each child's diet should be adjusted for individual food preferences, family eating patterns, and biochemical needs. This is often not an easy task. In addition, care must be taken not to place too much emphasis on the diet to avoid food becoming a manipulative tool and an attention-getting device. Special encouragement, creativity, and attention are required to help the child with CKD consume the necessary energy. When possible, PD is given intermittently during the day and continuously at night because it allows liberalization of the diet. The child is more likely to meet nutritional requirements with fewer dietary restrictions and therefore experience better growth.

Other treatments that help renal disease in children include the use of rHuEPO and recombinant deoxyribonucleic acid–produced human growth hormone. EPO usually is started when the child's serum hemoglobin falls below 10 g/dL, with a goal of maintaining hemoglobin between 11 and 12 g/dL. Correction of anemia with the use of rHuEPO may increase appetite, intake, and feeling of well-being, but it has not been found to affect growth, even with seemingly adequate nutrition support.

Medical Nutrition Therapy for Transplantation

The nutritional care of the adult patient who has received a transplanted kidney is based mainly on the metabolic effects of the required immunosuppressive therapy. Medications typically used for the long term include azathioprine (Imuran), corticosteroids (e.g., prednisone), calcineurin inhibitors (cyclosporine A, Gengraf, SangCya, Sandimmune, tacrolimus [Prograf, F506]), sirolimus (Rapamune), everolimus (Zortress), mycophenolate mofetil (CellCept), and mycophenolic acid (Myfortic). Corticosteroids are associated with accelerated protein catabolism, hyperlipidemia, sodium retention, weight gain, hyperglycemia, osteoporosis, and electrolyte disturbances. Calcineurin inhibitors are associated with hyperkalemia, hypertension, hyperglycemia, and hyperlipidemia. The doses of these medications used after transplantation are decreased over time until a maintenance level is reached.

During the first 6 weeks after surgery, a high-protein diet is often recommended (1.2 to 1.5 g/kg IBW), with an energy intake of 30 to 35 kcal/kg IBW, to prevent negative nitrogen balance. A moderate sodium restriction of 2 to 3 g/day during this period minimizes fluid retention and helps to control blood pressure. After recovery, protein intake should be decreased to 1 to 1.5 g/kg IBW, with calorie intake providing sufficient energy to maintain or achieve an appropriate weight for height. A balanced low-fat diet aids in lowering cardiac complications, whereas sodium intakes are individualized based on fluid retention and blood pressure.

Hyperkalemia warrants a temporary dietary potassium restriction. After transplantation, many patients exhibit hypophosphatemia and mild hypercalcemia caused by bone resorption; this is associated with persistent hyperparathyroidism and the effects of steroids on calcium, phosphorus, and vitamin D metabolism. The diet should contain adequate amounts of calcium and phosphorus (1200 mg of each daily) and cholecalciferol (vitamin D₃, 2000 IU daily). Supplemental phosphorus also may be necessary to correct hypophosphatemia.

Hydration must also be monitored closely after transplantation. Because most kidney recipients required a fluid restriction while on dialysis, they must be reminded of the importance of maintaining fluid intake after transplant. Typically, patients are encouraged to drink 2 L/day, but their overall needs depend on their urine output.

The majority of transplant recipients have elevated serum triglycerides or cholesterol for a variety of reasons. Intervention consists of medications, calorie restriction for those who are overweight, cholesterol intake limited to less than 300 mg/day, and limited total fat (see Chapter 32). In patients with glucose intolerance, limiting carbohydrates and a regular exercise regimen are appropriate. Tissue weight gain with resultant obesity is common after transplantation. Medication side effects, fewer dietary restrictions, and the lack of physical exercise can contribute to posttransplant weight gain.

Because of immunosuppression, care must be taken with food safety similar to other significantly at-risk groups. Handwashing, food temperature monitoring, and avoidance of uncooked foods remain appropriate infection control behaviors.

Referral to bariatric surgery is being seen in patients needing weight loss to qualify for a transplant. Much coordination and collaboration is needed between the bariatric RDN and the renal RDN to be sure that the patient's very specific diet needs are met based on their treatment modality and progression of kidney disease (see Chapter 20).

Counseling and Education of Patients with End-Stage Renal Disease

For effective intervention, it is important to look at the long-range goals for educating patients with ESRD about their nutritional needs.

The average patient survives on dialysis 7 to 10 years, the average mortality is approximately 20% per year, equal to that of serious cancers such as ovarian cancer. However, some patients with a relatively benign diagnosis may look forward to life spans of 20 to 40 years, particularly if they receive kidney transplants as a part of their treatment. The challenge for the dietitian nutritionist is educating patients with a chronic disease who will be primarily responsible for implementing nutritional recommendations for the rest of their life. Thus intervention for ESRD and that for diabetes share many similarities.

It is incumbent on the renal dietitian nutritionist to develop a long-standing rapport with patients and their families, and to serve as an ally to help them make the best nutritional choices over an extended period. Understanding the burdens of a complex, challenging, ever-changing diet suggests the transfer of information to the renal patient and family in a workable, flexible, and easily understood manner. Skills for this task are just as challenging, if not more so, than maintaining a patient's iron status or keeping the patient at a good body weight. Empathy and use of techniques such as motivational interviewing or cognitive behavioral therapy are essential tools (see Chapter 13).

Coordination of Care in End-Stage Renal Disease

The position of the registered dietitian nutritionist (RDN) in the care of dialysis patients is unique because it is a federally mandated position. So, too, is the RDN's place on the mandated interdisciplinary health care team that exists within each dialysis unit. The team approach is an important aspect of all health care; however, its importance is magnified in the dialysis team, which consists of the patient, renal nurse, renal social worker, nephrologist, and renal dietitian nutritionist. Care of these complex, long-term ESRD patients requires the skill and compassion of each member of the health care team working together. Advanced levels of practice are available for dietitians who wish to be certified as renal RDNs; they can be certified through examination by the Academy of Nutrition and Dietetics and become a Board Certified Specialist in Renal Nutrition.

Emergency Diets for Dialysis Patients

When power outages, flooding, storms, hurricanes, or earthquakes threaten a community, they threaten the most vulnerable people in that community. Patients on HD require power and water sources to do their own treatments at home. PD patients need a clean environment and access to their supplies. If they travel to a dialysis unit, they need access to transportation. Because of poor outcomes in recent natural disasters, the federal government's ESRD program has specified that patients and caregivers must be familiar with alternative nutritional therapies when dialysis is not available because of a natural or manmade emergency. [Box 34.3](#) demonstrates the type of nutrient and practical information that must be considered when patients may be without dialysis for days, or because they must be evacuated to a site that cannot meet their urgent nutritional needs.

Medical Management (Conservative Treatment) or Palliative Care

The decision to forego or discontinue dialysis and opt for end-of-life care is a difficult and emotional one. Factors such as religious practices, age, quality of life, and comorbid disease play a role. Patients who are poor candidates for dialysis or transplantation may benefit from a low-protein, low-sodium diet to minimize physical symptoms, such as shortness of breath and uremia. Palliative care can be offered with the goal of balancing patient wishes for food choice with these complex side effects ([Rak et al, 2017](#)).

BOX 34.3 Emergency Dialysis Diet Plan

This plan will work for short periods (5 days or less) when patients cannot dialyze.

The Emergency Diet Plan does not replace dialysis; it should be used only in case of an emergency.

Guidelines

1. Limit meat to 3-4 oz/day.
2. Avoid all high-potassium fruits and vegetables.
3. Consume only one to two 8-oz cups of fluid per day.
4. Choose low-salt foods.
5. Do not use salt or salt substitute.
6. Use fats and sugars for extra calories.
7. If the power is off for a day, foods in refrigerator should be eaten first.
8. Patients should eat food from the freezer while they still have ice crystals in the center.
9. Patients should have a portable emergency kit they can take with them to a disaster relief center. Sample foods are listed in the following diet plan.

Emergency Diet Plan

If a food is not on this list, dialysis patients should not eat it.

Meat and Protein Foods (three to four 1-oz choices/day)

- 1 egg
- 1 oz meat, fish, tofu, or poultry
- ¼ cup unsalted or rinsed canned fish or poultry
- 2 tablespoons unsalted peanut butter
- ¼ cup cottage cheese
- ½ can commercial liquid nutritional supplement

Starch (six to ten choices/day)

- 1 slice white bread
- ½ English muffin or bagel
- 5 unsalted crackers
- 2 graham crackers
- 6 shortbread cookies, vanilla wafers
- 1 cup unsalted rice, noodles, pasta
- 1 cup puffed wheat, rice, shredded wheat
- 1 cup of rice or pasta

Vegetables (one choice/day)

½-cup serving of green beans, summer squash, corn, beets, carrots, or peas
Should be fresh or frozen, not canned

Fruits (three to four choices/day)

- 1 small apple
- 15 grapes
- ½ cup serving of berries, cherries, applesauce, canned pears, or canned pineapple

Fats and Oil (six or more choices/day)

1 tsp butter, margarine, oil, or mayonnaise

Fluids (one to two choices/day)

- 1 cup water, coffee, tea, soda
- ½ cup Ensure Plus, Boost Plus, or Nepro
- ½ cup serving of milk, half and half, soy, or rice milk
- Cranberry, apple, or grape juice; or Kool-Aid

Emergency Kit

Have the following things stored in a box or bag easily accessible:

- Foods listed in the Emergency Diet Plan
- Can opener
- Two-gallon jugs of distilled water
- Bleach, 1 Tbsp/gallon of water to sterilize
- Flashlight and extra batteries
- Sharp knife
- Aluminum foil
- Plastic mixing containers and lids
- Measuring cup
- Fork, knife, spoon
- Battery-operated transistor radio
- One-week supply of personal medicines kept in a handy place, including blood pressure medications and phosphate binders (insulin and some other medications must be kept refrigerated or cold)

Storage Tips

1. Store things in a clean, dry place such as a new garbage can or rubber tub.
2. Label and date when food is put in storage.
3. Change all food and water once a year. Eat unused food or donate to a food bank.

Dialysis Emergency Diet information from Katy Wilkens, MS, RDN. Copyright Northwest Kidney Centers, 2019. For more emergency diet info see <https://www.nwkidney.org> or your local Network Coordinating Council website.

CLINICAL CASE STUDY

HC is a 67-year-old Japanese American male.

Serum creatinine 3.3 mg/dL, BUN 72 mg/dL, albumin 2.9 mg/dL, potassium 3.3 mEq/L, phosphorus 6.7 mg/dL, calcium 8.5 mg/dL

Hx: Type 2 diabetes mellitus (DM), heart attack, A-Fib

Pt seen re: 5 kg wt loss/1mo. Pt reports a poor appetite x 3mo.

c/o "I just don't enjoy eating like I used to...food tastes funny."

c/o being too weak to do anything but read or watch TV.

Diet hx reveals pt eats 0% to 10% of meals. Declines enteral supplements.

DW: 48.0 kg, % IBW: 91, BMI: 17.6, moderate fat and muscle wasting.

Pt is reported to have a stage III pressure injury on his coccyx.

Nutrition Care Questions

1. What is HC's calculated eGFR?
2. What is his stage of chronic kidney disease (CKD)?
3. What is the first goal for education?
4. What dietary factors would you address based on these laboratory values?
5. What is the goal for protein intake?
6. How would you assess for improvement or stability of his CKD?
7. What would you expect for him during the next few years if no diet intervention is followed?

Medical Nutrition Therapy for Cancer Prevention, Treatment, and Survivorship

Ginger Hultin, MS, RDN, CSO

KEY TERMS

antiangiogenic agents	hematopoietic growth factors	palliative care
antineoplastic therapy	hormonal therapy	pancytopenia
antioxidants	hospice	peripheral neuropathy
apoptosis	initiation	phytochemicals
benign	insulin-like growth factor-1 (IGF-1)	polycyclic aromatic hydrocarbons (PAHs)
biotherapy	isotonic	progression
bisphenol A (BPA)	malignant neoplasm	promotion
cancer cachexia	metastasis	radiation enteritis
carcinogen	mitogen	radiation therapy
carcinogenesis	mucositis	thrombocytopenia
certified specialist in oncology nutrition (CSO)	mutations	trismus
chemoprevention	myelosuppression	tumor
chemotherapy	neoplasm	tumor angiogenesis
cytokines	neutropenia	tumor necrosis factor- α (cachectin)
dumping syndrome	nutrigenomics	tumor-node-metastasis (TNM) staging system
emetogenic	nutrition impact symptoms	tumor suppressor genes
graft-versus-host disease (GVHD)	oncogenes	xerostomia
hematopoietic cell transplantation (HCT)	oncology	
	osteoradionecrosis	

Cancer is a group of diseases that involves the abnormal and uncontrolled division and reproduction of cells that can spread throughout the body. Some cancers can be monitored over time and treated like a chronic disease while others are harder to treat and lead to early death. The etiology of cancer is not clearly understood but is likely multifactorial with genetic, environmental, medical, and lifestyle factors interfacing to produce a given malignancy (American Cancer Society [ACS], 2019b; National Institutes of Health [NIH], 2019) and National Cancer Institute [NCI], 2019b). The ACS predicts the lifetime risk for developing cancer in the United States is slightly less than half of men and a little more than one third of women (ACS, 2019b). Annually in the United States, cancer is responsible for almost one in four deaths and is the second most common cause of death after heart disease (ACS, 2019b). It is estimated that one third of the more than 580,000 anticipated cancer deaths can be attributed to nutrition and lifestyle behaviors such as poor diet, physical inactivity, alcohol use, and overweight and obesity. Tobacco use contributes significantly to death from cancer with more than 15 million lives lost since the surgeon general released the warning in 1964. Today, nearly

one in five deaths from cancer and other diseases in the United States are caused by tobacco use (ACS, 2019b).

Overall, fewer Americans are dying from cancer, a trend that began more than 20 years ago. For many, cancer is now a chronic disease, like heart disease and diabetes. According to the ACS, there are 15.5 million American cancer survivors living with a history of cancer; this means they are cancer free, are living with evidence of disease, or are undergoing cancer treatment (ACS, 2019b). As a result of progress in early detection of cancer and the development of new anticancer therapies, survivorship for all cancers is now 70% among whites and 63% among blacks, up from 39% and 27% respectively in the 1960's (ACS, 2019b). The Annual Report to the Nation on the Status of Cancer 1999 to 2015 found that cancer incidence rates decreased among men but were stable among women. Overall, cancer death rates are significantly declining in men and women yet differences in rates and trends by race and ethnicity do remain (Cronin et al, 2018).

The cost of cancer care in the United States is a burden to patients, their families, and society, estimated to be more than \$216.6 billion annually—\$80.2 billion for direct medical costs and \$130 billion for loss of productivity resulting from lost income and premature death (ACS, 2019b; Inoue-Choi and Robien, 2013) (Fig. 35.1).

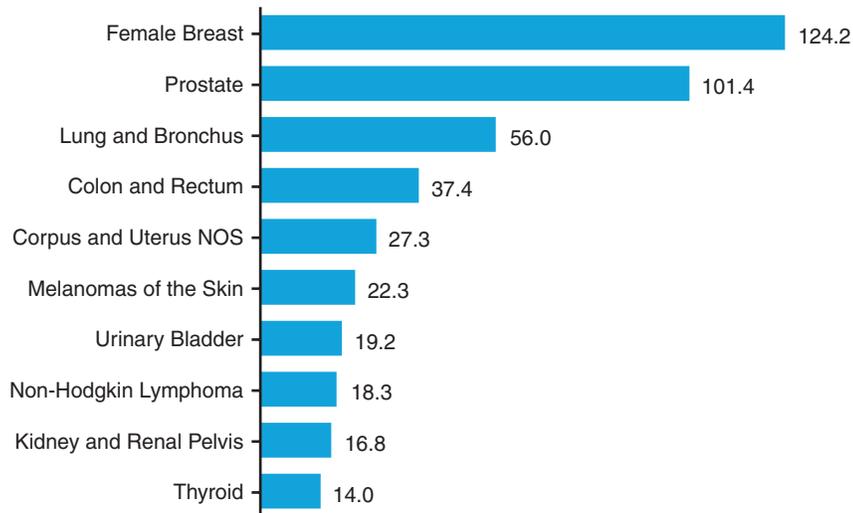

The ACS has created guidelines for the prevention and early detection of cancer (Box 35.1). These prevention guidelines, for those who do not use tobacco, include weight control, dietary choices, and levels

Portions of this chapter were written by Barbara Grant and Kathryn Hamilton.

Top 10 Cancers by Rates of New Cancer Cases

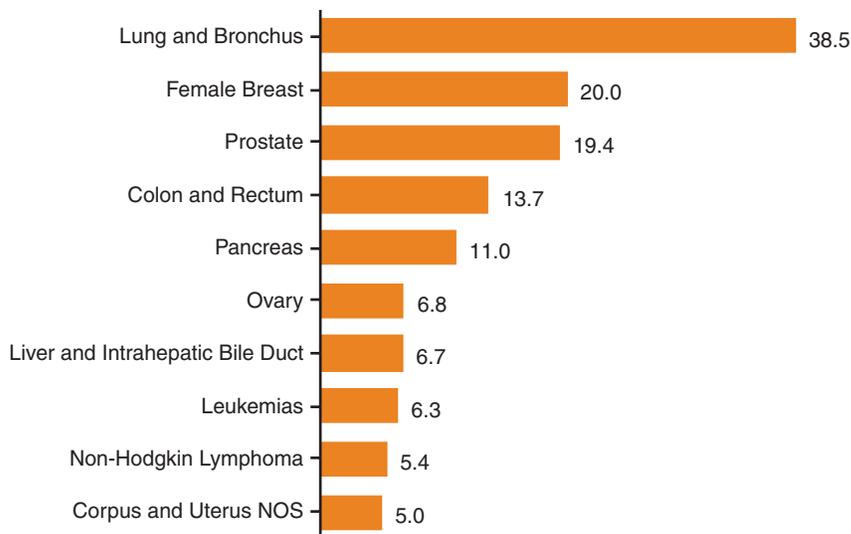

All Types of Cancer, United States, 2016

A Rate per 100,000 people, male and female

Top 10 Cancers by Rates of Cancer Deaths

All Types of Cancer, United States, 2016

B Rate per 100,000 people, male and female

Fig. 35.1 U.S. Cancer Statistics Working Group. U.S. Cancer Statistics Data Visualizations Tool, based on November 2018 submission data (1999-2016); U.S. Department of Health and Human Services, Centers for Disease Control and Prevention and National Cancer Institute; www.cdc.gov/cancer/dataviz, June 2019.

BOX 35.1 Cancer Prevention Recommendations

American Cancer Society

- Adopt a physically active lifestyle. Adults should engage in at least 150 minutes of moderate intensity or 75 minutes of vigorous intensity activity each week, or an equivalent combination, preferably spread throughout the week.
- Achieve and maintain a healthy body weight throughout life. Be as lean as possible throughout life without being underweight. Avoid excess weight gain at all ages.
- Consume a healthy diet, with an emphasis on plant sources. Choose foods and beverages in amounts that help achieve and maintain a healthy weight. Limit consumption of processed meat and red meat. Eat at least 2½ cups of vegetables and fruits each day. Choose whole grains instead of refined grain products.
- If you drink alcoholic beverages, limit consumption. Drink no more than one drink per day for women or two per day for men.

American Institute for Cancer Research/World Cancer Research Fund

- Body Fatness: Be as lean as possible within the normal range of body weight.
- Physical Activity: Be physically active as part of everyday life.
- Foods and Drinks That Promote Weight Gain: Limit consumption of energy-dense foods. Avoid sugary drinks.
- Plant Foods: Eat foods mostly of plant origin.
- Animal Foods: Limit intake of red meat and avoid processed meat.
- Alcoholic Beverages: Limit alcoholic beverages.
- Preservation, Processing, Preparation: Limit consumption of salt. Avoid moldy cereals (grains) or pulses (legumes).
- Dietary Supplements: Aim to meet nutritional needs through diet alone.
- Breastfeeding: Mothers to breastfeed; children to be breastfed.
- Cancer Survivors: Follow the same recommendations.

Data from Kushi LH, et al: American Cancer Society guidelines on nutrition and physical activity for cancer prevention: reducing the risk of cancer with healthy food choices and physical activity, *CA Cancer J Clin* 62:30, 2012; World Cancer Research Fund (WCRF), American Institute for Cancer Research (AICR): Food, nutrition, physical activity, and the prevention of cancer: a global perspective, Washington, DC, 2007, WCRF and AICR.

of physical activity as the most important modifiable determinants of cancer risk (ACS, 2018b).

PATHOPHYSIOLOGY

Carcinogenesis is the origin or development of cancer. **Oncology** is the branch of medicine that specializes in the prevention, diagnosis, and treatment of cancer. Researchers believe changes in gene function cause normal cells to transform into cancerous cells.

Oncogenes are altered genes that promote tumor growth and inhibit **apoptosis** (programmed cell death). The inhibition of cell death pathways allows for survival of the genetically damaged cancer cells. **Tumor suppressor genes** are the opposite of oncogenes; these genes become deactivated in cancer cells. This loss in function can lead to unregulated cell growth and, ultimately, cancer. Examples of tumor suppressor genes include adenomatous polyposis coli (APC), breast cancer types BRCA1 and BRCA2, and tumor suppressor, a protein that

is involved in preventing cancer. Only approximately 5% to 10% of all cancers occur as result of inherited genetic alterations, also called **mutations** (ACS, 2018b). Factors observed in families with hereditary cancers include the following:

- Many cases of an uncommon or rare type of cancer
- A cancer diagnosis at an earlier age than normal for certain kinds of cancer
- Individuals with one type of cancer being diagnosed with a second type of cancer
- More than one childhood cancer diagnosed in a set of siblings
- Cancers occurring in a pair of organs like both eyes, both kidneys, or both breasts
- Cancers occurring in the gender not usually affected (e.g., breast cancer in men)
- Cancers occurring in many generations
- Certain types of cancers observed in specific ethnic populations (e.g., individuals of Ashkenazi Jewish ancestry with breast and ovarian cancer)
- Recognized cancer syndromes, such as hereditary nonpolyposis colorectal cancer or Lynch syndrome, which cause individuals to be at greater risk for developing gastrointestinal (GI), ovarian, uterine, brain, or skin cancer (NIH, 2019a; NCI, 2018a)

Genetic counselors assist individuals and their families to evaluate their risk of hereditary predisposition, such as testing positive for gene mutations and assessing risk.

Phases of Carcinogenesis

A **carcinogen** is a physical, chemical, or viral agent that induces cancer. **Carcinogenesis** is a biologic, multistage process that proceeds on a continuum in three distinct phases: initiation, promotion, and progression. **Initiation** involves transformation of cells produced by the interaction of chemicals, radiation, or viruses with cellular deoxyribonucleic acid (DNA). This transformation occurs rapidly, but cells can remain dormant for a variable period until they are activated by a promoting agent. After the initial cellular damage has occurred, transformation from normal cells to a detectable cancer can take many years or even decades. During **promotion**, initiated cells multiply and escape the mechanisms set in place to protect the body from uncontrolled growth and spread. A **neoplasm**, new and abnormal tissue with no useful function, is established. In the third phase, **progression**, tumor cells aggregate and grow into a fully **malignant neoplasm** or a **tumor**.

In the process known as **metastasis**, the neoplasm has the capacity for invasion that can spread to distant tissues and organs. For a cancer to metastasize, it must develop its own blood supply to sustain its growth of rapidly dividing abnormal cells. In normal cells, angiogenesis promotes the formation of new blood vessels, which are essential to supply the body's tissues with oxygen and nutrients. In cancer cells, **tumor angiogenesis** occurs when tumors are able to develop new blood vessels needed for their growth and metastasis.

NUTRITION AND CARCINOGENESIS

Nutrition may modify the carcinogenic process at any stage, including carcinogen metabolism, cellular and host defense, cell differentiation, and tumor growth. Estimates produced by the World Cancer Research Fund indicate one quarter to one third of all of the cancers that occur in higher-income countries such as the United States, Canada, and Australia are due to poor nutrition, physical inactivity, and excess weight (ACS, 2019b).

Studies looking at the role of nutrition and diet as causal factors of cancer seek to identify relationships between the diets of population

TABLE 35.1 Phytochemicals in Vegetables and Fruits that May Have Cancer Protective Properties

Color	Phytochemical	Vegetables and Fruits	Potential Benefits
Red	Lycopene	Tomatoes and tomato products, papaya, pink grapefruit, watermelon	Protect against prostate cancer
Red and purple	Anthocyanins, polyphenols	Berries, grapes, red wine, plums, purple cabbage, peanuts	Prevent cancer formation, decrease inflammation and provide antioxidant support
Orange	Alpha- and beta-carotene	Carrots, mangos, pumpkin, sweet potato	Protect against oral, esophageal, pharynx, larynx, and lung cancers. Improve immune response
Yellow and green	Lutein, zeaxanthin	Kale, spinach, collard, dandelion, mustard and turnip greens, asparagus, cooked winter squash	Protect DNA from damage
Green	Sulforaphanes, indoles	Arugula, Bok choy, cabbage, broccoli, Brussels sprouts, cauliflower, watercress	Change DNA methylation that directly and indirectly regulates cancer progression
White and green	Allyl sulfides	Leeks, onion, garlic, chives	Protect against stomach and colorectal cancer

American Institute for Cancer Research/World Cancer Research Fund: *Diet – what to eat to lower cancer risk*, 2018b; Bender A, Collins K, Higginbotham S: Nutrition and cancer prevention. In Leser M, Ledesma N, Bergerson S, et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Dietetic Practice Group.

groups and categories of individuals and the incidence of specific cancers (Thomson et al, 2014). Sets of individuals are compared in case control, cohort, or cross-sectional studies. In cancer research, epidemiologists look at human populations and evaluate how many people are diagnosed with cancer, what types of cancer occur in different populations and cultures, and what factors (such as diet and lifestyle) play a role in the development of the cancers.

The sheer complexity of diverse diet patterns presents a difficult challenge for research. Thousands of compounds are found in a normal diet; some are well studied and some are less known and unmeasured. Some dietary carcinogens are naturally occurring pesticides or herbicides produced by plants for protection against fungi, insects, animal predators, or mycotoxins, which are secondary metabolites produced by molds present in foods (e.g., aflatoxins, fumonisins, or ochratoxins). Food preparation and preservation methods also may contribute to dietary carcinogen ingestion. Examples of dietary enhancers of carcinogenesis may be the saturated fat in red meat or the **polycyclic aromatic hydrocarbons (PAHs)** that form on the surface of meat when grilling at high temperatures. Fortunately, diets also contain inhibitors of carcinogenesis. Dietary carcinogen inhibitors include **antioxidants** (e.g., vitamin C, carotenoids, vitamin E, selenium, zinc) and **phytochemicals** (biologically active components of plants) (Table 35.1). Dietary antioxidants scavenge and neutralize free radicals, preventing them from causing damage in the body (NCI, 2017).

Complicating the study of nutrition, diet, and cancer is the fact that an alteration of one major component of the diet can precipitate a change in other facets of the diet. For example, decreasing animal protein also decreases saturated fat. This cascade makes the interpretation of research findings difficult because the effects cannot be associated clearly with one single factor. Additional complications in interpretation can result from the fact that cancer cells can either be fast growing or have a long latent or dormant period. The slow-growing, latent, or dormant aspect of the disease progression makes pinpointing dietary patterns at the time of cancer cell initiation or promotion, and not at time of diagnosis, difficult. Epidemiologic research, together with animal studies, provides a viable method for discovering the links between nutrition and cancer in humans.

Alcohol

Alcohol consumption was responsible for 3 million deaths each year globally, in 2018, and is a modifiable risk factor for cancer-related deaths in the United States (Bender et al, 2013; World Health Organization

[WHO], 2018). It is associated with increased cancer risk for cancers of the oral cavity, pharynx, larynx, esophagus, colon, rectum, stomach, pancreas, gallbladder, liver, and breast (pre- and postmenopausal women). For colorectal, stomach, liver, and kidney cancers, daily consumption of two or more drinks increases risk significantly compared with non-drinkers. (Bagnardi et al, 2015; World Cancer Research Fund/American Institute for Cancer, 2018).

Alcohol can also negatively affect health outcomes for some cancer survivors. Alcohol consumption was associated with an increased risk of overall mortality in cancer survivors particularly in head and neck cancer leading to lower survival rates. Alcohol intake recommendations should be tailored to the individual given the type of cancer, dietary history, and health goals (Rock et al, 2012). An increased risk for cancer recurrence was also found when data for pre- and postdiagnosis levels of alcohol were combined. Alcohol is associated with an increased risk of breast cancer recurrence and increased mortality rates among survivors of hepatocellular carcinoma, non-Hodgkin's lymphoma, laryngeal and pharyngeal, and head and neck cancer (Schwedhelm et al, 2016).

Concurrent tobacco and alcohol use greatly increases cancer risk, particularly for cancers of the upper digestive area and respiratory tract (WCRF/AICR, 2018). In addition, malnutrition associated with alcoholism is likely to be important in the increased risk for certain cancers. In the United States if individuals choose to drink, men are recommended to limit alcohol intake to no more than two drinks per day and women to one drink per day. Serving sizes of alcoholic drinks include beer (12 oz), wine (5 oz), and liquors (1.5 oz of 80-proof liquors) though the WCRF/AICR recommends that it is best to not drink alcohol at all (Dietary Guidelines for Americans, 2018; Kushi et al, 2012; WCRF/AICR, 2018). (Fig. 35.2).

Energy Intake and Body Weight

Obesity is a risk factor for some cancers and may account for up to 20% of all cancer-related mortality (Arnold et al, 2016; Arnold et al, 2017; Bender et al, 2013; Kushi et al, 2012). This makes maintaining a healthy body weight status the second most important lifestyle factor to reduce cancer risk after not using tobacco (Bender et al, 2013). Currently 70.2% of American adults are overweight or obese (Centers for Disease Control and Prevention [CDC], 2018). The relationship between body weight, body mass index (BMI), or relative body weight and site-specific cancer has been widely investigated; a positive association has been seen with cancers of the mouth/larynx/pharynx,

Fig. 35.2 Centers for Disease Control. Fact Sheet – Moderate Drinking (website). <https://www.cdc.gov/alcohol/fact-sheets/moderate-drinking.htm>.

TABLE 35.2 American Cancer Society: Moderate and Vigorous Physical Activity

	Moderate Activities (moving fast enough that you can speak but cannot sing)	Vigorous Activities (moving fast enough that you can speak a few words but not in complete sentences)
Exercise and leisure	Walking, dancing, leisurely bicycling, ice and roller skating, horseback riding, canoeing, yoga	Jogging or running, fast bicycling, circuit weight training, aerobic dance, martial arts, jumping rope, swimming
Sports	Volleyball, golfing, softball, baseball, badminton, doubles tennis, downhill skiing	Soccer, field or ice hockey, lacrosse, singles tennis, racquetball, basketball, cross-country skiing
Home activities	Mowing the lawn, general yard and garden maintenance	Digging, carrying and hauling, masonry, carpentry
Workplace activity	Walking and lifting as part of the job (custodial work, farming, auto or machine repair)	Heavy manual labor (forestry, construction, firefighting)

American Cancer Society (ACS): <https://www.cancer.org>; Kushi LH, et al: American Cancer Society guidelines on nutrition and physical activity for cancer prevention: reducing the risk of cancer with healthy food choices and physical activity, *CA Cancer J Clin* 62:30, 2012.

esophagus, pancreas, gallbladder, breast (postmenopausal), endometrium, kidney, colon, rectum, gastric cardia, liver, ovary, thyroid, multiple myeloma, and meningioma (Arnold et al, 2016; Arnold et al, 2017). Body fat is a metabolically active tissue that produces estrogen and proteins that cause high levels of insulin and other hormones including insulin-like growth factor-1 (IGF-1) and leptin that can lead to inflammation. The longer a person is overweight, the more significant the association with the incidence of all obesity-related cancers. For example, in postmenopausal breast and endometrial cancer, every 10-year increase in adulthood overweight status is associated with a 5% and 17% increase in risk, respectively (Arnold et al, 2016; Arnold et al, 2017; AICR, 2018a; Bender et al, 2013).

Obesity, age, hyperglycemia, and the incidence of metabolic syndrome play a role in the circulating levels of **insulin-like growth factor-1 (IGF-1)**. IGF-1 is a polypeptide secreted primarily by the liver and plays a key role in normal growth and development, acting as a **mitogen**, a chemical substance that encourages cells to divide, that may promote growth and reproduction of cancer cells while inhibiting apoptosis. High circulating levels have been associated with the development and progression of prostate, breast, lung, and colon cancer (Adachi et al, 2016; Bender et al, 2013). IGF-1 secretion is increased when insulin levels are elevated. Obesity and high simple carbohydrate intakes potentially increase insulin resistance and raise circulating insulin levels. This area of research connects several known risk factors between nutrition, diet, and cancer (Park et al, 2014).

Physical activity is a critical component of weight management, optimal lean body mass, and energy balance. The ACS Nutrition and Physical Activity Guidelines for Cancer Prevention and the Guidelines

for Cancer Survivors encourage individuals to strive for a minimum of 150 minutes per week of moderate activity or a minimum of 75 minutes per week of vigorous activity (Kushi et al, 2012; Rock et al, 2012) (Table 35.2).

Achieving and maintaining energy balance and a reasonable weight should be a primary health goal for all individuals, including cancer survivors, because being overweight or obese appears to increase risk of developing cancer, cancer recurrence, and decreased survival (Kushi et al, 2012; Rock et al, 2012) (Box 35.2).

BOX 35.2 Does Eating Less Reduce the Risk for Cancer?

Animal studies have demonstrated that both chronic restriction of calories and intermittent calorie restriction have shown anticancer effects. Both forms of restriction may decrease insulin-like growth factor-1 (IGF-1) and leptin while increasing adiponectin and improving insulin sensitivity. There have been population-based studies on breast cancer and chronic caloric restriction though compliance has been low in some studies due to the challenges of constant restriction. For this reason, intermittent fasting (IF) may be better suited to some individuals and has been linked to weight loss and significantly lower serum IGF-1 in some participants. IF can be done several ways including alternate day fasting, fasting 2 days per week, or fasting for 12 to 16 hours out of 24 hours. This is also referred to as time restricted feeding. Caloric restriction, without malnutrition, appears to have a positive effect on cancer prevention in animals; it is unclear whether that effect translates to humans and if chronic restriction or IF may be more desirable for compliance and cancer outcomes (Chen et al, 2016; Fontana et al, 2016; Harvie and Howell, 2016).

Fat

Dietary fat has been studied in relationship to cancer risk and recurrence. There appears to be an inconsistent link between certain types of cancer and the amount of fat in the diet. Of note, diets that contain a significant amount of fat often contain more meat and more calories, which can contribute to overweight and obese conditions and increased cancer risk.

To further complicate the picture, an additional link a fat, meat, and cancer risk results from meat preparation and processing, such as the presence of heterocyclic amines (HCAs) and/or PAHs from cooking, formation of carcinogenic N-nitroso compounds (NOCs) from processing, and the potential cancer-promoting influence of heme-iron (Bender et al, 2013; WCRF/AICR, 2018).

Because dietary fat intake is correlated with the intake of other nutrients and dietary components, it is difficult to distinguish between the effects of dietary fat, protein, total calories, and carcinogenic compounds in cancer prevention. So the current ACS recommendation is to limit consumption of processed meats and red meats (Kushi et al, 2012).

A large prospective randomized trial examined dietary fat consumption as part of the diet composition, and all cancer mortality showed mixed results. The Women's Health Initiative (WHI) found that adoption of a low-fat dietary pattern led to a lower incidence of deaths after breast cancer but no reduction in mortality from other cancer sites (Chlebowski et al, 2018). Current recommendations focus on limiting highly processed foods high in fat and added sugar as well as limiting red meat. Doing so naturally reduces the amount of trans and saturated fat in the diet (WCRF/AICR, 2018).

Eating more omega-3 fatty acids (foods such as fatty fish, flaxseed oil, walnuts, and certain algae) in relation to omega-6 fatty acids (polyunsaturated fats such as safflower oil and sunflower oil) potentially reduces risk of cancer by acting to decrease inflammation, cell proliferation, and angiogenesis while increasing apoptosis (Bender et al, 2013). However, there have been contradictory results in human studies so the benefit remains unclear (Weylandt et al, 2015). The differences seen are possibly due to the difference in response to omega-3 in food versus taking omega-3 as a supplement.

Sugar and Nonnutritive Sweeteners

Studies suggest that high glycemic diets that raise postprandial blood glucose may increase cancer risk by creating higher levels of IGF-1 in the body. A large prospective study (EPIC-Italy) found that a high glycemic diet was associated with an increased risk of colon and bladder cancer (Sieri et al, 2017). The 2015–2020 Dietary Guidelines for Americans recommends limiting calories from added sugars in the diet, specifically consuming less than 10% of calories per day from added sugars (Dietary Guidelines for Americans, 2018). Sugary drinks, energy-dense foods, and highly processed foods can promote weight gain so consumption should be limited for cancer prevention (Bender et al, 2013).

The Food and Drug Administration (FDA) has approved eight nonnutritive sweeteners (acesulfame-potassium, aspartame, luo han guo fruit extract [monk fruit], neotame, saccharin, stevia, advantame, and sucralose) for use in the food supply and regulates them as food additives; they are generally recognized as safe (GRAS) when used in moderation (Academy of Nutrition and Dietetics [AND], 2012 ; FDA, 2018). Described as “high-intensity” sweeteners, nonnutritive sweeteners provide little or no energy because they sweeten in minute amounts. Nonnutritive sweeteners have been investigated primarily in relation to potential adverse health concerns, including long-term safety and

carcinogenicity, but multiple studies during the past 20 or more years have indicated that when consumed in reasonable amounts, they are safe (NCI, 2016a). Additional sugar substitutes on the market include sugar alcohols (e.g., mannitol, sorbitol, xylitol). Sugar alcohols are not considered nonnutritive sweeteners even though they are used in a similar way (AND, 2012).

Protein

Most diets that contain significant amounts of protein also contain significant amounts of meat and fat and lower amounts of fiber. The effect of protein on carcinogenesis depends on origin and type of tumor as well as the type of protein consumed and the overall calorie content of the diet as it relates to body weight regulation. Some studies suggest that restricting protein intake can lower IGF-1 levels and be cancer protective, even slowing tumor progression in animal models. Note that human studies state protein restriction is not appropriate for older adults age 65+ and people undergoing cancer treatment at any age also have increased needs. Because of the link between red and processed meat consumption and cancer, the American Cancer Society and the American Institute for Cancer Research recommend limiting these foods and eating more plant based proteins such as legumes, nuts, and seeds. (Levine et al, 2014; Melina 2016; WCRF/AICR, 2018).

Smoked, Grilled, and Preserved Foods and Processed Meats

Processed meats are treated in some way to preserve flavor generally by smoking, curing, salting, or adding chemical preservatives. Processed meats include beef jerky, bologna, pepperoni, ham, bacon, hot dogs and frankfurters, pastrami, salami, and sausages. Nitrates are added as preservatives to processed meats. Nitrates can be readily reduced to form nitrites, which can interact with dietary substrates such as amines and amides to produce NOCs nitrosamines and nitrosamides, which are known mutagens and carcinogens. Nitrates or nitrites are used in smoked, salted, and pickled foods. They are linked especially to colorectal cancer (WCRF/AICR, 2018). Twenty-two experts from 10 countries reviewed more than 800 studies and found that eating 50 grams of processed meat every day increased the risk of colorectal cancer by 18%. That is the equivalent of about four strips of bacon or one hot dog. For those eating any red meat, there was evidence of increased risk of colorectal, pancreatic, and prostate cancer (WHO, 2015).

Charring or cooking meat at high temperatures over an open flame (400° F/204.4° C or more) can cause the formation of PAHs and HCAs. Polycyclic aromatic hydrocarbons (PAHs) have shown clear indications of mutagenicity and carcinogenicity. Normal roasting or frying food does not produce large amounts of PAHs compared with the amount produced when cooking over open flames. Animal proteins that produce the greatest dripping of fat on to the flames register the highest PAH formation. For example, grilled beef produces larger amounts of PAHs than grilled chicken, which produces higher amounts than oven-grilled chicken. The source of the flame can also influence PAH production; charcoal grilling promotes the most, followed by flame gas, and finally oven grilling (Ewa and Danuta, 2017).

Organic and Genetically Modified (GM) Foods

Food growing techniques and modifications made to food leave some patients fearing that conventionally grown or GM foods can be cancer promoting. Though studies have shown that organically produced foods are less likely than conventionally grown foods to contain

pesticide residues, a large study presented in the *British Journal of Cancer* found that consumption of organic food was not associated with a reduction in the incidence of all cancer, soft tissue sarcoma, or breast cancer (Bradbury et al, 2014). While some studies have suggested that organic foods are higher in certain nutrients, others have found that not to be true to a notable degree. At this time, risk of cancer or a decreased nutritional value are not reasons to avoid conventionally grown produce (Bradbury et al, 2014; Brantsæter et al, 2017). For patients who are concerned about limiting their pesticide exposure or who have environmental concerns, purchasing organic foods is an option. See Chapter 8 for further discussion of organic versus conventional agriculture.

Biotechnology in agriculture includes genetically modified organisms (GMOs) such as corn and soybean crops among others in the United States. Some people fear that there is a link between cancer and GMOs though studies do not show that the process of genetic modification is a risk. Some studies have suggested a link between tumors in animals and non-Hodgkin's lymphoma in humans due to the use of herbicide glyphosate used on GM crops. It was previously deemed a probable human carcinogen by the International Agency for Research on Cancer (IARC). One benefit to GMOs can be to decrease the number of herbicides used directly on crops. However, some GMO crops have been developed to be resistant to herbicides, so while GMO crops decrease the amount of pesticide needed, the amount of herbicide is actually increased. The National Academy of Sciences has reviewed the safety of GM crops and found that they pose no unique hazards to human health, including cancer incidence. Ongoing evaluation of GMO safety is important to understanding the long-term effects of GMOs on human health and the environment (Kushi et al, 2012; Landrigan and Benbrook, 2015).

Chemical Exposures

The Environmental Protection Agency (EPA) was established in 1970 to oversee the acute and long-term health threats caused by substances in the environment. As part of this protection, the Toxic Substances Control Act passed in 1976 requires manufacturers to submit health and safety information on all new chemicals. However, many were grandfathered in with the passage of this law and are still untested. To date, 248 compounds have been identified by the NIH as carcinogenic (NIH/National Institute of Environmental Health Services [NIEHS], 2016).

Everyday activities expose people to a myriad of chemicals through air, water, food, and beverages. In fact, an estimated 12% of cancers diagnosed each year are likely caused by these very common exposures (Israel, 2010; NIH/NIEHS, 2016). Studies of people with high exposures to pesticides such as agricultural workers including farmers and crop duster pilots, have higher rates of overall cancer incidence as well as increased risk of lymphohematopoietic cancers; leukemia; non-Hodgkin's lymphoma; multiple myeloma; breast, bladder, prostate, brain, lung, pancreatic, and colorectal cancers; and melanoma. There are specific types of cancer associated with specific types of pesticide application and exposure (Alavanja, 2009; Weichenthal et al, 2010).

A good environmental history can be performed at clinical visits and then quickly reviewed for outdoor air pollutants such as nitrogen dioxide, ozone, and carbon monoxide, which pose health risks. Exposure to heavy metals, pesticides, herbicides, and occupational exposures also may be noted. Oxidative stress caused by these environmental exposures can be reduced by changes in lifestyle, including eliminating smoking and implementing dietary changes such as the consumption of phytonutrient-rich foods and a nutrient-rich diet (Kushi et al, 2012).

BOX 35.3 Tips from the FDA to Minimize Exposure to Bisphenol A (BPA)

- Check plastic container recycle codes on the bottom of container. Some, but not all, plastics that are marked with recycle codes 3 or 7 may be made with BPA.
- Avoid putting very hot or boiling liquids in plastic containers made with BPA. BPA levels rise in food when containers and products made with the chemical are heated and come in contact with the food. Don't microwave polycarbonate plastic food containers.
- Reduce your use of canned foods or choose BPA-free products. Opt instead for glass, porcelain, or stainless-steel containers.

Food and Drug Administration: *Bisphenol A (BPA): for use in food content application*, 2014; Environmental Protection Agency: *Risk management for bisphenol A (BPA)*, 2017; National Institutes of Health: *Bisphenol A (BPA)*, 2017.

Bisphenol A (BPA)

Bisphenol A (BPA) is an industrial chemical used since the 1960s in the manufacturing of many hard, plastic bottles and the epoxy linings of metal-based food and beverage cans. It is also an ingredient in the production of epoxy resin used in paints and adhesives. Studies done when the product was developed indicated it was safe to use in food and beverage containers. However, multiple studies have demonstrated that BPA may disrupt the function of some hormones, including sex hormones, leptin, insulin, and thyroxin causing hepatotoxic, immunologic, and carcinogenic effects (Michalowicz, 2014).

Other findings from the combined efforts of the NIEHS, the National Toxicology Program, and FDA scientists at the National Center for Toxicologic Research Program conclude that the health threat from BPA is less than previously estimated and safe at the levels occurring in foods. Health damage from BPA may not be as likely because based on mathematical models, BPA rapidly metabolizes in the body, rather than accumulating (FDA, 2014).

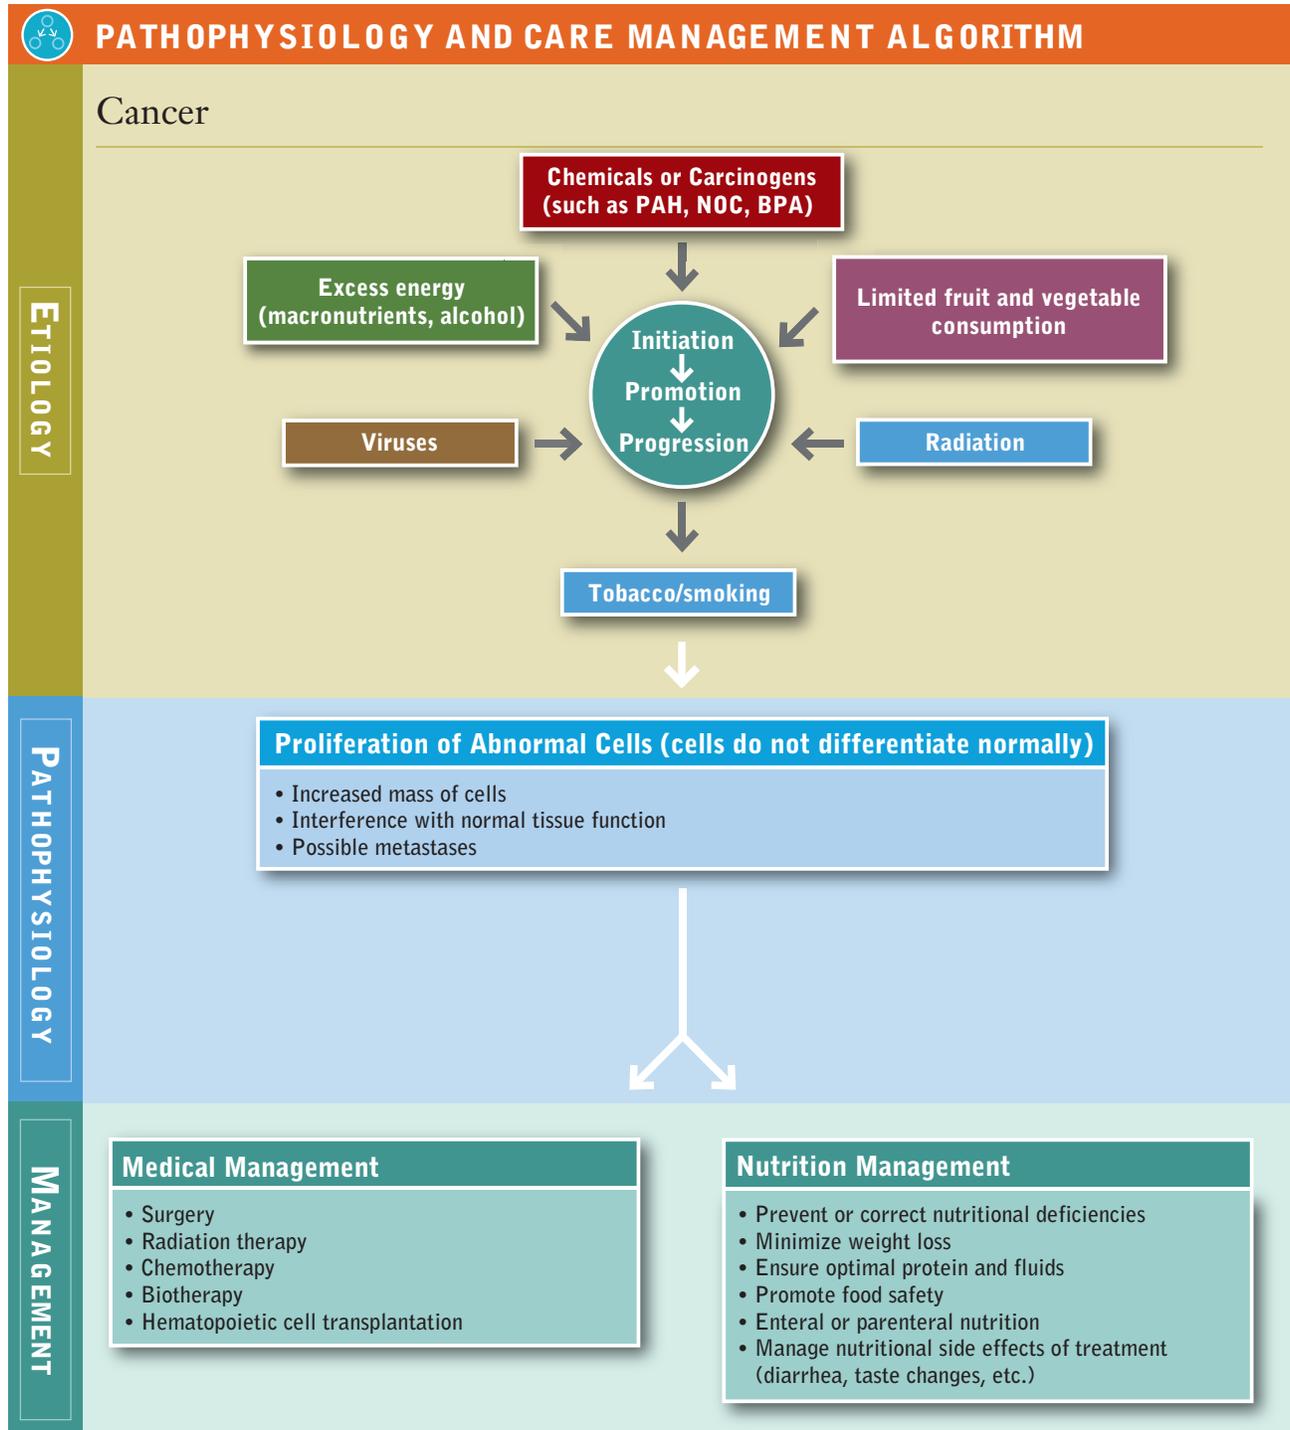

Until more is known, the current goal is to reduce the use and exposure to BPA through several actions: restricting the use of BPA in plastic bottles, using alternatives to the glue resins used in food containers, and increasing the oversight on the use of BPA in manufacturing and testing. The U.S. Department of Health and Human Services (USDHHS) supports eliminating BPA from all food-related product production. Originally it was thought to leech from the plastic only when exposed to heat; now it is believed to leech even at cold temperatures (FDA, 2014). Note that BPA-free products are now easy to find. Consumers can read labels and choose BPA-free cans or foods packaged in BPA-free boxes or glass (Box 35.3).

CHEMOPREVENTION

Eating behaviors play an important role in health promotion and disease prevention. **Chemoprevention** is defined as the use of drugs, vitamins, or other agents to reduce the risk of, or delay the development or recurrence of cancer (NIH and NCI, 2015). Examples include nonsteroidal antiinflammatory drugs that may protect against colon cancer, and metformin, a commonly used medication to treat diabetes; these are currently being explored as cancer prevention and treatment agents (Guppy et al, 2011; Quinn et al, 2013). Other natural products or molecules currently being investigated include the hundreds of

polyphenols in fruits and vegetables, green tea, curcumin (turmeric), and resveratrol from red grapes and berries. Phenolic acid, flavonoids, terpenes, and lignans are the most abundant polyphenols; the chemopreventive potential of these compounds comes from their ability to modulate epigenetic alterations in cancer cells (Choi and Friso, 2010). Many of these substances likely have complementary and overlapping mechanisms including antioxidant, antiangiogenesis, immune modulating, detox enzyme enhancing, antiproliferative, and nitrosamine formation inhibiting properties in addition to diluting and binding carcinogens in the digestive tract and altering hormone metabolism, all relevant to cancer prevention (see Table 35.1).

The epigenetic modification step occurs early in the development of a cancer cell, at a time when it is potentially reversible. Scientists do not fully understand how this process works, yet it is reasonable to recommend a health-promoting and possibly cancer-preventing diet rich in fruits, vegetables, soy, therapeutic culinary herbs such as turmeric and cinnamon, green tea, and coffee (Link et al, 2010). The overall evidence of association between these and other dietary factors enable health organizations to draft diet and lifestyle recommendations for the purpose of reducing cancer risk (see the ACS website <https://www.cancer.org> and Box 35.1).

Antioxidants and Bioactive Compounds

The American Institute for Cancer Research (AICR) lists 19 foods that fight cancer based on bioactive compounds that inhibit the reproduction of cancer cells, slow the growth of tumors, inhibit division of cancer cells, and decrease risk of developing cancer. Bioactive compounds including saponins, protease inhibitors, phytic acid, quercetin, resveratrol, glucosinolates, chlorogenic acid, and many more can act as chemoprotective agents (AICR, 2018c). (Table 35.3).

Studies have shown promise that diets higher in antioxidants including vitamins C and E, selenium, flavonoids, and carotenoids may prevent certain types of cancer including breast cancer. A large prospective cohort study, the Rotterdam Study, found that high overall dietary antioxidant capacity was associated with a lower risk of developing breast cancer (Pantavos et al, 2015). Research supports potential chemoprotection from dietary antioxidant sources but not from supplement sources (Bender et al, 2013).

Vitamin D

Some studies have reported an association of poor vitamin D status and greater incidence of cancer though other studies do not support this hypothesis. Vitamin D is the precursor to steroid hormone calcitriol—1,25-dihydroxyvitamin D₃ (1,25[OH]₂ D₃), which mediates numerous actions in many tissues of the body. It is known that calcitriol regulates multiple signaling pathways involved in proliferation, apoptosis, differentiation, inflammation, invasion, angiogenesis, and metastasis, creating a potential to affect cancer development and growth. Studies on what blood levels of serum 25-hydroxy vitamin D (25[OH]D) provide the most protection but concentrations of 45 to 50 ng/mL levels experienced lower incidence of colon and breast cancer than those with lower levels ranging from 8 to 12 ng/mL

(American Academy of Dermatology [AAD], 2018; Baggerly et al, 2015; Feldman et al, 2014).

More work must be done in this area to determine whether supplementation with vitamin D can prevent cancer, or if low levels of the vitamin simply increases an individual's cancer risk. Until more is learned about the interaction between vitamin D₃ and cancer prevention, taking 600 IU of vitamin D per day to maintain normal serum 25(OH)D levels is considered safe for males and females ages 1-70 years at which time recommendations increase to 800 IU (Kushi et al, 2012). Individuals with abnormal serum levels should consult their medical team for supplement suggestions, monitoring, and evaluation. Correcting a deficiency in vitamin D may be important for its health promotion benefits as well as its effect on calcium absorption and bone health.

Coffee and Tea

Coffee contains various antioxidant and phenolic compounds, some of which have been shown to have anticancer properties. Coffee also contains caffeine, a compound in the alkaloid phytochemical family. Coffee as a major source of antioxidants in the American diet may offer a protective effect against cancer. Though coffee does contain acrylamide, created during high temperature roasting, there is no evidence that regular consumption of coffee is associated with increased risk of cancer. It has shown to be potentially carcinogenic when given to animals at high levels but is not a concern for humans at this time (AICR, 2018c; NIH and NCI, 2010; Wilson et al, 2010).

Tea is also a good source of phenols and antioxidants. Green tea is made from leaves that have been pressed and dried but not roasted. Because of this, green tea, more so than black tea, contains catechins, including epigallocatechin-3-gallate (EGCG) that possess potentially anticancer biologic activity (AICR, 2018c; NIH and NCI, 2010).

TABLE 35.3 Foods that Fight Cancer

Food	Bioactive Compound
Apples	Fiber, vitamin C, quercetin, flavonoids, triterpenoids
Blueberries	Fiber, vitamins C and K, manganese, anthocyanins, catechins, quercetin, kaempferol, ellagitannins, pterostilbene, resveratrol
Cruciferous Vegetables	Vitamins C, K, and manganese, glucosinolates that form isothiocyanates and indoles
Carrots	Fiber, vitamins A and K, beta-carotene and alpha-carotene, luteolin, falcarinol
Cherries	Fiber, vitamin C, potassium, anthocyanins, hydroxycinnamic acid, perillyl alcohol
Coffee	Riboflavin, chlorogenic acid, quinic acid, cafestol and kahweol, N-methylpyridinium (NBM)
Cranberries	Fiber, vitamin c, flavonoids, ursolic acid, benzoic and hydroxycinnamic acid
Dark Leafy Greens	Fiber, folate, carotenoids (lutein and zeaxanthin), saponins and flavonoids
Legumes	Fiber, lignans, saponins, triterpenoids, inositol, sterols, protease inhibitors, resistant starch that produce short-chain fatty acids (SCFA)
Flaxseed	Fiber, magnesium, manganese, thiamin, selenium, lignans, alpha-linolenic acid (ALA), gamma-tocopherol: a form of vitamin E
Garlic	Allicin, S-allyl cysteine, flavonoids (kaempferol and quercetin), inulin, saponins
Grapefruit	Vitamin C, naringenin, limonin, beta-carotene, lycopene
Grapes	Resveratrol
Soy	Isoflavones (genistein, daidzein and glycitein), saponins, phenolic acids, phytic acid, sphingolipids
Squash	Fiber, vitamins A and C, potassium, beta-carotene and alpha-carotene, lutein, zeaxanthin
Tea	Theophylline and theobromine, catechins (epigallocatechin gallate [EGCG], epicatechin, epigallocatechin [EGC], epicatechin-3-gallate [ECG], thearubigins and theaflavins (black tea), theasinensins (oolong tea), flavonols quercetin, kaempferol and myricetin, L-theanine
Tomatoes	Vitamins A and C, potassium, lycopene, phytoene and phytofluene
Walnuts	Ellagitannins, gamma-tocopherol, ALA, polyphenols including (flavonoids and phenolic acids), phytosterols, melatonin
Whole Grains	Fiber, polyphenols (phenolic acids and flavonoids), lignans, saponins alkylresorcinols, phytic acid, protease inhibitors, tocotrienols

American Institute for Cancer Research: *Foods that fight cancer*, 2018c. <http://www.aicr.org/foods-that-fight-cancer/>

Fruits and Vegetables

Fruit intake is protective against cancers of the esophagus, lung, and stomach (WCRF/AICR, 2018). Nonstarchy vegetables, such as spinach, tomatoes, and peppers, probably provide protection against mouth, pharynx, larynx, esophageal, lung, and breast cancers. All vegetables, but particularly green and yellow ones, probably protect against stomach cancer (WCRF/AICR, 2018). The Dietary Guidelines for Americans suggests 2 cups per day of fruit and 2 ½ cups per day of vegetables including dark green and red and orange colored varieties (Dietary Guidelines for Americans, 2018).

Anticarcinogenic agents found in fruits and vegetables include antioxidants such as vitamins C and E, selenium, and **phytochemicals**. Phytochemicals include carotenoids, flavonoids, isoflavones, lignans, organosulfides, phenolic compounds, and monoterpenes. It is still unclear which specific substances of fruits and vegetables are the most protective against cancer (Kushi et al, 2012). It appears extremely unlikely that any one substance is responsible for all the observed associations. See Table 35.1 for a discussion of chemoprotective agents in fruits and vegetables.

Soy and Phytoestrogens

Soy is a plant-based protein that contains isoflavones such as genistein and daidzein, plant based estrogens (phytoestrogens). Diets containing modest amounts of soy protect against breast cancer (ACS, 2019a), especially if the soy foods have been consumed early in life (ACS, 2019a). Confusion regarding soy abounds because soy isoflavones have been shown to promote in vitro growth of breast cancer cells and mammary tumor growth in rodent models, creating some concern about the potential adverse effect of soy consumption on prognosis in women who have been diagnosed with breast cancer. Soy is metabolized differently in humans and recent large epidemiologic studies have found no adverse effects of soy food intake on breast cancer recurrence or total mortality, alone or in combination with tamoxifen. The ACS and other researchers state that there is the potential for these foods to exert a beneficial synergistic effect with tamoxifen (ACS, 2019a; Rock et al, 2012).

Commercially prepared soy supplement powders and foods made from soy products can but may not always contain isoflavones at much higher concentrations than traditional whole soy foods such as edamame beans, tofu, tempeh, miso, or soy milk (U.S. Department of Agriculture [USDA], 2016). According to the ACS current evidence does not support that consuming soy foods will have an adverse effect on recurrence or survival of breast cancer patients. (Rock et al, 2012). Men with hormone-sensitive cancer such as prostate cancer may also benefit from regular consumption of soy foods. Prostate cancer is a testosterone-driven cancer and phytoestrogens are antagonists. Tofu and other soy foods are also linked to lower rates of heart disease and may help to lower cholesterol (ACS, 2019a).

Vegetarian and Vegan Plant-Based Diets

Plant foods may aid in cancer prevention by functioning as cancer inhibitors through antiinflammatory mechanisms and changes in gene expression and hormone activity (Bender et al, 2013). Diets primarily composed of plant foods including vegetarian and vegan dietary patterns may provide anticancer properties. Results from the Adventists Health Study 2 found an association between vegetarian diets and lower overall cancer risk, especially a lower risk of GI cancer (Melina et al, 2016). In fact, a vegan diet appeared to protect against cancer more than any other dietary pattern (Melina et al, 2016). Fruits, vegetables, and whole grains contain biologically active phytochemicals,

BOX 35.4 Nutrigenomics: The Future of Personalized Cancer Prevention?

Nutrigenomics, is the interaction between nutrients and the genome as they impact host health and disease risk. Because the progression of cancer is enhanced by the genetic instability of cells due to defective DNA repair processes, damage to the genome and what could be done to prevent it is an area of interest for further study. It is known that nutrients and other environmental factors interact with the genome and could either further DNA damage or perhaps help prevent it. Human nutrigenomic and cancer research is an area of exciting possibility as nutrition professionals position themselves as experts in the field and are involved in discussing genetic concepts with patients (Sharma and Dwivedi, 2017; Camp and Trujillo, 2014; Spees and Grainger, 2013).

vitamins, minerals, and dietary fiber that have demonstrated functions in preventing and treating disease. In fact, vegetarian and vegans are at reduced risk of ischemic heart disease, type 2 diabetes, hypertension, and obesity (Melina et al, 2016). Vegetarians typically consume higher levels of fiber compared with other diets which may target a reduction in colorectal cancer risk (Melina et al, 2016). In addition, the ACS Prevention Guidelines suggest that individuals who eat more vegetables and fruits further benefit by experiencing less weight gain and greater satiety and are at a lower risk of developing obesity, thereby reducing overall cancer risk (Kushi et al, 2012).

Physical Activity

Physical activity is an important part of cancer prevention, treatment, and survival. Studies clearly show that increasing physical activity reduces cancer risk. Engaging in moderate to vigorous levels of activity reduces the risk of developing breast, colon, and endometrial cancers as well as advanced prostate cancer and pancreatic cancer (Kushi et al, 2012). Physical activity helps regain and maintain muscle; regain strength, energy, and flexibility; and relieve symptoms of stress, anxiety, and even depression. Physical activity may reduce risk of cancer by strengthening the immune system and regulating sex hormones, insulin, and prostaglandins (Kushi et al, 2012). Evidence reflects that exercising during and after treatment is safe and even associated with improved quality of life and positive outcomes due to reduced risk of other chronic diseases including heart disease, diabetes, osteoporosis, and hypertension (Kushi et al, 2012). Research is particularly strong for breast and colorectal cancer survivors undergoing treatment. With medical clearance for safety, cancer survivors in all phases of the cancer-care spectrum should be as physically active as possible (Marian, 2013) (see Table 35.2 and Box 35.4).

MEDICAL DIAGNOSIS AND STAGING OF CANCER

Despite the progress made in understanding possible prevention strategies, cancer remains a significant health threat. Assessing symptoms of cancer at the earliest stage is critical for treatment effectiveness and survival. Many symptoms of early or metastatic cancer affect an individual's ability to eat, digest, or absorb. According to the ACS, the following early warning signs and symptoms of cancer are described using the acronym CAUTION:

- Change in bowel or bladder habits
- A sore that does not heal
- Unusual bleeding or discharge
- Thickening or lump in breast or elsewhere
- Indigestion or difficulty in swallowing or chewing

TABLE 35.4 Imaging Studies for Cancer Diagnosis and Disease Monitoring

Type of Imaging	Description and Use in Cancer Diagnosis and Treatment
Computed tomography (CT) scan	Description: A CT scan is a radiographic procedure in which a series of detailed pictures of areas inside the body are taken from different angles. Images are created by a computer and are linked to an x-ray machine. Use: A CT scan is used to evaluate for abnormalities of possible cancer in a general anatomic area such as the head, chest, abdomen, or pelvis. Radiologists use CT scans to visualize suspicious lesions, internal organs, and lymph nodes.
Magnetic resonance imaging (MRI) scan	Description: An MRI scan is an imaging procedure that uses radio waves and a powerful magnet linked to a computer to create detailed pictures of areas inside the body. This type of scanning often creates better images of body organs and soft tissue than other type of scanning methods. Use: Images produced show differences between normal and cancerous tissue. An MRI scan is commonly used to evaluate suspicious areas of the brain, spinal cord, and liver.
Positron emission tomography (PET) scan	Description: A PET scan is a procedure in which a small amount of radioactive glucose is injected into a vein and a scanner is used to make detailed, computerized pictures of areas where glucose is used in the body. Use: Cancerous cells have an enhanced rate of glycolysis, using more glucose than normal cells. Areas of glucose metabolism with high activity or “hot spots” appearing on the PET scan generally correlate to findings of cancer.

Data from American Cancer Society (ACS): *Cancer Glossary* (website). <http://www.cancer.org/cancer/cancerglossary/index>; National Institutes of Health (NIH), National Cancer Institute (NCI): *NCI Dictionary of Cancer Terms*. <http://www.cancer.gov/publications/dictionaries/cancer-terms?expand>.

Obvious change in a wart or mole

Nagging cough or hoarseness

When symptoms or screening tests suggest cancer, physicians use the following to establish a definitive diagnosis: evaluation of an individual’s medical, social, and family histories; physical examination; laboratory tests; imaging procedures; and tissue biopsy. Laboratory evaluation is composed of analysis of blood, urine, and other body fluids. Oncologists evaluate tumor markers (e.g., α -fetoprotein [AFP], cancer antigen [CA] 125, CA 19-9, carcinoembryonic antigen [CEA], prostate-specific antigen [PSA]) and other substances in blood or body fluids that can be elevated when someone has cancer. Imaging procedures help determine a diagnosis (Table 35.4). Pathologists perform cytologic examinations by analyzing body fluids, sputum, urine, or tissue under a microscope. To detect malignant cells, they use a histopathologic examination to review specially stained tissue flow cytometry to count and examine cells and chromosomes, immunohistochemistry to review antibodies for specific cell proteins, and cytogenetics to visualize genetic defects.

Staging is used to identify how much a cancer has spread throughout the body. The stage of the cancer at the time of diagnosis is a strong predictor of survival, and it directs oncologists to the most effective treatment plan. Cancer staging is most frequently described as stage I, II, III, or IV—stage I being the least amount of disease and stage IV being the most advanced. The **tumor-node-metastasis (TNM) staging system** is also commonly used by oncologists. *T* stands for the size of the tumor, *N* stands for nodes or whether it has spread into lymph nodes, and *M* stands for metastasis, or whether the cancer has spread to distant organs (Fig. 35.3) (American Joint Committee on Cancer, 2018).

Classification and Common Types of Cancer

For classification, solid cancers are often referred to as tumors and hematologic-related cancers are frequently called blood cancers. The classification of tumors is based on their tissue of origin, their growth properties, and their invasion of other tissues. Tumors that are not malignant typically are described as **benign**.

Because cancer occurs in cells that are replicating, patterns are different in children and adults. In early life the brain, nervous system, bones, muscles, and connective tissues are still growing; therefore, cancers involving these tissues are more prevalent in children. Common childhood cancers include neuroblastoma; medulloblastoma; osteosarcoma; and soft tissue sarcomas such as rhabdomyosarcoma,

schwannoma, and germ cell tumors. Conversely, adult cancers frequently involve epithelial tissues that cover and line the body’s internal and external surfaces. Cancers of the epithelial tissues include cancers of the skin, and circulatory, digestive, endocrine, reproductive, respiratory, and urinary systems. Cancers arising from these tissues are referred to as carcinomas, and common types are classified as adenocarcinomas, basal cell carcinomas, papillomas, and squamous cell carcinomas.

Leukemias, lymphomas, and myelomas are cancers of the immune system and can occur in children or adults. Leukemias arise most frequently from white blood cells of the bone marrow. Lymphomas are cancers that develop in the lymphatic system—in nodes, glands, and organs. Myeloma is cancer that originates in the plasma cells of the bone marrow and most frequently occurs in older adults. These cancers are diagnosed using blood tests and bone marrow biopsies.

Other types of cancer are related to infectious causes and cancer experts recommend antibiotics, vaccines, and changes in behavior for their prevention (ACS, 2018a). Examples include hepatocellular carcinoma linked to hepatitis B virus (HBV) exposure and alcoholic-related cirrhosis leading to liver cancer, oropharyngeal and cervical cancers linked to human papillomavirus infection (HPV), and stomach cancer caused by chronic inflammation by *Helicobacter pylori* (see Chapter 26).

MEDICAL TREATMENT

In the United States and many other countries around the world, cancer treatment is guided by oncologists, medical doctors specializing in the prevention, treatment, and palliation of cancer, and by evidence-based standards known as the National Comprehensive Cancer Network (NCCN) Clinical Practice Guidelines in Oncology (NCCN, 2018). The NCCN Guidelines encompass evidence-based care for 97% of all cancers treated in oncology practice. Also listed with these guidelines are evidence-based recommendations for providing supportive care (e.g., survivorship, palliative care, cancer-related pain, fatigue, and antiemesis).

Conventional modalities include **antineoplastic therapy** (e.g., chemotherapy, biotherapy, or hormonal therapy), radiation therapy, and surgery used alone or in combination with other cancer therapies. Solid tumors and hematologic malignant diseases such as leukemias, lymphomas, and multiple myelomas may be treated with hematopoietic cell transplantation (HCT).

THE STAGING OF CANCER

In the Tumor-Node-Metastasis (TNM) system:

- The T refers to the size and extent of the main tumor. The main tumor is usually called the primary tumor.
- The N refers to the number of nearby lymph nodes that have cancer.
- The M refers to whether the cancer has metastasized. This means that the cancer has spread from the primary tumor to other parts of the body.

Primary tumor (T)

- TX: Main tumor cannot be measured.
- T0: Main tumor cannot be found.
- T1, T2, T3, T4: Refers to the size and/or extent of the main tumor. The higher the number after the T, the larger the tumor or the more it has grown into nearby tissues. T's may be further divided to provide more detail, such as T3a and T3b.

Regional lymph nodes (N)

- NX: Cancer in nearby lymph nodes cannot be measured.
- N0: There is no cancer in nearby lymph nodes.
- N1, N2, N3: Refers to the number and location of lymph nodes that contain cancer. The higher the number after the N, the more lymph nodes that contain cancer.

Distant metastasis (M)

- MX: Metastasis cannot be measured.
- M0: Cancer has not spread to other parts of the body.
- M1: Cancer has spread to other parts of the body.

Stage	What it means
Stage 0	Abnormal cells are present but have not spread to nearby tissue. Also called carcinoma in situ, or CIS. CIS is not cancer, but it may become cancer.
Stage I, Stage II, and Stage III	Cancer is present. The higher the number, the larger the cancer tumor and the more it has spread into nearby tissues.
Stage IV	The cancer has spread to distant parts of the body.

Fig. 35.3 The tumor-node-metastasis (TNM) system of grading cancer tumors and the staging of cancer. Adapted from the National Cancer Institute (website). <https://www.cancer.gov/about-cancer/diagnosis-staging/staging>.

Chemotherapy is the use of chemical agents or medications to systematically treat cancer. These agents interfere with the steps or phases of the cell cycle, specifically with the synthesis of DNA and replication of cancer cells. Treatment regimens often involve the use of more than one type of chemotherapy to maximally interrupt the cancer cell growth cycle. The basic five phases of cell reproduction in normal and malignant cells are the following (Polovich et al, 2014):

- G0—resting phase
- G1—postmitotic phase; ribonucleic acid (RNA) and protein are synthesized
- S—DNA is synthesized
- G2—premeiotic phase; the second phase where RNA and protein are synthesized
- M—mitosis; cell division

Most chemotherapy agents are categorized by their biochemical activity and their mechanism of action such as alkylating agents (cell-cycle nonspecific), antimetabolites (cell-cycle specific, usually S-phase), and taxanes (M-phase specific). **Biotherapy** is the use of biologic

agents to produce anticancer effects indirectly by inducing, enhancing, or suppressing an individual's own immune response. **Antiangiogenic agents** are used to inhibit the development of new blood vessels needed by cancers (tumor vasculature) and thus prevent their growth, invasion, and spread. **Hormonal therapy** is systemic therapy used for the treatment of hormone-sensitive cancers (e.g., breast, ovarian, prostate) by blocking or reducing the source of a hormone or its receptor site.

Radiation oncologists use **radiation therapy**, high-energy (ionizing radiation) in multiple fractionated doses, or radioactive chemicals to treat cancer. Cancerous tissue can also be removed using surgery.

Response to cancer treatment is defined as complete or partial response, stable disease, or disease progression. Factors that affect an individual's response to treatment include tumor burden because the larger the tumor the greater risk of metastatic disease, rate of tumor growth because rapidly growing tumors are usually more responsive to therapy, and drug resistance. Tumors mutate as they grow, and with

successive mutations new cancer cells can become resistant to therapy. Other factors contributing to an individual's response to cancer treatment include comorbid diseases (e.g., diabetes, renal disease, cardiopulmonary disease), age, performance status, psychosocial support systems, bone marrow reserve, and overall general health (NIH and NCI, 2018c; Polovich et al, 2014).

Goals of Treatment

The goal of cancer treatment may be to cure, control, or palliate (remove symptoms without curing). A cure is a complete response to treatment. Even when treatment does not cure the cancer, it can diminish its effects and extend life. Cancer treatment can last for years, even decades. When the treatment is no longer working or the side effects cause a patient to reject further treatment, palliative care is offered. **Palliative care** helps individuals be as comfortable as possible and promotes quality of life. Palliation is designed to relieve pain and manage symptoms of illness; lessen isolation, anxiety, and fear; and help maintain independence as long as possible (National Hospice and Palliative Care Organization [NHPCO], 2018). **Hospice** is care for individuals with a life expectancy of 6 months or less. It focuses on relieving symptoms, controlling pain, and providing emotional and spiritual support to patients and their families. Patients are made as comfortable as possible through the end of their lives.

Cultural Considerations

Cultural competency in health care providers is a critical piece of cancer treatment. Aside from existing racial and health disparities in racial and ethnic minority populations in the United States regarding screening, diagnosis, and treatment of cancer, there is some evidence that interventions to improve cultural competency can improve patient/client health outcomes (Truong et al, 2014). Cultural and linguistic barriers can negatively affect health care delivery. Treatment preferences, end-of-life values, health literacy, and dietary patterns should all be assessed when working with a diverse population in cancer care (see Chapter 10).

MEDICAL NUTRITION THERAPY

Medical nutrition therapy (MNT) improves treatment tolerance, reduces the need for breaks in treatment, decreases unintentional weight and lean body mass loss, and can improve quality of life. Nutrition therapy has been shown to decrease unplanned hospitalizations by >50%, reduce length of hospital stays, and improve overall survival for patients undergoing cancer treatment (Trujillo et al, 2018). The Commission on Dietetic Registration has developed a board certification in oncology nutrition: **certified specialist in oncology nutrition (CSO)**. To further assist clinicians working in the cancer care setting, the AND has developed the Oncology Toolkit with MNT protocols for breast, colorectal, esophageal, gastric, head and neck, hematologic, lung, and pancreatic cancers (AND, 2010). Another AND resource for clinicians when providing MNT in the cancer care setting is the Pocket Guide to the Nutrition Care Process in Cancer (Grant, 2015).

Nutrition Screening and Assessment

Validated Screening Tools

With the continued shift of cancer care from the hospital setting to outpatient settings, nutrition screening and assessment should continue throughout the continuum of care. Ideally, nutrition screening and assessment for risk of nutrition problems should be interdisciplinary, instituted at the time of diagnosis, and reevaluated and monitored throughout treatment and recovery. See Chapter 4 for

screening tools validated for use with individuals diagnosed with cancer (AND Evidence Analysis Library [EAL], 2013) including the Patient Generated-Subjective Global Assessment (PG-SGA) for inpatient and outpatient settings, Malnutrition Screening Tool (MST) for inpatient and outpatient settings, and Malnutrition Universal Screening Tool (MUST) for inpatient and outpatient settings. (AND EAL, 2013; PG-SGA©, 2014).

Other assessment tools specific to patients with cancer are the Activities of Daily Living (ADLs) Tool, the Common Toxicity Criteria for Adverse Events (CTCAE), and the Karnofsky Performance Scale (KPS) Index. CTCAE is an outcome measure used in anticancer therapy that compares acute toxicities of cancer treatment, and KPS is a scoring index that associates an individual's functional status with disease status and survival (Polovich et al, 2014).

In-depth assessment including a nutrition-focused physical examination is used to obtain more information and to identify nutrition problems and assess degree of risk (see Chapter 5 and Appendix 11). Careful review of the individual's appetite and oral intake is required, with an assessment of symptoms (e.g., nausea, vomiting, and diarrhea), weight status, comorbidities, and laboratory studies. Components of this type of assessment include a general survey of the body, review of vital organs and anthropometrics, and an evaluation of the subcutaneous fat stores, muscle mass, and fluid status (see Chapter 5).

General Assessment

When working with patients in active treatment for cancer, it is important to first assess where each patient is in their journey without assumption or bias. For example, during treatment, some people have a range of classic side effects including pain, nausea, and vomiting while others experience few if any of these. As treatment options expand and improve, patients are thriving during treatment and are often able to carry on with their normal life activities. Recommendations should be prioritized with input from the patient. Whether the focus is on food safety due to **neutropenia** (reduced white blood cells), hydration status, undesired weight loss or gain, individual nutrient needs, or emotional well-being, patient safety is the first concern for a dietetic practitioner. Use critical assessment to treat each patient as an individual, meeting their unique needs that prioritize challenges in each stage of treatment.

Patients have highly variable side effects with cancer treatment that can effect their energy level, mood, and tolerance of foods. Each patient should be approached in an individualized manner based on their unique needs and treatment plan.

During nutrition screening, assess factors that may affect intake and well-being. Discuss gastrointestinal function with each patient to assess for diarrhea, constipation or other factors related to digestion and absorption of nutrients. Inquire about energy levels, sleep, and fatigue, considering how this may affect food acquisition or preparation. Cancer treatment can be highly stressful and potentially traumatic for patients. Cancer-related posttraumatic stress disorder (PTSD) has been documented in patients and family members. Studies show that cancer-related fatigue, sleep disturbances, stressful life events, and psychological distress do contribute to higher levels of breast cancer-mortality (Haller et al, 2017). As part of the medical team, the dietitian can help advocate for psychological support and counseling for the patient (Chasen and Dippenaar, 2008; Cordova et al, 2017) (Box 35.5).

Energy

Determining individualized energy needs is vital to helping people maintain energy balance during treatment and prevent unintentional

BOX 35.5 Social Support in Cancer Treatment

Research shows optimism and social support serve as protective factors against distress in medically ill patients. Higher levels of social support from friends, family, and community have been significantly associated with a better quality of life in patients with advanced cancer. Social support in these patients is linked to fewer psychological symptoms and greater well-being. Promoting psychological resilience is an area that may be gaining traction in treatment plans of the future (Applebaum et al, 2014; Haller et al, 2017).

weight gain or loss. Not every person who undergoes cancer treatment will lose weight. In fact, some may gain, so energy adjustments should be made to support a healthy weight depending on the unique needs of each individual. Methods used to estimate energy requirements for adults include using standardized equations or measuring resting metabolic rate using indirect calorimetry (Hamilton, 2013; see Chapter 2 for methods for determining energy requirements). To ensure that adequate energy is being provided, the individual's diagnosis, presence of other diseases, intent of treatment (e.g., curative, control, or palliation), therapies (e.g., surgery, chemotherapy, biotherapy, or radiation therapy), presence of fever or infection, and other metabolic complications such as refeeding syndrome must be considered. Evidence-based guidelines from the American Society for Parenteral and Enteral Nutrition (ASPEN) for quickly estimating energy and fluid needs of people with cancer based on body weight are shown in Table 35.5.

Protein

An individual's need for protein is increased during times of illness and stress. Additional protein is required by the body to repair and rebuild tissues affected by cancer treatments and to

maintain a healthy immune system (Hamilton, 2013). Adequate energy should be provided as a fuel source and to prevent lean tissue loss. The degree of malnutrition, extent of disease, degree of stress, and ability to metabolize and use protein are factors in determining protein requirements (Hamilton, 2013). For example, though the dietary reference intake (DRI) for protein for healthy individuals is 0.8 g/kg/day, protein needs for a catabolic patient may be 1.2 to 2.0 g/kg/day or more, and protein needs for an individual undergoing a hematopoietic cell transplant are estimated at 1.5 g/kg/day. Daily protein requirements generally are calculated using actual body weight rather than ideal body weight unless the patient is obese and not at risk for malnutrition during treatment. If appropriate based on individualized assessment, adjusted body weight may be used (see Table 35.5).

Fluid

Dietitians managing cancer patients must ensure adequate hydration and electrolyte balance to prevent dehydration and hypovolemia. Altered fluid balance may occur with fever, ascites, edema, fistulas, profuse vomiting or diarrhea, multiple concurrent intravenous (IV) therapies, impaired renal function, or medications such as diuretics. Individuals need close monitoring for dehydration (e.g., intracellular fluid losses caused by inadequate intake of fluid because of mucositis or anorexia), hypovolemia (e.g., extracellular fluid losses from fever or GI fluids such as vomiting, diarrhea, or malabsorption), and nephrotoxic effects from anticancer treatments.

Signs and symptoms of dehydration include fatigue, acute weight loss, hypernatremia, poor skin turgor, dry oral mucosa, dark or strong-smelling urine, and decreased urine output. To carefully assess for hypovolemia, levels of serum electrolytes, blood urea nitrogen, and creatinine also should be evaluated. A general guideline for estimating fluid needs for all adults without renal concerns is 20 to 40 mL/kg though some patients may experience increased needs (30 to 40 mL/kg) due to chemotherapy (Hamilton, 2013). Other methods including mL per kcal and using Body Surface Area (BSA) are listed in Table 35.5. IV hydration may be recommended for individuals struggling to achieve adequate hydration, but infusion frequency and volume must be determined on an individual basis, considering fluid intake and output (see Table 35.5).

Micronutrients

For patients undergoing cancer treatment, micronutrient status may be affected by the severity of illness, type of treatment, location type of tumor, and ability to consume a normal diet. If individuals are experiencing difficulty with eating and treatment-related side effects, a standard multivitamin and mineral supplement that provides no more than 100% of the DRIs is considered safe (Rock et al, 2012). People who are ill can experience deficiencies in zinc, iron, selenium, and vitamins A, B, and C. Inflammation can increase demands for selenium, copper, iron, and zinc (Hamilton, 2013).

To date, vitamin and mineral supplements have not proven effective for cancer prevention. The AICR encourages all people including cancer survivors not to use dietary supplements for cancer prevention because evidence is insufficient to assess the potential benefits versus harm of doing so (WCRF/AICR, 2018). There are some emerging exceptions. In the most recent WCRF/AICR report, calcium supplements showed a probable decreased risk for colorectal cancer (WCRF/AICR, 2018). In the Physicians Health Study II, a daily multivitamin modestly but significantly reduced risk of total cancer in male physicians (Gaziano et al, 2012). Purified eicosapentaenoic acid (EPA)/docosahexaenoic acid (DHA) omega-3 supplements up to 2 grams/day

TABLE 35.5 Estimating Energy and Fluid Needs of People with Cancer

Condition	Energy Needs	Protein Needs
Cancer, nutritional repletion, weight gain	30-35 kcal/kg/day	1.0-1.5 g/kg/day
Cancer, inactive, nonstressed	25-30 kcal/kg/day	0.8-1.0 g/kg/day
Cancer, hypermetabolic, stressed	35 kcal/kg/day	1.5-2.5 g/kg/day
Hematopoietic cell transplant	30-35 kcal/kg/day	1.5 g/kg/day
Sepsis	25-30 kcal/kg/day	1.5-2.0 g/kg/day
Fluid needs:		
Typical fluid requirements for adults 20 to 40 mL/kg/day or 1 to 1.5 mL/kcal energy expended		
RDA Method: 1 mL per 1 kcal consumed		
Body Surface Area (BSA) Method: 1500 mL/m ² or BSA x 1500 mL		

Data from Gottschlich MM, editor: *The A.S.P.E.N. nutrition support core curriculum: a case-based approach—the adult patient*, Silver Spring, Md, 2007, American Society for Parenteral and Enteral Nutrition; Hamilton KK: Nutrition needs of the adult oncology patient. In Leser M et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group of the Academy of Nutrition and Dietetics.

have shown antitumor activity and reduced neuropathy in patients treated for neuropathy (Vernieri et al, 2018).

In some instances, during and after a cancer diagnosis, supplementation or restriction of specific micronutrients may be required above or below DRI levels, depending on medical diagnosis and laboratory analysis (e.g., iron supplementation for iron-deficiency anemia, B₁₂ injections, and folic acid supplementation during treatment with the chemotherapy agent pemetrexed ([Alimta]). There is evidence that some supplements may be harmful before or during treatment. Food sources of antioxidants are safe, but some supplemental forms of antioxidants have proven ill effects. For example, high-dose beta-carotene supplements in people who smoke have been shown to increase the risk of lung cancer while dietary derived beta-carotene has been shown to decrease lung cancer risk (WCRF/AICR, 2018). Curcumin, a phytochemical in turmeric, provides some proven anti-inflammatory and anti-cancer benefits and is generally well tolerated in supplement forms. Patients treated with irinotecan or cyclophosphamide should avoid taking curcumin until more data can clear potential antagonistic interactions shown in a laboratory setting. Although drinking green tea is safe, studies on green tea extracts are mixed and carry the risk of potential liver damage at very high doses. Vitamin C can cause GI distress and is still under investigation for efficacy and potential for reducing chemotherapy cytotoxicity (Vernieri et al, 2018). Until more research is available, best practices are for patients to focus on food sources of nutrients and antioxidants.

Nutrition Diagnosis

Nutrition diagnosis identifies the specific nutrition problems that can be resolved or improved through nutrition intervention (AND, 2018; Box 35.6).

Nutrition Intervention

The Oncology Toolkit (<https://www.eatright.org>) includes the recommendation for careful appraisal if the planned nutrition intervention

will negatively affect patient safety or possibly interfere with the cancer treatment (AND, 2010). The Toolkit also advises evaluation of the nutrition intervention's likely effectiveness for improving nutrition status, possible financial burden, and patient acceptance.

Intervention goals should be specific, achievable, and individualized to maximize benefit. Goals must be directed toward an objective measure such as body weight or some other meaningful index. Another goal is to minimize the effects of nutrition impact symptoms and to maximize the individual's nutritional parameters. **Nutrition impact symptoms** can be defined as symptoms and side effects of cancer and cancer treatment that directly affect the nutrition status resulting in a depletion of nutrient stores and deterioration in nutrition status. Consultation with the individual, caregivers, or family members regarding expected problems and their possible solutions should be initiated early in the course of cancer therapy and should continue in conjunction with follow-up nutrition assessment and care. Malnutrition, anorexia (loss of appetite), and weight loss are significant issues in cancer care and are often present in many individuals at the time of diagnosis, even in children.

The incidence of malnutrition among individuals with cancer has been estimated to be between 15% and 80% depending on the type of cancer and intensity of treatment (Santarpia et al, 2011). Studies consistently show that even small amounts of weight loss (less than 5% of body weight) before treatment is associated with a poorer prognosis and decreased quality of life, thus reinforcing the importance of early MNT (Arends et al, 2017).

Oral Nutrition Management Strategies

Oral feeding is the goal though individuals often experience symptoms that make it difficult. The causes of impaired oral intake are multifactorial and include oral ulceration, **xerostomia** (dryness of the mouth from decreased saliva), poor dentition, intestinal obstruction, malabsorption, constipation, diarrhea, nausea, vomiting, reduced intestinal motility, chemosensory alteration, uncontrolled pain, and medication side effects (Arends et al, 2017). Strategies for

BOX 35.6 Common Nutrition Diagnoses for Patients with Cancer Using the Problem, Etiology, and Signs and Symptoms Format

Intake Domain

- Inadequate protein-energy intake related to decreased ability to consume sufficient protein and/or energy as evidenced by >5% weight loss in 1 month, estimated energy intake from diet less than estimated, and conditions associated with a diagnosis (colon cancer).
- Excessive energy intake related to food- and nutrition-related knowledge deficit concerning energy intake as evidenced by body mass index (BMI) of 37, intake of energy in excess of estimated energy needs, and reports of higher consumption of nutritional supplements than recommended.
- Inadequate oral intake related to conditions associated with head and neck cancer treatment as evidenced by 5% weight loss in past week, decreased appetite, estimates of insufficient intake of energy and high-quality protein from diet compared with requirements.

Clinical Domain

- Swallowing difficulty related to mechanical causes (tongue cancer) as evidenced by decreased estimated food intake, avoidance of foods, and pain while swallowing.
- Biting/chewing (masticatory) difficulty related to xerostomia after chemotherapy as evidenced by dry mouth, and eating ~30% of meals.

- Altered gastrointestinal (GI) function related to side effect from chemotherapy as evidenced by patient reports of cramping, pain, and diarrhea.
- Malnutrition (undernutrition) related to alteration in GI tract function as evidenced by evidence of temporomandibular wasting, and intake <50% of estimated energy requirement.

Behavioral-Environmental Domain

- Food- and nutrition-related knowledge deficit related to new breast cancer diagnosis and lack or prior dietary education as evidenced by pt report and multiple questions about foods to eat or avoid during chemotherapy.
- Inability to manage self-care related to lack of permanent housing and financial stress as evidenced by skipping one or more meals each day while under treatment for cancer.
- Limited access to food related to lack of financial resources to purchase a sufficient quantity of appropriate healthful foods as evidenced by BMI <18.5, estimated inadequate intake of energy, and patient reports of lack of resources for food.

modifying dietary intake may be necessary and depend on the specific eating problem and the individual's nutritional status. Food choices, preparation, and presentation may need modification. Liquid medical food supplements may be recommended for those unable to consume enough energy and protein to maintain weight and nutrition status (see Chapter 13). Education materials with suggestions for improving oral intake and managing treatment-related side effects are at the end of the chapter and include Eating Hints,

Chemotherapy and You, and Radiation Therapy and You (NIH and NCI, 2011, 2018a, 2016a). Table 35.6 outlines examples of nutrition intervention strategies.

Managing Anorexia and Alterations in Taste and Smell

Sometimes even before diagnosis, and throughout cancer treatment, individuals may report anorexia, early satiety, and decreased food intake. Alterations in taste and smell are common problems. Taste

TABLE 35.6 Nutrition Intervention Strategies for Patients with Cancer

Side Effect or Symptom	Strategies
Anorexia, poor appetite	<ul style="list-style-type: none"> • Encourage small, more frequent nutrient-dense meals and snacks. • Add protein and fats to favorite foods. • Use protein and calorie-containing supplements (e.g., whey or soy powder, nutritional supplements). • Keep nutrient-dense foods close at hand and snack frequently. • Maximize intake at times when feeling best. • Eat meals and snacks in a pleasant atmosphere. • View eating as part of treatment. • Have high protein and calorie liquid supplements and smoothies • Eat by the clock instead of waiting for hunger cues (set a timer). • Consume liquids between meals rather than with meals. • Engage in light physical activity as able.
Nausea and vomiting	<ul style="list-style-type: none"> • Eat small, more frequent meals and snacks. • Sip on cool or room temperature clear liquids in small amounts. • Avoid high-fat, greasy, spicy, or overly sweet foods. • Avoid foods with strong odors such as fish or eggs. • Consume bland, soft, easy-to-digest foods on scheduled treatment days. • Encourage compliance with medications that are prescribed to control nausea. • Rest with head elevated for 30 minutes after eating. • Consider complementary therapies including ginger tea, relaxation techniques, or acupuncture bracelets.
Diarrhea	<ul style="list-style-type: none"> • Encourage the intake of hydrating liquids such as water, clear juices, broth, gelatin, popsicles, and commercially prepared hydration fluids (see Chapter 27). • Avoid high-fiber foods, such as nuts, raw fruits and vegetables, and whole-grain breads and cereals and avoidance of dairy foods is sometimes helpful. • Avoid sugar alcohol-containing foods such as sugar-free candies and gums (e.g., mannitol, xylitol, sorbitol). • Choose high-soluble fiber such as applesauce, bananas, canned peaches, and oatmeal. • Encourage compliance with medications prescribed to control diarrhea.
Constipation	<ul style="list-style-type: none"> • Increase the intake of high-fiber foods such as whole grains, fresh or cooked fruits and vegetables, especially those with skins and seeds, dried fruits, beans, and nuts. • Consume at least 64 ounces of fluid each day. • Use probiotic-containing foods or supplements. • Include activities of daily living and physical activity as able. • Encourage compliance with fiber supplements and/or medications that affect bowel function and are prescribed to manage constipation. • Schedule adequate bathroom time to facilitate bowel movements without psychological stress and pressure.
Sore throat, esophagitis Sore mouth, mucositis, or thrush	<ul style="list-style-type: none"> • Recommend the intake of soft, moist foods with extra sauce, dressing or gravy. • Avoid dry, coarse, or rough foods. • Avoid alcohol, citrus, caffeine, tomatoes, vinegar, and hot peppers or other spicy food. • Experiment with food temperatures (e.g., warm, cool, or icy) to find which temperatures are most soothing. • Prepare smoothies with low acid fruits like melon, banana, peaches and add yogurt, milk, or silken tofu. • Encourage compliance with medications prescribed to manage esophagitis, painful swallowing, oral pain, and/or infection.
Fatigue	<ul style="list-style-type: none"> • Recommend the intake of small, frequent meals and snacks. • Choose easy-to-prepare, easy-to-eat foods. • Advise keeping nutrient-dense snacks close at hand and snack frequently. • Suggest eating when appetite is best. • Encourage activities of daily living and physical activity as able. • Consider physical therapy consult for strengthening.

Continued

TABLE 35.6 Nutrition Intervention Strategies for Patients with Cancer—cont'd

Side Effect or Symptom	Strategies
Neutropenia	<ul style="list-style-type: none"> • Advise frequent hand washing and keep kitchen surfaces and utensils clean. • Advise the avoidance of raw or undercooked animal products, including meat, pork, game, poultry, eggs, and fish. • Wash all fresh fruits and vegetables well before eating. • Ensure proper temperatures for cooking, cooling and reheating. • Check expiration dates on all foods. • Avoid bulk bins, salad bars and buffets. • Prevent cross contamination between raw meat and ready to eat foods. • “When in doubt, throw out” and “No oldy or moldy.”
Altered taste or smell	<ul style="list-style-type: none"> • Recommend good oral hygiene practices (e.g., rinse mouth frequently, keep mouth clean). • Use marinades and spices to mask altered tastes. • Use plastic utensils if metallic tastes are a problem. • Eat cooler foods, rather than warmer foods. • Flavor water with lemon or other fruit or herbs. • Choose nonmeat protein sources such as tofu, dairy, or beans.
Thickened saliva/or dry mouth (xerostomia)	<ul style="list-style-type: none"> • Suggest sipping on liquids throughout the day to keep the oral cavity moist. Aim for 8-10 cups per day. • Thin oral secretions with club soda or seltzer water. • Chew on carrots or celery. • Suck on frozen grapes or melon balls. • Recommend using a cool mist humidifier while sleeping. • Suggest trying tart foods to stimulate saliva, if open sores are not present. • Recommend alternating bites of food with sips of liquids at meals. • Recommend eating soft, moist foods with extra sauces, dressings, or gravies. • Advise avoidance of alcoholic beverages and alcohol-containing mouthwash as these will dry the mouth.

Data from Grant BL et al, editors: *American Cancer Society's complete guide to nutrition for cancer survivors*, ed 2, Atlanta, 2010, American Cancer Society; National Cancer Institute (NCI): *Eating Hints* (website). <http://www.cancer.gov/publications/patient-education/eatinghints.pdf>, 2018; Elliot L: Symptom management of cancer therapies. In Leser M et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group of the Academy of Nutrition and Dietetics.

alterations can be associated with the disease itself, certain chemotherapy agents, radiation therapy, or surgery to the head and neck. Chemotherapy-induced, learned taste aversions have been reported in adults and children. Individuals also may develop a heightened sense of smell that results in sensitivity to food preparation odors and aversions to nonfood items such as soaps or perfumes. These sensation abnormalities do not consistently correlate with the tumor site, extent of tumor involvement, tumor response to therapy, or food preferences and intake. Nutrition interventions that decrease the aroma of foods, such as serving foods cold instead of hot, may be helpful (See Table 35.6).

Alterations in Energy Metabolism Resulting from Cancer

Energy metabolism is related intimately to carbohydrate, protein, and lipid metabolism, all of which are altered by tumor growth. Tumors exert a consistent demand for glucose, exhibit a characteristically high rate of anaerobic metabolism, and yield lactate as the end product. This expanded lactic acid pool requires an increased rate of host gluconeogenesis via Cori cycle activity, which is increased in some people with cancer but not in others. Protein breakdown and lipolysis take place at increasing rates to maintain high rates of glucose synthesis. There is glucose intolerance and insulin resistance, characterized by excess fatty acid oxidation and decreased uptake and use of glucose by muscle.

Because cancer patients lose muscle tissue and have decreased energy utilization, they have an increased need for protein and calories. Most notable is the loss of skeletal muscle protein caused by increased protein breakdown, as well as decreased protein synthesis. Additional protein is especially critical when undergoing treatment or experiencing malnutrition or cachexia (Hamilton, 2013).

Managing Cancer Cachexia

A common secondary diagnosis in people with advanced cancer is a variant of protein-energy malnutrition. This syndrome is termed **cancer cachexia** and is characterized by progressive weight loss, anorexia, generalized wasting and weakness, immunosuppression, altered basal metabolic rate, and abnormalities in fluid and energy metabolism. There is also increased loss of adipose tissue, which is related to an increased rate of lipolysis, rather than a decrease in lipogenesis. Increased levels of lipid-mobilizing factor and proteolysis-inducing factor secreted by tumor cells will lead to increased loss of fat and muscle mass. Individuals at the time of diagnosis with breast or hematologic cancers rarely present with significant weight loss, whereas individuals with lung, esophageal, or head and neck cancers often exhibit substantial weight loss.

Cancer cachexia is caused in part by **cytokines** (immune-modulating agents), produced by the cancer itself or by the immune system in response to the cancer. Cytokines can cause metabolic changes and wasting that is similar to changes seen in inflammation (see Chapter 3). Proinflammatory cytokines include **tumor necrosis factor (TNF)- α (cachectin)** and TNF- β , interleukin (IL)-1, IL-6, and interferon- α . These cytokines have overlapping physiologic activities, which makes it likely that no single substance is the sole cause. Many people undergoing cancer treatment will be treated with steroids as part of their protocol, partially to address the inflammatory process. Resting energy expenditure (REE) is elevated, which is in contrast to the REE in chronic starvation, wherein the body adapts to conserve energy and preserve body tissue. Cancer cachexia and the associated wasting often increase closer to the time of death and are also indicated as a factor in the cause of death of 30% to 50% of all patients with cancer, which is why increased protein and calorie needs are indicated (Levin, 2013).

Pharmacotherapy

The pharmacologic management of cachexia and anorexia requires careful evaluation based on the individual's treatment goals and prognosis and on close monitoring of symptoms. Cancer cachexia cannot be reversed without medical management of the underlying inflammation and hypermetabolism. Anorexia, a common cancer-related condition, is amenable to treatment with nutrition counseling, diet modification, and pharmacotherapy. A number of pharmacologic agents are utilized when treating anorexia and cachexia, including antihistamines (Periactin), corticosteroids (Decadron, Solu-Medrol), progestational agents (Provera, Megace), prokinetic agents (Reglan), and antidepressants (Remeron) (Elliot, 2013).

Medical marijuana, or cannabis, is a controlled substance in the United States, though over 50% of states have now enacted laws to legalize its use. According to the NCI Physician Data Query (PDQ), cannabinoids, which are the active chemicals in cannabis, can provide relief from side effects including pain, nausea and vomiting, anxiety, and anorexia from cancer and cancer treatment (NIH, 2019b; NCI, 2017). The FDA has not approved medical marijuana for cancer or cancer treatment application; however, it has approved two cannabinoids, Marinol and Cesamet, for individuals experiencing chemotherapy-related nausea and vomiting (NIH, 2019b; NCI, 2017).

Managing Other Cancer-Related Metabolic Abnormalities

Metabolic alterations vary by tumor type. An individual's immunologic function can be impaired, as the result of the disease, cancer treatment, or progressive malnutrition. In addition to the cancer-induced metabolic effects, the mass of the tumor may anatomically alter the physiology of specific organ systems. The activity of several enzyme systems involved with digestion and absorption can be affected, as can certain endocrine functions.

Critical imbalances in fluid and electrolyte status can occur in people who have cancers or are undergoing cancer treatments that promote excessive diarrhea, vomiting, or malabsorption. Profuse and often severe diarrhea can result from partial bowel obstructions and endocrine-secreting tumors such as those secreting serotonin (carcinoid tumors), calcitonin, or gastrin (Zollinger-Ellison's syndrome). The use of antimetabolites, alkylating agents, and antibiotics may also lead to the development of severe diarrhea. In some instances, people who are immunocompromised or have undergone GI surgery may experience profuse diarrhea that is caused by intestinal pathogens such as *Clostridium difficile* (see Chapter 27).

Persistent vomiting is associated with intestinal obstruction, radiation therapy to the stomach and abdomen or brain, highly emetogenic (nausea-causing) chemotherapy agents, intracranial tumors, and advanced cancer (Iwamoto et al, 2012). Careful assessment and evaluation of the cause of diarrhea or vomiting is critical for effective management. Malabsorption may be caused by treatment-related pancreatic dysfunction, postsurgical short gut syndrome, acute or chronic radiation enteritis (inflammation of the GI tract tissues secondary to radiation), excess serotonin, steatorrhea, or chronic diarrhea.

Hypercalcemia may occur in individuals with bone metastases, caused by the osteolytic activity of tumor cells releasing calcium into the extracellular fluid causing nausea, weakness, fatigue, lethargy, and confusion. Hypercalcemia is potentially fatal and is associated most commonly with multiple myeloma, lung cancer, and advanced breast and prostate cancer. Medical management of hypercalcemia includes rehydration and use of antihypercalcemic agents. Calcium supplementation from dietary supplements and antacids should be avoided. Restricting the intake of foods containing calcium is not indicated because the consumption of these foods has little effect in the overall management of hypercalcemia.

INTEGRATIVE, COMPLEMENTARY, AND FUNCTIONAL ONCOLOGY

Research shows that 40% to 50% of cancer patients use complementary and integrative medicine during and after treatment though over 80% of health care providers report limited knowledge about the role of complementary therapies in the cancer care setting (King et al, 2015).

The health care team working in oncology must be informed on the different therapies and should be knowledgeable regarding resources used to evaluate and educate the individuals in their care. Increasing consumer demand has encouraged health care institutions to create integrative medicine departments with onsite complementary services. Cancer survivors look for open, honest discussions or recommendations from their health care teams. Nondisclosure with the care team regarding complementary therapies such as special dietary patterns or supplements is common because patients fear healthcare providers will suggest they stop or because they believe physicians have limited knowledge on the topic of supplements (Huebner et al, 2014). Medical, nursing, and nutrition assessments should include open-ended questions on dietary supplement use and questions regarding the additional integrative or complementary therapies or diets they are following at the time. The core components to discuss integrative or alternative therapies involve understanding and respecting the need for personal empowerment. Having a willingness to listen, explore, and respond frankly to questions; taking the time to discuss the options and offer advice; summarizing the discussion; documenting the dialog; and monitoring the progress of the therapy are critical to supporting patients going through cancer treatment (Abrams, 2013). The NIH established the National Center for Complementary and Integrative Health (NCCIH), which works to create a framework in which to evaluate and research these therapies. See Chapter 11 on Dietary Supplements and Integrative Medicine for more information.

Dietary Supplements

Nondisclosure of use is a common occurrence, with a reported 53% of individuals receiving chemotherapy not discussing use of dietary supplements with their health care team (Abrams, 2013; Davis et al, 2014). Data from the Intergroup Phase III Breast Cancer Chemotherapy Trial found that over half of all study participants received no advice on dietary supplements (Gröber et al, 2016). People may view dietary supplements as a more natural alternative to prescription medications or a quick, easy remedy to an underlying medical problem.

It is the position of the Academy of Nutrition and Dietetics that micronutrient supplements are warranted when requirements are not being met through the diet alone. This is a population that may greatly benefit from certain forms of supplementation. According to the European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines on enteral nutrition, it can be assumed that any patient with cancer who is able to consume <60% of their daily energy requirements for a period of 7 to 10 days has an inadequate supply of micronutrients (Gröber et al, 2016). Consumers are often not comfortable interpreting labels, understanding needs, and assessing safety when choosing supplements. When working with patients undergoing cancer treatment, assess the safety and efficacy of supplements they report taking, paying special attention to those that may interact with medications or cause increased risk of bleeding. For more information, refer to Appendix 13 and Chapter 11. (Marra and Bailey, 2018).

Some supplements show promise for malignancies including omega-3 fatty acids, vitamin D, curcumin, selenium, and medicinal mushrooms such as maitake, reishi, and turkey tail (Abrams, 2013; Baggerly et al, 2015; Blagodatki et al, 2018; Gröber et al, 2016;

TABLE 35.7 Popular Anticancer Dietary Plan

Diet	Description	Potential Benefit or Harm
Alkaline Diet	Attempts to create a more alkaline environment in the body by eliminating acidic foods (red meat, sugar, refined flours, alcohol, coffee).	While there is no evidence that supports the efficacy of this diet currently available because the body regulates its own pH balance, it does reduce or eliminate some foods that increase cancer risk (red meat, high glycemic foods, alcohol) and increases legumes and vegetables which could be helpful. Ensure adequate calorie and protein intake.
Budwig Diet	Flaxseed oil and cottage cheese preparation is consumed twice per day. Emphasis on natural, unprocessed foods low in added sugar or fat/oils; no dairy or animal fats, pork, seafood, soy, or corn.	No clinical trials available at this time. No evidence that flaxseed oil and cottage cheese are specifically anticancer though this mixture can be supportive in adding calories to a patient experiencing weight loss.
Essiac	An herbal mixture often taken as a tea, consumed three times per day designed to shrink tumors and strengthen the immune system.	No published clinical trials, no proven efficacy in animal studies, though some of the herbs do exhibit antitumor effects on their own in vitro. May have a laxative effect and cause nausea or vomiting.
Gerson Therapy	Vegetarian diet, raw juices, and coffee enemas. 15-20 pounds of organic fruit and vegetables are consumed, juiced, each day. Avoids fat. Nutritional and biological supplements are used including pancreatic enzymes.	The National Cancer Institute suggests avoiding this diet due to risk for protein energy malnutrition, dehydration, and concerns for food safety with neutropenic patients. Available studies are limited at this time regarding safety and efficacy.
Intermittent Fasting (IF)	Abstaining from food for various periods of time including before and during chemotherapy, alternate day, or for a number of hours each day in an effort to limit fuel to cancer cells. Preliminary studies have shown reduced tumor development in mouse studies.	Malnutrition and weight loss are serious consequences of fasting during treatment when calorie and protein needs are increased. Human studies are limited at this time though some short-term data (≤ 6 months) in overweight and obese participants have suggested IF improves insulin sensitivity and reduces inflammatory markers.
Ketogenic	High fat ($>80\%$), low carbohydrate ($<10\%$) diets used to treat childhood epilepsy, neurodegenerative diseases, and also as alternative therapy for some cancer treatment, often glioma and other brain cancers.	Though there is some promising preliminary research in rodent studies and the best efficacy currently for humans is likely for brain cancers, more research is needed to understand if ketogenic is a supportive diet for people undergoing cancer treatment. Ketogenic diets should be closely medically managed. They can cause fatigue, kidney damage, constipation, weight loss, and nutritional deficiencies.
Macrobiotic	A diet and lifestyle philosophy brought to the United States from Japan in the 1950s with an emphasis on organic, vegetarian foods high in grains and low in fat. Chewing food and special cooking techniques required.	This diet does focus on many potentially beneficial foods within a vegetarian dietary pattern. However, there is a potential for nutrient deficiencies given the exclusion of some foods. May be challenging to adhere to because of special cooking and preparation requirements.
Raw Food Diet	Allows only raw foods heated to 105° F or less. Usually avoids meat, dairy, and eggs unless raw which is dangerous (food safety issue).	May be deficient in protein, calories, and certain nutrients. Can irritate the gut, especially if diarrhea is a side effect. May be a food safety concern. A potential beneficial emphasis on unprocessed foods and high in fruit and vegetables.

Melina V, Craig W, Levin S: Position of the Academy of Nutrition and Dietetics: vegetarian diets, *J Acad Nut Diet* 116(12):1970–1980, 2016; Schwalfenberg GK: The alkaline diet: is there evidence that an alkaline pH diet benefits health? *J Environ Pub Health* 2012:727630, 2012; O'Brien S, Leser M, Ledesma N: Diets, functional foods and dietary supplements for cancer prevention and survival. In Leser M, Ledesma N, Bergerson S, et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group; National Cancer Institute: Gerson therapy, 2016b, NCI; Harvie MN, Howell T: Could intermittent energy restriction and intermittent fasting reduce rates of cancer in obese, overweight, and normal-weight subjects? LeMay-Nedjelski et al, 2018, Zhou et al, 2017). Others may cause damage in a variety of ways. For example, common supplements like garlic and vitamin E can increase bleeding risk and thin the blood (Marra and Bailey, 2018; Alsanad et al, 2014). Some interact negatively with common cancer medications. Garlic, green tea, mistletoe, Chinese herbs, iron, St. John's Wort, and ginger have been shown to interact with drugs including cyclophosphamide, nonsteroidal antiinflammatory drugs, irinotecan, vinorelbine, warfarin, and paclitaxel (Alsanad et al, 2014). Others are in fact toxic to the body. Anticancer supplement B₁₇/laetrile/amygdalin is a source of cyanide and is associated with toxicity and poisoning (Dang et al, 2017). Educating patients about the safety of supplements while maintaining an open mind is key for relationship building and safety when it comes to integrative, complementary, and functional oncology nutrition (Alsanad et al, 2014; Gröber et al, 2016; Table 35.7).

NUTRITIONAL IMPACT OF CANCER TREATMENTS

Chemotherapy

Chemotherapy uses chemical agents or medications to treat cancer. Classifications of chemotherapy cytotoxic agents are listed in Table 35.8. Once in the bloodstream, these agents are carried through the body to reach as many cancer cells as possible. Routes of administration for chemotherapy include the following:

- Oral: capsule, pill, or liquid
- IV: delivery of medication via an injection or an indwelling catheter into a vein
- Intraperitoneal: delivery of medication via a catheter directly into the abdominal cavity
- Intravesicular: delivery of medication via a Foley catheter directly into the bladder

- Intrathecal: delivery of medication via an injection into the central nervous system using an Ommaya reservoir or a lumbar puncture (Polovich et al, 2014)

Whereas surgery and radiation therapy are used to treat localized tumors, chemotherapy is a systemic therapy that affects the malignant tissue and normal cells as well. Cells of the body with a rapid turnover such as bone marrow, hair follicles, and the mucosa of the digestive tract are the most affected. As a result, nutrition intake and nutrition status can be adversely affected. Nutrition-related symptoms include **myelosuppression**, also called pancytopenia, (suppression of bone marrow production of neutrophils, platelets, and red blood cells), anemia, fatigue, nausea and vomiting, loss of appetite, mucositis,

changes in taste and smell, xerostomia (mouth dryness), dysphagia, and altered bowel function such as diarrhea or constipation (Table 35.8).

The severity of the side effects depends on the specific agents used, dosage, duration of treatment, number of treatment cycles, accompanying drugs, individual response, and current health status. The timely and appropriate use of supportive therapies such as anti-emetics, antidiarrheals, corticosteroids, hematopoietic agents, and antibiotics, as well as dietary changes, is important. Many people experience significant side effects, especially in “dose-intensive” multiple-agent chemotherapy regimens; neutropenia (reduced white blood cells or neutrophils), **thrombocytopenia** (low blood platelet counts), and

TABLE 35.8 Nutrition-Related Effects of Antineoplastic Agents: Chemotherapy, Biotherapy, and Hormone Therapy

Agent Classification	Common Side Effects and Nutrition Implications
<p>Chemotherapy Alkylating Agents</p> <ul style="list-style-type: none"> • Altretamine (Hexalen), Busulfan (Buselfex), Bendamustine (Treanda), carboplatin (Paraplatin), cisplatin (Platinol), cyclophosphamide (Cytosan), oxaliplatin (Eloxatin), temozolomide (Temodar) 	<ul style="list-style-type: none"> • Myelosuppression, anorexia, nausea, vomiting, fatigue, renal toxicity • Treat lung, breast, ovary cancers, leukemia, lymphoma, Hodgkin’s disease, multiple myeloma, and sarcoma by stopping cells from reproducing by damaging their DNA. They work in all phases of the cell cycle.
<p>Antitumor Antibiotics</p> <ul style="list-style-type: none"> • Bleomycin (Blenoxane), doxorubicin (Adriamycin), Mitomycin (Mutamycin), Epirubicin, Idarubicin, Daunorubicin 	<ul style="list-style-type: none"> • Myelosuppression, anorexia, nausea, vomiting, fatigue, diarrhea, mucositis, can damage the heart • Treat a wide variety of cancers because they change the DNA inside cancer cells to stop them from growing and multiplying.
<p>Antimetabolites</p> <ul style="list-style-type: none"> • Capecitabine (Xeloda), Pemetrexed (Alimta®), cytarabine (ARA-C), 5-fluorouracil (5-FU), Floxuridine, Fludarabine, 6-mercaptopurine (6-MP), gemcitabine (Gemzar), methotrexate 	<ul style="list-style-type: none"> • Myelosuppression, anorexia, nausea, vomiting, fatigue, diarrhea, mucositis • Treat leukemias and cancers of the breast, ovary, and intestinal tract by interfering with DNA and RNA, damaging the cells during the phase when chromosomes are being copied.
<p>Topoisomerase Inhibitors</p> <ul style="list-style-type: none"> • Topotecan (Hycamtin), irinotecan (CPT-11, Camptosar), etoposide (VP-16, Etopopos), teniposide, mitoxantrone • Treat leukemias, lung, ovarian, testicular, and gastrointestinal cancers by interfering with enzymes that help separate strands of DNA so it can be copied. 	<ul style="list-style-type: none"> • Anorexia, nausea, vomiting, diarrhea, constipation, muscle cramps, risk of infection
<p>Mitotic Inhibitors</p> <ul style="list-style-type: none"> • Docetaxel (Taxotere), estramustine (Emcyt), ixabepilone (Ixempra), paclitaxel (Abraxane), vinblastine, vincristine (Marqibo), vinorelbine (Navelbine) • Treat breast and lung cancers, myelomas, lymphomas, and leukemias by stopping cell division. 	<ul style="list-style-type: none"> • Anorexia, nausea, vomiting, fatigue, muscle and joint aches, mouth sores, hair loss, and peripheral neuropathy (tingling and nerve irritation in the hands and feet)
<p>Miscellaneous</p> <ul style="list-style-type: none"> • Procarbazine (Matulane) 	<ul style="list-style-type: none"> • Myelosuppression, nausea, vomiting, diarrhea, monoamine oxidase (MAO) inhibitor/avoid foods high in tyramine. • Treats non-Hodgkin’s lymphoma, brain tumors, melanoma, lung cancer.
<p>Biotherapy Cytokines</p> <ul style="list-style-type: none"> • Interferon-alfa (Intron A, Roferon), interleukin (IL-2, Aldesleukin) 	<ul style="list-style-type: none"> • Myelosuppression, anorexia, fatigue, nausea, flu-like symptoms, chills

Aromatase Inhibitors (AIs) <ul style="list-style-type: none"> Anastrozole (Arimidex), letrozole (Femara), exemestane (Aromasin) 	<ul style="list-style-type: none"> Hot flashes, nausea, vomiting, thromboembolic events, high cholesterol, fever, joint aches and pains
Progesteroes <ul style="list-style-type: none"> Megestrol acetate (Megace) 	<ul style="list-style-type: none"> Increased appetite, weight gain, fluid retention, hyperglycemia, thromboembolic events

Data from Polovich M, et al: *Chemotherapy and biotherapy guidelines and recommendations for practice*, ed 4, Pittsburgh, 2014, Oncology Nursing Society; Wilkes GM, Barton-Burke M: 2014 *Oncology nursing drug handbook*, Burlington, 2013, Jones and Bartlett; Chu E, Devita VT: *Physician's cancer chemotherapy drug manual*, Boston, 2014, Jones and Bartlett, <http://www.chemocare.com>; American Cancer Society: *How chemotherapy drugs work*, 2016; Grant BL: *Nutritional effects of cancer treatment: chemotherapy, biotherapy, hormone therapy and radiation therapy*. In Leser M, Ledesma N, Bergerson S, et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group.

myelosuppression are the primary factors limiting chemotherapy administration. Commonly experienced chemotherapy induced toxicities affecting the gastrointestinal system include mucositis, nausea, vomiting, diarrhea, and constipation. Chemotherapy related taste abnormalities can lead to anorexia and decreased oral intake.

Anemia of Chronic Disease

Certain chemotherapies are more likely to cause anemia including platinum-based chemotherapy such as cisplatin, carboplatin, and oxaliplatin. Certain tumor types such as lung or ovarian, may also increase the likelihood for anemia (ACS, 2017). Hallmark symptoms of anemia that can compound other side effects include severe fatigue, weakness, swelling in the hands and feet, and dizziness. Patients may inquire about what they can do nutritionally to aid in supporting healthy red blood cell counts but not all anemia during cancer treatment has a nutrition-based etiology. Anemia of chronic disease is different than iron deficiency anemia in that it is caused by myelosuppression from chemotherapy and other cancer treatments. Cancer patients can also become iron deficient due to malnutrition and blood

loss, which can also lead to anemia. It is important understand the difference in order to correctly assess patient needs. Severe anemia may need to be treated with blood transfusions or medications (ACS, 2017). Dietetic practitioners should ensure that nutrition status is adequate including adequate protein and calories plus vitamin A and dietary folate. See Chapter 31 on anemia.

Diarrhea

Diarrhea is a common side effect of certain chemotherapy agents, radiation therapy that covers the intestines and surgery. Left unmanaged, it can lead to depletion of fluids, electrolytes, malnutrition, and even hospitalization. The intestinal mucosa and digestive processes can be affected, thus altering digestion and absorption to some degree. Protein, energy, and vitamin metabolism may be impaired. It is essential to maintain hydration status and replace electrolytes if three or more stools per day compared with usual or an increase in liquidity of bowel movements occurs. Institute a low-fat, low-fiber, and possibly low-lactose diet that avoids gas producing foods, caffeine, and alcohol. Suggest foods such as applesauce, banana, oatmeal,

potatoes, and rice as soluble fiber bulking agents with diarrhea (Elliott, 2013).

Nausea and Vomiting

Chemotherapy induced nausea and vomiting are commonly classified as anticipatory (occurs before receiving treatment), acute (occurs within the first 24 hours after receiving treatment), or delayed (occurs 1 to 4 days after treatment), each of which is characterized by distinct pathophysiologic events and requires different therapeutic interventions. Effective agents for treatment-related nausea and vomiting are the serotonin antagonists (e.g., ondansetron, granisetron, and dolasetron), neurokinin-1 (NK-1) receptor antagonists (e.g., aprepitant), dopamine antagonists (e.g., metoclopramide, prochlorperazine), and corticosteroids such as dexamethasone (Polovich et al, 2014). Other antiemetic agents include cannabinoids (e.g., dronabinol, nabilone), benzodiazepines (e.g., lorazepam, diazepam), and ginger tea or extract (Elliott, 2013). To support patients with nausea and vomiting, suggest five to six small meals per day, cool and light foods without strong odors, resting with head elevated after eating, and consuming liquids between meals rather than with meals (Elliott, 2013) (see Table 36.6).

Food-Drug Interactions

Nutrition professionals can gain valuable insights regarding possible drug-nutrient interactions and contraindications by reviewing product medication inserts, pharmacy resource books, and medication databases or by consulting with pharmacy personnel (see Appendix 13). Some chemotherapy agents can cause potentially severe adverse events (Grant, 2013), for example:

- Individuals with certain types of lung cancer who are being treated with pemetrexed (Alimta) require vitamin B₁₂ (often by injection) and folic acid supplementation throughout the duration of their therapy to avoid significant anemia associated with this chemotherapy agent.
- A severe hypertensive event is possible when tyramine-rich foods and beverages are consumed while taking procarbazine (Matulane), a chemotherapy agent commonly used to treat brain cancer.
- Individuals with colon cancer receiving oxaliplatin (Eloxatin) should not drink, eat, or handle cold drinks or foods for up to 5 days because of treatment-related neuropathy or transient paresthesias of the hands, feet, and throat.
- To prevent unnecessary gastric upset, individuals taking the medication capecitabine (Xeloda) must take the medication within 30 minutes of eating food or a meal. Conversely, medications such as erlotinib (Tarceva) should not be taken with food; it can cause a rash and profound diarrhea unless taken on an empty stomach.
- Individuals with certain types of cancer or rheumatoid arthritis who are being treated with methotrexate (Trexall) may benefit from supplemental folate which can reduce the toxicity of treatment similar or better than a common medication given for the same effect, leucovorin. (Merzel, 2017). Always coordinate care with a physician to ensure appropriateness of supplementation with folate in cancer therapy.

Oral Changes

People with altered taste acuity (dysgeusia, hypogeusia, ageusia) may benefit from increased use of flavorings and seasonings during food preparation. Meat aversions may require the elimination of red meats and the substitution of alternative protein sources including soy foods, beans, dairy, or eggs. Herpes simplex virus and *Candida albicans* (thrush) account for most oral infections. In addition to causing oral infections, some agents, especially corticosteroids, can cause hyperglycemia and can lead to excessive losses of urinary protein, potassium, and calcium. Support patients with oral changes by trialing fruity and

salty flavors. Fruit marinades on meat and other foods including lemon, herbs, and spices can help. Prepare foods without strong smells including foods that are not cooked or are covered with a lid. Suggest patients follow good oral hygiene and brush teeth before eating (Elliott, 2013) (see Chapter 24).

Mucositis

The rapidly dividing epithelial cells of the mouth are vulnerable to the side effects of therapy and oral mucositis can be a serious consequence. An inflammation of the mucous membranes lining the oropharynx and esophagus, mucositis is among the most common debilitating complication of chemotherapy and radiation. It can result in pain, inability to eat, and increased susceptibility to infection due to open sores. It is known that a good oral care regimen can help prevent or decrease the severity of mucositis and, just as important, help prevent the development of infection through open mouth sores. The mainstay of an effective oral care regimen is mouth rinses, and numerous studies have determined that a rinse with $\frac{3}{4}$ teaspoon salt and 1 teaspoon of baking soda in 4 cups of water is one of the best and most cost-effective mouth rinses available (Elliott, 2013). A mouth rinse aids in removing debris and keeping the oral tissue moist and clean.

General care guidelines include avoidance of tobacco, alcohol, and irritating foods such as spicy or acidic including citrus, tomato, chilies, and hot sauce. Bland liquids and soft solids are usually better tolerated in individuals with oral or esophageal mucositis and strong-flavored, acidic, or spicy foods also should be avoided. Chewing on ice can sometimes help (Elliott, 2013) (see Chapter 24).

The amino acid L-glutamine, often taken in a powder mixed into water, has been shown to decrease the severity of mucositis at 5 grams three times daily (Elliott, 2013; Tsuimoto et al, 2015).

Biotherapy

Biotherapy is immunotherapy in which a group of cancer treatment drugs prescribed to stimulate the body's own immune system and natural defenses are used to treat cancer. Biotherapy is sometimes used by itself, but it is given most often in combination with chemotherapy drugs. Different kinds of biotherapy drugs used to help the immune system recognize cancer cells and strengthen its ability to destroy them include the following:

- Cytokines such as interferon and IL-2 for treatment of malignant melanoma and metastatic melanoma.
- Monoclonal antibodies such as trastuzumab (Herceptin) for treatment of specific types of breast cancer, and rituximab (Rituxan) for treatment of non-Hodgkin's lymphoma.
- Antiangiogenesis inhibitors prevent and reduce the growth of new blood vessels and prevent tumor invasion. These agents are most frequently used in combination with other chemotherapy agents to maximize their effectiveness. An example of an antiangiogenic agent used to treat colon or brain cancer is bevacizumab (Avastin).
- Cancer vaccines such as sipuleucel-T (Provenge) made from an individual's own cancer or substances from tumor cells are currently under investigation in clinical cancer trials (Grant, 2013; Wilkes and Barton-Burke, 2013).

Other types of biotherapy drugs are groups of proteins that cause blood cells to grow and mature (NIH and NCI, 2015). These drugs are called **hematopoietic growth factors**. They include supportive care medications such as darbepoetin (Aranesp) or epoetin alfa (Procrit) to stimulate red blood cell production, and filgrastim (Neupogen) or pegfilgrastim (Neulasta) to stimulate the production of neutrophils in the bone marrow. Individuals receiving these agents may experience fatigue, chills, fever, and flu-like symptoms.

Hormone Therapy

Hormone therapy adds, blocks, or removes hormones to slow or stop the growth of hormone-sensitive breast or prostate cancer (NIH and NCI, 2015). Examples of these agents include tamoxifen (Nolvadex) and anastrozole (Arimidex) for breast cancer and leuprolide (Lupron) or bicalutamide (Casodex) for prostate cancer. Side effects commonly include hot flashes, decreased libido and sexual function, and bone pain (Wilkes and Barton-Burke, 2013).

Radiation Therapy

Radiation therapy, ionizing radiation used in multiple fractionated doses, is used to cure, control, or palliate cancer. Radiation therapy can be delivered externally into the body from a megavoltage machine or with brachytherapy by placing a radioactive source (implant) in or near the tumor to deliver a highly localized dose. Advances in technology to deliver radiation therapy with precise accuracy include radiation surgery (e.g., stereotactic radiosurgery) and intensity-modulated radiation therapy (IMRT). Whereas chemotherapy is a systemic therapy, radiation therapy affects only the tumor and the surrounding area. The side effects of radiation therapy are usually limited to the specific site being irradiated. Chemotherapy agents may also be given in combination with radiation therapy to produce a radiation-enhancing effect. People receiving multimodality therapy often experience side effects sooner and with greater intensity.

The acute side effects of radiation therapy when used alone generally occur around the second or third week of treatment and usually resolve within 2 to 4 weeks after the radiation therapy has been completed. Late effects of radiation therapy may happen several weeks, months, or even years after treatment. Commonly experienced nutrition-related symptoms include fatigue, loss of appetite, skin changes, and hair loss in the area being treated (Table 35.9).

Radiation to the Head and Neck

Treatment for head and neck cancer usually includes a multimodal approach with aggressive chemotherapy, radiation therapy, and often surgery. Radiation therapy to the head and neck can cause acute nutrition-related symptoms: sore mouth, altered taste and smell, dysphagia and odynophagia, mucositis, xerostomia, anorexia, fatigue, and weight loss (Havrila et al, 2010). Diminished oral intake, weight loss, and dehydration are a serious risk due to impaired chewing and swallowing during treatment. In fact, patients with head and neck cancers experience among the highest rates of malnutrition of any cancer diagnosis (25% to 50%) (Nguyen and Nadler, 2013). Prophylactic placement of percutaneous endoscopic gastrostomy (PEG) feeding tubes can help to reduce treatment-associated weight loss and malnutrition particularly for patients who have experienced undesired preoperative weight loss of 10 or more pounds, advanced (stage IV) tumors, pharyngeal tumors, or a planned combined surgery and radiotherapy treatment plan (Nguyen and Nadler, 2013).

Salivary stimulants and substitutes or oral lubricants are beneficial for temporary relief of xerostomia (diminished salivation or loss of salivation) caused by head and neck radiation therapy or certain types of medications (e.g., pain medications). In addition, liquids and foods with sauces and gravies are usually well tolerated. Late effects of radiation therapy may include dental caries, permanent xerostomia, **trismus** (an inability to fully open the mouth), and **osteoradionecrosis** of the jaw (necrosis of the bone caused by exposure to radiation therapy).

Radiation to the Thorax

Nutrition-related symptoms of radiation therapy to the thorax (chest) can include heartburn and acute esophagitis, accompanied by dysphagia and odynophagia. Late effects include possible esophageal fibrosis and stenosis. When this occurs, individuals are generally able to

TABLE 35.9 Nutrition-Related Effects of Radiation Therapy

Site of Radiation Therapy	Common Nutrition-Related Symptom
Central nervous system (brain and spinal cord)	<p>Acute Effects</p> <ul style="list-style-type: none"> Nausea, vomiting Fatigue Loss of appetite Hyperglycemia associated with corticosteroids <p>Late Effects (>90 days after treatment)</p> <ul style="list-style-type: none"> Headache, lethargy

Data from Iwamoto RR, et al: *Manual for radiation oncology and nursing practice and education*, ed 4, Pittsburgh, 2012, Oncology Nursing Society; Grant B: Nutritional effects of cancer treatment: chemotherapy, biotherapy, hormone therapy and radiation therapy. In Leser M et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group of the Academy of Nutrition and Dietetics.

swallow only liquids, and the use of medical food supplements and enteral nutrition (EN) support may be necessary to meet nutritional needs (see Chapter 12). Often individuals undergo esophageal dilations or swallowing therapy and rehabilitation to improve swallowing function.

Radiation to the Abdomen or Pelvis

Radiation therapy to the abdomen or pelvis may cause gastritis or enteritis that can be accompanied by nausea, vomiting, diarrhea, and anorexia. Late effects can include lasting GI damage such as malabsorption of disaccharides (e.g., lactose), fats, vitamins, minerals, and electrolytes. Proactive management includes encouraging affected individuals to consume soluble fiber, to increase intake of hydrating liquids, and to avoid eating high nonsoluble fiber or lactose-containing foods. To alleviate symptoms, medications such as antidiarrheals like loperamide may be given to reduce intestinal motility.

Chronic **radiation enteritis** can develop with diarrhea, ulceration, or obstruction, intensifying the risk of malnutrition. Chronic radiation enteritis combined with or without significant bowel resection can result in bowel dysfunction and short bowel syndrome (SBS). The severity of this condition depends on the length and location of the nonfunctional or resected bowel and generally is diagnosed when the individual has less than 150 cm of small intestine remaining. The sequelae of SBS include malabsorption, malnutrition, dehydration, weight loss, fatigue, and lactose intolerance (Havrila et al, 2010) (see Chapter 27).

Initially parenteral nutrition (PN) may be required, and frequent monitoring of fluids and electrolytes may be necessary for weeks or months. Individuals with SBS may require an oral diet restricted to defined formula tube feedings or to frequent small meals high in protein, low in fat and fiber, and lactose-free. Dietary supplements that contain vitamin B₁₂, folic acid, thiamin, calcium, and vitamins A, E, and K often are indicated to prevent deficiencies. Serum concentrations of various minerals also should be monitored and adjusted as needed.

Total-Body Irradiation

Total-body irradiation (TBI) is a technique of radiation therapy that is used in HCT to eliminate malignant cells, to ablate the bone marrow and make room for the engraftment of the infused hematopoietic cells, and to suppress the immune system to decrease the risk of rejection. Commonly encountered side effects are fever, nausea, vomiting, headache, mucositis, parotitis (inflammation of the parotid glands), xerostomia, diarrhea, anorexia, fatigue, and associated weight loss.

Surgery

The surgical resection or removal of any part of the alimentary tract (mouth to anus), as well as the malignant disease process, can potentially impair normal digestion and absorption. Surgery may be used as a single mode of cancer treatment, or it may be combined with preoperative or postoperative adjuvant chemotherapy or radiation therapy. After surgery, individuals commonly experience fatigue, temporary changes in appetite and bowel function caused by anesthesia, and pain. They often require additional energy and protein for wound healing and recovery. Most side effects are temporary and dissipate a few days after surgery. However, some surgical interventions have long-lasting nutritional implications (Table 35.10). When performing a nutrition assessment, it is important to understand which part of the alimentary tract has been affected or surgically removed so that the appropriate nutrition intervention can be recommended (see Chapter 1 for a review in GI physiology).

Head and Neck Cancer

Individuals with head and neck cancer often have difficulty with chewing and swallowing caused by the cancer itself, the specific surgical intervention required to remove cancerous tissues, and/or radiation therapy. There can be additional problems due to history of smoking and alcohol abuse, illicit drug use, and subsequent poor nutrition intake, which place these individuals at high risk for malnutrition and postoperative complications. Surgery often necessitates temporary or long-term reliance on EN support (e.g., PEG tube feedings) (see Chapter 12). Individuals who resume oral intake often have prolonged dysphagia and require modifications of food consistency and extensive training in chewing and swallowing. Referrals to a speech therapist can yield dramatic positive results through evaluation and individualized instruction in swallowing and positioning techniques, as well as evaluation for aspiration risk (see Chapter 39).

Esophageal Cancer

Surgical intervention for treatment of esophageal cancer often requires partial or total removal of the esophagus. The stomach is commonly used for esophageal reconstruction. A feeding jejunostomy tube, which allows for early postoperative tube feedings, can be placed before an individual undergoes surgery or at the time of surgery. Usually the individual is able to progress to oral intake with specific dietary recommendations to minimize nutrition-related symptoms, which include reflux, dumping syndrome (discussed later in this chapter), dysmotility, gastroparesis, early satiety, vomiting, and fluid and electrolyte imbalances (Huhmann and August, 2010). Postsurgical recommendations include a low-fat diet with small, frequent feedings of energy-dense foods and avoidance of large amounts of fluids at any one time (see Chapter 26).

Gastric Cancer

Surgery is the most common treatment for cancer of the stomach, although chemotherapy and radiation therapy can be used before or after surgery to improve survival. Surgical interventions include partial, subtotal, or total gastrectomy. Placement of a jejunostomy feeding tube at surgery is advisable, and EN support using a jejunal feeding tube is generally feasible within a few days after surgery.

Postgastrectomy syndrome encompasses a myriad of symptoms, including dumping syndrome, general and fat malabsorption, gastric stasis, lactose intolerance, anemias, and metabolic bone disease (osteoporosis, osteopenia, osteomalacia). **Dumping syndrome** is a common complication of gastric surgery, manifested by the rapid transit of foods or liquids, and the dilutional response of the small remaining stomach to highly osmotic bolus feedings. Individuals may experience GI and vasomotor symptoms such as abdominal cramps, diarrhea, nausea, vomiting, flushing, faintness, diaphoresis, and tachycardia (Huhmann and August, 2010). Individuals experiencing malabsorption may have deficiencies in iron, folic acid, and vitamin B₁₂, which can lead to anemia. Micronutrient deficiencies of calcium and fat-soluble vitamins are also common (Gill, 2013; Huhmann and August, 2010).

Pancreatic Cancer

Cancer of the pancreas, with or without surgical resection, can have significant nutritional consequences. The Whipple procedure and the pylorus-sparing pancreatic duodenectomy are the most common pancreatic cancer surgeries. Postsurgical complications include delayed gastric emptying, early satiety, glucose intolerance, bile acid insufficiency, diarrhea, and fat malabsorption. Pancreatic enzyme replacement, the use of small, more frequent low-fat meals and snacks, and avoidance of simple carbohydrates aid digestion and absorption (see Chapter 28).

TABLE 35.10 Nutrition-Related Effects of Surgery in Cancer Treatment

Anatomic Site	Nutrition Impact Symptoms
Oral cavity	Difficulty with chewing and swallowing Aspiration potential Sore mouth and throat Xerostomia Alteration in taste and smell
Larynx	Alterations in normal swallowing, dysphagia Aspiration
Esophagus	Gastroparesis Indigestion, acid reflux Alterations in normal swallowing, dysphagia Decreased motility Anastomotic leak
Lung	Shortness of breath Early satiety
Stomach	Dumping syndrome Dehydration Early satiety Gastroparesis Fat malabsorption Vitamin and mineral malabsorption (vitamin B ₁₂ and D; calcium, iron)
Gallbladder and bile duct	Gastroparesis Hyperglycemia Fluid and electrolyte imbalance Vitamin and mineral malabsorption (vitamin A, D, E, and K; magnesium, calcium, zinc, iron)
Liver	Hyperglycemia Hypertriglyceridemia Fluid and electrolyte malabsorption Vitamin and mineral malabsorption (vitamin A, D, E, K, B ₁₂ and folic acid, magnesium, zinc)
Pancreas	Gastroparesis Fluid and electrolyte imbalance Hyperglycemia Fat malabsorption (vitamin A, D, E, K, B ₁₂ ; calcium, zinc, iron)
Small bowel	Chyle leak Lactose intolerance Bile acid depletion Diarrhea Fluid and electrolyte imbalance Vitamin and mineral malabsorption (vitamin A, D, E, K, B ₁₂ ; calcium, zinc, iron)
Colon and rectum	Increased transit time Diarrhea Dehydration Bloating, cramping, gas Fluid and electrolyte imbalance Vitamin and mineral malabsorption (vitamin B ₁₂ , sodium, potassium, magnesium, calcium)
Ovaries and uterus	Early satiety Bloating, cramping, and gas
Brain	Nausea, vomiting Hyperglycemia associated with corticosteroids

Data from Leser M et al, editors: *Oncology nutrition for clinical practice*, Chicago, 2013, Oncology Nutrition Dietetic Practice Group of Nutrition of the Academy of Nutrition and Dietetics; Huhmann MB, August D: Surgical oncology. In Marian M, Roberts S, editors: *Clinical nutrition for oncology patients*, Sudbury, Mass, 2010, Jones and Bartlett.

Cancers of the Intestinal Tract

Partial or total resections of the intestinal tract because of colorectal cancer or carcinoid syndrome may induce profound losses of fluid and electrolytes secondary to decreased transit time and diarrhea, the severity of which are related to the length and site of the resection. Resections of as little as 15 cm of the terminal ileum can result in bile salt losses that exceed the liver's capacity for resynthesis, and vitamin B₁₂ absorption is affected. With depletion of the bile salt pool, steatorrhea develops. Nutrition intervention strategies consist of a diet low in fat, osmolality, lactose, and oxalates (see Chapters 27 and 37).

Hematopoietic Cell Transplantation (HCT)

Hematopoietic cell transplantation (HCT), commonly referred to as a “stem cell transplant,” is performed for the treatment of certain hematologic cancers such as leukemia, lymphoma, and multiple myeloma. The stem cells used for HCT arise from bone marrow, peripheral blood, or umbilical cord blood. The preparative regimen includes cytotoxic chemotherapy, with or without TBI, followed by IV infusion of hematopoietic cells from the individual (autologous), or from a histocompatible related or unrelated donor (allogeneic), or from an identical twin (syngeneic) (*National Marrow Donor Program, 2018*). Autologous transplants often have a shortened period of **pancytopenia** (reduction in the cellular components of the blood), when individuals are at risk for bleeding, serious infections, or sepsis.

The HCT procedure is associated with severe nutritional consequences that require prompt, proactive intervention. The patient should have a thorough nutrition assessment before the initiation of therapy, ongoing reassessments, and monitoring throughout the entire transplant course. The acute toxicities of immunosuppression can last for 2 to 4 weeks after the transplant and include nausea, vomiting, anorexia, dysgeusia, stomatitis, oral and esophageal mucositis, fatigue, and diarrhea. In addition, immunosuppressive medications can also adversely affect nutrition status. Complications of delayed-onset nutrition-related symptoms include varying degrees of mucositis, xerostomia, and dysgeusia. Mucositis, which is often severe and extremely painful, develops in more than 75% of transplant patients (*Macris Charuhas, 2013*).

Depending on the transplant regimen, individuals may have little or no oral intake, and the GI tract can be significantly compromised in the early posttransplant period. For many patients, PN is a standard component of care and is indicated for those who are unable to tolerate oral or enteral feeding (*AND EAL, 2013; Macris Charuhas, 2013*). In addition, administration of optimal levels of PN often is complicated by the frequent need to interrupt it for the infusion of antibiotics, blood products, and IV medications. Careful monitoring and the use of more concentrated nutrient solutions, increased flow rates and volumes, and double- or triple-lumen catheters often are needed to achieve optimal nutrition intakes.

Graft-Versus-Host Disease (GVHD)

Graft-versus-host disease (GVHD) is a major complication seen primarily after allogeneic transplants, in which the donated “donor” stem cells react against the tissues of the transplant recipient “host.” The functions of several target organs (skin, liver, gut, lymphoid cells) are disrupted and are susceptible to infection. Acute GVHD can occur within the first 100 days after the transplant (*Macris Charuhas, 2013*). It may resolve, or it may develop into a chronic form that requires long-term treatment and dietary management. Chronic GVHD can develop up to 3 months after transplant and is observed with increased frequency in nonidentical related donors and unrelated donors. Chronic GVHD can affect the skin, oral mucosa (ulcerations, stomatitis, xerostomia), and the GI tract (anorexia, reflux symptoms, diarrhea) and can

cause changes in body weight. Skin GVHD is characterized by a maculopapular rash. GVHD of the liver, evidenced by jaundice and abnormal liver function tests, often accompanies GI GVHD and further complicates nutrition management. Other acute or chronic complications of HCT include osteoporosis, pulmonary disease, impaired renal function, rejection of the graft, growth abnormalities in children, sepsis, and infection (*Flowers et al, 2018; Macris Charuhas, 2013*). Nutrition-related symptoms associated with HCT may persist; individuals receiving outpatient marrow transplantation require frequent monitoring and intervention (*Macris Charuhas, 2013*).

The symptoms of acute GI GVHD can be severe; individuals may experience gastroenteritis, abdominal pain, nausea, vomiting, and large volumes of secretory diarrhea. Immunosuppressive medications and a phased dietary regimen should be instituted (*Flowers et al, 2018; Macris Charuhas, 2013*). The first phase consists of total bowel rest and the use of PN until diarrhea subsides. The second phase reintroduces oral feedings of beverages that are **isotonic** (mimic the balance of water, salt, and sugar that can be as easily taken up by the body as water), low residue, and lactose-free so as to compensate for the loss of intestinal enzymes secondary to alterations in the intestinal villi and mucosa (*Flowers et al, 2018*). If these beverages are tolerated, phase three includes the reintroduction of solids that contain low levels of lactose, fiber, fat, and total acidity, and no gastric irritants. In phase four dietary restrictions are progressively reduced as foods are gradually introduced and tolerance is established. Phase five is the resumption of the individual's regular diet (*Flowers et al, 2018*).

Nutrition Precautions with Neutropenia

Individuals receiving HCT become immunocompromised and require supportive therapy, including medications and dietary changes to prevent infection. Some cancer centers and hospitals continue to prescribe a low-microbial, low-bacteria, “neutropenic” diet for people with neutropenia. However, there is no clear evidence that a restrictive diet of only cooked foods reduces overall rates of infection or death (*Wolfe et al, 2018*). Current recommendations are for nutrition education to include dietary counseling on safe food handling and avoidance of foods that pose a risk of infection while patients are neutropenic and until immunosuppressive therapy has been completed (*Macris Charuhas, 2013; Wolfe et al, 2018*). These patients should avoid foods that contain unsafe levels of bacteria (raw meats, spoiled or moldy foods including some artisanal and soft cheeses, and unpasteurized beverages) and use special handling of raw meats, game, poultry, eggs, utensils, cutting boards, and countertops. Thorough hand washing is critical to food safety as is the avoidance of untested well water. Store foods at appropriate temperatures (below 40° F and above 140° F) (*Macris Charuhas, 2013*) (see Table 35.6).

NUTRITION MONITORING AND EVALUATION

Dietetic professionals must determine and quantify their patients' nutrition care goals by monitoring progress, measuring and evaluating outcomes and changes, and documenting this information throughout the process. Symptoms can evolve throughout treatment so monitoring and evaluation needs to be tailored to each person's therapeutic needs based on the severity of disease and intensity of treatment. Monitoring and evaluation of these factors is needed to effectively diagnose nutrition problems that should be the focus of future nutrition interventions (*AND EAL, 2013*) (see Chapter 9; *Box 35.7*).

PEDIATRIC CANCER

Like adults, children with cancer can experience malnutrition and nutrition-related symptoms as a result of their cancer and its treatment.

BOX 35.7 Monitoring and Evaluation of Adult Oncology Patients

- Anthropometric measurements: weight change; body mass index (BMI)
- Food/nutrition-related history: energy and protein intake; changes in food and fluid intake; adequacy and appropriateness of nutrition intake/nutrient administration; actual intake from enteral nutrition (EN) and parenteral nutrition (PN); changes in type, texture, or temperature of foods and fluids; use of medical food supplements; meal/snack pattern changes; prescription medications, over-the-counter medications, herbal preparations and supplements; factors affecting access to food; and feeding method or need for placement (e.g., oral, enteral, parenteral)
- Biochemical data, medical tests and procedures: biochemical indices and implications of diagnostic tests and therapeutic procedures
- Nutrition-focused physical findings: vital signs; loss of muscle mass; loss of subcutaneous fat; nutrition impact symptoms including but not limited to nausea, vomiting, diarrhea, constipation, stomatitis, mucositis, alterations in taste and smell, and anxiety; presence of pressure ulcers or wounds; functional indicators (e.g., grip strength); and localized or generalized fluid accumulation (see Appendix 11)
- Client history including patient/family/client medical/health history and social history

Academy of Nutrition and Dietetics (AND), Evidence Analysis Library (EAL): *Oncology nutrition evidence-based nutrition practice guidelines*, Chicago, 2013, Academy of Nutrition and Dietetics.

Malnutrition can have long-term side effects with childhood cancer treatment such as slow or stunted growth and development, compromised bone health, eating disorders, and decreased quality of life (Fatemi and Sheridan-Neumann, 2013). Children with advanced cancer are at greater risk of severe nutritional depletion than adults are due to the frequent use of more aggressive, multimodality treatment. Deficiencies in energy and protein can affect growth adversely, although the effects may be temporary, and catch-up growth depends on how much energy children are able to consistently consume (Fatemi and Sheridan-Neumann, 2013). Some cancer treatment regimens may have an effect on growth and development that is independent of nutritional deprivation. HCT is now an accepted and increasingly successful intensive therapy for a wide range of disorders in children.

Psychogenic food refusal in children requires interventions that address underlying psychological issues. Families and caregivers often express their fears through a preoccupation with eating and maintaining weight. Creative efforts are required to minimize the psychological effects of fear, unpleasant hospital routines, unfamiliar foods, learned food aversions, and pain. Nutrition intervention strategies that use oral intake should stress the maximum use of favorite, nutrient-dense foods during times when intake is likely to be best, and food aversions are least likely to occur. Oral medical foods can be useful, but their acceptance is often a problem.

EN support by nasogastric tube (up to 3 months) or gastrostomy tube (more than 3 months) may be indicated for some children who are able to cooperate and who have functional GI tracts. PN is indicated for children who are receiving intense treatment associated with severe GI toxicity (intractable vomiting and severe diarrhea) and for children with favorable prognoses who are malnourished or have a high risk of developing malnutrition. PN is seldom indicated for children with advanced cancer associated with significant deterioration or with diseases that are unresponsive to therapy.

American Society for Parenteral and Enteral Nutrition has established standards for the nutrition screening and specialized nutrition

support for all hospitalized pediatric patients. The nutritional requirements of pediatric patients with cancer are similar, with an adjustment for activity, to those of normal growing children. Often pediatric patients with cancer are not bedridden but are as active as their healthy peers. Factors that may alter nutrient requirements in cancer include the effect of the disease on host metabolism, the catabolic effects of cancer therapy, and physiologic stress from surgery, fever, malabsorption, and infection. Fluid requirements are increased during anticancer therapy or in the presence of fever, diarrhea, or renal failure. Micronutrients may require supplementation during periods of poor intake, stress, or malabsorption. The best long-term indicator of adequate nutrient intake is growth. Children have increased nutritional requirements for growth and development that must be met despite extended periods of cancer treatment (see Chapters 15 through 17). A special vulnerability exists during the adolescent growth spurt.

Advanced Cancer and Palliative Care

Palliative care is the care of an individual when curative measures are no longer considered an option by either the medical team or the individual. Hospice care focuses on relieving symptoms and supporting individuals with a life expectancy of months, not years (NHPCO, 2018c). The objectives are to provide for optimal quality of life; relieve physical symptoms; alleviate isolation, anxiety, and fear associated with advanced disease; and to help patients maintain independence as long as possible. The goals of nutrition intervention should focus on managing nutrition-related symptoms such as pain, weakness, loss of appetite, early satiety, constipation, weakness, dry mouth, and dyspnea (Trentham, 2013). Another important goal is maintaining strength and energy to enhance quality of life, independence, and the ability to perform activities of daily living. Nutrition should be provided as tolerated, according to patient preference or as desired along with emotional support and awareness of and respect for individual needs and wishes. The pleasurable aspects of eating should be emphasized.

The use of nutrition support and hydration in individuals with advanced, incurable cancer is a difficult and often controversial issue and should be determined on a case-by-case basis. Providing hydration to a terminal patient may cause pain, is intrusive, and may cause symptoms including vomiting, ascites, edema, and pulmonary congestion (Trentham, 2013). Dehydration can be part of the natural transition process. Advance directives are legal documents that guide health care providers regarding the specific wishes of individuals, outlining the extent of their desired medical care, including the provision of artificial nutrition and hydration.

NUTRITION RECOMMENDATIONS FOR CANCER SURVIVORS

Recommendations for survivors are very similar to the recommendations for cancer prevention already discussed. The ACS defines anyone living with a cancer diagnosis as a cancer survivor from the time of diagnosis through the balance of life (Rock et al, 2012). The ACS guidelines as well as the WCRF and AICR recommendations provide sound diet, nutrition, and physical activity advice for primary cancer prevention and health for all individuals, including cancer survivors. See the recommendations on cancer prevention (Rock et al, 2012; WCRF/AICR, 2018).

Cancer survivorship encompasses three phases: active treatment and recovery, living after recovery (including living disease-free or with stable disease), and advance cancer and end of life (Rock et al, 2012). Cancer survivors represent one of the largest groups of people living with a chronic disease. It is estimated that there will be 15.5 million survivors in the United States in 2018 (ACS, 2019b). The majority of

individuals with cancer are able to return to full function and regain quality of life. This trend is expected to continue because of recent awareness in cancer prevention, advances in cancer detection, development of more effective cancer treatments, and advancements

in determining the genetic causes of cancer. Long-term cancer survivors should now focus on healthy weight management, healthy diets, and physical activity geared toward secondary cancer and chronic disease prevention (Box 35.8).

Box 35.8 Physical Activity for Survivors

Before participating in any type of physical activity and exercise program, individuals should be advised to undergo evaluation by qualified professional to first assess for cardiovascular fitness post cancer treatment and design an individualized physical assessment and activity plan if safe and appropriate.

- The Survivorship Training and Rehab (STAR) certified specialists are available around the country in large and small cancer centers; the program's goal is the health care professionals seeking certification how rehab can help cancer

patients and about the unique needs of cancer survivors after cancer treatment (Oncology Rehab Partners [ORP], 2018).

- The American College of Sports Medicine (ACSM) offers a certification program for trainers working with people diagnosed with cancer (a certified cancer exercise trainer) (ACSM, 2018).
- The YMCA's Livestrong (<http://www.ymca.net/livestrong-at-the-ymca>) is available across the United States and offers physical activity and exercise opportunities to support cancer survivors.

CLINICAL CASE STUDY

Daniel is a 54-year-old white man with a recent diagnosis of colon cancer. He has experienced some blood in the stool over time but never followed up on his doctor's referral. He lost 20 pounds in the 3 months before his diagnosis because of lack of appetite and lower intestinal discomfort. Prediagnosis, his diet consisted of drinking protein shakes his son purchased at the local gym. He has been very pleased with his weight loss as he has struggled with obesity over time but knew something was wrong. His medical history also includes hypertension and elevated cholesterol levels.

Daniel underwent surgery to remove the tumor and 2 rounds of chemotherapy. He recalls that he received some nutrition information from the inpatient registered dietitian nutritionist right before he was discharged but was anxious to go home, did not pay attention to the diet instruction, and could not find the paperwork once he got home. He has lost an additional 15 pounds in the past month and has been admitted once for dehydration caused by lack of fluid intake and because of symptoms related to ongoing episodes of diarrhea after eating. He states he is not sleeping well and doesn't feel rested.

His current food and nutrition history includes small meals with a usual intake of approximately 1500 calories daily. He eats three times a day and reports he does not have the energy to prepare food, so while his wife is at work, he has started drinking the prepared protein shakes again and is warming canned soup in the microwave. He is also drinking sports drinks because he has been encouraged to increase his fluid intake. He has a sweet tooth, and because his appetite is low, he rewards himself with ice cream or sherbet. His beverages include whole milk, apple juice, and an occasional "finger" of scotch each night. He has been referred to see the outpatient registered dietitian nutritionist.

Biochemical Data

WBC count: 4.2 th/mm³ (low end WNL)
 Hematocrit: 32% (L)
 Fasting Blood Glucose: 93 mg/dL (WNL)
 Hematocrit: 31 mg/dL (L)
 Ferritin 21 ng/mL (L)
 Serum sodium: 147 mmol/L (H)

Anthropometric Data

Height: 70"
 Weight history: Usual body weight: 220 lb, preoperative weight: 200 lb,
 1-month postoperative weight: 185 lb
 Current body mass index (BMI): 28

Medications

Metoclopramide (Reglan) 30 minutes before each meal
 Metoprolol (Toprol)

Hydrochlorothiazide
 FOLFOX (Folinic Acid, 5-Fluorouracil (5-FU) and Oxaliplatin)

Dietary Supplements

One-A-Day for Men
 Lycopene

Nutrition Diagnostic Statements

- Inadequate fluid intake related to increased needs from chemotherapy and surgery induced diarrhea as evidenced by typical day intake and high serum sodium level.
- Inadequate protein and energy intake related to poor appetite and diarrhea as evidenced by decreased food and beverage and unintended weight loss.

Nutrition Care Questions

1. Assess Daniel's labs and medical history. What kind of a daily eating plan would you design with Daniel so that he can meet his nutritional requirements with food and fluid?
2. After reviewing Daniel's medical, social, and physical activity history, what other factors could be contributing to his difficulty with eating and his inability to regain weight?
3. Would you include Daniel's family members in your counseling sessions? If so, why? If not, why?
4. As Daniel continues to be seen for survivorship care at your clinic, what late-occurring side effects of cancer treatment should you anticipate and continue to monitor? Could any of these side effects affect his ongoing nutritional status? If so, should any laboratory tests be ordered or evaluated? What other factors should be monitored as a part of your nutritional care?
5. What type of integrative strategies would you deploy with Daniel to support his healing and survivorship?

Nutrition Interventions

Nutrition prescription: Small, frequent meals consisting of energy-dense, well cooked, low residue and moderate fat foods and limited simple carbohydrates. Monitor white blood cell count and educate on principles of food safety.

Nutrition education: Update Daniel's knowledge of appropriate nutrition therapy after a colon resection. Discuss tolerance of different food groups; sources of protein; energy-dense, easy-to-prepare menu options; and healthy beverage selections, including advising him to discontinue consumption of daily alcoholic beverage; and goal caloric intake needed for slow, steady weight gain. Suggest he consider eating every 2 hours to create an external reminder to eat. Recommend he review his hypertension and cholesterol lowering medications and doses with his physicians because his need for medication may have changed with his significant weight loss.

Continued

CLINICAL CASE STUDY—cont'd

At follow-up visits address weight stabilization, bowel function, food and beverage intake and tolerance; encourage physical activity (physician approved) starting with short walks to regain muscle strength. Daniel should be accompanied by a friend or family member on these walks. Encourage Daniel to follow-up with his primary care physician to discuss his problems sleeping.

Nutrition counseling: Coordinate with patient and family members to ensure appropriate foods and beverages are available for consumption. Discuss expected acute and long-term side effects from surgery. Establish physical activity goals for next 3 months.

Nutrition Monitoring and Evaluation

1. Body weight trends
2. Hydration status
3. Serum prealbumin levels and creatinine levels (over 3 months)
4. Physical activity
5. Schedule follow-up session in 2 weeks, with optional phone call between visits

Medical Nutrition Therapy for HIV and AIDS

*Maureen Lilly, MS, RDN
Solenne Vanne, MS, RDN*

KEY TERMS

acquired immune deficiency syndrome (AIDS)
acute HIV infection
antiretroviral therapy (ART)
asymptomatic HIV infection
Bioelectrical Impedance Analysis (BIA)
CD4+ cells
CD4 count

clinical latency
drug resistance
HIV-associated lipodystrophy syndrome (HALS)
HIV ribonucleic acid (RNA)
human immunodeficiency virus (HIV)
lipoatrophy
lipohypertrophy

long-term nonprogression
opportunistic infections (OIs)
people living with HIV/AIDS (PLWHA)
preexposure prophylaxis or PrEP
seroconversion
symptomatic HIV infection
T-helper lymphocyte cells
viral load

Acquired immune deficiency syndrome (AIDS) is caused by the **human immunodeficiency virus (HIV)**. HIV affects the body's ability to fight off infection and disease, which if left untreated, can ultimately lead to AIDS and death. Medications used to treat HIV have enhanced the quality of life and increased life expectancy of **people living with HIV/AIDS (PLWHA)**. These **antiretroviral therapy (ART)** medications slow the replication of the virus but do not eliminate HIV infection. With increased access and improvements to ART, people are living longer with HIV.

THE CHANGING FACE OF HIV IN THE UNITED STATES

During the start of the HIV epidemic in the 1980s much of the nutrition therapy focused on symptoms such as anorexia, catabolism and wasting syndrome, chronic infection, fever, poor nutrient intake, nausea, vomiting, diarrhea, malabsorption, metabolic disturbances, lack of access to food, depression, and side effects of drugs and treatment (Young, 1997). Life expectancy before treatment became available was around 12 years from time of infection. Since the release of the first antiretroviral therapy AZT (azidothymidine) in 1996 to the release of the newest single tablet regimens starting in 2006, the face of HIV has changed dramatically. In a recent study on life expectancy in PLWHA, researchers found that the average life expectancy of a 20-year-old patient who started ART after 2008 and had a low viral load was 78 years, similar to the general population (Trickery, 2017). With these new advancements in treatment much of the nutrition therapy focus has shifted. Unfortunately, health issues such as cardiovascular disease and insulin resistance are increasingly prevalent, and

PLWHA are at a greater risk of the same chronic diseases as the general population.

Special consideration should be taken into account when working with the aging population of PLWHA who are more likely to have experienced trauma during the beginning of the HIV epidemic. Many have a long history of loss of close friends and partners, isolation and criminalization, and years of poor health due to drug side effects and opportunistic infections (OIs).

A New Era in HIV Prevention

Even though antiretroviral therapy (ART) has been a revolutionary advance in keeping HIV positive individuals from progressing to AIDS, it is estimated that globally an average of about 5000 new HIV infections occur daily (UNAIDS, 2018).

The primary route of HIV transmission remains sexual contact. Although prevention efforts have reduced sexual transmission significantly, the rate of new infection demonstrates the need for better tools. In 2012 the Food and Drug Administration approved an antiretroviral drug combination for **preexposure prophylaxis, or PrEP**. In a study of heterosexual partners in which one partner was HIV positive and one partner HIV negative, consistent use of the drug Truvada (emtricitabine/tenofovir) reduced infections by at least 90% (Baeten et al, 2012). Similarly, in a study of 2500 HIV-negative men and transgender women who have sex with men, participants were randomly assigned to receive either Truvada or a placebo once daily. Participants with detectable levels of the antiretrovirals in their blood showed a 92% to 99% greater protection against HIV (Grant et al, 2010).

Short-term side effects of Truvada for PrEP have been reported to be gastric distress, diarrhea, headaches, and weight loss. The long-term side effects of PrEP in HIV-negative individuals are still unknown. However, the same possible long-term effects observed in HIV-positive individuals using Truvada should be monitored in this patient population. Monitoring for lactic acidosis, liver damage, renal issues, and bone density are important (Gilead Sciences, 2017).

Portions of this chapter were written by Kimberly R. Dong MS, RDN, and Cindy Mari Imai, PhD, RDN.

Furthermore in the advancement of HIV prevention and ending stigmatization, there is now strong evidence showing that a PLWHA who is on ART medication with an undetectable viral load, cannot sexually transmit the virus to an HIV-negative individual. The public health campaign that has launched from two long-term PARTNER studies starting in 2009 is called U=U (Undetectable=Untransmittable). This messaging is key to public health and provider understanding of HIV. (Eisinger et al, 2019).

Other prevention efforts being researched have focused on HIV vaccines, microbicides, and antibodies. Development of a prophylactic HIV vaccine has been difficult as HIV's ability to elude the immune system makes traditional vaccines like those used for smallpox and measles ineffective. However, two potential vaccines, Imbokodo and HVTN 702, show some promise. Two vaccine efficacy trials are currently underway in Africa for Imbokodo, and trials for HVTN 702 are set to begin in 2020 (National Institutes of Health [NIH], 2017). A microbicide vaginal ring, dapivirine, has been shown to partially reduce risk of HIV infection in clinical trials. Additional trials are underway while waiting for regulatory approval (Microbicide Trials Network, 2016). Antibody-mediated prevention has shown great potential in laboratory studies; the antibody VRC01 prevented over 90% of nearly 200 sample HIV strains from infecting human cells. Two multinational placebo-controlled trials using intravenous infusion of VRC01 have also recently begun (National Institute of Allergy and Infectious Diseases [NIAID], 2016). These efforts give hope to greatly reducing the transmission of HIV, especially in areas where there is poor access to medication.

Nutritional status plays an important role in maintaining a healthy immune system and preventing the progression of HIV to AIDS. To develop appropriate nutrition recommendations, the nutrition professional should be familiar with the pathophysiology of HIV infection, the medication and nutrient interactions, and the barriers to adequate nutrition.

EPIDEMIOLOGY AND TRENDS

Global Status of HIV and AIDS

The first cases of AIDS related to HIV were described in 1981. In 1983 HIV was isolated and identified as the core agent leading to AIDS. Since then, the number of people with HIV has increased gradually, leading to a global pandemic affecting socioeconomic development worldwide. The continuing rise in the population of people living with HIV is reflective of new HIV infections and the widespread use of ART, which has delayed the progression of HIV infection to death. Globally, an estimated 36.9 million people were living with HIV or AIDS in 2017. The number of new HIV infections and related deaths has fallen in the last decade. In 2017 there were 1.8 million new HIV infections and 960,000 AIDS-related deaths reported (UNAIDS, 2018).

Despite increased prevention efforts and availability of ART, geographic variation in HIV infection is evident. The majority of infections continue to occur in the developing world (Fig. 36.1). Sub-Saharan Africa remains the region most heavily affected by HIV, accounting for 66% of new HIV infections and 61% of AIDS-related deaths (UNAIDS, 2018). Within sub-Saharan Africa, heterosexual transmission is the most prevalent mode of HIV transmission. Other populations particularly at risk of HIV infection include injection drug users, men who have sex with men, sex workers, and clients of sex workers (Fig. 36.2).

The United States

Within the United States, more than 1.1 million people are living with HIV infection and 14% may be unaware of their HIV status (Dailey

et al, 2017). Although more people are living with a diagnosis of HIV or AIDS, incidence has remained relatively stable since the 1990s. In 2016 men accounted for 70% of all diagnoses of HIV infection, and the most common route of transmission was male-to-male sexual contact (Centers for Disease Control and Prevention [CDC], 2017a). The rate of new infections among women, primarily through heterosexual contact, has decreased since 2011 (CDC, 2017a). The largest percentage of persons living with HIV infection is among those aged 50 to 54. However, in 2016, people aged 25 to 29 accounted for the highest rate of new HIV infections. Ethnic populations disproportionately affected by HIV include African Americans and Latinos, who accounted for 44% and 25% of new HIV diagnoses, respectively, in 2016 (CDC, 2017a). The most common route of transmission among men is male-to-male sexual contact and among women is heterosexual contact (see Fig. 36.2).

While there is limited research on transgender PLWHA (those with a differing gender identity than the sex assigned at birth), growing evidence indicates a disproportionately high rate of HIV infection within the transgender (also referred to as trans) community. According to the Report of the 2015 Transgender Survey, the rate of HIV among transgender respondents is 1.4%, among trans women (male-to-female) the rate is 3.4%, and an estimated 19% of black trans women are living with HIV (James et al, 2016). Additionally, the 2009–2014 National HIV Surveillance System reported that 2351 of U.S. transgender people were newly diagnosed with HIV. Of those diagnosed, 84% were transgender women, 15.4% were transgender men (female-to-male), and 0.7% were an additional gender identity. Moreover, more than half of those diagnosed lived in the South and 52% identified as African American (Clark et al, 2017).

PATHOPHYSIOLOGY AND CLASSIFICATION

Primary infection with HIV is the underlying cause of AIDS. HIV invades the genetic core of the CD4+ cells, which are T-helper lymphocyte cells, and which are the principal agents involved in protection against infection. HIV infection causes a progressive depletion of CD4+ cells, which eventually leads to immunodeficiency.

HIV infection progresses through four clinical stages: acute HIV infection, clinical latency, symptomatic HIV infection, and progression of HIV to AIDS. The two main biomarkers used to assess disease progression are HIV ribonucleic acid (RNA) (also known as the viral load) and CD4+ T-cell count (CD4 count).

Acute HIV infection is the time from transmission of HIV to the host until **seroconversion**, the production of detectable antibodies against the virus, occurs. Half of individuals experience physical symptoms such as fever, malaise, myalgia, pharyngitis, or swollen lymph glands at 2 to 4 weeks after infection, but these generally subside after 1 to 2 weeks. Because of the nonspecific clinical features and short diagnostic window, acute HIV infection is rarely diagnosed. HIV seroconversion occurs within 3 weeks to 3 months after exposure. If HIV testing is done before seroconversion occurs, a false negative may result despite HIV being present. During the acute stage, the virus replicates rapidly and causes a significant decline in CD4+ cell counts. Eventually, the immune response reaches a viral set point, when the viral load stabilizes and CD4+ cell counts return closer to normal.

A period of **clinical latency**, or **asymptomatic HIV infection**, then follows. Further evidence of illness may not be exhibited for as long as 10 years postinfection. The virus is still active and replicating, although at a decreased rate compared with the acute stage, and CD4+ cell counts continue to steadily decline. In 3% to 5% of HIV-infected individuals, **long-term nonprogression** occurs, in which CD4+ cell

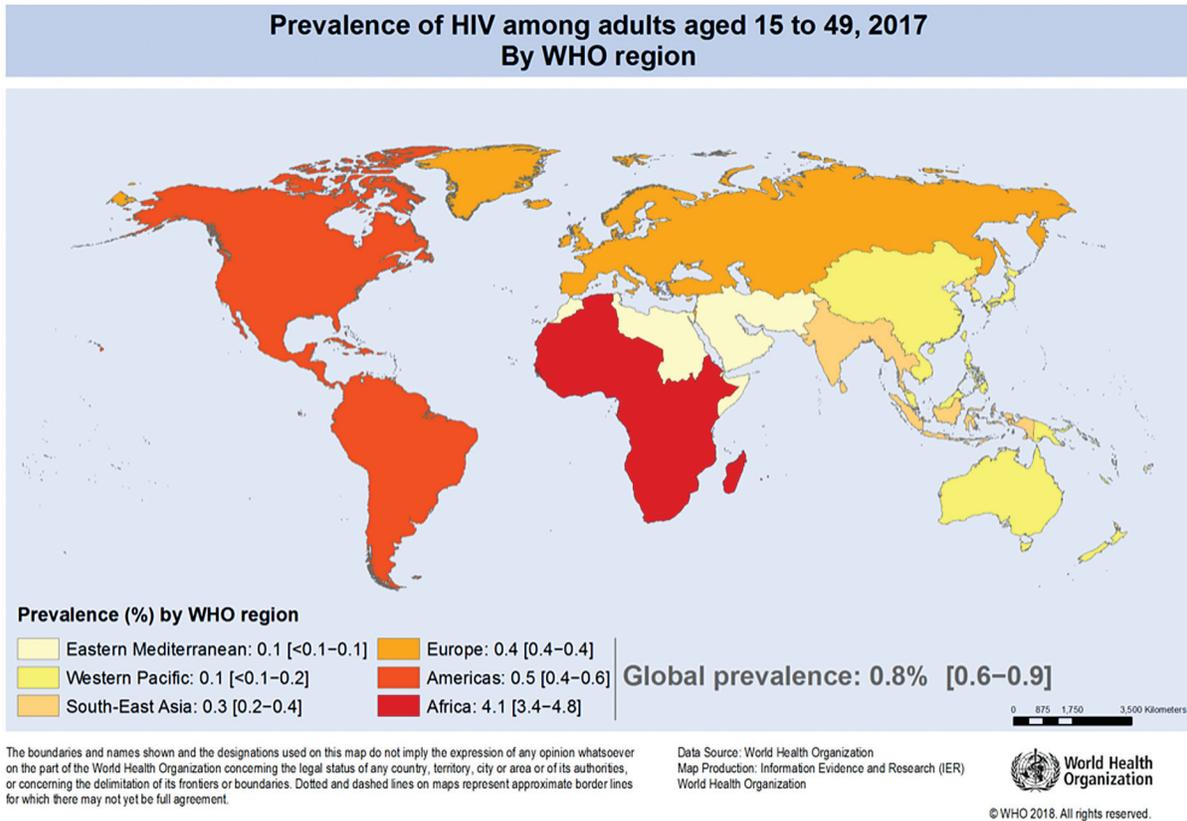

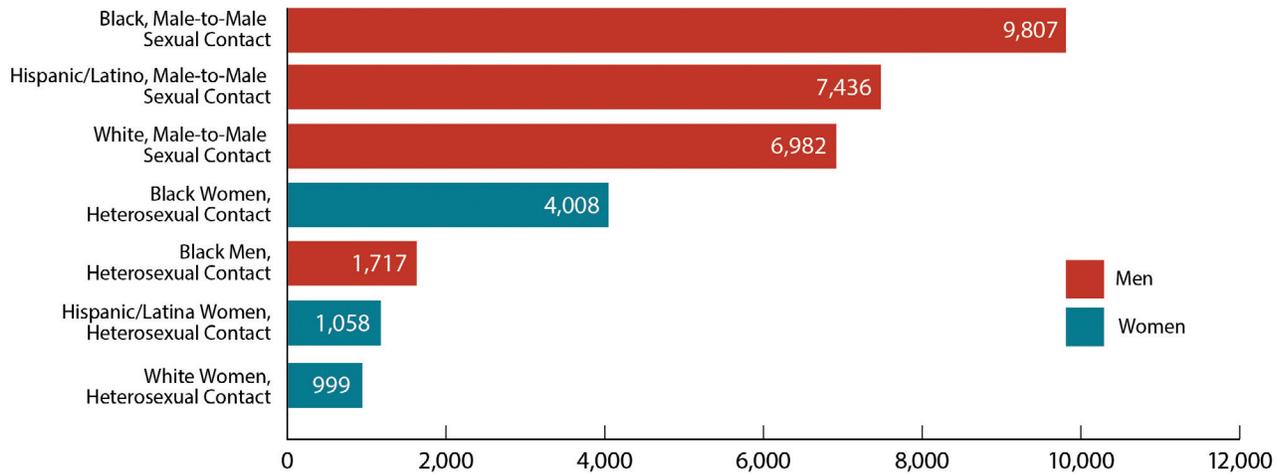

Fig. 36.1 Global prevalence of HIV/AIDS among adults aged 15 to 49. (World Health Organization [website]. https://www.who.int/gho/hiv/epidemic_status/prevalence/en/.)

Note: Subpopulations representing 2% or less of all people who received an HIV diagnosis in 2017 are not represented in this chart.

Fig. 36.2 Estimated percentage of HIV diagnoses by route of transmission in the United States, 2013. (Centers for Disease Control and Prevention [CDC]: *HIV Surveillance Report* [website]. <https://www.cdc.gov/hiv/library/reports/surveillance>, 2015.)

counts remain normal and viral loads can be undetectable for years without medical intervention (Department of Health and Human Services [DHHS], 2017). It has been suggested that this unique population has different and fewer receptor sites for the virus to penetrate cell membranes (Wanke et al, 2009).

In the majority of cases, HIV slowly breaks down the immune system, making it incapable of fighting the virus. When CD4+ cell counts fall below 500 cells/mm³ individuals are more susceptible to developing signs and symptoms such as persistent fevers, chronic diarrhea, unexplained weight loss, and recurrent fungal or bacterial infections, all of which are indicative of **symptomatic HIV infection**.

As immunodeficiency worsens and CD4 counts fall to even lower levels, the infection becomes symptomatic and progresses to AIDS. The progression of HIV to AIDS increases the risk of **opportunistic infections (OIs)**, which generally do not occur in individuals with healthy immune systems. The CDC classifies AIDS cases as positive laboratory confirmation of HIV infection in persons with a CD4+ cell count less than 200 cells/mm³ (or less than 14%) or documentation of an AIDS-defining condition (Box 36.1).

HIV is transmitted via direct contact with infected body fluids such as blood, semen, preseminal fluid, vaginal fluid, and breastmilk. Cerebrospinal fluid surrounding the brain and spinal cord, synovial fluid surrounding joints, and amniotic fluid surrounding a fetus are other fluids that can transmit HIV. Saliva, tears, and urine do not contain enough HIV for transmission. In the United States sexual transmission is the most common way HIV is transmitted, and injection drug use is the second most prevalent method of transmission (see Fig. 36.2).

Most HIV positive people have HIV-1 infection, which, unless specified, is the type discussed in this chapter. HIV-1 mutates readily and has become distributed unevenly throughout the world in different strains, subtypes, and groups. HIV-2, first isolated in Western Africa, is less easily transmitted, and the time between infection and illness takes longer.

MEDICAL MANAGEMENT

HIV-related morbidity and mortality stem from the HIV virus weakening the immune system as well as the virus's effects on organs (such

as the brain and kidneys). If untreated, the HIV virion (virus particle) can replicate at millions of particles per day and rapidly progress through the stages of HIV disease. Due to the ability of the virus to rapidly replicate and become drug resistant, taking more than one class of drugs allows for significantly decreased viral replication through targeting HIV on different pathways of replication. The introduction of three-drug combination ART in 1996 transformed the treatment of patients living with HIV and has significantly decreased AIDS-defining conditions and mortality (see Box 36.1). Previously, most drugs were formulated as individual medications, but increasingly many are available as fixed-dose (two or more drugs in a single pill) combinations to simplify treatment regimens, decrease pill burden, and potentially improve patient medication adherence.

CD4 count is used as a major indicator of immune function in people with HIV infection. CD4 counts generally are monitored every 3 to 4 months. In addition, HIV RNA (**viral load**) is monitored on a regular basis because it is the primary indicator to gauge the efficacy of ART. Initiation of ART is recommended for all individuals with HIV regardless of CD4 levels. There are a few occasions when ART would be deferred due to clinical and or psychosocial factors, but initiation of therapy is to be started as soon as possible (Roberts et al, 2016).

The fundamental goals of ART are to achieve and maintain viral suppression, reduce HIV-related morbidity and mortality, improve the quality of life, and restore and preserve immune function. This generally can be achieved within 10 to 24 weeks if there are no complications with adherence or resistance to medications (DHHS, 2017). Because the guidelines for HIV management evolve rapidly, it is beneficial to frequently check for updated recommendations.

Classes of Antiretroviral Therapy Drugs

Currently ART includes more than 25 antiretroviral agents from six mechanistic classes of drugs:

- Nucleoside and nucleotide reverse transcriptase inhibitors (NRTIs)
- Nonnucleoside reverse transcriptase inhibitors (NNRTIs)
- Protease inhibitors (PIs)
- Integrase inhibitors (INSTIs)

BOX 36.1 CDC Case Definition AIDS-Defining Clinical Conditions/Opportunistic Infections (OIs)

Bacterial infections, multiple or recurrent (among children <13 years)
 Candidiasis (bronchi, trachea, or lungs)
 Candidiasis (esophagus)
 Cervical cancer (invasive)
 Coccidioidomycosis (disseminated or extrapulmonary)
 Cryptococcosis (extrapulmonary)
 Cryptosporidiosis (intestinal, >1-month duration)
 Cytomegalovirus disease (other than liver, spleen, or nodes)
 Cytomegalovirus retinitis (with loss of vision)
 Encephalopathy (HIV related)
 Herpes simplex: chronic ulcers (>1-month duration)
 Herpes simplex: bronchitis, pneumonitis, or esophagitis
 Histoplasmosis (disseminated or extrapulmonary)
 Isosporiasis (intestinal, >1-month duration)
 Kaposi sarcoma
 Lymphoid interstitial pneumonia or pulmonary lymphoid hyperplasia complex
 Lymphoma, Burkitt (or equivalent term)

Lymphoma, immunoblastic (or equivalent term)
 Lymphoma, primary (brain)
Mycobacterium avium complex (disseminated or extrapulmonary)
Mycobacterium kansasii (disseminated or extrapulmonary)
Mycobacterium tuberculosis (any site, pulmonary, disseminated, or extrapulmonary)
Pneumocystis jirovecii pneumonia
 Pneumonia (recurrent)
 Progressive multifocal leukoencephalopathy
Salmonella septicemia (recurrent)
 Toxoplasmosis (brain)

Wasting syndrome attributed to HIV: >10% involuntary weight loss of baseline body weight plus (1) diarrhea (two loose stools per day for ≥30 days) or (2) chronic weakness and documented fever (≥30 days, intermittent or constant) in the absence of concurrent illness or condition other than HIV infection that could explain the findings (e.g., cancer, tuberculosis).

Schneider E et al: Revised surveillance case definitions for HIV infection among adults, adolescents, and children aged <18 months and for HIV infection and AIDS among children aged 18 months to <13 years—United States, 2008, *MMWR Recomm Rep* 57(RR-10):1, 2008.
 AIDS, Acquired immune deficiency syndrome; CDC, Centers for Disease Control and Prevention; HIV, human immunodeficiency virus.

- Fusion inhibitors
- Chemokine receptor 5 (CCR5) antagonists

Advances in HIV ART treatments have been moving rapidly. The focus of medication development includes continuing to create single tablet regimens, decreasing metabolic complications, decreasing overall toxicities, and better prevention of **drug resistance**. Nonadherence to ART can lead to drug resistance due to HIV's tendency to rapidly mutate.

Predictors of Adherence

When initiating ART, patients must be willing and able to commit to lifelong treatment, and they should understand the benefits and risks of therapy and the importance of adherence. The patient's understanding about HIV disease and the specific regimen prescribed is critical. A number of factors have been associated with poor adherence, including low levels of health literacy, neurocognitive impairment, psychosocial issues (e.g., mental illness, housing instability, low social support, stressful life events, dementia, or psychosis), active substance use, stigma, denial, difficulty with taking medication (e.g., trouble swallowing pills, daily schedule issues), complex regimens (e.g., pill burden, dosing frequency, food requirements), adverse drug effects, treatment fatigue, and inconsistent access to medication (DHHS, 2017).

Food insecurity has been associated with increased behaviors that can transmit HIV and decreased access to HIV treatment and care; it also can be a predictor of poor adherence (Singer et al, 2015; Young et al, 2014) because medications are costly and they often compete with food for available resources. Continued encouragement is needed to help patients adhere as closely as possible to the prescribed doses for all ART regimens.

Illicit Drug Use

In the United States injection drug use is the second most common mode of HIV transmission after sexual contact. The most commonly used illicit drugs associated with HIV infection are heroin, cocaine, and methamphetamine. The chaotic lifestyle associated with drug use is associated with poor or inadequate nutrition, food insecurity, homelessness, and mental health concerns. This complicates treatment of HIV if the individual is using drugs and potentially can lead to poor adherence with ART medications.

Injection drug use is linked strongly to transmission of blood-borne infections such as HIV, hepatitis B virus, and hepatitis C virus (HCV), especially if needles are reused or shared (see *Focus On: HIV and Hepatitis C Virus Coinfection*). Coinfection of HIV and HCV increases the risk of cirrhosis. Chronic HCV infection also complicates HIV treatment because of ART-associated hepatotoxicity. Special medical and nutrition treatment considerations should be taken into account if the liver is damaged from drug use, if there is coinfection with hepatitis, or if there is increased nutrient excretion from diuresis and diarrhea (Hendricks and Gorbach, 2009; Tang et al, 2010).

Food-Drug Interactions

Some ART medications require attention to dietary intake. It is important to ask individuals with HIV to report all medications, including vitamins, minerals, other supplements, and recreational substances that they consume in order to assess their needs fully and prevent drug interactions and nutrient deficiencies. Some nutrients can affect how drugs are absorbed or metabolized. Interactions between food and drugs can influence the efficacy of the drug or may cause additional or worsening adverse effects. For example, grapefruit juice and

FOCUS ON

HIV and Hepatitis C Virus Coinfection

About one quarter of people in the United States who have human immunodeficiency virus (HIV) also are coinfecting with hepatitis C virus (HCV). According to the Centers for Disease Control and Prevention (CDC), 70% of HIV-infected injection drug users also have HCV (CDC, 2017b). Although it is unknown if HCV accelerates HIV disease progression, it has been shown to damage the liver more quickly in HIV-infected persons. In the presence of hepatic impairment, the metabolism and excretion of antiretroviral medications may be impaired, affecting the efficacy of HIV treatment. In addition, three classes of anti-HIV medications (nucleoside and nucleotide reverse transcriptase inhibitors, nonnucleoside reverse transcriptase inhibitors, and protease inhibitors) are associated with hepatotoxicity. Therefore it is important for HIV-infected patients to be tested for HCV, preferably before starting ART, to appropriately manage treatment and prolong healthy liver function.

HCV is viewed as an opportunistic infection (OI) (not an acquired immune deficiency syndrome-defining illness) in HIV-infected persons because there are higher titers of HCV, more rapid progression to liver disease, and increased risk of cirrhosis (DHHS, 2017). Nutrition recommendations and dosing and choice of HIV medications must be adjusted for those with liver failure (see Chapter 29).

In 2014 the Food and Drug Administration (FDA) approved Harvoni, a simple one-pill-a-day regimen taken for 12 weeks.

Clinical studies show a 96% to 99% cure rate in individuals with HCV genotype 1 (Gritsenko and Hughes, 2015). The most common side effects of treatment are slow heart rate, weakness, fatigue, and headaches (Gilead Sciences, 2018).

PIs compete for the cytochrome P450 enzymes; thus individuals taking PIs who also drink grapefruit juice may have either increased or decreased blood levels of the drug. [Table 36.1](#) provides potential nutrient interactions with ART medications (see Appendix 13).

Some ART medications can cause diarrhea, fatigue, gastroesophageal reflux, nausea, vomiting, dyslipidemia, and insulin resistance. Timing is also important for ART efficacy, so patients with HIV must take medications on a schedule. Some medications indicate that they must be taken with food or on an empty stomach. Sometimes food must be taken within a specific time frame of administering a medication. Refer to [Table 36.1](#) for timing considerations with ART.

Medical Management

HIV infection should be confirmed by laboratory testing and not based on patient report (CDC, 2019). The presence of comorbidities such as heart disease, diabetes, hepatitis, and OIs may complicate the patient's treatment profile. Important assessment information includes the patient's past medical history and pertinent immediate family history for heart disease, diabetes, cancers, or other disorders. Metabolic issues such as dyslipidemia and insulin resistance are common in people with HIV due to inflammation from the viral infection and medication side effects, and are important to monitor. Biochemical measurements should be documented to determine the course of HIV treatment, efficacy of ART, and underlying malnutrition and nutrient deficiencies. Some common biochemical measurements include CD4 count, viral load, albumin, hemoglobin, iron status, lipid profile, liver function tests, renal function tests, glucose, insulin, and vitamin levels. [Table 36.2](#) discusses conditions associated with HIV and their nutritional implications.

TABLE 36.1 Medication Interactions and Common Adverse Effects

	Take with Meal or Snack	Take on Empty Stomach	Take Without Regard to Food	Nausea	Vomiting	Diarrhea	Hyperlipidemia	Hyperglycemia	Fat Maldistribution	Pancreatitis	Taste Alterations	Loss of Appetite	Anemia	Vitamin or Mineral Deficiencies	Liver Toxicity

TABLE 36.2 HIV-Related Conditions with Specific Nutrition Implications

Condition	Brief Description	Nutrition Implications
Pneumocystis pneumonia (PCP)	Potentially fatal fungal infection	Difficulty chewing and swallowing caused by shortness of breath
Tuberculosis (TB)	Bacterial infection that attacks the lungs	Prolonged fatigue, anorexia, nutrient malabsorption, altered metabolism, weight loss
Cryptosporidiosis	Infection of small intestine caused by parasite	Watery diarrhea, abdominal cramping, malnutrition and weight loss, electrolyte imbalance
Kaposi sarcoma	Type of cancer-causing abnormal tissue growth under the skin	Difficulty chewing and swallowing caused by lesions in oral cavity or esophagus Diarrhea or intestinal obstruction caused by lesions in intestine
Lymphomas	Abnormal, malignant growth of lymph tissue	Side effects from chemotherapy and cancer treatment - diarrhea, poor appetite, difficulty eating, neutropenia (see Chapter 35)
Brain abnormalities	Changes in motor and cognitive abilities	Inability to prepare food and coordinate movement
Small bowel abnormalities	Malabsorption	Weight loss, diarrhea, loss of appetite
Cytomegalovirus (disseminated)	Infection caused by herpes virus	Loss of appetite, weight loss, fatigue, enteritis, colitis
Candidiasis	Infection caused by fungi or yeast	Oral sores in mouth, difficulty chewing and swallowing, change in taste
HIV-induced enteropathy	Idiopathic, direct or indirect effect of HIV on enteric mucosa	Chronic diarrhea, weight loss, malabsorption, changes in cognition and behavior
HIV encephalopathy (AIDS dementia)	Degenerative disease of brain caused by HIV infection	Loss of coordination and cognitive function, inability to prepare food
<i>Pneumocystis jirovecii</i> pneumonia	Infection caused by fungi	Fever, chills, shortness of breath, weight loss, fatigue
<i>Mycobacterium avium</i> complex (disseminated)	Bacterial infection in lungs or intestine, spreads quickly through bloodstream	Fever, cachexia, abdominal pain, diarrhea, malabsorption

MEDICAL NUTRITION THERAPY

For people living with HIV, adequate and balanced nutrition intake is essential to maintain a healthy immune system, delay disease progression, and prolong life. As ART medications have evolved the overall risk for AIDS-related wasting has decreased and a shift to an increase in prevalence of obesity and cardiometabolic disease has occurred. Proper nutrition may help maintain lean body mass, reduce the severity of HIV-related symptoms (including cardiometabolic and digestive), improve quality of life, and enhance adherence to and effectiveness of ART. Therefore medical nutrition therapy (MNT) is integral to successfully manage HIV (see *Pathophysiology and Care Management Algorithm: Human Immunodeficiency Virus Disease*).

A registered dietitian nutritionist (RDN) can help patients mitigate potential adverse effects from medications or disease states and address nutritional concerns. Some common nutrition diagnoses in this population include the following:

- Inadequate oral food intake NI-2.1
- Inadequate energy intake NI-1.2
- Increased nutrient needs NI-5.1
- Swallowing difficulty NC-1.1
- Biting and chewing difficulty NC-1.2
- Altered gastrointestinal (GI) function NC-1.4
- Food-medication interaction NC-2.3
- Involuntary weight loss NC-3.2
- Overweight and obesity NC-3.3
- Food- and nutrition-related knowledge deficit NB-1.1
- Impaired ability to prepare foods or meals NB-2.4
- Poor nutrition quality of life NB-2.5

- Limited access to food NB-3.2
- Intake of unsafe foods NB-3.1

Having regular access to an RDN or other qualified nutrition professional can help PLWHA maintain a better quality of life. Patients are recommended to undergo a baseline nutrition assessment upon diagnoses with HIV (see Chapters 4 and 5). Because patients with HIV can have multifactorial complications, those who receive ongoing nutrition assessments have lower risk of complications from treatment. The Academy of Nutrition and Dietetics (AND) recommends that an RDN provide at least one to two MNT encounters per year for individuals with asymptomatic HIV infection and at least two to six MNT encounters per year for those with symptomatic but stable HIV infection (Willig, 2018). Individuals diagnosed with AIDS usually need to be seen more often because they may require nutrition support (see Chapter 12).

Ultimately, RDNs need to individualize MNT and determine frequency of nutrition counseling based upon the patient's needs. The major goals of MNT for persons living with HIV infection are to optimize nutritional status, immunity, and well-being; to maintain a healthy weight and lean body mass; to prevent nutrient deficiencies and reduce the risk of comorbidities; and to maximize the effectiveness of medical and pharmacologic treatments. Thus screening should be performed on all patients medically diagnosed with HIV to identify those at risk for nutritional deficiencies or in need of MNT. Due to the effects of HIV on the immune system, education around food safety concerns is important to discuss with clients, especially for individuals with low CD4 counts.

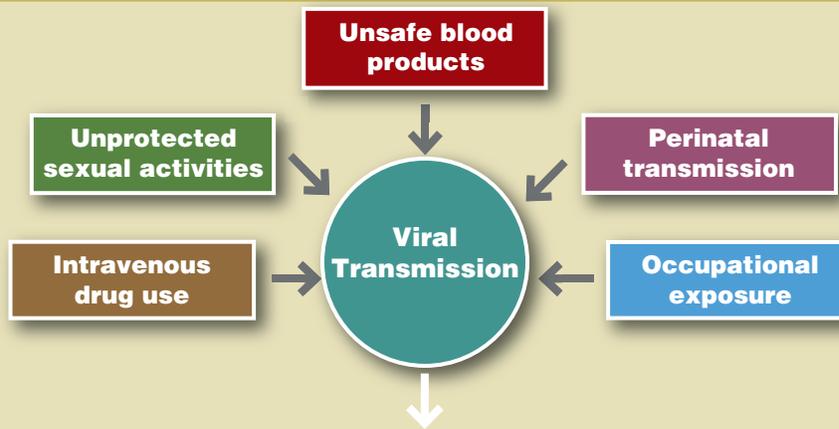

Patients who exhibit the various HIV-related symptoms or conditions listed in Table 36.3 would benefit from a referral to an RDN with

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Human Immunodeficiency Virus Disease

ETIOLOGY

PATHOPHYSIOLOGY

Clinical Findings

Acute HIV infection (Acute retroviral syndrome) Fever, fatigue, rash, headache, generalized lymphadenopathy, pharyngitis, myalgia, nausea/vomiting, diarrhea, night sweats, adenopathy, oral ulcers, genital ulcers, neurological symptoms, malaise, anorexia, weight loss, wasting syndrome

Seroconversion

HIV Positive Test HIV rapid tests; ELISA test, Western blot; PCR test

Asymptomatic HIV infection Abnormal metabolism, change of body composition (body cell mass loss with/without weight loss, lipodystrophy, lipohypertrophy), vitamin B₁₂ deficiency, susceptibility to pathogens

Symptomatic HIV infection Weight loss, thrush, fever, loss of LBM with/without weight loss, diarrhea, oral hairy leukoplakia, herpes zoster, peripheral neuropathy, idiopathic thrombocytopenic purpura, pelvic inflammatory disease

Asymptomatic AIDS

Symptomatic AIDS (AIDS defined conditions) CD4 cell count <200/mm³, opportunistic infectious diseases (pneumocystis jirovecii, pneumonia, others), Kaposi's sarcoma, lymphoma, HIV-associated dementia, HIV-associated wasting, vitamins/minerals deficiencies

MANAGEMENT

Medical Management

Treat possible co-morbidities

Hyperglycemia, hyperlipidemia, hypertension, body composition changes, pancreatitis, kidney and liver diseases, hypothyroidism, hypogonadism, osteopenia, hepatitis-C

Monitoring

Fasting blood lipid, fasting glucose/insulin level, protein status, blood pressure, TSH/testosterone level, CD4 cell count, and viral load

Medication

Antiretroviral therapy, lipid lowering agents, antidiabetic agents, antihypertensive agents, appetite stimulants, hormone replacement therapy, treatment for coinfectious diseases (i.e. hepatitis), prophylaxis and treatment for opportunistic infectious diseases

Nutrition Management

Considerations for generally healthy individuals with a well controlled viral load.

- Complete nutrition assessment 2-6 times/year
- Emphasize importance of early/ongoing nutritional intervention
- Promote adequate intake of nutrients and fluids, including vitamins A, B12, C, D, selenium, and zinc
- Emphasize regular exercise and physical activity
- Assess for psychosocial and economic barriers to food and provide resources
- Assess need for dietary supplementation, emphasizing food first when possible
- Inform patient of possible side effects, symptoms, and/or complications
- Monitor/manage metabolic and cardiovascular abnormalities (fasting glucose, blood lipids) and digestive complaints

Special considerations for symptomatic individuals with a high viral load and low CD4.

- Emphasize importance of food safety and sanitation
- Small, frequent, nutrient dense meals if necessary
- Monitor/manage gastrointestinal symptoms
- Appetite stimulants if necessary
- Parenteral nutrition if necessary
- Anabolic therapies

Management of drug side effects

TABLE 36.3 Nutrition Recommendations for Typical Adverse Effects

Adverse Effect	Nutrition Recommendations
Nausea, vomiting	<p>Eat small, frequent meals.</p> <p>Avoid drinking liquids with meals.</p> <p>Drink cool, clear liquids.</p> <p>Try dry crackers, rice cakes, or toast.</p> <p>Try bland foods such as potatoes, noodles, rice, or canned fruits.</p> <p>Try adding ginger to meals and sipping on ginger tea between meals.</p> <p>Limit high-fat, greasy foods or foods that have strong odors such as ripe cheese or fish.</p> <p>Eat foods at room temperature or cooler.</p> <p>Wear loose-fitting clothes.</p> <p>Rest sitting up after meals.</p> <p>Keep a log of when nausea and vomiting occur and which foods seem to trigger it.</p> <p>Try eating ready-to-eat foods to eliminate smells from cooking.</p> <p>Incorporate mindful eating techniques into meal and snack times.</p>
Diarrhea	<p>Eat low residue, well-cooked foods</p> <p>Try plain carbohydrates such as white rice, rice congee, noodles, crackers, or white toast.</p> <p>Try low-fiber fruits like bananas and applesauce.</p> <p>Drink fluids that will replace electrolytes such as broths and oral hydration drinks.</p> <p>Try small, frequent meals.</p> <p>Avoid fatty, greasy foods.</p> <p>Avoid highly spiced foods.</p> <p>Avoid sugary items such as soda and fruit juice.</p> <p>Avoid milk and milk products or choose lactose free.</p> <p>Limit caffeine.</p> <p>Try gentle probiotic and prebiotic foods such as Greek yogurt and bananas.</p> <p>Try supplementing with glutamine (5-10 grams 2-3 times per day).</p>
Loss of appetite	<p>Eat small, frequent meals.</p> <p>Avoid drinking too many liquids that contain no calories.</p> <p>Focus on nutrient-dense foods such as yogurt smoothies and high calorie meal replacement drinks and bars, eggs, avocado, Greek yogurt, nut butters, cheese and whole grain breads. Add extra oils and fats to foods.</p> <p>Try to eat in a pleasant environment or eating with friends and family.</p> <p>Assess for signs of depression or changes in mental health that could be factoring into appetite changes.</p>
Taste alterations	<p>Add spices and herbs to foods.</p> <p>Avoid canned foods or canned oral supplements as these can have a metallic taste.</p> <p>Keep mouth clean by frequently brushing teeth and rinsing mouth before and after eating.</p> <p>Use plastic utensils if metal ones taste bad.</p>
Hyperlipidemia	NCEP diet (see Chapter 32).
Hyperglycemia	Diet for patients with elevated blood sugar and diabetes (see Chapter 29).
Mouth and esophageal ulcers and sore throat	<p>Try soft foods such as oatmeal, rice, applesauce, scrambled eggs, refried beans, shredded lean meat or fish, avocado, pureed soups, smoothies, or yogurt.</p> <p>Avoid acidic foods such as citrus, vinegar, spicy, salty, or hot foods.</p> <p>Moisten foods with gravy or sauces.</p> <p>Drink liquids with meals.</p> <p>Avoid acidic beverages.</p> <p>Try foods and beverages at room temperature.</p> <p>Use a food processor or blender to create desired consistency</p>
Pancreatitis	<p>Focus on low-fat foods and limit fat at each meal (see Chapter 28).</p> <p>May need pancreatic enzymes to aid in digestion.</p>
Weight loss	<p>Eat small, frequent meals.</p> <p>Focus on nutrient-dense foods such as protein and calorie rich smoothies and meal replacement beverages, eggs, nut butters, avocado, Greek yogurt, trail mixes, and tofu.</p> <p>Add rice, barley, avocado, and legumes to soups.</p> <p>Add dry milk powder, Greek yogurt, or protein powder to casseroles, hot cereals, and smoothies.</p> <p>Add a little olive oil, avocado, or nuts to meals.</p>
Weight gain	<p>Balanced Mediterranean, anti-inflammatory or DASH dietary pattern.</p> <p>Identify triggers for overeating.</p> <p>Increase physical activity and strength training.</p>

NCEP, National Cholesterol Education Program.

TABLE 36.4 Factors to Consider in Nutrition Assessment

Medical	Stage of HIV disease Comorbidities Opportunistic infections Metabolic complications Biochemical measurements
Physical	Changes in body shape Weight or growth concerns Oral or gastrointestinal symptoms Functional status (i.e., cognitive function, mobility) Anthropometrics
Social	Living environment (support from family and friends) Behavioral concerns or unusual eating behaviors Mental health (i.e., depression)
Economical	Barriers to nutrition (i.e., access to food, financial resources)
Nutritional	Typical intake Food shopping and preparation Food allergies and intolerances Vitamin, mineral, and other supplements Alcohol and drug use

HIV, Human immunodeficiency virus.

expertise in managing this disease. A comprehensive nutrition assessment should be performed at the initial visit. In addition, regular monitoring and evaluation are essential to detect and manage any undesirable nutritional consequences of medical treatments or the disease process. Strategies for managing the adverse effects are given in [Table 36.3](#). Key factors to assess are listed in [Table 36.4](#).

Anthropometry and Body Composition Measurements

Historically, the prevalence of undernutrition, AIDS-related wasting syndrome, and **HIV-associated lipodystrophy syndrome (HALS)** were much higher, but with advancements in HIV care and treatments these conditions occur less frequently ([Table 36.5](#)). Even though rates are lower, it is still important to assess patients early and evaluate for both undernutrition and overnutrition. Taking anthropometric measurements during the initial assessment provides a baseline for understanding the patients' nutritional status. Patients with HIV are aware of changes in their body shape and are instrumental in identifying these changes. Asking patients about body shape changes every 3 to 6 months helps practitioners catch any changes early on. Changes in body shape and fat redistribution can be monitored by anthropometric measurements. Commonly these are taken as circumferences around the waist, hip, midupper arm, and thigh, and as skinfold measurements of the triceps, subscapular, suprailiac, thigh, and abdomen. The use of **Bioelectric Impedance Analysis (BIA)** (see Chapter 5) can be a helpful tool for monitoring changes in both lean body mass and fat mass. Due to the decreased reliability of BIA in the presence of dehydration, which commonly can occur in individuals experiencing wasting and chronic diarrhea, the use of Bioelectric Impedance Vector Analysis (BIVA) can be a more useful aid in assessing nutritional status.

Wasting

Wasting implies unintentional weight loss and loss of lean body mass that is equal to or greater than 10% of a person's body weight and may be seen along with diarrhea and fever that is not associated with an infection ([U.S. Department of Veterans Affairs, 2018](#)). Wasting is strongly associated with an increased risk of disease progression and mortality.

TABLE 36.5 HIV-Associated Lipohypertrophy and Lipoatrophy

Lipohypertrophy: Fat buildup	Lipoatrophy: Fat loss
Can occur: <ul style="list-style-type: none"> • Around the organs in the abdomen • On the back of the neck between the shoulders (buffalo hump) • In the breasts • Just under the skin, causes fatty bumps called lipomas 	Can occur: <ul style="list-style-type: none"> • In the arms and legs • In the buttocks • In the face
Primary interventions: <ul style="list-style-type: none"> • Diet and exercise • Metformin (in patients with diabetes mellitus) 	Primary interventions: <ul style="list-style-type: none"> • Switch HIV medications that contain a thymidine analog (stavudine or zidovudine to abacavir or tenofovir)

Guzman N, Al About AM: HIV-associated lipodystrophy. In: *StatPearls [Internet]*. Treasure Island (FL), StatPearls Publishing, 2019. Available from: <https://www.ncbi.nlm.nih.gov/books/NBK493183/>. Updated October, 27 2018.

HIV, Human immunodeficiency virus.

The populations most at risk of experiencing wasting are individuals not receiving ART. Although wasting may be caused by a combination of factors, including inadequate dietary intake, malabsorption, and increased metabolic rates from viral replication or complications from the disease. Inadequate dietary intake can be caused by several issues related to conditions that affect the ability to chew or swallow food, gastrointestinal motility, neurologic diseases that affect perceptions of hunger or ability to eat, food insecurity related to psychosocial or economic factors, and anorexia from medications, malabsorption, systemic infections, or tumors ([Mankal and Kotler, 2014](#)). Until the underlying cause of weight loss is discovered, it will remain difficult to target effective nutrition therapy. It is important to closely monitor patients for unintentional weight loss because it can indicate progression of HIV disease.

HIV-associated Lipodystrophy Syndrome (HALS)

There is no consensus on the clinical definition of HALS, and the manifestations vary greatly from patient to patient. The syndrome encompasses both the metabolic abnormalities and body shape changes seen in some, but not all patients with HIV, similar to metabolic syndrome found in the general population. The lipodystrophy body shape changes that can occur include a buildup of body fat (**lipohypertrophy**) or loss of body fat (**lipoatrophy**). Individuals typically present with one or the other, but some present with a mixed picture of both ([Figs. 36.3 and 36.4](#)). Metabolic abnormalities have been associated with both lipohypertrophy and lipoatrophy and can also develop separately with no body composition changes ([Currier, 2018](#)). The most common metabolic abnormalities include hyperlipidemia (particularly high triglycerides and low-density lipoprotein [LDL] cholesterol and low high-density lipoprotein [HDL] cholesterol) and insulin resistance. These factors raise concern for increased risk of cardiovascular disease.

Cardiometabolic Risk

Individuals living with HIV are at a 1.5 to 2.0 increased risk for cardiovascular disease (CVD), compared with the general population ([Glesby, 2017](#)). Increasing evidence shows that this elevated risk is in

Fig. 36.3 **A**, Preoperative view of a 48-year-old man with cervicodorsal lipodystrophy that developed 7 years before his initial consultation. He also complained of anterior neck lipodystrophy and facial lipoatrophy. **B**, Postoperative view 21 months after excisional lipectomy, SAL of the cervicodorsal fat pad, rhytidectomy, anterior neck lift with submental fat excision, and autologous fat transfer from the abdomen to the nasolabial folds bilaterally.

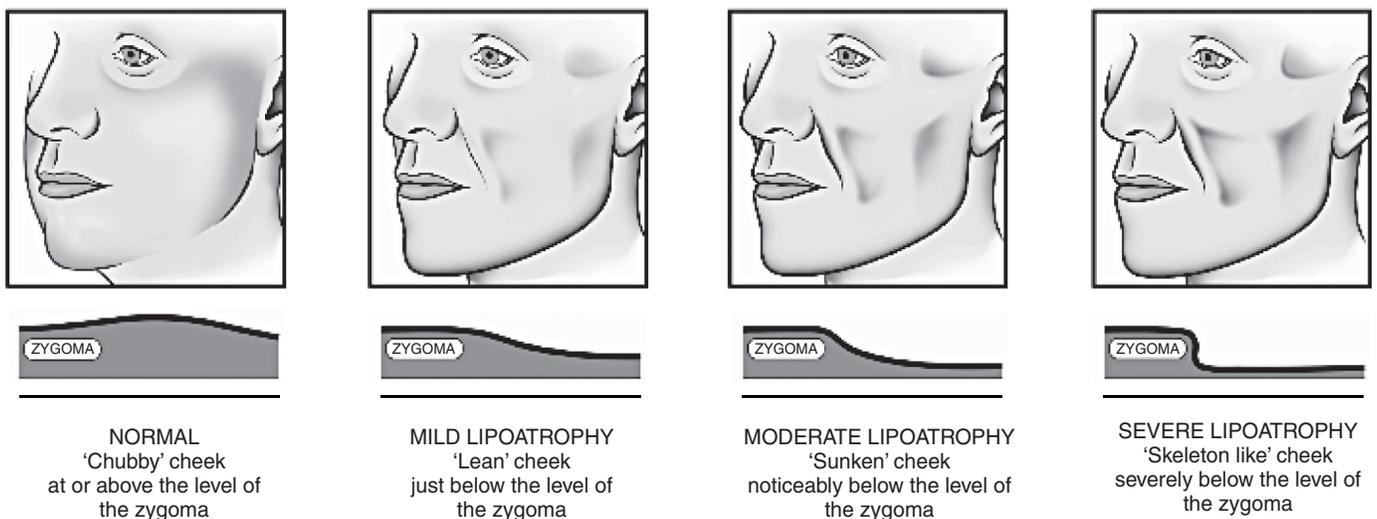

Fig. 36.4 Lipoatrophy over the zygoma or cheekbone. Note: Zygoma = cheekbone. Source: St Stephens AIDS Trust, Chelsea and Westminster Hospital

part due to chronic immune activation and inflammation from the HIV virus itself, as well as the effects of ART on lipid profiles.

Inflammation plays a role in the general development of atherosclerosis, and HIV has been linked to an increase in several markers of inflammation including C-reactive protein (CRP) and interleukin (IL)-6. This low-level chronic activation of the immune system may adversely affect endothelial cells and promote a prothrombotic environment leading to atherosclerosis and plaque rupture (Currier, 2019).

Additionally, various medications have been shown to elicit a greater effect on lipid profiles than others (see Table 36.1). Even though receiving ART has been shown to increase risk of cardiovascular events,

not starting or being on ART increases risk of CVD to a greater extent (Currier, 2018).

Other general risk factors of CVD must also be taken into account when assessing an individual's CVD risk such as hypertension, diabetes mellitus, dyslipidemia, and cigarette smoking.

The cause of HALS is multifactorial and includes duration of HIV infection, duration and type of ART medications, age, gender, race and ethnicity, increased viral load, and increased body mass index (BMI). It is important to monitor individual anthropometric measurements along with blood lipid profile, A1C, and blood glucose.

For nutrition recommendations regarding lipohypertrophy and metabolic abnormalities, the guidelines set by the American Heart Association (AHA), the American College of Cardiology (ACC), and the American Diabetes Association are followed (see Chapters 29 and 32). Patients who complement a cardio-protective diet (see Chapter 32) with regular physical activity, such as aerobic exercise and resistance training, are likely to see further improvements in their health.

For patients who have high triglycerides, omega-3 fatty acids may be useful. Studies focusing on the impact of omega-3 fatty acids in individuals with HIV are limited. Some studies have shown 2 to 4 g of fish oil supplements per day lower serum triglyceride levels in patients with HIV (Paranandi et al, 2014). In a meta-analysis, which included four studies, omega-3 fatty acids intake lowered serum triglyceride concentrations in PLWHA on ART (Oliveira and Rondó, 2011). However, because the studies were not homogenous with regards to dose, population, and length of intervention, it is challenging to determine the amount of omega-3 fatty acids needed to see positive benefits. Nevertheless, supplementing with omega-3 fatty acids tends to be low risk and potentially beneficial. Coordination of care is advised for supplementation above 3 grams eicosapentaenoic acid (EPA)/ docosahexaenoic acid (DHA). This can help to mitigate potential side effects from supplementation including GI distress, hyperglycemia, and increased LDL cholesterol levels. It is important to discuss and monitor use of dietary supplements with each patient's health care team.

Obesity

Obesity in people with HIV also has been noted. Unintentional weight loss in HIV infection has been associated with mortality, but more careful review of individuals with a BMI greater than 25 kg/m² is needed. Recently a lower risk of developing a noncommunicable disease was observed among HIV-positive adults initiating ART who had a BMI of 25 to 29.9 kg/m² compared with HIV-positive adults initiating ART with a BMI of less than 25 kg/m² (Koethe et al, 2015). However, excess adiposity is associated with cardiovascular risk factors and inflammation. In the era of ART, it is no longer believed that continuously gaining body weight is a protective cushion against HIV-related wasting and progression to AIDS.

Some of the ART medications increase the risk of hyperlipidemia, insulin resistance, and diabetes. It is important to monitor these risk factors and provide nutrition recommendations to maintain a healthy weight. Physical activity, aerobic exercise, and resistance training are recommended to work synergistically with optimal nutrition intake to achieve a healthy weight and maintain lean body mass.

Social and Economic Factors

Depending on a patient's mental status, psychosocial issues may take precedence over nutrition counseling. Mental health conditions such as depression, bipolar disorder, anxiety, and posttraumatic stress disorder (PTSD) are common. Monitoring for mental health issues is important in order to provide referrals or engage in coordination of care with the patient's health care providers.

When individuals are unable to care for themselves, discussion with caretakers may be necessary to understand the patient's nutrition history. Particular habits, food aversions, timing of meals with medications, and related concerns should be documented.

Evaluation of access to safe, affordable, and nutritious food is a priority as this information will guide appropriate interventions. Common barriers include cost, location of supermarkets, lack of transportation, and lack of knowledge of healthier choices. Furthermore, stigma not only is a predictor of ART adherence, but also may prevent individuals with HIV from using nutrition programs and seeking support systems. HIV-related stigma is hypothesized to be a strong deterrent from seeking medical care, treatment, or support.

Marginalized populations, such as racial/ethnic minorities and those in the lesbian, gay, bisexual, transgender, queer (LGBTQ) community, often face increased discrimination and stigma, making them less likely to engage in health care. Additionally, some PLWHA, such as young gay African American males and transgender women, may be more likely to be experiencing multiple layers of marginalization and decreased community support (Arnold et al, 2014; Mayer et al, 2016). Providers who are mindful of individual considerations, such as preferred gender pronouns (e.g., he, she, they) and cultural food preferences, help to reduce stigmatization (see Chapter 10).

Nutrient Recommendations

When collecting the diet history, include a review of current intake, changes in intake, limitations with food access or preparation, food intolerances or allergies, supplement use, current medications, and alcohol and recreational drug use to help determine the potential for any nutrient deficiencies and assist in making individualized recommendations (see Chapter 4).

Adequate nutrition intake can help patients with HIV with symptom management and improve the efficacy of medications, disease complications, and overall quality of life (see Fig. 36.5 for a sample nutrition screening form). Note that a one-size-fits-all approach does not address the complexity of HIV. Recommendations in Box 36.2 to improve nutritional status, immunity, and quality of life; address drug-nutrient interactions or side effects; and identify barriers to desirable food intake should be personalized for the patient.

Energy and Fluid

When determining energy needs, take into consideration factors such as weight loss or gain, altered metabolism, nutrient deficiencies, severity of disease, comorbidities, and OIs, which can impact energy needs. Calculating energy and protein needs for this population is difficult because of other issues with wasting, obesity, HALS, and lack of accurate prediction equations. Some research suggests that resting energy expenditure is increased by approximately 10% in adults with asymptomatic HIV (Kosmiski, 2011). Limited research suggests that energy expenditure may increase by a similar amount in virally immune suppressed individuals on antiretrovirals. After an OI, nutritional requirements may increase up to 20% to 50% in adults and children (World Health Organization [WHO], 2005a). Continuous medical and nutrition assessment is necessary to make adjustments as needed. Individuals with well-controlled HIV are encouraged to follow the same principles of healthy eating and fluid intake recommended for the general population (see Chapter 10).

Generalized nutrient recommendations for transgender HIV patients are not yet established so clinicians need to determine which comparative standards to use when calculating energy needs. Gender-neutral kcal/kg calculations may be preferred. Notable metabolic changes following hormone therapy include the potential for transgender women on antiandrogens and estrogen therapy to exhibit a decrease in lean body mass and an increase in body fat. In turn, transgender men who receive androgen therapy may exhibit an increase in lean body mass and a decrease in body fat (World Professional Association for Transgender Health [WPATH], 2012; Wellington et al, 2012).

Protein

Currently, limited evidence-based research exists around ideal protein intake for PLWHA. When determining protein needs the clinician must take into account an individual's weight, activity level, other comorbidities, and complications related to HIV. The Association of Nutrition Services Agency (ANSA) proposed protein recommendations between 1.0 g/kg to 1.4 g/kg for weight maintenance and 1.5 g/kg

HIV/AIDS Screening Form

DATE: _____
 Patient Name: _____ MR#: _____
 DOB: _____ Age: ___ Yrs. ___ Mos. Gender: Male Female
 Medical Provider: _____

Ensure that all people with HIV infection are screened for nutrition-related problems, based on referral criteria regardless of setting, at each primary care provider visit. **Review and check all that apply:**

High Risk (HR) To Be Seen by RDN Within One Week	Moderate Risk (MR) To Be Seen by RDN Within One Month	Low Risk (LR) To Be Seen by RDN at Least Annually
A. HIV Diagnosis and Nutrition Assessment		
	<input type="checkbox"/> 1. HIV or AIDS newly diagnosed <input type="checkbox"/> 2. No nutrition assessment by a registered dietitian or not seen by a registered dietitian in 12 months <input type="checkbox"/> 3. Patient requests RDN consult	
B. Body Composition and Weight Concerns		
<input type="checkbox"/> 1. New wasting diagnosis <input type="checkbox"/> 2. Poor growth, lack of weight gain or failure to thrive in pediatric patients <input type="checkbox"/> 3. Five (5%) or more unintentional weight loss within four weeks <input type="checkbox"/> 4. Ten (10%) or more unintentional weight loss over four to six months, (% weight change = last body wt – current body weight / last body weight x 100)	<input type="checkbox"/> 1. Underweight (< 20 BMI) <input type="checkbox"/> 2. Evidence or suspected muscle loss <input type="checkbox"/> 3. Obesity (>30 BMI) <input type="checkbox"/> 4. Client or provider initiated weight management <input type="checkbox"/> 5. Evidence for body fat change: <input type="checkbox"/> a. Central fat adiposity <input type="checkbox"/> b. Fat accumulation: <input type="checkbox"/> 1. Neck <input type="checkbox"/> 2. Upper back <input type="checkbox"/> 3. Breasts <input type="checkbox"/> 4. Other: _____	<input type="checkbox"/> 1. BOX 36.2 Nutrition Education and MNT for the HIV Infected

Pregnancy, Lactation, Infancy, and Childhood

Nutrition and food choices for healthy pregnancy and lactation
 Transmission risk in breastfeeding and replacement feeding alternatives
 Growth failure and developmental delay in children
 Support for normal growth trends in children

Adolescents and Adults

Basic nutrition concepts and healthy habits, cardio-protective diet
 Physical activity recommendations
 Body image and altered body weight and shape
 Attention to cultural or ethnic practices

Nutrition Interactions

Prevention, restoration, and maintenance of optimal body composition with an emphasis on lean tissues

Food medication interactions

Management of barriers to nutritional wellness, nutrition-related side effects of treatments, and symptoms requiring attention

Review of beverage or nutrient supplements

Review of potential interactions with nonprescription medications and herbal supplements

Evaluation of alcohol and recreational drug use

Life Skills and Socioeconomic Issues

Safe food handling and water sources

Access to adequate food choices

Food preparation skills and abilities

to 2.0 g/kg for increasing lean body mass. Recognize that these recommendations are educated guesses, not based on experimental studies; however, evidence suggests that protein needs tend to increase as CD4 counts drop below 500, particularly when HIV progresses to AIDS (Cervero and Watson, 2015). It is important for dietitians to individualize protein needs and consider weight changes and OIs (AND, 2010). With an OI, an additional 10% increase in protein intake may be recommended because of increased protein turnover (WHO, 2005b).

Fat

Currently PLWHA without other risk factors for CVD are recommended to follow the dietary reference intake (DRI) for dietary fat intake, 20% to 35% total calories as fat and <10% saturated fat (Richmond et al, 2010). If individuals have hyperlipidemia, tailor fat intake to help reduce risk of CVD (AND, 2010) (see Chapter 32). Additionally, promising research suggests that increasing the intake of omega-3 fatty acids may decrease serum triglycerides, reduce inflammation, and improve depression (Paranandi et al, 2014; Ravi et al, 2016).

Micronutrients

Vitamins and minerals are important for optimal immune function. Nutrient deficiencies can affect immune function and lead to disease progression. Micronutrient deficiencies are common in people with HIV infection as a result of malabsorption, drug-nutrient interactions, altered metabolism, gut infection, and altered gut barrier function. Vitamin A, zinc, and selenium serum levels are often low during a response to infection, so it is important to assess dietary intake to determine whether correction of serum micronutrients is warranted (Coyne-Meyers and Trombley, 2004).

There are benefits to correcting some depleted serum levels of micronutrients. Low levels of vitamins A, B₁₂, and zinc are associated with faster disease progression. Higher intakes of vitamins C and B have been associated with increased CD4 counts and slower disease progression to AIDS (Visser et al, 2017).

Studies on micronutrients are difficult to interpret because there are a variety of study designs and outcomes. Serum micronutrient levels reflect conditions such as acute infection, liver disease, technical parameters, and recent intake. Adequate micronutrient intake can be achieved through consumption of a balanced, healthy diet. However, diet alone may not be sufficient for some people living with HIV. A multivitamin and mineral supplement that provides 100% of the DRI also may be recommended for PLWHA who are unable to consistently meet daily micronutrient recommendations solely through dietary intake (Forrester and Sztam, 2011; Visser et al, 2017).

Research has been increasing in the area of micronutrient supplementation in people with HIV. It is important to consider the populations in which these studies have been conducted, and the findings need to be individualized to the client's needs. Factors to consider are underlying nutritional status, the stage of HIV infection or AIDS, use of ART medications, the presence of coinfections, and indication of an actual micronutrient deficiency (preferably from laboratory documentation), as well as intended length of supplement use. Caution should be used when recommending micronutrient supplementation for all people with HIV, because megadosing on some micronutrients such as vitamin A and zinc can have adverse outcomes (Coyne-Meyers and Trombley, 2004; Forrester and Sztam, 2011).

Studies have suggested that selenium supplementation may slow HIV progression (Baum et al, 2013). However low serum 25-hydroxy vitamin D levels may hasten HIV disease progression and increase disease progression and all-cause mortality, alluding to a possible benefit of vitamin D supplementation in people with HIV with a vitamin D deficiency (Shepherd et al, 2014; Eckard and McComsey, 2014). Certain medications, such as Efavirenz, have also been found to interfere with the metabolism of Vitamin D, making individuals on these medications at

greater risk for deficiency. Vitamin D₃ supplementation has been effective at correcting these deficiencies (Eckard and McComsey, 2014). Recent studies also suggest that Vitamin D₃ and calcium supplementation may slow bone loss following initiation of ART (Overton et al, 2015).

The challenging question is whether a low serum micronutrient laboratory value is indicative of a true deficiency or an acute phase response to the virus (Forrester and Sztam, 2011). Because of these uncertainties, micronutrient supplementation should be thoroughly evaluated before being prescribed and, if indicated, be monitored to determine the optimal dosage and duration for supplementation.

The most beneficial levels of micronutrient supplementation have yet to be determined. At this time, there is not enough evidence to support micronutrient supplementation in adults with HIV infection above the recommended levels of the DRI (Kawai et al, 2010; AND, 2010) (Table 36.6).

Gastrointestinal Health

While PLWHA are experiencing less side effects overall, gastrointestinal symptoms are some of the most commonly reported side effects from use of ART (see Table 36.1). Additionally, emerging research indicates that HIV-positive individuals have significantly altered intestinal microbiota composition compared with HIV-negative individuals, regardless of medical management. This appears to be more prevalent among those with lower CD4 count, as CD4 T cells are involved in the regulation and promotion of beneficial microbes (Lozupone et al, 2013; Bandera et al, 2018). Dietitians play an important role in helping patients mitigate symptoms such as nausea, poor appetite, or diarrhea. Recommendations may range from suggesting more easily digestible foods for someone with diarrhea or helping a patient with nausea figure out the most tolerable foods to eat before taking medications. Nutrition recommendations are listed in Table 36.3.

Dietary supplements such as protein powder and protein-rich smoothies or soups may be helpful for patients who have difficulty meeting protein needs. Probiotics, yogurt, and glutamine may help those with gastrointestinal side effects. Although the evidence is conflicting whether glutamine may reduce antiviral (ARV) drug-related diarrhea, more promising research suggests it may improve intestinal permeability. The best results came from clinical trials where glutamine was combined with other amino acids, such as alanyl-glutamine, or glutamine in combination with arginine and beta-hydroxy-beta-methylbutyrate (Cervero and Watson, 2015; Clark et al, 2000; Leite et al, 2013). The recommended dosage of glutamine has yet to be determined; however, studies have demonstrated enhanced intestinal absorption with well-tolerated doses ranging from 3 g to 40 g and improved nelfinavir-associated diarrhea with doses of 10 g taken three times daily (Cervero and Watson, 2015; Huffman and Walgren, 2003).

Probiotics are beneficial microorganisms that may be consumed in the form of cultured or fermented foods, or as a dietary supplement. Probiotics are used clinically to help support intestinal barrier function. Certain strains, such as *Lactobacillus rhamnosus* GG, have been beneficial in helping to prevent diarrhea and inflammatory bowel diseases (Rao and Samak, 2013). Studies illustrate mixed results with the use of probiotics for antiretroviral-associated diarrhea, with most studies showing some benefit (Carter et al, 2016; D'Angelo et al, 2017). It is important to note that supplements vary in concentration, absorption, and product integrity. Products with the *live and active cultures* seal are preferential as these products should contain at least 100 million (10⁸) cultures per gram at the time of manufacture (Sanders, 2003). The best food sources of probiotics include lactic acid fermented foods such as yogurt, sauerkraut, and olives (Hakansson and Molin, 2011). In order to get the most benefits from probiotics, in any form, it is best for individuals to regularly consume probiotics along with prebiotics which feed probiotics. Good food sources of prebiotics include chicory root, dandelion greens, garlic, onion, oats, barley, and bananas.

TABLE 36.6 Common Micronutrient Deficiencies and Indications for Supplementation

Vitamin or Mineral	Potential Cause for Deficiency	Results of Vitamin Deficiency	Supplementation Indications
B ₁₂	Malabsorption Inadequate intake	Increased risk of progression to AIDS Dementia Peripheral neuropathy Myelopathy Diminished performance (information processing and problem-solving skills)	Little evidence for benefits of supplementation beyond correcting low serum levels
A	Inadequate intake Fat malabsorption	Increased risk of progression to AIDS	Necessary to correct low levels Should not exceed DRI when serum levels are normal High intakes beyond correcting low levels can be detrimental to health and potentially increase risk of mortality from AIDS (Coyne-Meyers and Trombley, 2004) Needs more research
Beta-carotene	Inadequate intake Fat malabsorption	Potential relationship with oxidative stress Potentially weakens immune function	May increase lung cancer risk in smokers, avoid mega-doses Needs more research
E	Inadequate intake Fat malabsorption	Potential increased progression to AIDS Oxidative stress Impaired immune response	High intake: may be associated with increased surrogate markers of atherosclerosis Needs more research
D	Inadequate intake Inadequate exposure to sunshine Fat malabsorption Kidney disease Medications	Immune suppression Poor calcium absorption Low bone mineral density	Correct low levels Needs more research
Selenium	Inadequate intake	Potential increased progression to AIDS Weakened immune function Oxidative stress	Multivitamin/mineral providing DRI Higher doses not recommended at this time until further research
Zinc	Inadequate intake Diarrhea	Increased risk for HIV-related mortality Weakened immune system Impaired healing processes Lower CD4 counts	Recommend supplementing to intakes of DRI High levels above DRI may lead to faster disease progression Needs more research
Iron	Low levels during initial asymptomatic HIV infection caused by inadequate absorption Inadequate intake	Anemia Progression and mortality in HIV infection Increased susceptibility to and severity from other infections such as TB	Correct low levels as needed Recommend intakes at DRI High levels potentially lead to increased viral load Needs more research

HIV IN WOMEN

Around the world, women represent about half the people who are living with HIV or AIDS. In the United States women accounted for 7529 (19%) of the estimated number of new HIV infections in 2017 (CDC, 2017a). The highest rate of new HIV infection was seen in African American women, representing 61% of new diagnosis, more

than 3 times higher than white or Latina women, although the rate has decreased by 20% since 2013 (CDC, 2017a).

Women contract HIV less than men in the United States, but several factors put them at higher risk. Biologically, women are more likely to get HIV during unprotected vaginal sex because the lining of the vagina provides a larger area that can be exposed to HIV-infected semen. Barriers to receiving appropriate medical care also exist. Social

and cultural stigma, lack of financial resources, responsibility of caring for others, and fear of disclosure may prevent women from seeking proper care. Stigma and discrimination is thought to be particularly high among African American women living with HIV in the Southern states (Fletcher et al, 2016).

Preconception and Prenatal Considerations

Receiving counseling before conception can help HIV-positive women of childbearing age decrease the risk of perinatal transmission. Current recommendations include prenatal screening for HIV, hepatitis C virus, and tuberculosis infection; initiation of ART during pregnancy; and ART for the child once they are born. In the United States these interventions have reduced the risk of perinatal transmission to less than 2% (DHHS, 2012). Monitoring HIV-positive pregnant women during pregnancy can help prevent nutritional deficiencies.

Postpartum and Other Considerations

In the United States breastfeeding is not recommended for HIV-infected women, including those on ART, or where safe, affordable, and feasible alternatives are available and culturally appropriate (Kemp, 2017; CDC, 2018). Banked milk from human milk banks is an option (see *Focus On: What Is a Human Milk Bank?* in Chapter 41). In developing countries, recommendations may differ depending on safety and availability of formula and access to clean drinking water and availability of human milk banks.

HIV IN CHILDREN

An estimated 180,000 new HIV infections occurred globally among children younger than the age of 15 in 2017. In 2016 in the United States, 99 children under the age of 13 received a diagnosis of perinatally acquired HIV. The majority of these infections stem from perinatal transmission in utero, during delivery, or through consumption of HIV-infected breastmilk (UNAIDS, 2017). Premastication (chewing foods or medicine before administering to a child) also has been reported as a route of transmission through blood in saliva (CDC, 2011).

Growth is the most valuable indicator of nutritional status in childhood. Poor growth may be an early indicator for progression of HIV disease. Growth failure can result from HIV infection itself and HIV-associated OIs (Vreeman et al, 2015; WHO, 2010) (see Appendices 4 through 11).

HIV treatment has improved the clinical outcomes for children, with ART initiation resulting in significant catch-up in weight and height, but not to the level of uninfected children. The presence of HALS seen in adults is also seen in children (Miller et al, 2012). Multivitamin and micronutrient supplementation may be beneficial at the DRI levels for children who are malnourished. Research does not currently support any supplementation at higher doses.

INTEGRATIVE AND FUNCTIONAL NUTRITION (IFN)

The use of IFN is prevalent in patients with HIV infection. The Natural Medicines Database suggests that IFN use in people living with HIV and AIDS is about 53% (Natural Medicines Clinical Management Series, 2019). Vitamins, herbs, and supplements are the most common followed by prayer and other spiritual approaches (Lorenc and Robinson, 2013). People experiencing greater HIV symptom severity and longer disease duration are more likely to use complementary and integrative medicine (CIM) (Lorenc and Robinson, 2013).

Despite the high percentage of IFN use, less than one third of patients disclose IFN use to their health care providers (Reed and Lagunas, 2012). Some patients with HIV have noted benefits with taking dietary supplements; however, patients need to be made aware of any potential interactions with ART medications. In addition, caution with anecdote-based remedies should be monitored regarding credibility for a vulnerable population such as PLWHA (Kalichman et al, 2012). It is important to gather a detailed list of all dietary supplements in order to screen for potential drug-nutrient interactions and side effects.

Several popular dietary supplements have a significant potential drug-nutrient interactions with ART medication. For example concentrated garlic supplements and St. John's wort (*Hypericum perforatum*) decrease blood levels of ART medications, decreasing the efficacy of ART and potentially leading to drug resistance. Additionally, while some studies have shown potential antiretroviral properties of spirulina blue-green algae, supplemental use is not advised as there is potential for it to be contaminated with pathogenic microorganisms (Ngo-Matip et al, 2015; Winter et al, 2014).

Probiotic supplements, with or without prebiotics, are commonly used for reducing HIV/AIDS-related infectious diarrhea and general dysbiosis (see Gastrointestinal Health). Current research is also examining how altering microbiota may impact immune health. Probiotics are hypothesized to support immune health by supporting healthy intestinal microbiota, improving barrier function, and helping to regulate immune supportive natural killer cells, lymphocytes, and antibodies (Carter et al, 2016; Sanders et al, 2013). A 2016 meta-analysis analyzed the impact of probiotics and prebiotics on CD4 count. While overall results were inconclusive, most of fifteen experimental studies analyzing the impact of probiotics and prebiotics on CD4 count illustrated an increase in CD4 count (nine with significant improvements). More promising results came from using probiotics and synbiotics with *Bifidus* or *Lactobacilli* probiotic strains, in pill, or in food form (yogurt) (Carter et al, 2016). While probiotics tended to be well tolerated in these studies, there have been rare cases of pathogenic infection from probiotics (Riquelme et al, 2003). Because of the way dietary supplements are regulated, it is prudent to recommend brands that carry 3rd party certification, thus assuring their potency and quality (see Chapter 11 for more details on dietary supplement regulation). Taking probiotics and prebiotics in food form may be a safer and more economical choice for PLWHA, especially those with limited income.

Recreational and medical cannabis use is common among PLWHA to help improve appetite, reduce pain and neuropathy, enhance mood, and reduce nausea. While current research is investigating the effectiveness of cannabis on these symptoms, more specific research is needed within the HIV-positive population. Evidence on the specific benefits in the population is increasing. According to the Natural Medicines Database smoking marijuana is possibly effective in stimulating appetite, increasing calorie intake, and increasing weight gain in PLWHA experiencing poor appetite. Furthermore, it may possibly be effective in reducing the intensity of pain associated with neuropathy (Natural Medicines Clinical Management Series, 2019).

While some dietary supplements and integrative therapies may help support immune function, reduce side effects, and improve nutrient status and quality of life, a food-first strategy should be primary. This is particularly relevant when working with clients that have limited resources. Making specific IFN recommendations might be more costly as this can lead to individuals losing funds that would otherwise be spent on basic healthy food.

CLINICAL CASE STUDY

Edwin is a 42-year-old white male who has been human immunodeficiency virus (HIV) positive for 20 years. His viral load is undetectable and his CD4+ count is 643. Edwin's medical history also includes depression, gastroesophageal reflux disease (GERD), high blood pressure, and hyperlipidemia. His current HIV antiretroviral regimen was recently changed to Genvoya; he also takes atorvastatin (Lipitor), and ranitidine (Zantac). His height is 5'9" and his current weight is 188 lb, up from 175 lb. His fasting lipid profile shows a total cholesterol 235 mg/dL, triglycerides 304 mg/dL, high-density lipoprotein 25 mg/dL, and low-density lipoprotein 96 mg/dL. Since his last visit 3 months ago, he has been having moderate diarrhea with general gastrointestinal (GI) upset that he states is "left over" from when he had the flu and took 2 rounds of antibiotics a few months ago. Edwin lives by himself and doesn't like to cook. He also receives one meal per day from a community program and gets groceries once per week from a food bank. He walks his dog for 30 minutes daily. Upon taking a 24-hour recall, you find his caloric intake to be 2700 kcal/day coming primarily from ready-to-eat items. He also expresses that ice cream is his emotional comfort food, which he eats 5 to 7 days per week.

Nutrition Diagnostic Statements

- Excessive dietary intake (NB-1.7) related to frequent intake of highly processed foods and limited food access as evidenced by 24-hour recall

reflecting intake of 2700 kcal per day and weight gain of 13 lb (7.4%) in the past 3 months.

- Altered GI function (NC-1.4) related to history of antibiotic use and high intake of lactose as evidenced by patient report of moderate diarrhea since taking 2 rounds of antibiotics in past few months and diet recall revealing eating ice cream 5 to 7 days a week.

Nutrition Care Questions

1. What factors may be contributing to the GI symptoms that Edwin is experiencing? What recommendations do you suggest for these symptoms? Are there any drug-nutrient interactions of which you need to be aware?
2. What nutrition and lifestyle interventions would you recommend to address his nutrition diagnoses?
3. What are some biochemical and nutritional parameters you would monitor to determine whether the nutrition interventions are effective?
4. How would you evaluate the desired nutrition outcomes to determine whether they have been met?
5. Are there any integrative therapies that may help Edwin? Any potential drug nutrient interactions you would need to consider?

Medical Nutrition Therapy in Critical Care

*Britta Brown, MS, RD, LD, CNSC
Katherine Hall, RD, LD, CNSC*

KEY TERMS

abdominal compartment syndrome
acute-phase proteins
adrenocorticotrophic hormone
catecholamines
cortisol
counterregulatory hormones
cytokines
ebb phase
epithelial barrier function (EBF)
flow phase

hemodynamic
ileus
interleukin-1 (IL-1)
interleukin-6 (IL-6)
multiple organ dysfunction syndrome (MODS)
nutrition support therapy
quick sequential organ failure assessment criteria (qSOFA)
sepsis

shock
systemic inflammatory response syndrome (SIRS)
tight junction
total body surface area (TBSA) burned
tumor necrosis factor (TNF)

Critical care is the complex medical management of a seriously ill or injured person. This level of illness or injury involves acute impairment of one or more vital organ systems with a high probability of life-threatening deterioration of the patient's condition. Critical care requires complex decision making and support of vital organ systems to prevent failure involving one or more of the following: the central nervous system, the circulatory system, the renal and hepatic systems, the metabolic and respiratory systems, and shock. Critical care patients are treated in an intensive care unit (ICU) that contains specialized equipment and highly trained staff. The presence of multiple monitors, tubes, catheters, and infusions makes these patients difficult to assess nutritionally (Fig. 37.1). Critical illness and injury results in profound metabolic alterations, beginning at the time of injury and persisting until wound healing and recovery are complete. Whether the event involves sepsis (infection), trauma, burns, or surgery, the systemic response is activated. The physiologic and metabolic changes that follow may lead to shock and other negative outcomes (Fig. 37.2). Disorders that frequently are treated in an ICU include, but are not limited to, acute respiratory distress syndrome (ARDS), asthma, burn, chronic obstructive pulmonary disease (COPD), pneumonia, respiratory distress syndrome, sepsis, and trauma.

METABOLIC RESPONSE TO STRESS

The metabolic response to critical illness, traumatic injury, sepsis, burns, or major surgery is complex and involves most metabolic pathways. Accelerated catabolism of lean body or skeletal mass

occurs, which clinically results in net negative nitrogen balance and muscle wasting. The response to critical illness, injury, and sepsis characteristically involves ebb and flow phases. The **ebb phase**, occurring immediately after injury, is associated with hypovolemia (decreased blood volume circulating in the body), shock, and tissue hypoxia. Typically, decreased cardiac output, oxygen consumption, and body temperature occur in this phase. Insulin levels fall in direct response to the increase in glucagon, most likely as a signal to increase hepatic glucose production. Increased cardiac output, oxygen consumption, body temperature, energy expenditure, and total body protein catabolism characterize the **flow phase** that follows fluid resuscitation (the replacement of bodily fluids typically using crystalloids [intravenous fluid solutions], colloids [i.e., albumin or blood]) and restoration of oxygen transport. Physiologically, in this phase is a marked increase in glucose production, free fatty acid release, circulating levels of insulin, **catecholamines** (epinephrine and norepinephrine released by the adrenal medulla), glucagon, and cortisol. The magnitude of the hormonal response appears to be associated with the severity of injury.

HORMONAL AND CELL-MEDIATED RESPONSE

Metabolic stress is associated with an altered hormonal state that results in an increased flow of substrate but poor use of carbohydrate, protein, fat, and oxygen. **Counterregulatory hormones**, which are elevated after injury and sepsis, play a role in the accelerated proteolysis (muscle and tissue breakdown). Glucagon promotes gluconeogenesis, amino acid uptake by the liver, ureagenesis, and protein catabolism. **Cortisol**, which is released from the adrenal cortex in response to stimulation by **adrenocorticotrophic hormone** secreted by the anterior pituitary gland, enhances skeletal muscle catabolism and promotes

Portions of this chapter were written by Marion Winkler and Ainsley Malone.

hepatic use of amino acids for gluconeogenesis, glycogenolysis, and acute-phase protein synthesis (Table 37.1).

After injury or sepsis, energy production increasingly depends on protein. Branched-chain amino acids (BCAAs leucine, isoleucine, and valine) are oxidized from skeletal muscle as a source of energy for the muscle; carbon skeletons are made available for the glucose-alanine cycle and muscle glutamine synthesis. The mobilization of **acute-phase proteins** (secretory proteins produced by the liver) are altered in response to injury or infection, resulting in rapid loss of lean body

mass and an increased net negative nitrogen balance, which continues until the inflammatory response resolves. Breakdown of protein tissue also causes increased urinary losses of potassium, phosphorus, and magnesium. Lipid metabolism also is altered in stress and sepsis. Increased circulation of free fatty acids is thought to result from increased lipolysis caused by elevated catecholamines and cortisol, as well as a marked elevation in the ratio of glucagon to insulin.

Most notable is the hyperglycemia observed during stress. This initially results from a marked increase in glucose production and

TABLE 37.1 The Metabolic Response to Injury

Physiologic Changes in Catabolism	
Carbohydrate metabolism	↑ Glycogenolysis
	↑ Gluconeogenesis
	Insulin resistance of tissues
	Hyperglycemia
Fat metabolism	↑ Lipolysis
	Free fatty acids used as energy substrate by tissues (except brain)
	Some conversion of free fatty acids to ketones in liver (used by brain)
	Glycerol converted to glucose in the liver
Protein metabolism	↑ Skeletal muscle breakdown
	Amino acids converted to glucose in liver and used as substrate for acute-phase proteins
	Negative nitrogen balance
	Total energy expenditure is increased in proportion to injury severity and other modifying factors
Progressive reduction in fat and muscle mass until stimulus for catabolism ends

uptake secondary to gluconeogenesis and elevated levels of hormones, including epinephrine, that diminish insulin release. Stress also initiates the release of aldosterone, a corticosteroid that causes renal sodium retention, and vasopressin (antidiuretic hormone), which stimulates renal tubular water resorption. The action of these hormones results in conservation of water and salt to support the circulating blood volume.

The response to injury also is regulated by metabolically active **cytokines** (proinflammatory proteins) such as **interleukin-1 (IL-1)**, **interleukin-6 (IL-6)**, and **tumor necrosis factor (TNF)**, which are released by phagocytic cells in response to tissue damage, infection, inflammation, and some medications. IL-6 is secreted by T cells and macrophages to stimulate the immune response to trauma or other tissue damage leading to inflammation; it has proinflammatory and antiinflammatory actions (see Chapter 7). Cytokines are thought to stimulate hepatic amino acid uptake and protein synthesis, accelerate muscle breakdown, and induce gluconeogenesis. IL-1 appears to have a major role in stimulating the acute-phase response. The vagus nerve helps to regulate cytokine production through a cholinergic antiinflammatory pathway, releasing nicotinic acetylcholine receptor alpha-7 to reduce excessive cytokine activity.

As part of the acute-phase response, serum iron and zinc levels decrease, and levels of ceruloplasmin increase, primarily because of sequestration and, in the case of zinc, increased urinary zinc excretion. The net effect of the hormonally and cell-mediated response is an increase in oxygen supply and a greater availability of substrates for metabolically active tissues.

STARVATION VERSUS STRESS

The metabolic response to critical illness is very different from simple or uncomplicated starvation in which loss of muscle is much slower in an adaptive response to preserve lean body mass. Stored glycogen, the primary fuel source in early starvation, is depleted in approximately 24 hours. After the depletion of glycogen, glucose is available from the

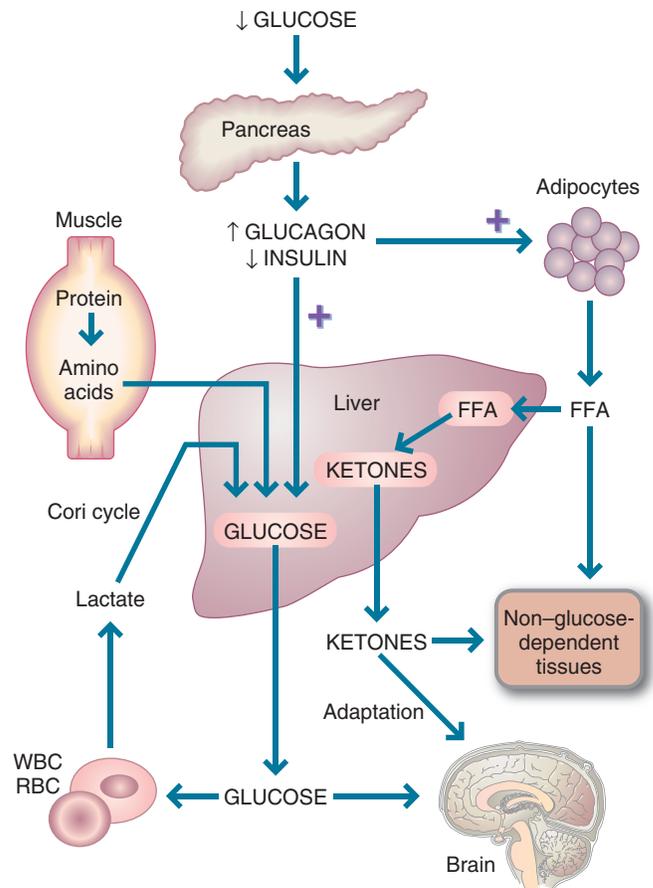

Fig. 37.3 Metabolic changes in starvation. FFA, Free fatty acid; RBC, red blood cell; WBC, white blood cell. (From Simmons RL, Steed DL: *Basic science review for surgeons*, Philadelphia, 1992, Saunders.)

breakdown of protein to amino acids, depicted in Fig. 37.3. The depressed glucose levels lead to decreased insulin secretion and increased glucagon secretion. During the adaptive state of starvation, protein catabolism is reduced, and hepatic gluconeogenesis decreases.

Lipolytic activity is also different in starvation and in stress. After approximately 1 week of fasting or food deprivation, a state of ketosis develops, in which ketone bodies supply the bulk of energy needs, thus reducing the need for gluconeogenesis and conserving body protein to the greatest possible extent. In late starvation, as in stress, ketone body production is increased, and fatty acids serve as a major energy source for all tissues. Starvation is characterized by decreased energy expenditure, diminished gluconeogenesis, increased ketone body production, and decreased ureagenesis. Conversely, energy expenditure in stress is increased markedly, as are gluconeogenesis, proteolysis, and ureagenesis. As discussed, the stress response is activated by hormonal and cell mediators—counterregulatory hormones such as catecholamines, cortisol, and growth hormone. This mediator activation does not occur in starvation.

SYSTEMIC INFLAMMATORY RESPONSE SYNDROME, SEPSIS, AND ORGAN DYSFUNCTION OR FAILURE

Pathophysiology

Sepsis and the systemic inflammatory response syndrome (SIRS) often complicate the course of a critically ill patient. The term sepsis is used

BOX 37.1 Systemic Inflammatory Response Syndrome (SIRS)

Two or more of the following are present:

- Body temperature $>38^{\circ}\text{C}$ or $<36^{\circ}\text{C}$
- Heart rate >90 beats/minute
- Respiratory rate >20 breaths/minute (tachypnea)
- White blood cell count $>12,000/\text{mm}^3$ or $<4000/\text{mm}^3$ or $>10\%$ immature bands (immature neutrophils in the absence of chemotherapy-induced neutropenia and leukopenia)

From Bone RC, et al: American College of Chest Physicians/Society of Critical Care Medicine Consensus Conference: definitions for sepsis and organ failure and guidelines for the use of innovative therapies in sepsis, *Crit Care Med.* 20:864, 1992.

when a patient has a life-threatening organ dysfunction caused by a dysregulated host response to infection (Singer et al, 2016). Bacteria and their toxins lead to a strong inflammatory response during critical illness. Other microorganisms that lead to an inflammatory response include viruses, fungi, and parasites.

Systemic inflammatory response syndrome (SIRS) describes the widespread inflammation that can occur in infection, pancreatitis, ischemia, burns, multiple trauma, hemorrhagic shock, or immunologically mediated organ injury. The inflammation is usually present in areas remote from the primary site of injury, affecting otherwise healthy tissue. Each condition leads to release of cytokines, proteolytic enzymes, or toxic oxygen species (free radicals) and activation of the complement cascade. Currently used SIRS criteria were published by Bone et al in 1992. Patients are classified with SIRS if they demonstrate any two of the following: heart rate >90 beats per minute, respiratory rate >20 breaths per minute, body temperature $>38^{\circ}\text{C}$ or $<36^{\circ}\text{C}$, or white blood cell count $>12,000/\text{mm}^3$ or $<4000/\text{mm}^3$ or $>10\%$ immature bands (Bone et al, 1992) and are shown in Box 37.1. The authors of the Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3) also recommend using the **quick sequential organ failure assessment (qSOFA)** tool as a practical scoring system to define organ dysfunction of a potentially septic patient (Table 37.2).

A common complication of SIRS is the development of organ dysfunction or failure, often referred to as **multiple organ dysfunction syndrome (MODS)**. The syndrome generally begins with lung failure and is followed by failure of the liver, intestines, and kidney in no particular order. Hematologic and myocardial failures usually manifest later; however, central nervous system changes can occur at any time. MODS may occur as the direct result of injury to an organ from trauma, major surgery, burns, sepsis, acute kidney injury, or acute

pancreatitis. Secondary MODS occurs in the presence of inflammation or infection in organs remote from the initial injury.

Patients with SIRS and MODS are clinically hypermetabolic and exhibit high cardiac output, low oxygen consumption, high venous oxygen saturation, and lactic acidemia. Patients generally have a strong positive fluid balance associated with massive edema and a decrease in plasma protein concentrations.

Multiple hypotheses have been proposed to explain the development of SIRS or MODS. In some studies, SIRS leading to MODS appears to be mediated by excessive production of proinflammatory cytokines and other mediators of inflammation. The gut hypothesis suggests that the trigger is injury or disruption of the gut barrier function, with corresponding translocation of enteric bacteria into the mesentery lymph nodes, liver, and other organs. Unique gut-derived factors carried in the intestinal lymph but not the portal vein usually lead to acute injury- and shock-induced SIRS and MODS. **Shock** results in gut hypoperfusion; the hypoperfused gut is a source of proinflammatory mediators. Early gut hypoperfusion causes an **ileus** or lack of peristalsis in the stomach and small bowel, and late infections cause further worsening of this gut dysfunction. Early enteral feeding is thought to restore gut function and influence the clinical course. The mechanism for this effect is due to the enhanced functional and structural integrity of the gut.

Enteral nutrition (EN) may have a role in maintaining **tight junctions** between the intraepithelial cells, stimulating blood flow and inducing the release of trophic factors (Fig. 37.4). Maintenance of villous height supports the secretory immunocytes that make up the gut-associated lymphoid tissue. With central parenteral nutrition (PN), mucosal atrophy and a loss of **epithelial barrier function (EBF)** may occur. Clinical trials evaluating the use of parenteral and enteral glutamine supplementation have demonstrated mixed results without clear clinical benefit, such as reduction in mortality, infectious complications, and faster recovery of organ dysfunction (Rhodes et al, 2017). Both the Surviving Sepsis Campaign Guidelines and the Society for Critical Care Medicine (SCCM) and American Society for Parenteral and Enteral Nutrition (ASPEN) Guidelines for the Provision and Assessment of Nutrition Support Therapy in the Critically Ill Patient recommend against exogenous glutamine supplementation (Rhodes et al, 2017; McClave et al, 2016).

MALNUTRITION: THE ETIOLOGY-BASED DEFINITION

The historical approach to defining malnutrition in the patient undergoing the stress response has recently been reevaluated. In an effort to provide consistency in its definition, in 2009 an international group of nutrition support leaders developed an etiology basis for the definition of malnutrition for hospitalized adult patients (see Appendix 11). This approach focuses on the following three causes: starvation-related malnutrition, chronic disease-related malnutrition, and acute disease-related malnutrition (Fig. 37.5). Using this framework, a collaborative workgroup of ASPEN and the Academy of Nutrition and Dietetics (AND) published a consensus document outlining specific criteria for diagnosing severe and nonsevere malnutrition. Each malnutrition cause is defined by specific criteria and thresholds (Box 37.2 for criteria specific to the acute illness and injury malnutrition cause). This specific category includes those patients experiencing SIRS and MODS and is characterized by a heightened cytokine response, which in turn leads to profound losses in fat-free mass. In this setting, multiple factors impede the body's ability to maintain or replace lean body mass despite provision of nutrition support therapy (Looijaard et al, 2018; Jensen et al, 2009, 2010).

TABLE 37.2 Quick Sequential Organ Failure Assessment (qSOFA) Criteria

Criteria	Points*

BOX 37.2 Consensus Malnutrition Criteria for Acute Illness and Injury Cause

Severe Malnutrition

- Energy intake
 - ≤50% of estimated energy requirement for ≥5 days
- Weight loss (percentage of usual body weight over time period)
 - >2% over 1 week
 - >5% over 1 month
 - >7.5% over 3 months
- Loss of body fat
 - Moderate
- Loss of muscle mass
 - Moderate
- Fluid accumulation
 - Moderate to severe
- Hand grip strength
 - Measurably reduced

Nonsevere Malnutrition

- Energy intake
 - <75% of estimated energy requirement for >7 days
- Weight loss (percentage of usual body weight over time period)
 - 1% to 2% over 1 week
 - 5% over 1 month
 - 7.5% over 3 months
- Loss of body fat
 - Mild
- Loss of muscle mass
 - Mild
- Fluid accumulation
 - Mild
- Hand grip strength
 - Not applicable

From Consensus statement: Academy of Nutrition and Dietetics and American Society for Parenteral and Enteral Nutrition: characteristics recommended for the identification and documentation of adult malnutrition (undernutrition). From White JA, et al: *J Parent Enteral Nutr* 36:275, 2012.

Medical Nutrition Therapy

The critically ill patient typically enters an ICU because of a cardiopulmonary diagnosis, intraoperative or postoperative complication, multiple trauma, burn injury, or sepsis. Traditional methods of assessing nutritional status are often of limited value in the ICU setting. The severely injured patient is usually unable to provide a dietary history. Values for weight may be erroneous after fluid resuscitation, and anthropometric measurements are not easily attainable, nor are they sensitive to acute changes. Hypoalbuminemia reflects severe illness, injury, and inflammation; thus serum albumin should not be used as a marker of nutritional status (McClave et al, 2016). Other plasma proteins such as prealbumin and transferrin often drop precipitously, related not to nutrition status but to an inflammation-induced decrease in hepatic synthesis and changes caused by compartmental shifts in body fluid. This is part of the acute-phase response in which secretory and circulating proteins are altered in response to inflammation or injury (see Chapters 5 and 7).

The critical role of physical assessment cannot be overlooked. Loss of lean body mass and accumulation of fluid are common among ICU patients, and the ability to recognize these changes, as well as other important physical parameters, is essential. In addition to conducting a nutrition-focused physical examination, researchers are evaluating

body composition technologies including computed tomography (CT), dual-energy x-ray absorptiometry (DEXA), bioelectrical impedance analysis (BIA), and ultrasound (US) to evaluate their efficacy in characterizing nutritional status in an ICU setting (Teigen et al, 2017). In general, assessment and care planning focus on the preadmission, preoperative, or preinjury nutrition status; presence of any organ system dysfunction; the need for early nutrition support therapy; and options that exist for enteral or parenteral access.

Because the patient is so ill, oral intake of food or fluid may be severely limited. Some common nutrition diagnoses used in critical illness include the following:

- Inadequate oral food and beverage intake (requiring another mode of nutrient or fluid administration)
- Inadequate or excessive intake from EN or PN infusion
- Inappropriate infusion of EN or PN (e.g., using PN when EN is possible)
- Inadequate or excessive fluid intake (e.g., intravenous [IV] infusions, nutrient solutions, tube flushes)
- Increased nutrient needs (e.g., protein requirements for wound healing)
- Excessive carbohydrate intake (e.g., dextrose-containing [IV] infusions or PN, especially among patients who are malnourished or at risk for refeeding)
- Abnormal nutrition-related laboratory values
- Altered gastrointestinal (GI) function (e.g., vomiting, diarrhea, constipation, ileus)

If malnutrition or an inflammatory response is present, the nutrition diagnosis should be framed around those conditions. The rationale for focusing on malnutrition and the inflammatory response is that these conditions increase the risk of complications related to nutritional status. An example of such a problem, etiology, and signs and symptoms (PES) statement would be the following: Increased nutrient needs (energy and protein) related to an inflammatory response to injury as evidenced by elevated body temperature and minute ventilation.

Nutrition Support Therapy

Nutrition support therapy incorporates early EN (within 48 hours of ICU admission) when feasible, appropriate macro- and micronutrient delivery, and glycemic control. Favorable expected outcomes from these practices include reduced disease severity, decreased length of time in the ICU, and decreased infectious disease morbidity and overall mortality.

The traditional goals of nutrition support therapy during sepsis and after injury include minimization of starvation, prevention or correction of specific nutrient deficiencies, provision of adequate calories to meet energy needs while minimizing associated metabolic complications, and fluid and electrolyte management to maintain adequate urine output and normal homeostasis (see *Pathophysiology and Care Management Algorithm: Hypermetabolic Response*). Clinicians focus on attenuating the metabolic response to stress, preventing oxidative cellular injury, and modulating the immune response. The first emphasis of care in the ICU is establishing **hemodynamic** stability (maintenance of airway and breathing, adequate circulating fluid volume and tissue oxygenation, and acid-base neutrality). It is important to follow the patient's heart rate, blood pressure, cardiac output, mean arterial pressure (MAP), and oxygen saturation to assess hemodynamic stability because this determines when nutrition support therapy can commence. It is common practice to withhold EN if a patient's MAP is <50 mm Hg (McClave et al, 2016).

Glycemic control and its relationship to improved outcomes has been the focus of extensive study. It is now recognized that more

moderate (blood glucose 140 to 180 mg/dL), rather than tight (blood glucose 80 to 110 mg/dL), control is associated with positive outcomes in critically ill patients (AND, 2018a). Dietitians must recognize the significant contribution of dextrose in PN formulas or IV fluids and its influence on glycemic control.

Nutritional Requirements

Energy. Ideally, indirect calorimetry (IC) should be used to determine energy requirements for critically ill patients (see Chapter 2). Oxygen consumption is an essential component in the determination of energy expenditure. Septic and trauma patients have substantial increases in energy expenditure associated with the magnitude of injury. IC can be performed serially as a patient's clinical status changes (AND, 2018b); this allows for a more accurate assessment of energy requirements during a patient's stay in the ICU. IC is not appropriate for all patients, however, and should be performed and interpreted by experienced clinicians (AND, 2018b). High oxygen requirements, the presence of a chest tube, acidosis, and the use of supplemental oxygen are factors that may lead to invalid results. In these situations measurement of energy expenditure by IC is not recommended (AND, 2018b).

In the absence of a metabolic cart for IC, energy requirements may be calculated as 25 to 30 kcal/kg/day (McClave et al, 2016) or by using one of the many published predictive equations (see Chapter 2). Avoidance of overfeeding in the critically ill patient is important. Although adequate energy is essential for metabolically stressed patients, excess calories can result in complications such as hyperglycemia, hepatic steatosis, and excess carbon dioxide production, which can exacerbate respiratory insufficiency or prolong weaning from mechanical ventilation.

There has been long-standing controversy about the value of increased energy intake for critically ill patients. Newer research may differentiate the conflicting outcomes observed in prior studies by stratifying patient populations by the degree of malnutrition or nutritional risk. For example, the Nutrition Risk in the Critically Ill (NUTRIC) score (Heyland et al, 2011) (Table 37.3) has been used to distinguish between low- and high-risk patients. Using this tool, greater energy and protein intake has been associated with lower mortality and faster time to discharge alive among high-risk (NUTRIC score ≥ 5) patients, but not among nutritionally low-risk patients (Compher et al, 2017).

Some debate also exists in practice regarding what value should be used for body weight in predictive equations. Actual body weight is a better predictor of energy expenditure than ideal body weight in obese individuals (Breen and Ireton-Jones, 2004). The 2012 Critical Illness Update recommends that when IC is unavailable, the Penn State University (PSU [2003b]) equation, using actual body weight, should be used in obese and nonobese patients who are younger than 60 years of age. For obese patients 60 years or older, the PSU (2010) equation should be used. Research indicates that these equations have the best prediction accuracy (AND, 2018b).

Available research suggests that hypocaloric, high-protein nutrition support therapy or "permissive underfeeding" in critically ill obese patients results in achievement of net protein anabolism and minimizes complications resulting from overfeeding. The SCCM and ASPEN guidelines suggest that clinical outcomes in patients supported with high-protein hypocaloric feeding are at least equivalent to those supported with high-protein eucaloric feeding (McClave et al, 2016). Furthermore, the guidelines recommend that for all classes of obesity, goal EN should not exceed 60% to 70% of target energy requirements as measured by IC. If IC is unavailable, 11 to 14 kcal/kg actual body weight (body mass index [BMI] 30 to 50) and 22 to 25 kcal/kg ideal body weight (BMI >50) can be used to estimate energy needs. Protein can be provided in a range from 2.0 grams/kg ideal body weight (BMI 30 to 40), up to 2.5 grams/kg ideal body weight

TABLE 37.3 Nutrition Risk in the Critically Ill (NUTRIC) Score

Variable	Range	Points
Age	<50	0
	50 to <75	1
	≥ 75	2

(BMI >40) (McClave et al, 2016). Hypocaloric low protein feedings are associated with unfavorable outcomes and should be avoided. Clinical vigilance for adequate protein provision is important, and nitrogen balance studies may help guide in the establishment of protein goals. More research is needed to validate hypocaloric feeding as the standard approach to nutrition support in obese patients, especially because of the wide variability in body composition (Choban and Dickerson, 2005; Port and Apovian, 2010).

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Hypermetabolic Response

ETIOLOGY

PATHOPHYSIOLOGY

EBB Phase

Hypovolemia
Shock
Tissue hypoxia
Decreased:

- Cardiac output
- O₂ consumption
- Body temperature

Flow Phase

Acute-phase proteins
Hormonal responses
Immune responses (cell-mediated and antibody)
Increased:

- Cardiac output
- O₂ consumption
- Body temperature
- Energy expenditure
- Protein catabolism

MANAGEMENT

Medical Management

- Treat cause of hypermetabolism
- Hemodynamic stability

Nutrition Management

- Minimize catabolism
- Meet energy requirements, but do not overfeed
 - Use indirect calorimetry if possible
 - Non-obese: 25-30 kcal/kg/day
 - Obese: 14-18 kcal/kg/day of actual body weight
- Meet protein, vitamin, and mineral needs
- Establish and maintain fluid and electrolyte balance
- Plan nutrition therapy (oral, enteral, and/or parenteral nutrition)
- Need for individualized therapeutic nutrient repletion
- Physical therapy
- Exercise as tolerated

Protein. Determination of protein requirements is difficult for critically ill patients. Patients typically require 1.2 to 2 g/kg/day depending on their baseline nutritional status, degree of injury and metabolic demand, and abnormal losses (e.g., through open abdominal wounds or burned skin) (Hoffer and Bistrian, 2012). Patients with acute kidney injury undergoing continuous renal replacement therapy (CRRT) may have a higher protein requirement because of the increased loss via the filtration process (see Chapter 34). A systematic review of protein requirements in critical illness concluded that protein delivery of 2.0 to 2.5 g/kg/day is safe and may be optimal for most critically ill patients except for those with refractory hypotension, overwhelming sepsis, or severe liver disease (Hoffer and Bistrian, 2012). A multicenter, registration-based randomized control trial is currently underway to better define optimal protein requirements in critical illness. Administration of excessive amounts of protein does not decrease the characteristic net negative nitrogen balance seen among hypermetabolic patients.

Vitamins, minerals, and trace elements. No specific guidelines exist for the provision of vitamins, minerals, and trace elements in metabolically stressed individuals. Conditions such as wounds, burns, malnutrition, chemical dependency (i.e., alcohol), and refeeding syndrome can all affect a patient's micronutrient requirements. Supplementation with antioxidant vitamins E and C, and trace minerals (selenium, zinc, copper) may improve outcomes among burn, trauma, and mechanically ventilated critically ill patients, but dosing, frequency, and route of administration have not been standardized (McClave et al, 2016). Micronutrient needs are elevated during acute illness because of

increased urinary and cutaneous losses and diminished GI absorption, altered distribution, and altered serum carrier protein concentrations. With increased caloric intake there may be an increased need for B vitamins, particularly thiamin and niacin. Catabolism and loss of lean body tissue increase the loss of potassium, magnesium, phosphorus, and zinc. GI and urinary losses, organ dysfunction, and acid-base imbalance necessitate that mineral and electrolyte requirements be determined and adjusted individually. Fluid and electrolytes should be provided to maintain adequate urine output and normal serum electrolytes.

Feeding strategies. The preferred route for nutrient delivery is an orally consumed diet of whole foods. However, critically ill patients are often unable to eat because of endotracheal intubation and ventilator dependence. Furthermore, oral feeding may be delayed by impairment of chewing, swallowing, anorexia induced by pain-relieving medications, or posttraumatic shock and depression. Patients who are able to eat may not be able to meet the increased energy and nutrient requirements associated with metabolic stress and recovery. They often require combinations of oral nutritional supplements, EN, and PN. When EN fails to meet nutritional requirements or when GI feeding is contraindicated, PN support should be initiated.

Timing and route of feeding. Tools including the Nutritional Risk Screening (NRS 2002) and the NUTRIC score (see Table 37.3) have been used to identify critically ill patients who are most likely to benefit from nutrition support therapy (Kondrup et al, 2003; Heyland et al, 2011). The NRS 2002 is a simpler tool that includes the patient's BMI, weight loss in the past 3 months, reduced dietary intake in the last week, and presence of severe illness (Table 37.4), while the

TABLE 37.4 Nutrition Risk Screening [NRS 2002]

INITIAL SCREENING			
		Yes	No
1	Is BMI <20.5?		
2	Has the patient lost weight within the last 3 months?		
3	Has the patient had a reduced dietary intake in the last week?		
4	Is the patient severely ill? (e.g., intensive care)		
Yes: If the answer is "yes" to any question, further screening is performed (see below).			
No: Is the answer is "no" to all questions, the patient is rescreened weekly. If the patient is scheduled for major operation, a preventative nutritional care plan is considered to avoid the associated risk status.			
FINAL SCREENING			
Impaired nutritional status		Severity of disease (increase in requirements)	
Absent Score 0	Normal nutritional status	Absent Score 0	Normal nutritional requirements
Mild Score 1	Weight loss >5% in 3 months or food intake <50%-75% of normal requirement in preceding week	Mild Score 1	Hip fracture, chronic patients with acute complications: cirrhosis, COPD, chronic hemodialysis, diabetes, oncology
Moderate Score 2	Weight loss >5% in 2 months or BMI 18.5-20.5 + impaired general condition or food intake 25%-60% of normal requirement in preceding week	Moderate Score 2	Major abdominal surgery, stroke, severe hematologic malignancy
Severe Score 3	Weight loss >5% in 1 month (>15% in 3 months) or BMI <18.5 + impaired general condition or food intake 0%-25% of normal requirement in preceding week	Severe Score 3	Head injury, bone marrow transplantation, intensive care patients (APACHE >10)
Score:	+	Score:	= Total score
Age	If ≥70 years, add 1 to total score above = age – adjusted total score		
Score ≥3: The patient is nutritionally at risk and a nutritional care plan is initiated.			
Score <3: Weekly rescreening of the patient. If the patient is scheduled for a major operation, a preventative nutritional care plan is considered to avoid the associated risk status.			

APACHE, Acute physiologic assessment and chronic health evaluation; BMI, body mass index; COPD, chronic obstructive pulmonary disease. From Kondrup J, et al: ESPEN guidelines for nutrition screening 2002, *Clin Nutr*, 22:415, 2003.

NUTRIC score uses a rubric composed of the patient's age, acute physiologic assessment and chronic health evaluation (APACHE II), SOFA, number of comorbidities, days from hospital to ICU admission, and IL-6 (if available) (see Table 37.3).

EN is the preferred route of feeding for the critically ill patient who cannot eat food and yet has good intestinal function. Feedings should be initiated early within the first 24 to 48 hours of ICU admission and advanced toward goal calories during the next 48 to 72 hours. Intake of 50% to 65% of goal calories during the first week of hospitalization is thought to be sufficient to achieve the clinical benefit of EN. This practice is intended for patients who are hemodynamically stable. In the setting of hemodynamic instability (large fluid volume requirements or use of high-dose catecholamine agents), tube feeding should be withheld until the patient is resuscitated fully or stable to minimize risk of ischemic or reperfusion injury.

Either gastric or small-bowel feedings can be used. Small-bowel feedings are indicated for patients who do not tolerate gastric feeding or who are deemed high risk for aspiration (McClave et al, 2016). Nasoenteric or surgically placed feeding tubes can be placed intraoperatively for patients with severe head, major thoracic, or spinal injury; facial injury requiring jaw wiring; proximal gastric or esophageal injuries; major pancreatic or duodenal injury; and severe trauma with plans for repeated surgeries.

Enteral tolerance should be monitored by assessing the level of pain, presence of abdominal distention, passage of flatus and stool, physical examination, and, if appropriate, abdominal x-ray examination. Elevating the head of the bed and using promotility medication can reduce aspiration risk. The cause of diarrhea, when present, should be determined, including assessment for infectious diarrhea. Patients should be evaluated for intake of hyperosmolar medications and broad-spectrum antibiotics. PN is indicated for patients in whom EN is unsuccessful or contraindicated.

Formula selection and fluid, energy, and nutrient requirements, as well as GI function, determine the choice of an enteral product. Most standard polymeric enteral formulas can be used to feed the critically ill patient. However, intolerance to standard formulas sometimes occurs because of their fat content, and the patient may temporarily require a lower-fat formula or a product containing a higher ratio of medium-chain triglycerides. Several commercially available products (see Appendix 15) are marketed specifically for patients with trauma and metabolic stress. These products typically have higher protein content and a higher ratio of BCAAs and/or additional glutamine, arginine, or antioxidant vitamins and minerals.

Immune modulating enteral formulations that contain arginine, glutamine, nucleic acids, antioxidants, and omega-3 fatty acids potentially have beneficial effects and favorable outcomes for critically ill patients who have undergone GI surgery, as well as for trauma and burn patients. However, these formulations should not be used routinely for ICU patients with sepsis because they may worsen the inflammatory response (McClave et al, 2016). Insoluble fiber should be avoided in critically ill patients; however, soluble fiber may be beneficial for the hemodynamically stable, critically ill patient who develops diarrhea (McClave et al, 2016). Patients at high risk for bowel ischemia initially should not receive fiber-containing formulas or diets.

TRAUMA AND THE OPEN ABDOMEN

After major abdominal trauma, bowel distention, and states of shock, some patients experience increased intraabdominal pressure leading to hypoperfusion and ischemia of the intestines and other peritoneal and retroperitoneal structures. **Abdominal compartment syndrome**

occurs with increased intraabdominal pressure, often after major abdominal trauma or sepsis. This condition has profound consequences, including hemodynamic instability and respiratory, renal, and neurologic abnormalities. Because the abdominal cavity has become too small, management consists of emergent decompressive laparotomy (surgical incision through the abdominal wall) to release intraabdominal pressure. Closure of the abdomen is not performed, either because the visceral edema is too great to close or to help with future reexploration. Temporary abdominal closure (TAC) is applied. Negative pressure wound therapy with continuous fascial traction is the recommended method for managing TAC. Fascial closure should be done as soon as the patient can tolerate it (Coccolini et al, 2018).

Patients with an open abdomen have severe metabolic alterations, increased loss of fluids, and elevated nutritional requirements. The open abdomen also may be a significant source of protein loss depending on the amount of drainage. It is recommended that an extra 15 to 30 grams of protein per liter of exudate be added to the nutrition prescription (McClave et al, 2016). There has been some controversy as to whether patients with an open abdomen can be fed enterally. As long as the patient is hemodynamically stable and does not require large-volume fluid resuscitation or increasing doses of pressor agents, enteral feeding should be possible (McClave et al, 2016). Ideally, a nasojejunal feeding tube should be positioned at the time of surgery to facilitate early EN support therapy.

Management of patients with intestinal fistulas and large draining wounds is also challenging surgically and nutritionally because these patients have metabolic abnormalities associated with losses of fluid, electrolytes, and nutrients (Friese, 2012; Majercik et al, 2012). The priorities for management of intestinal fistulas are to restore blood volume, replace fluid and electrolyte losses, treat sepsis, control fistula drainage, protect the surrounding skin, and provide optimal nutrition support therapy. ASPEN-La Federación Latinoamericana de Terapia Nutricional (FELANPE) guidelines were created to help guide the clinician when caring for the adult patient with enterocutaneous fistula (Kumpf et al, 2017). EN is the preferred route of feeding if the fistula output is less than 500 mL/day and access can be gained through or distal to the fistula site. If output is >500 mL/day or if the output impairs skin integrity or electrolyte and fluid balance, PN may be needed. Recommended protein needs are 1.5 to 2.0 grams/kg or up to 2.5 grams/kg if the patient has a high output enteroatmospheric fistula. No specific calorie goals have been established, but needs are likely similar to that of other critically ill patients. Somatostatin or somatostatin analogs can decrease drainage and assist with spontaneous closure (see Chapters 12 and 27).

MAJOR BURNS

Pathophysiology

Major burns result in severe trauma, and this response can be more pronounced and prolonged than any other injury. The release of inflammatory mediators results in a multitude of metabolic challenges. Hypermetabolism, muscle protein catabolism, MODS, insulin resistance, and infection are all common. Energy requirements can increase as much as 100% above resting energy expenditure (REE), depending on the extent and depth of the injury (Fig. 37.6). Exaggerated protein catabolism and increased urinary nitrogen excretion accompany this hypermetabolism, and protein is also lost through the burn wound exudate. Mechanical ventilation is usually required, especially in

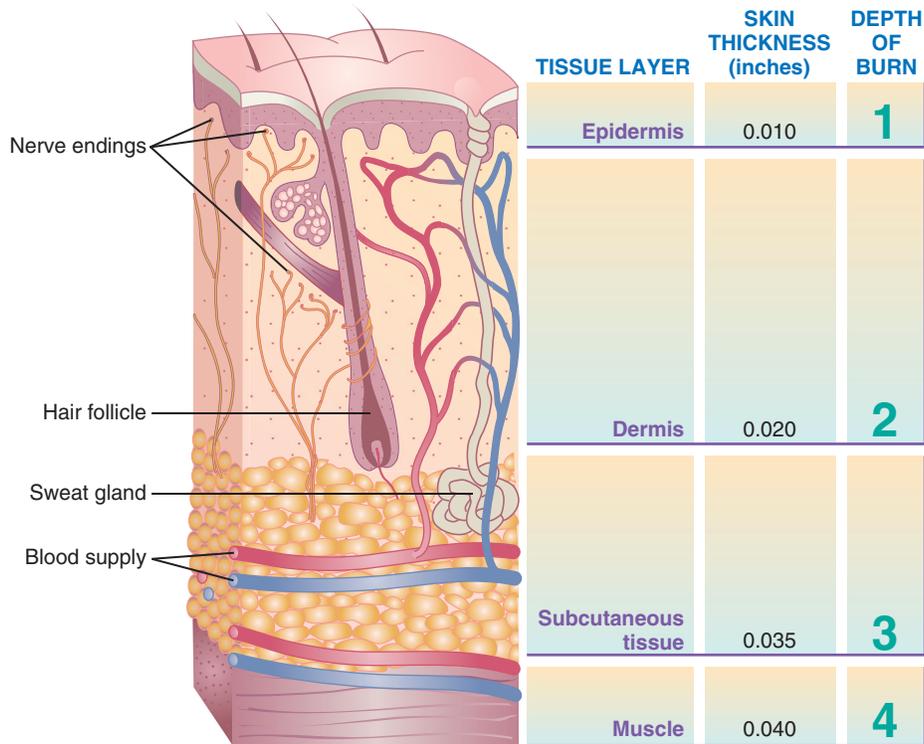

Fig. 37.6 Interpretation of burn classification based on damage to the integument.

patients who have been in a smoke environment for prolonged periods of time, resulting in an inhalation injury. Side effects such as ileus, nausea, anorexia, and dysphagia are common following injury and can further complicate a patient's ability to meet their nutritional needs. In children, healing after burn and trauma requires not only restoration of oxygen delivery and adequate calories to support metabolism and repair but also awareness of how children differ from adults in metabolic rate, growth requirements, and physiologic response (Cook and Blinman, 2010).

Medical Management

Fluid and Electrolyte Repletion

The first 24 to 48 hours of treatment for thermally injured patients are devoted to fluid resuscitation. The volume of resuscitation fluid is approximately 2 to 4 mL/kg body weight per percentage of burn depending on the patient's physiologic demands or response. Generally, half of the calculated volume for the first 24 hours is given during the first 8 hours after burn injury and the remaining half in the next 16 hours. Urine output is used to titrate the rate of IV fluid replacement.

The volume of fluid needed is based on the age and weight of the patient and the extent of the injury designated by percentage of **total body surface area (TBSA) burned**. Once resuscitation is complete, ample fluids must be given to cover maintenance requirements and evaporative losses that continue through open wounds. Evaporative water loss can be estimated at 2 to 3.1 mL/kg of body weight per 24 hours per percent of TBSA burn. Serum sodium, osmolar concentrations, and body weight are used to monitor fluid status. Providing adequate fluids and electrolytes as soon as possible after injury is paramount for maintaining circulatory volume and preventing ischemia.

Wound Management

Wound management depends on the depth and extent of the burn. Current surgical management promotes use of topical antimicrobial agents and biologic and synthetic dressings, early debridement, excision, and grafting. Energy expenditure may be reduced slightly by the practice of covering wounds as early as possible to reduce evaporative heat and nitrogen losses and prevent infection.

Ancillary Measures

Passive and active range of motion exercises should be started early in the hospital to prevent contracture formation. Physical and occupational therapy helps maintain function and prevents muscle wasting and atrophy. A warm environment minimizes heat loss and the expenditure of energy to maintain body temperature. Thermal blankets, heat lamps, and individual heat shields often are used to maintain environmental temperature near 86° F. Minimizing fear and pain with reassurance from the staff and adequate pain medication also can reduce catecholamine stimulation and help avoid increases in energy expenditure. Treatments such as biofeedback, guided imagery, and good sleep hygiene are helpful. A number of pharmacologic strategies have been used to attenuate the hypermetabolic state and net protein loss sustained by burn patients (Abdullahi and Jeschke, 2014). These anabolic agents including insulin, oxandrolone, and propranolol improve lean body mass through metabolic effects on skeletal muscle or fat tissue. Insulin decreases protein breakdown, oxandrolone decreases protein breakdown and fat oxidation, and propranolol decreases fat oxidation and promotes glucose homeostasis. These pharmacologic agents are used now in conjunction with nutrition support in the care of burn patients.

Medical Nutrition Therapy

A burn patient has greatly accelerated metabolism and needs increased energy, carbohydrates, proteins, fats, vitamins, minerals, and antioxidants to heal and prevent detrimental sequelae.

BOX 37.3 Medical Nutrition Therapy Goals for Burn Patients

1. Minimize metabolic stress response by
 - Controlling environmental temperature
 - Maintaining fluid and electrolyte balance
 - Controlling pain and anxiety
 - Excising and covering wounds early
 - Considering pharmacologic agents to attenuate metabolic demands
2. Meet nutritional needs by
 - Providing adequate calories to prevent weight loss of greater than 10% of usual body weight
 - Providing adequate protein to promote wound healing, improve immune function, and limit loss of lean body mass
 - Providing vitamin and mineral supplementation if indicated
3. Continue to reassess nutritional requirements
 - Repeat indirect calorimetry (IC) weekly in the early stages of burn injury and as needed thereafter
 - Compare enteral nutrition (EN) volumes received to volumes ordered and adjust rates when needed
 - Repeat physical assessment and monitor weight trends compared with admission (preresuscitation) weight

The goals of nutrition support therapy after major burn injury include provision of adequate calories to meet energy needs while minimizing associated metabolic complications, prevention or correction of specific nutrient deficiencies, and fluid and electrolyte management for adequate urine output and normal homeostasis (see [Box 37.3](#) for the nutritional goals for the burned person). Adequate surgical care, infection control, and nutrition should be implemented as soon as possible after burn resuscitation. Delays in admission to an organized burn unit can be detrimental, especially for children, because malnutrition is a common concern. Nutritional assessment of the adult burn patient should include evaluation of any preexisting substance abuse, psychiatric illness, or chronic disease that may be associated with malnutrition and could influence energy and nutrient requirements.

Many burn patients are able to eat food, and nutrition counseling should focus on selection of high protein and calorically dense food and fluids. It is not uncommon that patients require supplemental nutrition support, and EN should be considered for those patients who are unable to eat or cannot achieve adequate intake by food alone. With major burns, placement of enteral tubes should occur as soon as possible after the injury. Early initiation of EN support has been shown to blunt the hypermetabolic response and lessen the degree of protein catabolism. Postpyloric trophic feeds have been safely initiated 4 to 6 hours post burn and titrated to goal volumes following the resuscitation period. Feeding tube placement into the duodenum or jejunum also allows for uninterrupted delivery of nutrition during frequent surgical procedures ([Varon et al, 2017](#)). In contrast, many patients with gastric tubes must be made nothing by mouth (NPO) for wound excisions and skin grafting, thus limiting their ability to receive adequate nutrition.

Energy

Increased energy needs of the burn patient vary according to the size of the burn, with severely burned patients often approaching twice their predicted energy expenditure. Burn size makes the largest contribution to measured energy expenditure, followed by age ([Shields et al, 2013](#)). Most predictive equations used to calculate energy expenditure in severely burned adults do not correlate strongly with

measured energy expenditure ([Shields et al, 2013](#)). Therefore measuring energy expenditure via IC is the most reliable method for assessing energy expenditure in burn patients. It is believed that increasing energy requirements by 10% to 30% above measured REE may be necessary to limit weight loss in burn patients and account for energy expenditure associated with wound care and physical therapy. If IC is not an option, there is debate as to which predictive equation is optimal. Dickerson compared 46 predictive equations to the IC results of 24 adult patients and found Xie (1993), Zawacki (1970), and Milner (1994) to be the most precise, unbiased predictive equations ([Dickerson et al, 2002](#)), whereas Shields compared nine predictive equations to the IC results of 31 adult burn patients and found Milner (1994), Carlson (1992), and Harris-Benedict equations with an injury factor of 1.5 were the only equations that were not statistically different from measured energy expenditure ([Shields et al, 2013](#)). European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines suggest the Toronto equation for adult burn patients and the Schofield equation for burn children ([Rousseau et al, 2013](#)).

Additional calories may be required because of fever, sepsis, multiple traumas, or the stress of surgery. Although weight gain may be desirable for the severely underweight patient, this is generally not feasible until acute illness has resolved. Overfeeding can lead to difficulty weaning from mechanical ventilation, fatty liver, azotemia, and hyperglycemia. When a factor of 1.4 was added to measured REE, patients gained weight but it was an increase in fat mass without improvements in lean body mass ([Hart et al, 2002](#)). Adjustments in caloric goals may be required when patients receive a large amount of IV dextrose solutions and propofol (an anesthetic in a lipid-delivery system).

Weight maintenance should be the goal for overweight patients until the healing process is complete. Obese individuals may be at higher risk of wound infection and graft disruption. There is limited data on energy requirements for the obese burned patient, and while the PSU equation has been recommended for obese, critically ill patients, this has not been validated with the burn population. A small study including obese trauma as well as nine obese burn patients found that 21 kcal/kg/day was more similar to the average measured REE than the studied equations ([Stucky et al, 2008](#)).

Protein

The protein needs of burn patients are elevated because of losses through urine and wounds, increased use in gluconeogenesis, and wound healing. Recent evidence promotes the feeding of high amounts of protein. Providing 1.5 to 2.0 grams/kg in adults and 2.4 to 4.0 grams/kg in children is recommended ([McClave et al, 2016](#)).

The adequacy of energy and protein intake is best evaluated by monitoring wound healing, graft take, and basic nutrition assessment parameters. Wound healing or graft take may be delayed if weight loss exceeds 10% of the usual weight. An exact evaluation of weight loss may be difficult to obtain because of fluid shifts or edema, or because of differences in the weights of dressings or splints. The coordination of weight measurement with dressing changes or hydrotherapy may allow recording of a weight without dressings and splints. Monitoring weight trends compared with admission, preresuscitation weight, and ongoing physical assessment is necessary.

Nitrogen balance often is used to evaluate the efficacy of a nutritional regimen, but it cannot be considered accurate without accounting for wound losses, which is difficult to accomplish in a clinical setting. Nitrogen excretion should begin to decrease as wounds heal, are grafted, or are covered. Unfortunately, serum proteins such as albumin and prealbumin are more representative of the acute phase response than nutritional status. Using these laboratory

tests to monitor nutritional status is not recommended (SCCM and ASPEN, 2016).

Micronutrients and Antioxidants

Vitamin and trace elements are required for many stages of the burn healing process, and circulating levels of these nutrients have been shown to be lower than normal either due to the inflammatory process or due to losses in wound exudate. Although it is known that levels of many vitamins and minerals are low in this population after injury, exact supplementation guidelines have not been determined and practice among facilities is varied. The ASPEN and ESPEN guidelines both recommend supplementation but do not give dosing recommendations (McClave et al, 2016; Rousseau et al, 2013). A recent systematic review and meta-analysis evaluated supplementation of selenium, copper, and zinc either alone or combined. Results showed no effect on length of stay (LOS) nor mortality but a significant decrease in infectious episodes was found (Kurmis et al, 2016).

Vitamin C is involved in collagen synthesis, fibroblast and capillary formation, and immune system maintenance; it also acts as a powerful antioxidant (Nordlund et al, 2014). Furthermore, vitamin C levels decrease after burn injury and may be a result of cutaneous losses (Vinha et al, 2013). Vitamin C frequently is supplemented to promote wound healing (0.5 to 1.0 grams/day), and some centers are using high-dose vitamin C (0.66 mg/kg/h for 24 h) during the resuscitation period to minimize the amount of fluid resuscitation requirements (Rousseau et al, 2013).

Vitamin A is also an important nutrient for immune function and epithelialization. Vitamin A deficiency impairs collagen synthesis and may affect wound healing negatively. Toxicity is also possible, however, and vitamin A supplementation should be limited in patients with kidney and liver disease. Few clinical data suggest routine supplementation of vitamin A in burns, and vitamin A levels have been shown to return to normal 2 weeks after injury without supplementation (Nordlund et al, 2014).

Vitamin D deficiency has been reported in pediatric and adult burn patients. It is still unknown how to interpret vitamin D levels in critical illness, and optimal dosing levels for supplementation have not been established. Vitamin D is an area of ongoing research, especially in the burn population, as burn survivors have a long-term increased risk of vitamin D deficiency because the major source of vitamin D synthesis is in the skin (Al-Tarrach et al, 2018).

Electrolyte imbalances that involve serum sodium or potassium usually are corrected by adjusting fluid therapy. Hyponatremia may be seen in patients whose evaporative losses are reduced drastically by the application of dressings or grafts; who have had changes in maintenance fluids; or who have been treated with silver nitrate soaks, which tend to draw sodium from the wound. Restricting the oral consumption of free water and sodium-free fluids may help correct hyponatremia. Hypokalemia often occurs after the initial fluid resuscitation and during protein synthesis. Slightly elevated serum potassium may indicate inadequate hydration.

Depression of serum calcium levels may be seen in patients with burns that involve more than 30% TBSA. Hypocalcemia accompanies hypoalbuminemia. Calcium losses may be exaggerated if the patient is immobile or being treated with silver nitrate soaks. Early ambulation and exercise should help minimize these losses.

Hypophosphatemia also has been identified in patients with major burns. This occurs most commonly in patients who receive large volumes of resuscitation fluid along with parenteral infusion of glucose solutions and large amounts of antacids for stress ulcer prophylaxis. Serum levels must be monitored and appropriate phosphate supplementation provided. Magnesium levels also may require

attention because a significant amount of magnesium can be lost from the burn wound. Supplemental phosphorus and magnesium often are given parenterally to prevent GI irritation.

A depressed serum zinc level has been reported in burn patients, but whether this represents total body zinc status or is an artifact of hypoalbuminemia is unclear, because zinc is bound to serum albumin. Zinc is a cofactor in energy metabolism and protein synthesis. Supplementation with 220 mg of zinc sulfate (50 mg elemental zinc) is common (Nordlund et al, 2014). However, zinc content of enteral tube feedings and other multivitamins should be monitored to prevent long-term over-supplementation of zinc, which can result in copper deficiency. The anemia initially seen after a burn usually is unrelated to iron deficiency and is treated with packed red blood cells.

Methods of Nutrition Support Therapy

Methods of nutrition support therapy must be implemented on an individual basis. Most patients with burns of less than 20% TBSA are able to meet their needs with a regular high-calorie, high-protein oral diet. Often the use of concealed nutrients such as protein added to puddings, milks, and gelatins is helpful because consuming large volumes of foods can be overwhelming to the patient. Patients should have immediate access to food and fluids at the bedside. They should be encouraged to consume calorically dense, high-protein drinks. Involving family and caregivers during mealtimes helps to promote good oral intake.

Patients with major burns, elevated energy expenditure, or poor appetites may require tube feeding or PN. Enteral feeding is the preferred method of nutrition support therapy for burn patients, but PN may be necessary if unable to use the enteral route. Because ileus is often present only in the stomach, severely burned patients can be fed successfully by tube into the small bowel. PN may be needed for patients who do not tolerate tube feeds or do not have enteral access. Soybean oil-based parenteral lipid infusions may inhibit immune function. Alternative mixed oil lipid emulsions are now available, but they have not been specifically studied in the burn population. With careful monitoring, central lines for PN can be maintained through burn wounds (see Chapter 12).

SURGERY

The delivery of correctly formulated and safely administered nutritional and metabolic support is a matter of life or death in surgical and critical care units; obese patients have a higher surgical risk (Blackburn et al, 2010). Although surgical morbidity correlates best with the extent of the primary disease and the nature of the operation performed, malnutrition also may compound the severity of complications. A well-nourished patient usually tolerates major surgery better than a severely malnourished patient. Malnutrition is associated with a high incidence of operative complications, morbidity, and death. If a malnourished patient is expected to undergo major upper GI surgery and EN is not feasible, PN should be initiated 7 to 10 days preoperatively and continued into the postoperative period if the duration of therapy is anticipated to be longer than 7 days. For a patient who is not malnourished at the time of admission and EN is not feasible, PN should be delayed for 5 to 7 days following surgery (McClave et al, 2016; see Chapter 12).

Medical Nutrition Therapy

Preoperative Nutrition Care

The routine practice of requiring a patient take NPO at midnight before surgery has been discontinued in many settings. The American Society of Anesthesiologists historically recommended withholding

solids for 6 hours preoperatively and clear liquids for 2 hours before induction of anesthesia. This practice was intended to minimize aspiration and regurgitation. The use of a carbohydrate-rich beverage in the preoperative period has been shown to enhance glycemic control and decrease losses of nitrogen, lean body mass, and muscle strength after abdominal and colorectal surgery (Bilku et al, 2014).

Postoperative Nutrition Care

Postoperative patients who are critically ill and receiving care in the ICU should receive early EN unless there is an absolute contraindication (McClave et al, 2016). This practice after major GI surgery is associated with reduced infection and decreased hospitalization. If the patient is malnourished (severe or nonsevere), however, the use of PN is indicated to provide perioperative support until patients are able to tolerate goal enteral feeding regimens (McClave et al, 2016). The use of arginine-containing immune-enhanced enteral formulas is

associated with a decrease in wound complications and a reduced hospital LOS in patients who have undergone GI surgery (Drover et al, 2011; Marik and Zaloga, 2010).

If oral feeding is not possible or an extended NPO period is anticipated, an access device for enteral feeding should be inserted at the time of surgery. Combined gastrostomy-jejunostomy tubes offer significant advantages over standard gastrostomies because they allow for simultaneous gastric drainage from the gastrostomy tube and enteral feeding via the jejunal tube.

The timing of introduction of solid food after surgery depends on the patient's degree of alertness and condition of the GI tract. A general practice has been to progress over a period of several meals from clear liquids to full liquids and finally to solid foods. However, no physiologic reason exists for solid foods not to be introduced as soon as the GI tract is functioning and a few liquids are tolerated. Surgical patients can be fed a regular solid-food diet rather than a clear liquid diet.

CLINICAL CASE STUDY

Chronologic Clinical Case Study with Suggested Answers

First Assessment

A 44-year-old Native American man was admitted to a hospital with an incarcerated ventral hernia and probable bowel compromise. He underwent hernia repair and was found to have dusky areas of small bowel (clinical sign of lack of oxygenation). He was left in temporary abdominal closure and remained mechanically ventilated and sedated. On hospital day 5, 30 cm of jejunum was resected and the patient was left in discontinuity (the jejunum had not been reconnected yet) with a plan to return to the operating room in the next 24 hours.

Screening and Assessment Data

Height = 72" (183 cm)
 Weight = 364 lb (165 kg)
 Body mass index = 49 kg/m²
 Ideal body weight = 178 lb (81 kg)
 Weight change in the 1 month before admission: none
 Decreased intake in the previous month: no
 Physical examination: bilateral severe pitting edema of ankles and upper extremities.
 Abdominal examination: distended with absent bowel sounds
 Currently receiving 0.45% normal saline at 120 mL/h
 Intake/Output = 3305/3725 mL

Laboratory Values

Sodium: 138 mmol/dL
 Potassium: 3 mmol/dL
 Chloride: 105 mmol/dL
 Carbon dioxide: 27 mmol/dL
 Blood urea nitrogen: 13 mg/dL
 Creatinine: 1.28 mg/dL
 Glucose: 185 mg/dL
 Ionized calcium: 1.12 mm/L
 Magnesium: 1.6 mg/dL
 Phosphorus: 2.1 mg/dL
 Albumin: 1.9 g/dL

- Write pertinent nutrition diagnosis statements (problem, cause, and signs and symptoms [PES] format) in order of priority for this patient.
 - Malnutrition in the context of acute illness as evidenced by energy intake <50% of requirements (≥ 5 days) and severe fluid accumulation.
 - Altered nutrition-related laboratory values related to the metabolic response to stress and a lack of electrolyte intake in diet and intravenous fluids as evidenced by low serum sodium, potassium, and phosphorus.

- Should the patient be started on parenteral nutrition (PN)? Explain.

By the information presented in the case, the patient should be started on PN because he is malnourished, has been NPO for 6 days, and cannot begin enteral nutrition (EN).

- Calculate the patient's nutritional needs.

His caloric requirement should be estimated using the hypocaloric, high-protein approach because he is morbidly obese (grade III) and renal function is normal. Ideal body weight should be used.

Hypocaloric regimen for this patient is 11 to 14 kcal/kg actual body weight: 1815 to 2310 kcal/day.

Protein requirement may be set at 2 to 2.5 g/kg ideal body weight or 162 to 203 g/day.

First Change of Status with Reassessment

Patient returned to the operating room (OR) on hospital day 6 where remaining small bowel appeared viable. He was placed back in continuity (the jejunum was reconnected at the site of the prior resection) and the abdomen was closed. On hospital day 7 the patient's body temperature spiked to 39° C, and he was found to have multiple infected abdominal abscesses. He goes to the operating room for abscess drainage. During this time his blood pressure (BP) and urine output dropped considerably, requiring initiation of fluid resuscitation and vasopressor agents for BP stabilization. His kidney function is noted to worsen. There is no plan for renal replacement therapy at the present.

Current status is noted:

T_{max} 39.3° C
 VE = 15.6 L/min (minute ventilation)
 PN continues
 Intravenous fluids: 0.45% normal saline solution at 150 mL/h + additional fluid boluses
 Sodium: 131 mmol/dL
 Potassium: 5.1 mmol/dL
 Chloride: 96 mmol/dL
 Carbon dioxide: 15 mmol/dL
 Blood glucose: 225 mg/dL
 Ionized calcium: 1.01 mm/L
 Magnesium: 2.8 mg/dL
 Phosphorus: 4.8 mg/dL
 Albumin: 1.2 gm/dL
 Arterial blood gas: 7.31/24/115/11

CLINICAL CASE STUDY—cont'd

Chronologic Clinical Case Study with Suggested Answers

4. Upon monitoring, what is the patient's metabolic state?
He has become hypermetabolic and hypercatabolic, and he has worsening kidney function.
Hyperglycemia has worsened.
Electrolyte excess (potassium, phosphorus, magnesium).
5. What is the patient's acid-base status?
He has a metabolic acidosis resulting from an impaired renal excretion of acid, and reabsorption and regeneration of bicarbonate.
6. Write updated PES statements:
Increased nutrient needs (energy and protein) related to a systemic inflammatory response as evidenced by fever and elevated minute ventilation.
Altered nutrition-related laboratory values (hyperglycemia) related to stress metabolism and glucose intake as evidenced by blood glucose of 225 mg/dL.
Altered nutrition-related laboratory values related to acute kidney injury as evidenced by elevated potassium, phosphorus, and magnesium.
7. Is the patient's blood glucose control adequate? If not, why and what should be done?
His blood glucose is not adequately controlled. There is evidence that when glucose levels are controlled between 140 to 180 mg/dL, survival is better. The dextrose load in his PN should be reduced or a standardized insulin protocol should be instituted, or both. In addition, energy intake should be assessed to confirm absence of overfeeding because this could result in hyperglycemia.

8. Why is the patient's serum albumin level falling?
Decreased acute-phase proteins are a response to the inflammatory process his body has mounted to try to reestablish homeostasis.

Second Change of Status with Reassessment

On hospital day 10, the patient has not yet stoolled, but his abdomen is soft. His acute kidney injury continues, although hemodialysis has been initiated and electrolyte levels have normalized. On rounds, the dietitian asks whether the patient is stable enough to start tube feeding through a postpyloric feeding tube. The surgical and critical care teams believe that the patient's gastrointestinal status has improved sufficiently to initiate an enteral feeding.

9. What feeding formula should be used? Is an immune-enhancing tube feeding formula indicated?

Commercial immune-enhancing formulas that combine several nutrients thought to enhance immune function are not indicated for routine use, and may be contraindicated in the severely critically ill, such as this patient.

A polymeric enteral feeding was initiated via postpyloric access and gradually advanced to goal rate during the next 2 to 3 days. Tolerance was demonstrated via no change in abdominal distention, pain, or nausea and vomiting. As the feeding advanced, the PN was gradually weaned, then discontinued when > 60% of goal (EN) was achieved.

CLINICAL INSIGHT

Factors to consider when interpreting the literature with respect to conflicting data among nutrition support outcomes studies:

- Study designs may differ
- Sample size may be too small
- Patient sample may be heterogeneous; subjects may differ by underlying illness or injury, acuity level, mortality risk
- Inclusion of well-nourished patients who would likely not show an effect of nutrition intervention
- Preexisting malnutrition may or may not be present and may or may not be diagnosed with similar criteria

- Length of intensive care unit (ICU) stay may vary
- Short interval time of nutrition therapy in the ICU
- Differences may be present with respect to timing of initiation of enteral nutrition (EN) or parenteral nutrition (PN)
- Contribution of nonnutritional calorie sources such as D5W (5% dextrose in water) and medications in lipid delivery systems (i.e., propofol, clevidipine)
- Differences in techniques to establish target energy goals (i.e., indirect calorimetry, predictive equations, kcal/kg)

CLINICAL INSIGHT

Enhanced Recovery After Surgery (ERAS)

First presented in the late 1990s, this multimodal pathway for care of the surgical patient has become a standard of care for many conditions including colon, rectal, liver, and esophageal resections; pancreatoduodenectomy; bariatric surgery; major gynecologic procedures; and head and neck cancer surgery (Ljungqvist et al, 2017). This management approach involves aspects of the patient's care preoperatively, during the surgical procedure, and postoperatively (Fig. 37.7). The central elements of the ERAS pathway address key factors including pain control, gut dysfunction, the need for intravenous fluids, and ambulation. The ERAS components help clarify how these areas interact to affect patient recovery, and mounting evidence demonstrates that use of the ERAS pathway results in positive outcomes compared with standard surgical care.

In a meta-analysis, Varadhan and colleagues reported the ERAS pathway was shown to reduce surgical care time by more than 30% and reduce postoperative complications by up to 50% (Varadhan et al, 2010). An international ERAS society was formed in 2010 with its mission to "develop perioperative care and to improve recovery through research, audit education and implementation of evidence-based practice" (Gustafsson et al, 2012).

Medical Nutrition Therapy for Rheumatic and Musculoskeletal Disease

*F. Enrique Gómez, MSc, PhD
Gabriela E. Mancera-Chávez, MSc, NC
Martha Kaufer-Horwitz, MSc, DSc, NC, FTOS*

KEY TERMS

ankylosing spondylitis (AS)	hyperuricemia	rheumatic fever
antiinflammatory diet	leukotrienes (LT)	rheumatoid arthritis (RA)
antinuclear antibodies (ANA)	lipoxigenase (LOX)	rheumatic and musculoskeletal diseases (RMDs)
arachidonic acid (ARA)	maresins	rheumatoid factor (RF)
arthritis	monosodium urate (MSU) crystals	scleroderma
autoimmune arthritis	nonsteroidal antiinflammatory drug (NSAIDs)	Sjögren's syndrome (SS)
biologic response modifiers (BRMs)	osteoarthritis (OA)	specialized proresolving mediators (SPMs)
cyclooxygenase (COX)	polymyalgia rheumatica (PMR)	spondylarthritides
C-reactive protein (CRP)	polymyositis (PM)	systemic lupus erythematosus (SLE)
cytokines	polyunsaturated fatty acids (PUFAs)	systemic sclerosis (SSc)
dihomo- γ -linolenic acid (DGLA)	prostaglandins (PG)	temporomandibular disorders (TMDs)
disease-modifying antirheumatic drugs (DMARDs)	prostanoids	thromboxanes (Tx)
docosahexaenoic acid (DHA)	protectins	tophi
eicosanoids	purines	uric acid
eicosapentaenoic acid (EPA)	Raynaud's syndrome	uricostatic
gamma-linolenic acid (GLA)	resolvins	uricosuric
gout		

Rheumatic and musculoskeletal diseases (RMDs) are a diverse group of inflammatory diseases that commonly affect the connective tissue and joints but can affect any organ of the body. There are more than 200 different RMDs, affecting both children and adults. They are usually caused by immune dysregulation, infections, or gradual deterioration of joints, muscles, ligaments, and bones. Some of them have an autoimmune component while the origin of others is unknown. They are typically progressive, painful, and limit function. In severe cases, RMDs can result in significant disability, having a major impact on both quality of life and life expectancy (van der Heijde et al, 2018).

Medical nutrition therapy (MNT), pharmacotherapy, and physical and occupational therapies must be tailored and designed to treat each disease and its symptoms. A diet with adequate protein and energy content, rich in vitamins, minerals, and omega-3 **polyunsaturated fatty acids (PUFAs)** can promote a beneficial protective effect against tissue damage and suppression of inflammatory activity. Table 38.1 provides an overview of these disorders and their nutritional management.

RMDs are among the most prevalent chronic disease conditions in the United States. The annual cost for medical care to treat all forms of arthritis and joint pain is estimated to be \$303.5 billion (Murphy et al, 2018). Rheumatic disease affects all population groups. Data from the 2015 National Health Interview Survey estimated that arthritis affects 91.2 million adults in the United States, equivalent to 36.8% of the

total 247.7 million Americans (Jafarzadeh and Felson, 2018). Among persons with heart disease, diabetes, and obesity, the prevalence of doctor-diagnosed arthritis was 49.3%, 47.1%, and 30.6%, respectively (Barbour et al, 2017).

The National Arthritis Data Workgroup reviewed data to estimate national prevalence rates of various rheumatic diseases based on 2005 U.S. census data, finding that in the United States rheumatoid arthritis (RA) affects 1.3 million adults; juvenile arthritis 294,000 people; spondylarthritides (the current name of spondyloarthropathies) 0.64 to 2.4 million adults ages 25 and older; **systemic lupus erythematosus (SLE)** 161,000 to 322,000 adults; **systemic sclerosis (SSc)** 49,000 adults; **Sjögren's syndrome (SS)** 0.4 to 3.1 million adults; clinical osteoarthritis 27 million people aged 25 and older; **polymyalgia rheumatica** 711,000 people; gout 8 million adults; and fibromyalgia 5 million people (Helmick and Watkins-Castillo, 2014)

Arthritis is a generic term that comes from the Greek word *arthro*, which means “joint,” and the suffix *-itis*, which means “inflammation.” There are two distinct categories of disease: systemic, autoimmune arthritis and nonsystemic **osteoarthritis (OA)**. The more debilitating **autoimmune arthritis** group includes RA, psoriatic arthritis, juvenile RA, gout, SS, fibromyalgia, SLE, and scleroderma. The OA group includes OA, bursitis, and tendonitis. Other rheumatic diseases include spondylarthritides, polymyalgia rheumatica, and polymyositis.

TABLE 38.1 Summary of Medical Nutrition Therapy for Rheumatic Diseases

Disease	Medical Nutrition Therapy	Complementary and Integrative Medicine (CIM)	Supplements or Herbs that Can Be Safely Considered
Rheumatoid arthritis	Vegan, Mediterranean diet; antiinflammatory diet; appropriate calories for maintenance of normal body weight; RDA for protein unless malnutrition present; moderate-fat diet with emphasis on omega-3 PUFAs and fish 1-2 times per week and monounsaturated fats; modifications as needed for jaw pain, anorexia	Exercise, meditation, tai chi, spiritual practice, relaxation techniques; topical rubbing gels based on capsaicin. A gluten-free diet may be helpful to reduce inflammation.	Supplement diet as needed to meet DRI for antioxidant nutrients and calcium, folate, vitamins B ₆ , B ₁₂ , D; GLA from evening primrose oil, black currant oil, and borage oil; fish oils; bromelain, rosemary, turmeric, curry, ginger, and other culinary herbs. Probiotic supplementation may be helpful.
Osteoarthritis	Weight management; diet adequate in calcium, folate, vitamins B ₆ , D, K; magnesium; antiinflammatory diet (see Box 38.2)	Exercise, acupuncture; SAM-e; topical rubbing gels based on capsaicin, turmeric (curcumin), ginger	Supplement diet as needed to meet DRI for antioxidant nutrients and calcium, folate, vitamins B ₆ , B ₁₂ , and D; glucosamine and chondroitin (mixed results); fish oils; bromelain, type 2 collagen
Gout	Weight management; adequate fluid consumption; alcohol, particularly beer, restricted or eliminated; limit or eliminate fructose intake from sweetened beverages and fruit juice. Limit animal foods except dairy and moderate amounts of cold water, oily fish, eggs, and poultry; coffee is protective.	Exercise; alkaline-ash foods; see <i>Clinical Insight</i> on Acid and Alkaline Diets in Chapter 34.	Cherry juice, vitamin C
Lupus	Tailor diet to individual needs based on organ involvement; calories to maintain IBW; restriction of protein, fluid, and sodium if renal involvement; check for gluten intolerance.	Antiinflammatory diet, meditation, and stress reduction	Supplement diet as needed to meet DRI for antioxidant nutrients, omega-3 fatty acids, turmeric (curcumin)
Scleroderma	Adequate fluid; high-energy, high-protein supplements as needed to prevent or correct weight loss; moist foods; modifications for GERD if needed.		
Sjögren's syndrome	Balanced diet with adequate B ₆ or vitamin supplementation; restrict sugary foods and beverages; modify food portions to smaller size and soft consistency to improve chewing and swallowing processes.		GLA improves eye discomfort and tear production
TMD	Balanced diet with soft foods in small pieces to improve chewing and reduce pain.		

DRI, Dietary reference intake; GERD, gastroesophageal reflux disease; GLA, gamma-linolenic acid; IBW, ideal body weight; RDA, recommended dietary allowance; SAM-e, S-adenosyl-L-methionine; TMD, temporomandibular disorder.

ETIOLOGY

Body changes associated with aging—including decreased somatic protein, body fluids, and bone density—and obesity may contribute to the onset and progression of arthritis. The aging body mass causes changes in neuroendocrine regulators, immune regulators, and metabolism, which affect the inflammatory process. Therefore recent increases in the frequency of these conditions may be the result of aging of the U.S. population. It is estimated that by 2030 approximately 67 million Americans will be at risk for rheumatic disease (Barbour et al, 2017).

Rheumatic conditions are usually chronic and have no known cure but may present as acute episodes with short or intermittent duration. Chronic arthritic conditions are associated with alternating periods of remission without symptoms and flares with worsening symptoms that occur without any identifiable cause. Risk factors include repetitive joint injury, genetic susceptibility, and environmental factors, particularly smoking. Gender is a risk factor because women are more susceptible than men for most rheumatic diseases; the female to male ratio varies from 3:1 for RA, to 9:1 for SLE and SS. Only in gout is there a clear dominance of male over female patients. Recently a transcriptome analysis of RNA levels showed that healthy women carry a proinflammatory profile, particularly to develop RA (Jansen et al, 2014).

Patients with RMDs also have higher risk of developing other conditions such as cardiovascular disease (CVD) (Arida et al, 2018), metabolic syndrome (Medina et al, 2018), and psychiatric disorders such as depression (Marrie et al, 2018).

PATHOPHYSIOLOGY AND INFLAMMATION

Inflammation plays an important role in health and disease. The inflammatory process normally occurs to protect and repair tissue damaged by infections, injuries, toxicity, or wounds via accumulation of fluid and cells. Once the cause is resolved, the inflammation usually subsides. Whether inflammation is due to stress on the joints as in OA, or to an autoimmune response as in RA, an uncontrolled and long-lasting inflammatory reaction causes more damage than repair (see Chapter 7 for discussion of the inflammation and the pathophysiology of chronic disease) (see *Focus On: The Biochemistry of Inflammation*).

PUFAs play an important role in inflammation as precursors of a potent group of modulators of inflammation termed **eicosanoids** (*eicos* means “20” in Greek), which include the **prostanoids** and the **leukotrienes (LT)**. The prostanoids are the products of the enzyme **cyclooxygenase (COX)** and include the **prostaglandins (PG)** and **thromboxanes (Tx)**, whereas LTs are produced by the enzyme **lipoxigenase (LOX)** (Box 38.1).

FOCUS ON

The Biochemistry of Inflammation

Cyclooxygenase (COX, officially known as prostaglandin-endoperoxide synthase [PTGS]), has three isoforms: COX-1, COX-2, and COX-3 (the latter is a splice variant of COX-1, so it is sometimes called COX-1b or COX-1var). COX-1 is widely distributed and constitutively expressed in most tissues, whereas COX-2 is induced by inflammatory and proliferative stimuli. The difference in tissue distribution of COX expression may explain the existence of the two COX isoforms: COX-1 providing prostaglandin (PG) that is required for homeostatic functions (including gastric cytoprotection), and COX-2 playing the predominant role in PG formation during pathophysiological states, such as in inflammation (Seo and Oh, 2017).

In the synthesis of prostanoids, COX consumes two double bonds from the original polyunsaturated fatty acid (PUFA), whereas lipoxygenase (LOX) consumes none; therefore, depending on the PUFA used as substrate, different eicosanoids are produced. For instance, **arachidonic acid (ARA)** (20:4, omega-6) has four double bonds and is the precursor of the series 2 of PG and thromboxanes (Tx), and of the series 4 of leukotrienes (LT), which are the most potent inflammatory eicosanoids (Calder, 2017). The series 2 of prostanoids (PG₂ and Tx₂) are abundant because ARA is the most abundant in plasma membranes of cells involved in inflammation (macrophages, neutrophils, fibroblasts). If the substrate is **eicosapentaenoic acid (EPA)** (20:5, omega-3)

that has five double bonds, series 3 of PG and Tx, and series 5 of LT are produced. **Dihomo-γ-linolenic acid (DGLA)** (20:3, omega-6) has three double bonds and is the precursor of series 1 of PG and Tx, and of series 3 of LT that have antiinflammatory activities (Food and Agricultural Organization [FAO] of the United Nations [UN], 2010). Finally, **docosahexaenoic acid (DHA)** (22:6, omega-3) and EPA are converted to novel bioactive lipid mediators termed **specialized proresolving mediators (SPMs)**, which include three families: **resolvins (Rv)**, **protectins**, and **maresins**, which promote the resolution of inflammation. Rv of the E series (RvE1-2) derived from EPA, and Rv of the D series (RvD1-6) derived from DHA, are produced by the sequential actions of the enzymes 15-lipoxygenase (15-LO) and 5-lipoxygenase (5-LO). Recent studies have shown that PUFAs also may regulate the expression of genes associated with the inflammatory response (Serhan and Levy, 2018). Based on this information, it is desirable to increase the omega-3/omega-6 ratio by increasing the consumption of antiinflammatory EPA, DGLA, and DHA (oily fish), while reducing the intake of ARA (vegetable oils and meat). Similarly, the increase in vegetables and fruits consumption also results in reduced risk of rheumatic diseases by contributing phytonutrients that have antiinflammatory effects (van Breda and de Kok, 2018).

BOX 38.1 Production of Bioactive Lipid Mediators from Omega-3 and Omega-6 PUFAs

Eicosapentaenoic acid (EPA) (20:5, omega-3)

Thromboxane A₃: weak vasoconstrictor and weak platelet aggregator
 Prostacyclin PGI₃: vasodilator and platelet antiaggregator
 Leukotriene B₅: weak inflammation inducer and weak chemotactic agent
 E-series resolvins (RvE1 and 2): promote resolution of inflammation

Arachidonic Acid (ARA) (20:4, omega-6)

Thromboxane A₂: vasoconstrictor and potent platelet aggregator
 Prostaglandin E₂: vasodilator and platelet antiaggregator
 Leukotriene B₄: inflammation inducer and potent leukocyte chemotaxis and adherence inducer

Dihomo-γ-linoleic acid (DGLA) (20:3, omega-6)

Thromboxane A₁: antiinflammatory and pain reducer
 Prostaglandin E₁: vasodilator, inhibits monocyte and neutrophil function, platelet antiaggregator
 Leukotriene B₃: very weak proinflammatory effects

Eicosapentaenoic acid (EPA) (20:5, omega-3)

E-series resolvins (RvE 1-3): inhibit neutrophil recruitment, promote lymphatic removal of phagocytes, reduce PMN infiltration

Docosahexaenoic acid (DHA) (22:6, omega-3)

D-series resolvins (RvD 1-6): promote resolution of inflammation, analgesics, reduce leukocyte recruitment and activation, reduce interleukin (IL)-1 and tumor necrosis factor (TNF) production
 Protectins (PD1) and maresins 1 (MaR 1 and 2): promote resolution of inflammation

Calder PC: Omega-3 fatty acids and inflammatory processes: from molecules to man, *Biochem Soc Trans* 45: 1105, 2017; Food and Agricultural Organization (FAO) of the United Nations: Fat and fatty acid intake and inflammatory and immune response. MEDICAL DIAGNOSIS AND TREATMENT

A thorough history of symptoms and a detailed physical examination are the cornerstones for an accurate diagnosis. However, laboratory testing can help to further refine the diagnosis and identify appropriate treatment.

Biochemical Assessment

Acute-phase proteins are plasma proteins whose concentrations increase more than 25% during inflammatory states. Two acute-phase proteins traditionally used to screen for and monitor rheumatic disease are **rheumatoid factor (RF)** and **C-reactive protein (CRP)**, although they are nonspecific and, in the case of CRP, also may indicate an infection or even a recent cardiac event. The term RF is used to refer to a group of self-reacting antibodies (an abnormal IgM against normal IgG) found in the sera of rheumatic patients. The American College of Rheumatology (ACR) recommends periodic measurements of RF and CRP in addition to a detailed assessment of symptoms and functional status and radiographic examination to determine the current level of disease activity.

The detection of autoantibodies to a variety of antigens is important in the diagnosis of several rheumatic diseases (Jog and James, 2017). These antibodies can be directed against the nucleus (**antinuclear antibodies [ANA]**) either to double-stranded DNA (dsDNA), ribonucleoproteins (RNPs), or other nuclear structures. Some autoantibodies recognize intracellular structures, or proteins that constitute extracellular matrices. Very often, the presence of a particular set of autoantibodies is a distinct characteristic of a rheumatic disease such as anti-dsDNA and anti-Sm for SLE, anticitrullinated protein antigens (ACPAs) for RA, and anti-Ro/SSA, and anti-La/SSB for SS. Routine blood testing also should include complement levels, a complete blood count, serum creatinine, and hematocrit; urine or synovial fluid may be tested as well (Jog and James, 2017).

PHARMACOTHERAPY

Many of the drugs used in treating RMDs provide relief from pain and inflammation, with hopes of controlling symptoms and slowing disease progress rather than providing a cure. Table 38.2 describes the

TABLE 38.2 Nutritional Side Effects of Medications Used in the Treatment of Rheumatic and Musculoskeletal Diseases*

Drug Category	Nutritional Side Effects*
Analgesics	
Acetaminophen with codeine, hydrocodone with acetaminophen, hydrocodone with ibuprofen, methadone hydrochloride, morphine sulfate, morphine sulfate with naltrexone, oxycodone, oxycodone hydrochloride with acetaminophen, oxycodone with aspirin, tramadol	Constipation, nausea, vomiting, urinary retention, abdominal pain, diarrhea, dry mouth, flatulence, infection, insomnia, abdominal or stomach cramps, heartburn or indigestion
Acetaminophen and tapentadol	No gastrointestinal side effects
Biologics	
Belimumab, rituximab, canakinumab, ustekinumab, brodalumab, secukinumab, ixekizumab, brodalumab	Nausea, vomiting, abdominal pain, diarrhea, stomach ache
Adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, abatacept, anakinra, tocilizumab	No nutritional side effects
NSAIDs	
Diclofenac potassium, diclofenac sodium, diclofenac sodium with misoprostol, diflunisal, etodolac, fenoprofen calcium, ibuprofen, indomethacin, ketoprofen, meloxicam, naproxen, naproxen sodium, piroxicam, sulindac, celecoxib, acetylsalicylic acid, choline and magnesium trisalicylates	Abdominal cramps, pain or discomfort, peptic ulcer, constipation, diarrhea, gastrointestinal bleeding, heartburn or indigestion, acid reflux, nausea or vomiting
Corticosteroids	
Betamethasone, cortisone acetate, dexamethasone, hydrocortisone, methylprednisolone, prednisolone, prednisone	Elevated blood fats (cholesterol, triglycerides), elevated blood sugar, hardening of arteries (atherosclerosis), hypertension, increased appetite, indigestion, weight gain, ulcers
DMARDs	
Azathioprine	Liver problems, loss of appetite, nausea or vomiting
Cyclophosphamide	Loss of appetite, nausea or vomiting
Cyclosporine	Abdominal pain, gingivitis, high blood pressure, kidney problems, loss of appetite, nausea
Gold sodium thiomalate	Irritation and soreness of tongue, irritated or bleeding gums, metallic taste, ulcers or white spots on lips or in mouth or throat
Hydroxychloroquine	Abdominal cramps, diarrhea, loss of appetite, nausea or vomiting
Leflunomide	Gastrointestinal problems, heartburn, high blood pressure, liver problems, stomach pain
Methotrexate	Folic acid antagonist, abdominal pain, liver problems, mouth sores, nausea
Minocycline, Mycophenolate mofetil	Diarrhea, gastrointestinal ulcers or bleeding, nausea, vomiting
Sulfasalazine	Abdominal discomfort, diarrhea, headache, loss of appetite, nausea and vomiting
Tofacitinib	Diarrhea, hypertension, increased lipid level

*Some of these side effects are usually short term and go away gradually after treatment stops.

Arthritis Foundation: Arthritis today, Drug Guide. <https://www.arthritis.org/living-with-arthritis/treatments/medication/drug-guide/search-alphabetical.php>.

commonly used drugs and their nutritional side effects (also see Appendix 13).

Analgesics

Analgesics are drugs designed specifically to relieve pain. There are several types of analgesics: acetaminophen (Tylenol) and a variety of opioid analgesics (also called narcotics). Some products combine acetaminophen with an opioid analgesic for added relief. Opioid analgesics work by binding to receptors on cells mainly in the brain, spinal cord, and gastrointestinal system.

Nonsteroidal Antiinflammatory Drugs

Nonsteroidal antiinflammatory drugs (NSAIDs) are used to relieve pain and inflammation associated with arthritis and related conditions. All NSAIDs work by blocking the synthesis of PG, which are involved in pain and inflammation, as well as many other bodily functions including protecting the stomach lining.

Traditional NSAIDs include more than 20 different drugs. They work by blocking PG synthesis by inhibiting COX-1 and COX-2, making the lining of the stomach vulnerable to ulcers and bleeding. Aspirin (acetylsalicylic acid) is the only NSAID that inhibits all COX proteins by covalent modification; all other NSAIDs act noncovalently.

Ibuprofen and naproxen slow down the body's production of PG by inhibiting COX-1. They are considered useful tools in the management of most rheumatic disorders; however, long-term use of NSAIDs may cause gastrointestinal problems (see Table 38.2).

Because of the damage to the gastric mucosa caused by COX-1 inhibitors, a drug was developed to block only COX-2: celecoxib (Celebrex). Because it only inhibits COX-2 without affecting COX-1, this drug does not harm the stomach and is well tolerated by patients requiring long-term antiinflammatory therapy. However, celecoxib is not exempt of side effects, like increased thrombotic events, skin reactions, and cardiotoxicity, so continuous medical monitoring is advised. Calcitriol (1,25-dihydroxy-D₃, the active form of vitamin D), flavonoids,

and BDMC33 (a curcumin derivative) are also specific blockers of COX-2, they inhibit inflammation by interfering with COX-2 gene expression (Lee et al, 2015). In addition, calcitriol also blocks PG receptor expression in their target cells PG production and secretion of proinflammatory cytokines in macrophages (Wang et al, 2014).

Disease-Modifying Antirheumatic Drugs

Disease-modifying antirheumatic drugs (DMARDs) is a category of otherwise unrelated drugs defined by their use in RA and other diseases such as SLE and SS, to slow down disease progression. Each DMARD works in different ways to slow or stop the inflammatory process that damages the joints and internal organs.

Of particular interest is the drug methotrexate (MTX), originally used to treat certain types of cancer, which is widely used to treat RA alone, or in combination with other DMARDs. MTX works by competitively inhibiting dihydrofolate reductase (DHFR), an enzyme that converts folic acid to its active metabolite tetrahydrofolate (THF), which is required for nucleic acid (DNA and RNA) synthesis. Therefore patients taking MTX must consume supplemental folate to reduce the adverse effects caused by MTX such as anemia, abdominal pain, nausea, and mouth sores. Supplemental folate can be in the form of folic acid, folinic acid, or 5-methyltetrahydrofolate (5-MTHF) (see Appendix 31). Folinic acid (Leucovorin) is a folate derivative that is easily converted to THF and is unaffected by the inhibition of DHFR by MTX, while relieving some of the side effects of MTX (Shea et al, 2014). 5-MTHF (Metafolin) is the active form of folic acid used at the cellular level for DNA synthesis and also is not affected by MTX (Scaglione and Panzavolta, 2014). MTX should not be taken by pregnant and lactating women (Gerosa et al, 2016).

Biologic Response Modifiers or Biologics

Biologic response modifiers (BRMs), or biologics, are medications genetically engineered from a living organism, such as a virus, gene, or protein, to simulate the body's natural response to infection and disease. BRMs target proteins, cells, and pathways responsible for the symptoms and damage of RA and other types of inflammatory arthritis.

The biologics used for treating RMDs work in one of several ways: (1) by blocking proteins that are produced in response to injury such as interleukin-1 (IL-1), IL-6, IL-17, tumor necrosis factor alpha (TNF- α); (2) by blocking B cells, which produce antibodies that are produced excessively in some forms of arthritis and SLE; and (3) by inhibiting the activation of T cells, thereby preventing the chain reactions that result in inflammation. These molecules are administered by injection (intravenously or subcutaneously) because they are proteins and oral administration would destroy their biologic activities. Patients taking these drugs should be monitored for chronic infections or malignancies (Ramiro et al, 2017). The main drawback is their high cost, which varies depending on the information source, from \$43,000 dollars per patient per year to over \$110,000 (Popp et al, 2018).

Corticosteroids

Corticosteroids, sometimes called glucocorticoids, are medications that mimic the effects of the hormone cortisol, which is produced naturally by the adrenal glands. Cortisol affects many parts of the body, including the immune system. Corticosteroids are prescribed for patients who need quick relief from severe inflammation by lowering the levels of PG. In some cases of RA, corticosteroids pills are taken while waiting for other DMARDs to start to take effect. Low-dose corticosteroids also may be prescribed long term for some patients with RA. However, the use of corticosteroids in RA is debated, because some doctors believe the long-term benefits do not outweigh the risk of side effects. If used alone, the immediate relief corticosteroids provide may defer the start of treatment, which could make a difference in the course of the disease.

As the most potent of the antiinflammatory drugs used to treat RA, steroids have extensive catabolic effects that can result in negative nitrogen balance and blood sugar imbalance. Hypercalciuria and reduced calcium absorption can increase the risk of osteoporosis (see Chapters 8 and 24). Concomitant calcium and vitamin D supplementation and monitoring of bone status should be considered to minimize osteopenia. Many drugs used for treating RMDs can cause one or more nutritional side effects (see Table 38.2).

Vitamin D (cholecalciferol)

Vitamin D is a fat-soluble vitamin obtainable from the diet, as well as a prohormone produced in the skin by ultraviolet B from sunlight (see Appendix 38). The active form of vitamin D (1,25-dihydroxy vitamin D₃, termed calcitriol) binds to the vitamin D receptor (VDR), a protein that acts as a transcriptional factor and regulates the expression of several genes. The VDR forms a heterodimer with the retinoid-X receptor (RXR), and the VDR-RXR complex binds to vitamin D response element (VDRE) in the promoter region of its target genes to regulate mRNA expression.

The classical role of vitamin D is to regulate metabolism of calcium and phosphate. However, several nonclassical effects of vitamin D, such as regulation of cell proliferation and differentiation, have been recognized. Of particular interest is the regulatory effect of vitamin D on immune cells because virtually all immune cell types (macrophages/monocytes, neutrophils, T and B cells and dendritic cells) express VDR, making them susceptible to calcitriol-mediated modulation. Most of the immune cells (monocytes, dendritic cells, macrophages, B cells, and T cells) also have the capability to convert vitamin D into calcitriol, which allows for local regulation of its concentration at sites of inflammation and illustrates an important role for these cells in the systemic effects of vitamin D (Kongsbak et al, 2014).

Dendritic cells (DC) could be considered as the primary immune cell target of vitamin D. It inhibits DC maturation and differentiation and consequently impairs antigen processing and presentation to immune cells, resulting in a decline in proinflammatory cytokines (IL-6, IL-23, IL-1, IL-8, IL-12, TNF- α , and interferon [IFN]- α) along with an increase in tolerogenic molecules such as IL-10. Furthermore, through the DC modulation, vitamin D suppresses the activity of Th17, a T cell subset widely engaged in inflammatory responses, and enhances regulatory T (Treg) cell expansion (Vasile et al, 2017).

Extensive research over the past decades has suggested that low sunlight exposure and vitamin D deficiency are also associated with signs and symptoms of autoimmune diseases (Holick, 2016; Dankers et al, 2017). Body levels of vitamin D are documented to fluctuate with changing seasons, due to the influence of ultraviolet (UV) radiation exposure during different times of the year and to location. Seasonal relapses of autoimmune diseases could also be explained by low UV exposure, and, therefore, low levels of vitamin D. Vitamin D levels, which reach a nadir during late winter and early spring, are correlated with increased disease activity and clinical severity, as well as relapse rates in several disease entities noncutaneous flares of SLE, psoriasis, and RA (Watad et al, 2017). As most studies indicate that vitamin D insufficiency is associated with high disease activity of RA, it would be logical to supplement these patients with vitamin D (Jeffery et al, 2016; Pludowski et al, 2018). Most clinicians agree that with the increasing adverse health outcomes associated with hypovitaminosis D, screening and supplementation should be performed routinely in RA patients.

Vitamin A (retinol)

Vitamin A (retinol [ROL]) is essential for multiple functions, including the maintenance of the immune system. Vitamin A can be obtained preformed from animal products, or as its precursor (carotenes) from vegetables in the diet. Inside the cells, ROL is converted to retinaldehyde

(RAL) which is oxidized to form retinoic acid, the active form of vitamin A. Two isoforms of retinoic acid are produced, all-trans RA (at-RA) and 9-cis RA (9cis-RA), which are ligands for the nuclear retinoic acid receptors (RAR alpha, beta, and gamma) whereas the retinoid X receptors (RXR alpha, beta, and gamma) only bind to 9cis-RA. Therefore vitamin A regulates gene expression via RAR and RXR, which bind to specific sequences in the DNA known as RARE (retinoic acid response elements), as homodimers (RAR/RAR), or as heterodimers (RAR/RXR) (Kim, 2018).

Vitamin A plays an essential role in the proliferation and differentiation of immune cells via RAR and RXR interactions. T cells can be divided into two main subsets: proinflammatory and antiinflammatory, which are defined by the cytokines they produce. Th1 and Th17 are proinflammatory whereas Th2 and Treg are antiinflammatory. Vitamin A metabolites modulate specific functional aspects of the immune response, such as the Th1/Th2 cell balance and the differentiation of Treg cells and Th17 cells. In vitamin A deficiency there is an increase in the Th1 type response and an increase in the Th1/Th2 ratio. The addition of at-RA reestablishes the Th1/Th2 balance due to an increase in Th2 cells (Miyabe et al, 2015). Dietary retinoids have regulatory effects on immune cells and have been shown to improve rheumatic diseases in animal models. These findings suggest a possible role for dietary retinoids in the therapy for of rheumatic disease.

ANTIINFLAMMATORY DIET

The **antiinflammatory diet**, a diet resembling the Mediterranean diet, has been useful for the treatment of inflammatory diseases, including RMDs. The diet aims for the inclusion of as much fresh food as possible, the least amount of processed foods and fast food, minimal amounts of sugar (particularly fructose and sucrose), and an abundance of fruits (especially berries) and vegetables, lean proteins from animal sources such as chicken and fish, and vegetarian sources such as legumes and nuts, plus essential fatty acids and dietary fiber. If weight loss is a desired outcome to reduce inflammation, people may lose weight with these dietary changes (Arthritis Foundation [AF], 2014a) (Box 38.2; see Appendix 22). There is plenty of evidence for a relationship between a Mediterranean diet and lower levels of inflammation both in observational and intervention studies. A recent systematic review and meta analysis of randomized controlled trials showed that a Mediterranean dietary pattern decreases inflammation (Bonaccio et al, 2017). The antiinflammatory diet works by reducing the expression of genes involved in the inflammatory process such as IL-1, IL-6, and TNF- α .

One of the main components of the Mediterranean diet is extra virgin olive oil (EVOO). Diverse studies show evidence that EVOO and its components may have potential positive properties on the modulation of immune-inflammatory processes. The trend toward the use of natural compounds and diet, due to fewer side effects compared with classical pharmacotherapy, has given rise to EVOO and EVOO compounds consumption as an alternative therapy for the prevention and management of different immune-inflammatory diseases such as RA, SLE, and multiple sclerosis, because of the beneficial fatty acid profile of EVOO and the presence of a high content of phenolic compounds (Aparicio-Soto et al, 2016).

COMPLEMENTARY AND INTEGRATIVE HEALTH APPROACHES

Because of the chronic nature of arthritic diseases, their effects on quality of life, and the fact that most treatments result only in modest improvement in symptoms and function, patients commonly try complementary and integrative medicine (CIM). Rheumatologists

BOX 38.2 General Principles of the Antiinflammatory Diet

Aims for variety, with a whole foods, plant-based diet with minimal processed foods.

Consume a variety of fruits and vegetables; some people may need to avoid potatoes and other nightshade vegetables, which contain the alkaloid solanine

Low in saturated fat and devoid of trans fats

Low in omega-6 fats, such as vegetable oils and animal fat

High in Monounsaturated fatty acids (MUFAs) such as those found in olive oil, walnuts, pumpkin seeds, and those high in omega-3 fats found in flax and chia seeds and fatty cold-water oily fish such as salmon, sardines, mackerel, and herring.

Low in refined carbohydrates such as white pasta, white bread, white rice, other refined grains, sucrose (table sugar), and sucrose-containing products such as pastries, cookies, cakes, energy bars, and candy

Increase whole grains such as brown rice, bulgur wheat, and other unrefined grains such as amaranth, quinoa, and spelt

Includes lean protein sources such as chicken and fish

Limits eggs, red meat, butter, and other full-fat dairy products

Includes spices such as ginger, curry, turmeric, and rosemary, which have antiinflammatory effects

Includes good sources of phytonutrients: fruits and vegetables of all bright and dark colors, especially berries, orange and yellow fruits, and dark leafy greens; cruciferous vegetables (cabbage, broccoli, Brussels sprouts, cauliflower); soy foods; tea (especially white, green, or oolong), dark plain chocolate in moderation

Additionally, weight should be maintained within healthy parameters, and exercise should be included.

Note: Please refer to Appendix 22 for a thorough description of the antiinflammatory diet.
Arthritis Foundation. <https://www.arthritis.org/living-with-arthritis/arthritis-diet/anti-inflammatory/anti-inflammatory-diet.php>; Van Breda SGJ and de Kok TCM: Smart combinations of bioactive compounds in fruits and vegetables may guide new strategies for personalized prevention of chronic diseases, *Mol Nutr Food Res* 62: 1700597, 2018.

show moderate acceptance toward some types of CIM. A substantial proportion of rheumatologists perceive some integrative therapies, including bodywork, meditation, and acupuncture, to be beneficial for their patients (Grainger and Walker, 2014). CIM use is popular among patients with rheumatological diseases. An estimated 60% to 90% of arthritis patients have reported using CIM (Seca et al, 2016). A recent systematic review identified good quality randomized clinical trials using CIM as intervention in patients with different rheumatic diseases including acupuncture, Ayurvedic treatment, homeopathic treatment, natural products, megavitamin therapies, chiropractic and osteopathic manipulation. It is clear from this review that there is no particular type of CIM that proves effective for all types for rheumatic diseases, although some CIM interventions appear to be more effective than others. For example, acupuncture appears to be beneficial for OA but not RA. The review could not show evidence for all diseases because of scarcity of trials or contradictory findings. CIM interventions were associated, if at all, with minor adverse reactions (Phang et al, 2018). Some of the main categories in which CIM can be grouped are presented below (National Institutes of Health [NIH], National Center for Complementary and Integrative Health [NCCIH], 2018).

Mind and body practices include a large and diverse group of procedures or techniques administered or taught by a trained practitioner or teacher. These include acupuncture, massage therapies, meditation,

movement therapies (Feldenkrais method, Alexander technique, Pilates), relaxation techniques (breathing exercises, guided imagery, progressive muscle relaxation), spinal manipulation, tai chi, qi gong, and yoga.

Natural products encompass herbs (botanicals), vitamins and minerals, and probiotics. The most common dietary supplements used for AORD include glucosamine, chondroitin, *S*-adenosyl-*L*-methionine (SAM-e), fish oil, EVOO, curcumin, turmeric, boswellia, and methylsulfonylmethane (MSM). Capsaicin, the compound responsible for the burning sensation produced by chili peppers, is used as a rubbing topical gel to relieve pain, particularly in joints of OA and RA patients (see Chapter 11 for further discussion of botanicals).

Patients' decisions to try any CIM should be discussed with their physician. The main drawback for some patients is the additional costs of CIM, which are often not covered by insurance, and the potential for drug-nutrient interactions.

Elimination Diets and Other Therapeutic Diets

Adverse reactions to food can contribute to inflammatory symptoms in some people with rheumatic conditions, including trial elimination of gluten, animal products (vegan), and nightshade elimination (see Chapter 25 for strategies for testing for food allergies or sensitivities and implementing an elimination diet). Gluten-free diet has been associated with benefits in patients with RA though the existing evidence is inconclusive (Badsha, 2018). Eliminating any animal product or by-products has been reported to be clinically beneficial for disease remission in RA patients. Studies conclude that the improvements in disease activity might have been a result of reduction in immune-reactivity to certain food antigens in the gastrointestinal tract that were eliminated by changing the diet (Khanna et al, 2017). One dietary compound that has been suspected to increase painful swelling in the joints is nightshade plants. Nightshades are a diverse group of foods, herbs, shrubs, and trees that include more than 2800 species of plants of the *Solanaceae* family, such as potatoes, tomatoes, sweet and hot peppers, and eggplants. They contain a group of chemicals termed alkaloids, like solanine and chaconine, which are believed to cause damage to the joints and increase the loss of calcium from the bones. The nightshade elimination diet is believed to be safe, but there is always the risk that when eliminating certain foods from their diet, arthritis patients may not get enough of the necessary nutrients (vitamins, minerals, antioxidants; see Chapter 25). Although there are anecdotal claims of its effectiveness, the nightshade elimination diet has not been studied in depth, and no formal research has ever confirmed its beneficial effects.

Fasting has been actively studied as an alternative therapy for RA, and a number of clinical trials have been conducted to test its efficacy since the 1970s. Either periodic fasting or a fasting-mimicking diet followed by vegan diets have the potential to treat RA, although larger randomized studies are necessary to test this possibility (Choi et al, 2018).

MICROBIOTA AND ARTHRITIS

Increased levels of antibodies directed against antigens of certain species of gut bacteria point to the relationship between bacteria and arthritis (De Luca and Shoenfeld, 2018). Three sites have been associated particularly with it, mainly the lungs, oral mucosa, and gastrointestinal tract. The idea that intestinal microorganisms are associated with the development of RA is not new: alterations of microbiota (dysbiosis) are related to risk and severity of the disease. Mechanisms through which the microbiota may be involved in the pathogenesis of rheumatic diseases include altered epithelial and mucosal permeability, loss of immune tolerance to components of the indigenous microbiota, and trafficking of activated immune cells and antigenic material to the joints.

A previously unrecognized bacterium termed *Prevotella copri* was recovered from human feces. *P. copri* is an obligate anaerobic, nonmotile, gram-negative rod. The importance of this discovery is that *P. copri* has been recovered in 75% of patients with new-onset untreated RA (NORA) and only in 21.4% of healthy individuals (Bernard, 2014).

Studies on the effect of diet on the microbiota, particularly with regard to the proinflammatory effects of the Western diet, are needed to gain insight into the treatment of rheumatic diseases. Given that alterations in the intestinal microbiota are associated with arthritis, modifying the microbiota might be a valuable therapeutic strategy. The main approaches that have been used to modify the microbiota in disease are probiotics, the administration of single or multiple strains of beneficial bacteria or yeasts; dietary modification to increase fiber and prebiotics; and fecal microbial transplantation (Bravo-Blas et al, 2016), although currently fecal transplantation is undertaken only in the case of intractable diarrhea, not for the purpose of influencing inflammation.

Some bacterial infections have been related to the development of reactive arthritis, the most widely documented from infection with *Streptococcus pyogenes*, a Group A beta-hemolytic bacteria that is the cause of streptococcal pharyngeal infection. Rheumatic fever is a systemic disease affecting the peri-arteriolar connective tissue and can occur after an untreated *S. pyogenes* infection. Acute rheumatic fever commonly appears in children between the ages of 6 and 15, with only 20% of first-time attacks occurring in adults. The illness is so named because of its similarity in presentation to RA.

Diagnosis of acute rheumatic fever is based on the presence of documented Group A streptococcal infection. The most common symptoms include arthritis (most of the time unilateral, instead of the common bilateral presentation in RA), carditis (inflammation of the heart tissue), and Sydenham chorea (involuntary movements of the face, hands, and feet, also known as Saint Vitus' dance) (Rhodes et al, 2018). Heart complications may be long term and severe, particularly if valves are involved.

Molecular mimicry accounts for the tissue injury that occurs in rheumatic fever. In this process, the patient's immune responses are unable to distinguish between *S. pyogenes* structures and certain host tissues, attacking both. The resultant inflammation may persist well beyond the acute infection and produces the manifestations of rheumatic fever. The recurrence of rheumatic fever is relatively common in the absence of maintenance of low-dose antibiotics, especially during the first 3 to 5 years after the first episode. Survivors of rheumatic fever often have to take penicillin to prevent streptococcal infection, which could possibly lead to another case of rheumatic fever that could prove fatal.

OSTEOARTHRITIS

Osteoarthritis (OA), formally known as degenerative arthritis or degenerative joint disease, is the most prevalent form of arthritis. Obesity, aging, female gender, white ethnicity, greater bone density, and repetitive-use injury associated with athletics have been identified as risk factors. OA is not systemic or autoimmune in origin but involves cartilage destruction with asymmetric inflammation. It is caused by joint overuse, whereas RA is a systemic autoimmune disorder that results in symmetric joint inflammation.

Pathophysiology

OA is a chronic joint disease that involves the loss of habitually weight-bearing articular (joint) cartilage. This cartilage normally allows bones to glide smoothly over one another. The loss can result in stiffness, pain, swelling, loss of motion, and changes in joint shape, in addition to abnormal bone growth, which can result in osteophytes (bone spurs) (Fig. 38.1; see *Pathophysiology and Care Management Algorithm: Osteoarthritis*).

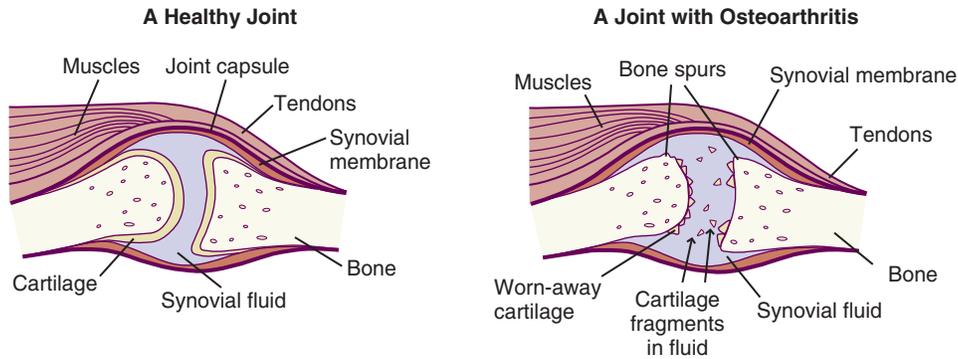

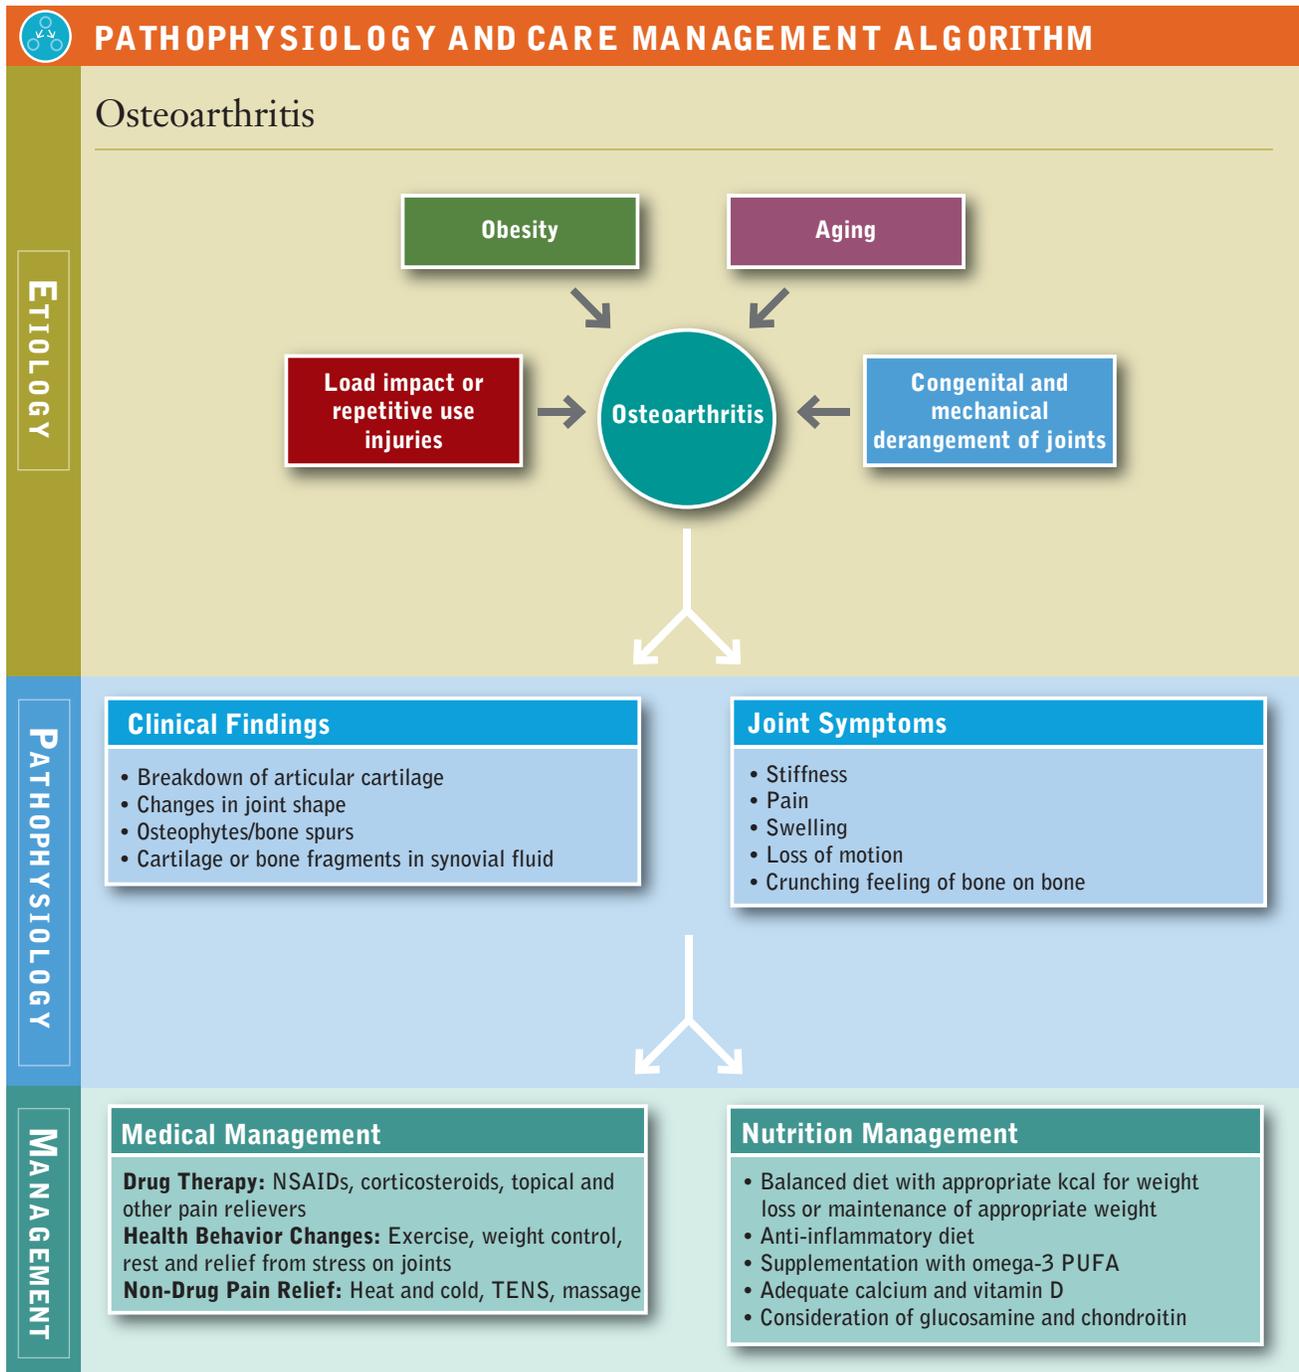

Fig. 38.1 A healthy joint and a joint with severe osteoarthritis. From National Institutes of Health, National Institute of Arthritis and Musculoskeletal and Skin Diseases. <https://www.niams.nih.gov/file/823>.

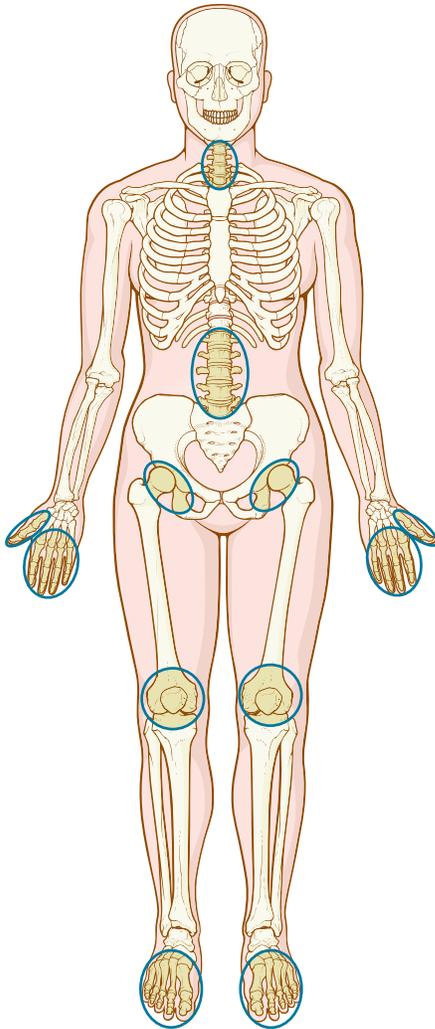

Fig. 38.2 Joints commonly affected by osteoarthritis.

The joints most often affected in OA are the distal interphalangeal joints, the thumb joint, and, in particular, the joints of the knees, hips, ankles, and spine, which bear the bulk of the body's weight (Fig. 38.2). The elbows, wrists, and ankles are less often affected. OA generally presents as pain that worsens with weight bearing and activity and improves with rest, and patients often report morning stiffness or “gelling” of the affected joint after periods of inactivity. Diseases of the joints influenced by congenital and mechanical derangements may contribute to OA as well. Inflammation occurs at times but is generally mild and localized.

Medical and Surgical Management

The patient's medical history and level of pain should determine the most appropriate treatment. This should include nonpharmacologic modalities (patient education, massage therapy, physical and occupational therapy), pharmacologic agents, and surgical procedures with the goals of pain control, improved function and health-related quality of life, and avoidance of toxic effects from treatment. Weight loss and/or achievement of ideal body weight (body mass index [BMI] of 18.5 to 24.9 kg/m²) should be part of the medical treatment because it improves OA dramatically (see Chapter 20).

Patients with severe symptomatic OA pain who have not responded adequately to medical treatment and who have been progressively limited in their activities of daily living (ADLs), such as walking, bathing, dressing, and toileting, should be evaluated by an orthopedic

surgeon. Surgical options include arthroscopic debridement (with or without arthroplasty), total joint arthroplasty, and osteotomy. Surgical reconstruction has been successful but should not be viewed as a replacement for overall good nutrition, maintenance of healthy body weight, and exercise (Smink et al, 2014).

Exercise

OA limits the ability to increase energy expenditure through exercise. It is critical that the exercise be done with correct form so as not to cause damage or exacerbate an existing problem. Physical and occupational therapists can provide unique expertise for OA patients by making individualized assessments and recommending appropriate exercise programs and assistive devices, in addition to offering guidance regarding joint protection and energy conservation. Nonloading aerobic (swimming), range-of-motion, and weight-bearing exercises have been shown to reduce symptoms, increase mobility, and lessen continuing damage from OA. Non-weight-bearing exercise also may serve as an adjunct to NSAID use.

Sports or strenuous activities that subject joints to repetitive high impact and loading increase the risk of joint cartilage degeneration. Therefore increased muscle tone and strength, correct form, general flexibility, and conditioning help protect these joints in the habitual exerciser. A walking program and lower-extremity strength training are beneficial for individuals with knee OA.

Medical Nutrition Therapy

Weight and Adiposity Management

Excess weight puts an added burden on the weight-bearing joints. Epidemiologic studies have shown that obesity and injury are the two greatest risk factors for OA. The risk for knee OA increases as BMI increases. Controlling obesity can reduce the burden of inflammation on OA and thus delay disease progression and improve symptoms. A well-balanced diet that is consistent with established dietary guidelines and promotes attainment and maintenance of a desirable body weight is an important part of MNT for OA (Bliddal et al, 2014).

An antiinflammatory diet combined with moderate exercise and diet-induced weight loss has been shown to be an effective intervention for knee OA. There is also an antiinflammatory effect from weight loss in OA management because the reduced fat mass results in the presence of less inflammatory mediators from adipose tissue (see Chapters 7 and 20).

Vitamins and Minerals

Cumulative damage to tissues mediated by reactive oxygen species has been implicated as a pathway that leads to many of the degenerative changes seen with aging.

At present, there are insufficient data to show benefit from antioxidant supplementation in OA. However, for general health, patients should be encouraged to eat a healthy diet that includes adequate amounts of dietary antioxidants (Thomas et al, 2018)

Many patients with OA consume deficient levels of calcium and vitamin D. Low serum levels of 25-OH-vitamin D are frequent and there is an inverse association between serum 25-OH-vitamin D and clinical findings (cartilage loss in the joint space) and joint pain. Calcitriol (1,25-dihydroxy vitamin D₃) binds to the VDR followed by their interaction with specific sequences in the DNA. However, the VDR gene also presents polymorphisms, and some of these have been associated with OA and another condition called intervertebral disc degeneration. Given the role of vitamin D in the cartilaginous tissue, the very common low levels of serum vitamin D, and the genetic polymorphism of the VDR, more studies are necessary to determine the role of vitamin D in the pathogenesis of OA (Liu et al, 2014; Thomas et al, 2018).

Complementary Integrative Therapies

A meta-analysis has found that capsaicin gel and SAM-e are useful in treating OA; articularin F (an ayurvedic mixture of *Withania*, *Boswellia*, curcuma, and zinc) improved pain and function (Phang et al, 2018).

Glucosamine and Chondroitin

Glucosamine and chondroitin are involved in cartilage production, but their mechanism for eliminating pain has not been identified. The Glucosamine/Chondroitin Arthritis Intervention Trial (GAIT) was a large, randomized, placebo-controlled trial conducted at several sites across the United States (NIH, 2017). The GAIT team, funded by the NCCIH of the NIH and the National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), actually conducted two studies: a primary, or original, study that investigated whether glucosamine and/or chondroitin could treat the pain of knee OA, and an ancillary, or additional, study that investigated whether the dietary supplements could diminish the structural damage of knee OA.

The results of the primary GAIT study showed that the popular dietary supplement combination of glucosamine plus chondroitin sulfate did not provide significant relief from OA pain among all participants. However, a smaller subgroup of study participants with moderate-to-severe pain showed significant relief with the combined supplements.

The results of the ancillary GAIT study showed that glucosamine and chondroitin sulfate, together or alone, appeared to fare no better than placebo in slowing loss of cartilage in knee OA (Sawitzke et al, 2010).

In a meta-analysis review of 43 studies with 9110 patients it was found that chondroitin may improve pain slightly in the short term (less than 6 months); chondroitin improves knee pain by 20% in slightly more people and probably improves quality of life slightly as measured by Lequesne's index (combined measure of pain, function, and disability). Chondroitin has little or no difference in adverse and serious adverse events versus other agents and slightly slows down the narrowing of joint space on x-rays of the affected joint. The combination of some

efficacy and low risk associated with chondroitin may explain its popularity among patients as an over-the-counter supplement (Singh et al, 2016).

RHEUMATOID ARTHRITIS

Rheumatoid arthritis (RA) is a debilitating and frequently crippling autoimmune disease with overwhelming personal, social, and economic effects. Although less common than OA, RA is usually more severe and occurs more frequently in women than in men, with a peak onset commonly between 20 and 45 years of age.

RA affects the interstitial tissues, blood vessels, cartilage, bone, tendons, and ligaments, as well as the synovial membranes that line joint surfaces. Measurements of RF, and **antinuclear antibodies (ANA)** and antibodies to citrullinated protein antigens (ACPAs), are useful in the diagnosis as well as the prediction of the course and outcomes of RA. For RA patients, one of the most important type of biomarkers at the moment is autoantibodies. Besides joint pain and inflammation, several serologic biomarkers are used to classify RA patients. Serologic biomarkers, described in the criteria, include autoantibodies such as RF and ACPA (Verheul et al, 2015; Jog and James, 2017).

Numerous remissions and exacerbations generally follow the onset of RA, although for some people it lasts just a few months or years and then goes away completely. Although any joint may be affected by RA, involvement of the small joints of the extremities—typically the proximal interphalangeal joints of the hands and feet—is most common (Fig. 38.3). Although the exact cause of RA is still unknown, certain genes have been discovered that play a role (Nigrovic et al, 2018).

Pathophysiology

RA is a chronic, autoimmune, systemic disorder in which **cytokines** and the inflammatory process play a role. RA has articular manifestations that involve chronic inflammation that begins in the synovial membrane and progresses to subsequent damage in the joint cartilage (see *Pathophysiology and Care Management Algorithm: Rheumatoid*

Fig. 38.3 A female patient with advanced rheumatoid arthritis. The twisted hands (**A**) and feet (**B**), and the puffiness of the metacarpal joints are typical of the disease. (Photos courtesy Dr. F. Enrique Gómez. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. Mexico City, México, 2015.)

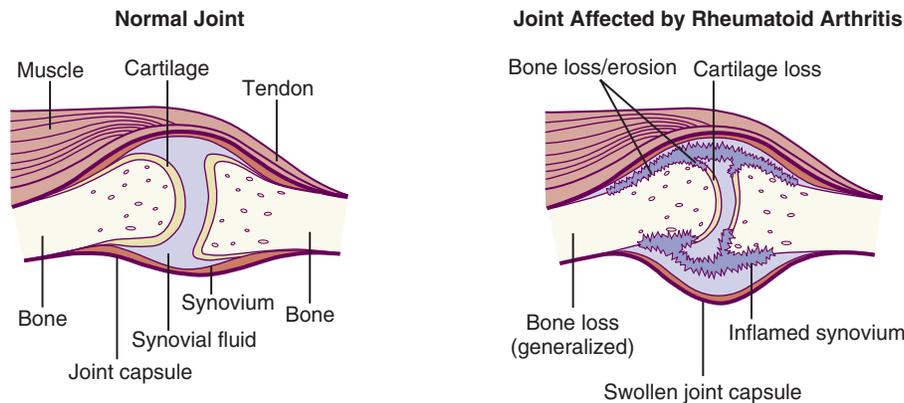

Fig. 38.4 Comparison of a normal joint and one affected by rheumatoid arthritis, which has swelling of the synovium. From National Institute of Arthritis and Musculoskeletal and Skin Diseases. <https://www.niams.nih.gov/file/813>.

Arthritis). Citrullination, also termed deimination, is a modification of arginine side chains catalyzed by peptidylarginine deiminase (PAD) enzymes. This posttranslational modification has the potential to alter the structure, antigenicity, and function of proteins. Four citrullinated antigens, fibrinogen, vimentin, collagen type II, and alpha-enolase, are expressed in the joints.

The appearance of RF may precede symptoms of RA. Pain, stiffness, swelling, loss of function, and anemia are common. The swelling or puffiness is caused by the accumulation of synovial fluid in the membrane lining the joints and inflammation of the surrounding tissues (Fig. 38.4).

Some controversy exists regarding green tea: It has been suggested that drinking large amounts of tea may increase the risk of developing RA, whereas other studies suggest a protective role (Lee et al, 2014). Smoking is the environmental risk factor that is most associated with RA. The association of smoking and the development of RA has been demonstrated through epidemiologic studies, as well as through in vivo and animal models of RA. With increased use of biological agents in addition to standard DMARDs, there has been interest in how smoking affects drug response in RA treatment. Recent evidence suggests the response and drug survival in people treated with anti-TNF therapy is less effective in heavy smokers (Chang et al, 2014). In a recent meta-analysis, lifelong cigarette smoking was positively associated with the risk of RA even among smokers with a low lifelong exposure. The risk of RA did not further increase with an exposure higher than 20 pack-years (Di Giuseppe et al, 2014). Coffee consumption also represents a risk factor for RA (Lee et al, 2014), whereas dietary antioxidants and breastfeeding may be protective (Chen et al, 2015).

Medical Management

RA patients are at increased risk for CVD, explained by the systemic inflammatory response. This is especially significant considering findings regarding COX-2 selective NSAIDs. In fact, many of the drugs used to treat RA (see Appendix 13) can result in hyperhomocysteinemia, hypertension, and hyperglycemia, all risk factors for CVD. Conveniently, treatment aimed at reducing inflammation may benefit both diseases.

Pharmacologic Therapy

Medications to control pain and inflammation are the mainstay of treatment for RA. Salicylates and NSAIDs are often the first line of treatment. MTX commonly is prescribed as well, but these drugs may cause significant side effects. The choice of drug class and type is based

on patient response to the medication, incidence and severity of adverse reactions, and patient compliance. Drug-nutrient side effects can occur with any of the drugs (see Chapter 5 and Appendix 13).

Salicylates are used commonly. However, chronic aspirin ingestion is associated with gastric mucosal injury and bleeding, increased bleeding time, and increased urinary excretion of vitamin C. Taking aspirin with milk, food, or an antacid often alleviates the gastrointestinal symptoms. Vitamin C supplementation is prescribed when serum levels of ascorbic acid are abnormally low. Statins have a significant antiinflammatory effect in RA patients by reduction of disease activity and several blood parameters like erythrocyte sedimentation rate (ESR), CRP, and lipid profile (Li et al, 2018).

DMARDs may be prescribed because of their unique ability to slow or prevent further joint damage caused by arthritis. These include MTX, sulfasalazine (Azulfidine), hydroxychloroquine (Plaquenil), azathioprine (Imuran), and leflunomide (Arava). In fact, the ACR recommends that the majority of patients with newly diagnosed RA be prescribed a DMARD within 3 months of diagnosis. Depending on which drug is selected, side effects can include myelosuppression or macular or liver damage. A main adverse effect of the DMARD MTX treatment is folate antagonism. Treatment with MTX induces a significant rise in serum homocysteine, which is corrected by folic acid supplementation and a properly balanced diet. Folate supplementation is advised to offset the toxicity of this drug, for protection against gastrointestinal disturbances, and for maintenance of red blood cell production without reducing the efficacy of MTX therapy. Long-term folate supplementation in patients on MTX is also important to prevent neutropenia, mouth ulcers, nausea, and vomiting.

D-penicillamine acts as an immunosuppressor by reducing the number of T cells, inhibiting macrophage function, and decreasing IL-1 and RF production. Additional DMARDs include gold salt therapy and antimalarials and may lead to a remission in RA symptoms. Proteinuria may occur with administration of gold and D-penicillamine; therefore, toxicity must be monitored continually.

Surgery

Surgical treatment for RA may be considered if pharmacologic and nonpharmacologic treatment cannot adequately control the pain or maintain acceptable levels of functioning. Common surgical options include synovectomy, joint replacement, and tendon reconstruction.

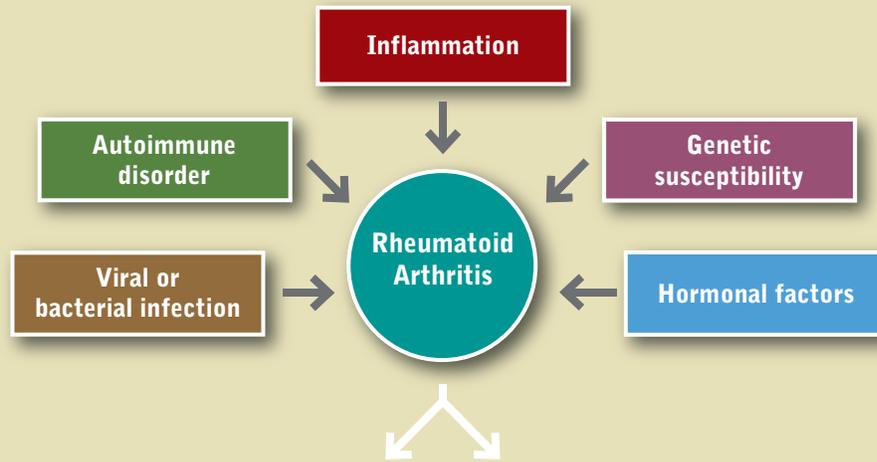

After substantial weight loss from bariatric surgery, obese patients with RA showed lower disease activity, decreased inflammatory markers (CRP, ESR, total leukocytes) and less RA-related medication use.

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Rheumatoid Arthritis

ETIOLOGY

PATHOPHYSIOLOGY

Joint Symptoms

- Warmth
- Redness
- Swelling
- Pain
- Stiffness
- Loss of function

Articular

- Chronic inflammation in synovial membranes
- Damage to joint cartilage and bone
- Weakening of surrounding muscles, ligaments, and tendons

Extra-Articular

- Generalized bone loss
- Rheumatoid cachexia
- Changes in GI mucosa
- Anemia
- Sjögren's syndrome
- Cardiovascular disease

MANAGEMENT

Medical Management

- Routine Monitoring and Ongoing Care** Doctor visits, blood, urine and lab tests, x-rays
- Drug Therapy** DMARDS, biological response modifiers, analgesics, NSAIDs, corticosteroids
- Health Behavior Changes**
- Rest and exercise
 - Joint care
 - Stress reduction
- Surgery** Joint replacement, tendon reconstruction, synovectomy

Nutrition Management

- Whole foods, balanced diet
- Avoidance of possible food allergens
- Adequate B vitamins
- Adequate calcium and vitamin D
- Supplementation with ω -3 PUFA
- Anti-inflammatory diet
- Intermittent fasting and a vegetarian diet may be helpful during an acute phase

These findings show that weight loss is important to reduce RA disease activity and should be encouraged by nutrition professionals (Sparks et al, 2015; Hassan and Hassan, 2016).

Exercise

Physical and occupational therapy are often part of the initial therapy for newly diagnosed RA but also may be integrated into the treatment plan as the disease progresses and ADLs are affected. To maintain joint function, recommendations may be given for energy conservation,

along with range-of-motion and strengthening exercises. Although the patient may be reluctant at first, individuals with RA can participate in conditioning exercise programs without increasing fatigue or joint symptoms while improving joint mobility, muscle strength, aerobic fitness, and psychological well-being.

Medical Nutrition Therapy

The nutrition care process and model serve as a guide for implementing MNT with RA patients. A comprehensive nutrition assessment

of individuals with RA is essential to determine the systemic effects of the disease process. A physical examination provides diagnostic signs and symptoms of nutrient deficiencies (see Appendix 11). Weight change is an important measure of RA severity. In cases where a person is overweight, weight loss (5 kg or more) can bring improvement in RA disease activity (Kreps et al, 2018). In some cases, patients with RA will present as underweight due to the progression of their disease. The characteristic progression of malnutrition in RA is attributed to excessive protein catabolism evoked by inflammatory cytokines and by muscle disuse atrophy resulting from functional impairment.

The diet history should review the usual diet, the effect of the physical impairment and impact on ADLs, types of food consumed, and changes in food tolerance. The effect of the disease on food shopping and preparation, self-feeding ability, appetite, and intake also must be assessed.

Articular and extraarticular manifestations of RA affect the nutrition status of individuals in several ways. Articular involvement of the small and large joints may limit the ability to perform nutrition-related ADLs, including shopping for, preparing, and eating food. Involvement of the temporomandibular joint can affect the ability to chew and swallow and may necessitate changes in diet consistency including a soft diet. Extraarticular manifestations include increased metabolic rate secondary to the inflammatory process, SS, and changes in the gastrointestinal mucosa.

Increased metabolic rate secondary to the inflammatory process leads to increased nutrient needs, often in the face of a diminishing nutrient intake. Taste alterations secondary to xerostomia and dryness of the nasal mucosa; dysphagia secondary to pharyngeal and esophageal dryness; and anorexia secondary to medications, fatigue, and pain may reduce dietary intake. Changes in the gastrointestinal mucosa affect intake, digestion, and absorption. The effect of RA and the medications used may be evident throughout the gastrointestinal tract. Based on the patient's unique profile, a registered dietitian nutritionist can determine the most appropriate nutrition intervention, followed by monitoring and evaluation.

The association of foods with disease flares should be discussed. Whether food intake can modify the course of RA is an issue of continued scientific debate and interest. Dietary manipulation by either modifying food composition or reducing body weight may give some clinical benefit in improving RA symptoms. A vegan, gluten-free diet causes improvement in some patients, possibly because of the reduction of immunoreactivity to food antigens (Badsha, 2018). Identification of possible food allergies and use of an elimination diet may be useful (Khanna et al, 2017) (see Chapter 25).

Fasting has been practiced for millennia but, only recently, studies have shed light on its role in adaptive cellular responses that reduce oxidative damage and inflammation. In humans, it helps reduce hypertension, asthma, and symptoms of RA. Thus findings from well-controlled studies in animal models, and emerging findings from human studies, indicate that different forms of fasting may provide effective strategies to minimize age-related debility, optimize health, and help prevent and treat diseases while minimizing the side effects caused by medications (Choi et al, 2017). Intermittent fasting during the acute phase of RA may provide some pain relief; however, after the normal diet is resumed, inflammation returns unless the fasting period is followed by a vegetarian diet. Thus the combination of fasting and a vegetarian diet may be beneficial for the treatment of RA (Longo and Mattson, 2014).

An antiinflammatory diet described in Box 38.2 should be considered. The similar Mediterranean-style eating plan includes foods that almost everyone should aim to consume on a daily basis, such as

moderate amounts of lean meat, unsaturated fats instead of saturated fats, plenty of fruits and vegetables, and fish (AF, 2018; van Breda and de Kok, 2018). These diets are also nutritionally adequate and cover all of the food groups (see Appendix 22 for additional description of the antiinflammatory diet).

Preliminary studies demonstrate the beneficial effects of probiotic supplementation in RA patients on their clinical and metabolic status, although it is still early to generalize recommendation of probiotics for RA patients (Zamani et al, 2016).

Energy

There are three unique aspects of energy metabolism in RA. The first is elevated resting energy expenditure. RA causes cachexia, a metabolic response characterized by loss of muscle mass and elevated resting energy expenditure. The second is elevated whole-body protein catabolism, a destructive form of muscle metabolism that translates to muscle wasting. The third is low body cell mass, which leads to increased fat mass. People with RA tend to be less active than people without it; the stiffness and swelling caused by inflammation naturally prompt them to pursue less physical, more sedentary lifestyles. Such habits lead to overall gains in fat mass. Being overweight puts an extra burden on weight-bearing joints when they are already damaged or under strain.

Total energy expenditure is significantly lower in RA patients, mainly because of less moderate-intensity physical activity performance. Disease activity and fatigue are important contributing factors. Energy requirements should be adjusted according to the weight and activity level of the individual as well as nutritional complications, for example metabolic syndrome, if present (Hugo et al, 2016).

People with RA should consume nutrient-rich diets and incorporate physical activity throughout the day to boost their total energy expenditure. This helps them improve their physical function and quality of life and maintain a healthy weight.

Protein

Protein requirements for individuals who are poorly nourished or who are in the inflammatory phase of the disease are 1.2 to 1.5 g protein/kg body weight. Well-nourished individuals do not have increased requirements.

Fat

Fat should contribute less than 30% of the total energy intake for the purposes of healthy eating and weight management. The type of fat included in the diet is important: An increase in the amount of omega-3 fatty acids primarily from fish and alpha-linolenic acid (found in flaxseed, soybean oils, and green leaves) has been shown to reduce inflammation in RA. There is evidence of the efficacy of marine omega-3 PUFAs on improvement in joint swelling and pain and duration of morning stiffness (Calder, 2015; Calder, 2017; Veselinovic et al, 2017). Fish oil at a high dose (3.5 g/day) has been shown to have additional benefits to those achieved by combination DMARD with similar MTX use, including reduced triple DMARD failure and a higher rate of remission (Proudman et al, 2015). Recently it was reported that the consumption of whole fish (tuna, salmon, sardines, trout, sole, halibut, poke, and grouper) more than two times/week by RA patients had a significant impact on their disease activity, but this effect was not observed in those patients who consumed whole fish with lesser frequency (less than one time/week) or ever (Tedeschi et al, 2018). Although these benefits along with improved dietary habits are known, they usually cannot replace conventional drug therapies.

CLINICAL INSIGHT

Fatty Acids in Foodstuffs and the Inflammatory Process

Inflammation is the body's attempt at self-protection to remove harmful stimuli, including damaged cells, irritants, or pathogens, and begin the healing process. When the offending stimuli are removed, inflammation subsides. The resolving phase of inflammation is not a passive process but actively "switches off" via the biosynthesis of endogenous antiinflammatory mediators. It could therefore be considered that chronic, nonresolving inflammation not only is associated with excessive production of proinflammatory mediators but also is attributed to a defect in the synthesis of antiinflammatory compounds.

Two classes of polyunsaturated omega-6 and omega-3 fatty acids are metabolized competitively, including conversion to their corresponding prostanoids (prostaglandins [PG] and thromboxanes [Tx]) and leukotrienes (LT). Eicosapentaenoic acid (EPA, 20:5) and docosahexaenoic acid (DHA, 22:6) are omega-3 polyunsaturated fatty acids (PUFA) that are abundant in cold-water fish such as salmon, sardines, mackerel, herring, tuna, fish oils, and some algae. Alpha-linolenic acid (ALA, 18:3) is also an omega-3 PUFA found in abundance in flaxseed, walnuts, and soy and canola (rapeseed) oils. EPA, DHA, and ALA have all been shown to replace the synthesis of inflammatory eicosanoids by competing with the conversion of arachidonic acid (ARA, 20:4 omega-6) to the series 2 of PG and Tx. Also, EPA and DHA are enzymatically converted to novel specialized proresolving mediators (SPMs) that involve three separate families termed resolvins, protectins, and maresins, which promote the resolution of inflammation (Serhan and Levy, 2018). ARA comes exclusively from animal foods. Linoleic acid (LA, 18:2), an omega-6 PUFA found in safflower and other vegetable oils, is a precursor of ARA; therefore its consumption should be limited in rheumatic patients.

The type of mediator that is produced is determined by the type of PUFAs present in the phospholipids of the cell membrane, which in turn is influenced by the type of PUFAs in the diet. Theoretically, a person can replace omega-6 PUFAs

with omega-3 PUFAs by increasing omega-3 PUFA consumption. This, in turn, will result in the synthesis of prostanoids (PG and Tx) with antiinflammatory effects. Similarly, reducing the amount of ARA minimizes inflammation and can enhance the benefits of fish oil supplementation.

Studies during the last 20 years clearly show beneficial changes in eicosanoid metabolism with fish oil supplementation in patients with RA, even when administered parenterally (Calder, 2017). Although fish oil seems to exert an antiinflammatory effect in short-term studies, these effects may vanish during long-term treatment because of decreased numbers of autoreactive T cells via apoptosis.

These oils should be used in conjunction with improved eating that includes more omega-3 PUFA. This means a diet that includes baked or broiled fish one to two times per week. However, the Food and Drug Administration (FDA) has identified shark, swordfish, king mackerel, and tilefish as high-mercury fish that should be avoided (see *Focus On: Childhood Methylmercury Exposure and Toxicity: Media Messaging* in Chapter 16).

A daily consumption of omega-3 PUFA (mainly EPA and DHA) for an RA patient varies from 2.7 g to 4.6 g (Akbar et al, 2017; Calder, 2017). Nowadays the quality of fish oil supplements is higher and with fewer side effects (mostly fishy odor, mild diarrheas, abdominal cramps).

The combination of fish oils with olive oil results in greater clinical improvements in RA patients than those consuming fish oils alone. These results are attributed to oleocanthal, a naturally occurring phenolic compound found in extra virgin olive oil. Oleocanthal exerts its antiinflammatory activity by inhibiting cyclooxygenase (COX)-1 and COX-2 in a similar way as ibuprofen does (Casas et al, 2018) as well as iNOS, interleukin (IL)-1, IL-6, and tumor necrosis factor (TNF) among others (Pang and Chin, 2018).

Minerals, Vitamins, and Antioxidants

Several vitamins and minerals function as antioxidants and therefore affect inflammation. Vitamin E is just such a vitamin, and along with omega-3 fatty acids may decrease proinflammatory cytokines and lipid mediators. Synovial fluid and plasma trace element concentrations, including zinc, change in inflammatory RA. Altered trace element concentrations in inflammatory RA may result from changes of the immunoregulatory cytokines. Degradation of collagen and eicosanoid stimulation are associated with oxidative damage.

RA patients often have nutritional intakes below the dietary reference intakes (DRIs) for folic acid, calcium, vitamin D, vitamin E, zinc, vitamin B, and selenium. In addition, the commonly used drug MTX is known to decrease serum folate levels with the result of elevated homocysteine levels (Kawami et al, 2018). Low serum level of pyridoxal-5-phosphate correlates with increased markers of inflammation (Ueland et al, 2017), and continuous use of NSAID (Naproxen) also impairs pyridoxine metabolism by a mechanism related to COX inhibition (Chang et al, 2013). Thus in these patients, adequate intakes of folate and vitamins B₆ and B₁₂ should be encouraged.

Calcium and vitamin D malabsorption and bone demineralization are characteristic of advanced stages of the disease, leading to osteoporosis or fractures. Prolonged use of glucocorticoids also can lead to osteoporosis. Therefore supplementation with calcium and vitamin D should be considered. Vitamin D status should be assessed and supplementation started if below normal. Indeed, vitamin D is a selective immunosuppressant and greater intakes of vitamin D may be beneficial. Because of drug-induced alterations in specific vitamin or mineral levels, mounting evidence supports supplementation beyond the minimum levels for vitamins D, E, folic acid, and vitamins B₆ and B₁₂.

In RA patients, inflammatory Th17 cells producing IL-17 are inversely associated with antiinflammatory Treg cells. Flavonoids found in many fruits, vegetables, cocoa, tea, and some herbs and spices have been used as therapeutic agents in autoimmune inflammatory diseases. The antiinflammatory properties of flavonoids are increasingly elucidated in vitro and in animal models of arthritis, as flavonoids have been shown to inhibit COX, to reduce the production of inflammatory cytokines, to suppress p38 MAPK, to inhibit Th17 cells, and to increase Tregs (Kelepouri et al, 2018). Elevated levels of copper and ceruloplasmin in serum and joint fluid are seen in RA. Plasma copper levels correlate with the degree of joint inflammation, decreasing as the inflammation is diminished. Elevated plasma levels of ceruloplasmin, the carrier protein for copper, may have a protective role because of ceruloplasmin's antioxidant activity.

Complementary and Integrative Therapies

The increasing popularity of the use of complementary treatments appears to be particularly evident with people afflicted with RA. Herbal therapy such as the use of turmeric and ginger have shown benefits in RA with very low risk of adverse events. As with all herbal therapies, it is important to fully assess the potential for drug nutrient interactions (Dragos et al, 2017).

Gamma-linolenic acid (GLA) is an omega-6 fatty acid found in the oils of black currant, borage, and evening primrose that can be converted into the antiinflammatory prostaglandin E (PGE)₁ or into ARA, a precursor of the inflammatory PGE₂. Because of competition between omega-3 and omega-6 fatty acids for the same enzymes, the relative dietary contribution of these fats appears to affect which pathways are favored. The enzyme delta-5 desaturase converts GLA into ARA, but a

diet high in omega-3 fats pulls more of this enzyme to the omega-3 pathway, allowing the body to use GLA to produce PGE₁ (see *Clinical Insight: Fatty Acids and the Inflammatory Process*). This antiinflammatory PGE₁ may relieve pain, morning stiffness, and joint tenderness with no serious side effects. Further studies are required to establish optimum dosage and duration.

SJÖGREN'S SYNDROME

Sjögren's syndrome (SS) is a chronic autoimmune inflammatory disease that affects the exocrine glands, particularly the salivary and the lacrimal glands, leading to dryness of the mouth (xerostomia) and of the eyes (xerophthalmia). SS can present alone (primary SS) or secondary as a result of a previous rheumatic disorder (commonly RA or SLE). It mainly affects middle-aged women, with a female to male ratio of 9:1 (Mariette and Criswell, 2018).

Common oral signs include thirst, burning sensation in the oral mucosa, inflammation of the tongue (glossitis) and lips (cheilitis), cracking of the corners of the lips (cheilosis), difficulties in chewing and swallowing (dysphagia), severe dental caries, oral infections (candidiasis), progressive dental decay, and nocturnal oral discomfort. Patients may also suffer from extraglandular disorders affecting the skin, lung, kidney, nerve, connective tissue, and digestive systems (Mariette and Criswell, 2018). SS patients also may develop disturbances in smell perception (dysosmia) and in taste acuity (dysgeusia) (Gomez et al, 2004; Al-Ezzi et al, 2017).

Pathophysiology

Although the pathogenesis of SS remains elusive, environmental, genetic, and hormonal contributors seem to be involved. The majority of lymphocytes infiltrating the salivary glands are mostly CD4 T cells. Increased levels of IL-1 and IL-6 in the saliva of SS patients suggest that a Th1 response participates in the pathogenesis of the disease. A recent meta-analysis reported an increase in IL-17 in serum and saliva of primary SS (pSS) patients (Zhang et al, 2018), which also was associated with the severity of the symptoms. Furthermore, patients with pSS without immunosuppressive treatment show markedly higher IL-17 levels.

Although T cells were originally considered to play the initiating role in SS, whereas B cells were restricted to autoantibody production, it has been shown that B cells play a central role in the development of the disease (Nocturne and Mariette, 2018). A distinctive hallmark of SS is the presence of anti-Ro/SSA and anti-La/SSB autoantibodies. Interestingly, anti-Ro/SSA may be found either solely or concomitantly with anti-La/SSB antibodies, whereas exclusive anti-La/SSB positivity is rare (Jog and James, 2017).

Recent studies indicate that dysbiosis may play a role in SS pathogenesis. The cause-effect direction is not clear yet because the dysfunction of salivary glands induces alterations in the microbiome, which is linked to worsening of symptoms and disease severity. Although this information is preliminary, dietary patterns that support a healthy microbiome including a plant-based, fiber-rich diet may be reasonable (Tsigalou et al, 2018).

Medical Management

The therapeutic management of SS is based on symptomatic treatment of glandular manifestations and on the use of DMARD for systemic involvement (van der Heijden et al, 2018). Symptomatic treatment has beneficial effects on oral and ocular dryness and prevents further complications such as oral candidiasis, periodontal disease, and corneal ulceration and perforation.

Topical treatment of xerostomia begins by avoiding irritants such as caffeine, alcohol, and tobacco, followed by appropriate hydration

(small sips of water) and the use of saliva substitutes, lubricating gels, mouth rinses, chewing gum, lozenges, or oils. Any of these treatments is effective in the short term, but none improves saliva production. After consumption of sugary foods or beverages, the teeth should be brushed and rinsed with water immediately to prevent dental caries. Topical treatment for xerophthalmia starts by avoiding dry, smoky, or windy environments and prolonged reading or computer use. Artificial tears can be used. The muscarinic receptor agonists pilocarpine (Salagen) and cevimeline (Evoxac) may be used for the treatment of dry mouth and dry eyes only in patients with residual gland function (Mariette and Criswell, 2018).

B-cell depletion therapy with rituximab (anti-CD20) improves the stimulated whole saliva flow rate and lacrimal gland function, as well as other variables including RF levels, extraglandular manifestations (arthritis, skin vasculitis), fatigue, and quality of life, indicating a major role of B cells in the pathogenesis of SS (Mariette and Criswell, 2018).

IL-1 and TNF- α play a major role in the development of SS. Blocking IL-1 (anakinra) is beneficial in the treatment of SS, whereas blocking TNF- α (etanercept) is ineffective in controlling SS symptoms (Nocturne and Mariette, 2018). The management of extraglandular features must be tailored to the specific organs involved. Antimalarials (hydroxychloroquine), besides improving salivary flow, can help SS patients with arthromyalgia. The use of corticosteroids may be used in patients with extraglandular manifestations, although they have no effect in salivary or lacrimal flow rates.

Medical Nutrition Therapy

The first goal of dietary management for patients with SS is to help them relieve their oral symptoms and reduce the eating discomfort derived from the difficulty with chewing and swallowing (Sjögren's Syndrome Foundation, 2018). Very often SS patients modify their dietary habits on a trial and error basis to cope with their oral symptoms, particularly to improve biting (cutting fruits, vegetables, and meats in small pieces), chewing (making foods softer by preparing them as soups, broths, casseroles, or as tender cooked vegetables and meats), and swallowing (moistening foods with sauces, gravies, yogurts, or salad dressings). Foods that worsen oral symptoms should be limited, such as citrus fruits, as well as irritating, hot, or spicy foods and alcohol (Sjögren's Syndrome Foundation, 2018).

Malnutrition or weight loss are not common in SS patients, although deficiencies of several nutrients are common. These include vitamin D (Garcia-Carrasco et al, 2017), vitamin B₆, vitamin B₁₂, folate, and iron, which can be corrected easily by proper nutritional counseling or supplementation (Erten et al, 2015). More importantly single nutrient deficiencies in SS have been associated with other diseases, such as low levels of vitamin D with neuropathy and lymphoma, suggesting a possible role of vitamin D deficiency in the development of other symptoms, and the plausible beneficial effect for vitamin D supplementation (Garcia-Carrasco et al, 2017).

Preliminary studies demonstrate that the beneficial effects of probiotic supplementation in RA patients might also benefit patients with SS and other autoimmune conditions, to shift their microbiome away from a disease promoting and proinflammatory pattern (Zamani et al, 2016).

TEMPOROMANDIBULAR DISORDERS

Temporomandibular disorders (TMDs) affect the temporomandibular joint, which connects the lower jaw (mandible) to the temporal bone. TMDs can be classified as myofascial pain, internal derangement of the joint, or degenerative joint disease. One or more of these conditions may be present at the same time, causing pain or discomfort in the muscles or joint that control jaw function.

Pathophysiology

Besides experiencing a severe jaw injury, little scientific evidence suggests a cause for TMD. It is generally agreed that physical or mental stress may aggravate this condition.

Medical Nutrition Therapy

The goal of dietary management is to alter food consistency to reduce pain while chewing. According to the National Institute of Dental and Craniofacial Research (NIDCR), diet should be soft in consistency; all foods should be cut into bite-size pieces to minimize the need to chew or open the jaw widely; chewing gum, sticky foods, and hard foods such as raw vegetables, candy, and nuts should be avoided (NIH, NIDCR, 2018). It is recommended to cut all foods into small pieces, select moist foods or use gravies or sauces to moisten foods to a comfortable consistency, peel fruits (with the exception of berries) and vegetables that have skin, chop whole foods to consistencies that can be comfortably tolerated, limit jaw opening to the extent that is comfortable, take small bites of food, and chew slowly. Although mechanically altering the patient's diet to enable pain-free eating is the goal, in some instances, patients may benefit from taking liquid oral supplements to meet their energy, protein, and micronutrient needs (Nasri-Heir et al, 2016). Nutrient intake of TMD patients appears to be the same as for the general population with regard to total calories, protein, fat, carbohydrates, vitamins, and minerals. However, during times of acute pain, intake of fiber is often reduced.

GOUT

Gout is one of the oldest diseases in recorded medical history. It is a disorder of purine metabolism in which abnormally high levels of **uric acid** accumulate in the blood (**hyperuricemia**). Contrary to what is observed in most rheumatic diseases, gout predominantly affects men. Gout is common in most countries in North America and Western Europe, with prevalence in the range 1% to 4%. By contrast, gout is reportedly rare in former Soviet Union regions, Guatemala, Iran, Malaysia, Philippines, Saudi Arabia, rural Turkey, and African countries. In all countries, men have a significantly higher prevalence of gout than women. The male to female ratio is generally in the order of 3:1 to 4:1 (Kuo et al, 2015).

Gout is associated with cardiovascular and renal diseases and is an independent predictor of premature death. The frequencies of obesity, chronic kidney disease (CKD), hypertension, type 2 diabetes, dyslipidemias, cardiac diseases (including coronary heart disease, heart failure, and atrial fibrillation), stroke, and peripheral arterial disease have been repeatedly shown to be increased in gout. Therefore the screening and care of these comorbidities as well as of cardiovascular risk factors are of utmost importance in patients with gout (Bardin and Richette, 2017).

Pathophysiology

Gout is a crystal deposition disease in which the clinical symptoms are caused by the formation of **monosodium urate (MSU) crystals** in the joints and soft tissues, and the elimination of these crystals "cures" the disease. **Uric acid** is the end-product of purine metabolism in humans, but it is an intermediary product in most other mammals. It is produced primarily in the liver by the action of the enzyme xanthine oxidase, a molybdenum-dependent enzyme. In most mammals, uric acid is further degraded by the enzyme urate oxidase (uricase), to allantoin, which is more soluble than uric acid, and hence more readily excreted by kidneys. In humans and higher primates, the gene encoding for uricase is nonfunctional and due to this evolutionary event,

uric acid levels are higher in humans than in many other mammals. Endogenous production of uric acid from degradation of **purines** accounts for two thirds of the body urate pool, the remainder being of dietary origin. Because most uric acid is excreted via the kidney (approximately 70%), hyperuricemia results from reduced efficiency of renal urate clearance.

Two proteins have been well characterized in urate clearance: the urate transporter 1 (URAT1) and the glucose and fructose transporter (GLUT9). URAT1 localizes in the brush border membrane of the proximal tubule kidney and is responsible mainly for renal reabsorption of uric acid, whereas GLUT9 is located in the apical and basolateral membrane of the distal tubule where it functions as the main exit of urate from the body (Mandal and Mount, 2015).

In the vast majority of people with gout, hyperuricemia results from reduced renal urate clearance. MSU crystals preferentially form within cartilage and fibrous tissues; however if shed from these sites, they are highly immunogenic particles that are quickly phagocytosed by monocytes and macrophages, activating the NALP3 inflammasome and triggering the release of IL-1 and other cytokines, thus initiating an inflammatory response that affects the joint. MSU crystals act as a danger signal that can be recognized by pattern recognition receptors at the cell surface and in the cytoplasm, indicating the importance of innate immunity in gout (Benn et al, 2018). Persistent accumulation of MSU crystals causes joint damage through mechanical effects (pressure erosion) leading to chronic symptoms of arthritis (Fig. 38.5). MSU crystals can deposit in the small joints and surrounding tissues, producing recurrent episodes of extremely painful and debilitating joint and soft tissue inflammation (acute gout). In chronic gout, classic sites are the big toe, wrists and finger joints, elbow (Fig. 38.6), ankle, knee, and the helix of the ear. Occasionally, uric acid crystals called **tophi** can be seen as white patches on the skin and in cartilage such as the ear.

Pseudogout, also called CPPD (calcium pyrophosphate deposition) disease has a prevalence of around 0.5% of the general population (for the U.S. and Europe). The average age of onset is over 68 years and is more common in men. There is no reported treatment (pharmacological or nutritional) that can lower the production and deposition of CPP in these patients. Although the treatment for the symptoms of CPPD (inflammation and pain) is identical to that of "classical" gout (due to monosodium urate crystals), there is no dietary intervention known to prevent or treat this condition (Zamora & Kaik 2019).

Medical Management

Colchicine is a medication used to treat the pain associated with acute flares of gout (within 12 to 24 hours) by reducing the inflammation caused by MSU crystals; it has no effect on serum urate levels. Colchicine may be used with other NSAIDs and only for a limited time because of its toxicity.

Because monocytes and macrophages produce IL-1 in response to MSU crystals, treatment with IL-1 antagonists (Anakinra) or with soluble IL-1 receptor (rilonacept) results in rapid and complete pain relief (Pascart and Richette, 2017).

Two classes of drugs have been used to lower serum urate: **uricostatic** drugs, which reduce the synthesis of uric acid by inhibiting xanthine oxidase, and **uricosuric** drugs, which increase the excretion of uric acid by blocking its renal tubular reabsorption. Allopurinol (Zyloprim) and febuxostat are uricostatic drugs; they are the drugs of choice for long-term treatment of hyperuricemia. On the other hand, sulfapyrazone, probenecid, and benzbromarone are uricosuric drugs that act by inhibiting URAT1, therefore increasing the urinary excretion of uric acid (Mandal and Mount, 2015; Pascart and Richette, 2017).

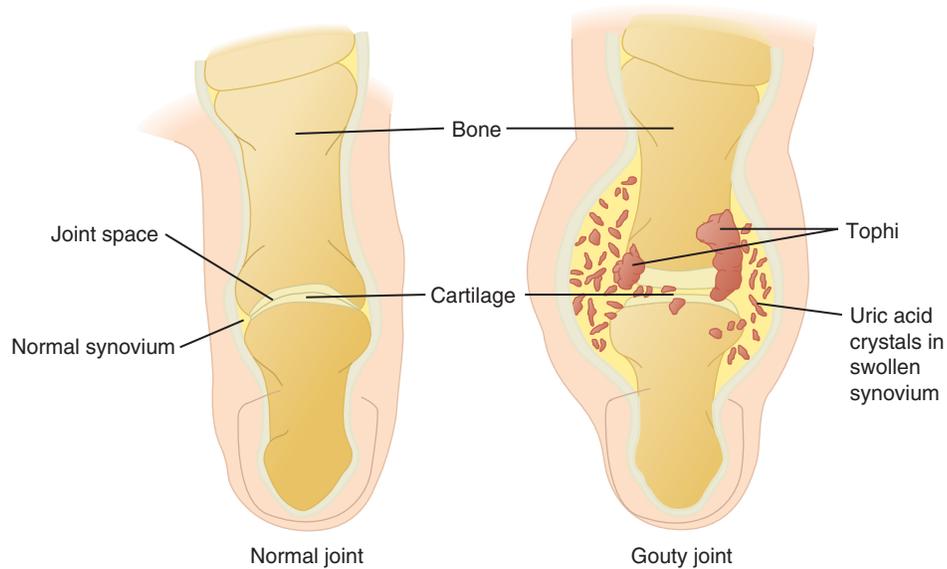

Fig. 38.5 Comparison of a gouty joint and a normal joint in the toe. (From Black JM, et al: *Medical surgical nursing*, ed 7, Philadelphia, 2005, Saunders.)

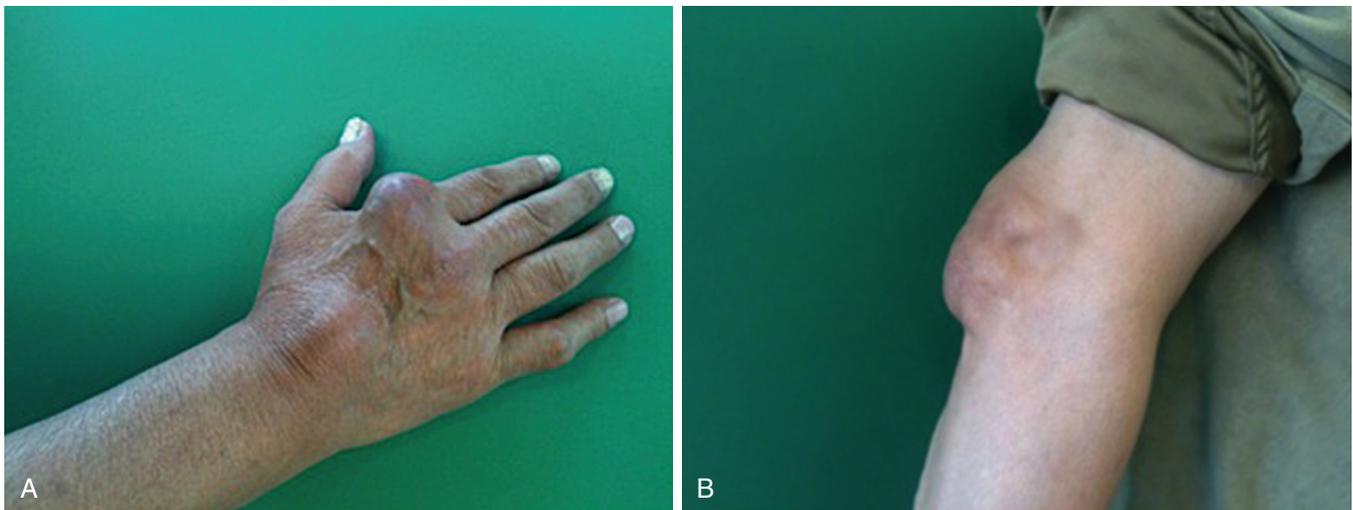

Fig. 38.6 A male patient with advanced gout. Severe deposits of monosodium urate (MSU) crystals in the hand (**A**, wrist and fingers) and in the elbow (**B**). (Photos courtesy Dr. F. Enrique Gómez. Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán. Mexico City, México, 2015.)

Pegloticase, a recombinant uricase, reduces serum urate levels by converting uric acid to allantoin, which is excreted rapidly in the urine (Guttmann et al, 2017). Pegloticase is used for rapid debulking of tophi, and together with colchicine it reduces the impact of acute gout flares.

Medical Nutrition Therapy

Purine-containing foods (such as meats, organ meat, seafood, legumes, yeast, mushrooms, and gravies) have been the target of many early gout diets, mainly on the basis of the concept that the biochemical degradation end product of purines is urate. More recent studies have found that this is not necessarily true. National Health and Nutrition Examination Survey data show that the age-adjusted differences in serum urate between the lowest and highest intake of meat was 0.48 mg/dL (95% CI 0.34-0.61 mg/dL, $p < 0.001$) and 0.16 mg/dL for

seafood (95% CI 0.06-0.27 mg/dL, $p = 0.005$). Total protein intake was not found to be related to increasing urate levels.

In a similar prospective study, the relative risk for gout in men with the highest meat intake compared with the lowest was 1.41 (95% CI 1.07-1.80), whereas seafood was 1.51 (95% CI 1.17-1.95). Each additional serving of meat per day increased the risk of gout by 21%, whereas each additional weekly seafood serving increased risk by 7%. The intake of dried beans and greens is not associated with gouty flares, as shown by a relative risk of 0.73 (95% CI 0.56-0.96).

Fructose is the only carbohydrate known to increase urate. Fructose and sugar intake also predispose to insulin resistance and metabolic syndrome, which further increase the risk of hyperuricemia (Beyl et al, 2016).

On the other hand, diets that contain low-fat dairy products and supplemental vitamin C have been associated with reduced

BOX 38.3 Purine Content of Foods

High Purine Content (100-1000 mg of Purine Nitrogen per 100 g of Food): Foods in This List Should be Omitted from the Diet of Patients Who have Gout (Acute and Remission Stages).

Anchovies	Meat extracts
Bouillon	Mincemeat
Brains	Mussels
Broth	Partridge
Consommé	Roe
Goose	Sardines
Gravy	Scallops
Heart	Sweetbreads
Herring	Yeast (baker's and brewer's), taken as supplement
Kidney	
Mackerel	

Moderate Purine Content (9-100 mg of Purine Nitrogen per 100 g of Food): One Serving (2-3 oz) of Meat, Fish, or Poultry Daily

Meat, fish and shellfish not listed above
Poultry

risk of gout. Consumption of black coffee (without sugar) is associated with low levels of serum urate, and therefore may be protective for gout.

Alcohol consumption, particularly beer (which is rich in purines), increases the risk of gout. Consumption of fructose, mainly as soft drinks sweetened with high fructose corn syrup, is associated with higher risk for gout. It is unclear whether this is a particular effect of fructose derived from high-fructose corn syrup, or whether it extends to sucrose (Beyl et al, 2016). Excess consumption of naturally occurring fructose such as in fruit juices also may increase risk of gout.

It is prudent to advise patients to consume a balanced meal plan with limited intake of animal foods and beer, avoidance of high-purine foods (Box 38.3), limited consumption of fructose and refined carbohydrates (sweetened soft drinks and juices, candies, and sweet pastries). If a patient is overweight, weight loss may also help reduce risk of gout. Liberal intake of plant proteins, nuts, vegetables, legumes, whole grains, lower sugar fruits, and plant oils is supported, and up to two servings daily of low-fat dairy products is recommended. Although fish intake can increase serum urate, there may be greater overall cardiovascular benefit from the addition of moderate amounts of cold water, oily fish such as tuna, salmon, and trout, which are high in omega-3 fatty acids. Eggs and poultry are lower risk protein sources when used in moderation. One or fewer servings of red meat or shellfish per week may be recommended. Wine in moderation is acceptable. Up to 6 cups of coffee daily has been shown beneficial but new initiation of coffee may exacerbate gout flares. Supplementation with vitamin C may be useful, but a dosing range and long-term safety recommendations have not been made. Cherry products may be beneficial, but better data are needed before making this a recommendation to patients. During an acute flare it is recommended to increase water intake to at least 8 cups per day and avoid alcohol or meat (Beyl et al, 2016).

Dairy products (milk or cheese), eggs, vegetable protein, and coffee appear to be protective, possibly because of the alkaline ash effect of these foods (see *Clinical Insight: Acid and Alkaline Diet* in Chapter 34). Cherry juice has also been studied for its ability to lower uric acid levels and gout flares.

SCLERODERMA (SYSTEMIC SCLEROSIS OR SSc)

Scleroderma (currently known as systemic sclerosis or SSc) is a chronic disease characterized by three features: early microvascular obliterative changes, early activation of the immune system with activation of T cells and B cells, and widespread fibrosis of skin and internal organs. SSc is characterized by multisystem involvement, mainly the skin, respiratory tract (lung parenchyma and pulmonary arteries), kidneys, skeletal muscles, the gastrointestinal tract and cardiovascular system (Eldoma and Pope, 2018). As with other RMDs, women are more prone to develop SSc but the incidence is very low (between 10 and 20/100,000).

Based on the extent of skin involvement, SSc is classified into two subtypes: limited cutaneous scleroderma (lcSSc), defined by thickened skin distal to elbows and knees, face, and neck, and diffuse cutaneous scleroderma (dcSSc) which involves the trunk and the proximal part of upper and lower limbs. It is important to identify the patient's subtype due to differences in prognosis and organ involvement. LcSSc is more likely to be associated with anticentromere autoantibodies (ACA) and Raynaud's syndrome before disease onset and a better prognosis. DcSSc is more likely to have internal organ involvement and a worse prognosis.

Pathophysiology

Systemic sclerosis (SSc) is characterized by vascular abnormalities, followed by hypoxia and coldness of the hands and feet (**Raynaud's syndrome**) as well as excessive production of extracellular matrix and collagen. The pathogenesis of SSc is incompletely understood, but immune activation and microvasculopathy could lead to the development of fibrosis. The activation of B cells results in the presence of autoantibodies, whereas activation of proinflammatory Th1 and Th17 cells is enhanced by a reduction in IL-10. Other cytokines such as IL-4, IL-13, IL-6, and TGF β , are among the profibrotic mediators implicated in SSc pathogenesis.

Scleroderma renal crisis (SRC) is a rare complication of SSc characterized by hypertension and oliguric or anuric acute renal failure. Intestinal involvement is frequent in SSc and represents a significant cause of morbidity. The pathogenesis of intestinal involvement includes vascular damage, nerve dysfunction, smooth muscle atrophy, and fibrosis, causing hypomotility, which may lead to small intestinal bacterial overgrowth (SIBO), malabsorption, malnutrition, diarrhea, pseudoobstruction, constipation, and fecal incontinence (Sakkas et al, 2018; Eldoma and Pope, 2018). Manifestations are often troublesome and reduce quality of life and life expectancy (Smirani et al, 2018; Sakkas et al, 2018).

Medical Management

SSc is a serious, sometimes life-threatening connective tissue disease with treatment options that have been shown to provide only mild to modest benefit. The limited efficacy of available therapies can be explained by several factors including heterogeneity of the disease, lack of complete understanding of pathophysiology, and limited use of combination or maintenance therapy. Treatment guidelines for SSc provide therapy options for disease manifestations based on the affected organs or systems. However, the current therapy available shows mild improvement in disease with mostly loss of benefit after discontinuation of treatment.

Several immunosuppressive treatments (MTX, cyclophosphamide, and mycophenolate mofetil) have been used to reduce the deposition of collagen in skin in early dcSSc. Immunomodulation should be considered early in intestinal involvement. Since the advent of

angiotensin-converting enzyme (ACE) inhibitors, mortality associated with SRC decreased from 76% to <10%. Some patients may progress to end-stage renal disease and need dialysis. SSc has been treated with biologicals (Abatacept, Tocilizumab) with some promising results (Eldoma and Pope, 2018).

Medical Nutrition Therapy

Management of concomitant digestive complaints is a primary focus of MNT for SSc. Patients with diarrhea are managed with a low-residue and low-fat diet, medium-chain triglycerides, avoidance of lactulose and fructose, and/or a low-FODMAP diet if SIBO is present. In diarrhea/malabsorption, bile acid sequestrant and pancreatic enzyme supplementation may help. General measures are applied for constipation (fiber, fluids, physical activity, and fermented foods or probiotics supplements), and intestine rest plus antibiotics for pseudoobstruction. Fecal incontinence is managed with measures for associated SIBO or constipation, and with behavioral therapies. A multidisciplinary approach to management of intestinal manifestations in SSc by gastroenterologists, rheumatologists, and dietitians is required for optimum management (Sakkas et al, 2018; Smirani et al, 2018).

Patients with SSc often experience dry mouth and dysphagia (see Chapter 39 and Appendix 20). Dry mouth with resultant tooth decay, loose teeth, and tightening facial skin make eating difficult. Consuming adequate fluids, choosing moist foods, chewing sugarless gum, and using saliva substitutes help moisten the mouth and offer temporary relief.

If gastroesophageal reflux is a concern, small, frequent meals are recommended along with avoidance of late-night eating, alcohol, caffeine, and spicy or fatty foods (see Chapter 26).

Malabsorption of lactose, vitamins, fatty acids, and minerals can cause further malnutrition and supplementation may be required. A high-energy, high-protein supplement or enteral feeding may prevent or correct weight loss. Home enteral or parenteral nutrition often is required when problems such as chronic diarrhea and malabsorption persist (see Chapter 12).

SYSTEMIC LUPUS ERYTHEMATOSUS

Systemic lupus erythematosus (SLE) is known commonly as lupus. SLE is a chronic autoimmune disease characterized by production of autoantibodies directed against nuclear (anti-dsDNA, anti-Sm, anti-RNP) and cytoplasmic antigens affecting several organs and tissues (Jog and James, 2017). SLE is most prevalent in women of childbearing age with a female to male ratio of 9:1, suggesting that sex-related factors are important in its development. It has also been shown that SLE is more common in African Americans and women of Hispanic, Asian, and Native American descent than in Caucasians. In the United States, SLE is among the top 20 leading causes of death in females between 5 and 64 years of age (Yen and Singh, 2018).

Pathophysiology

The cause of SLE is multifactorial and involves multiple genes and environmental factors such as infections, hormones, and drugs. In SLE, circulating ANA (anti-dsDNA, anti-Sm, anti-RNP) and others (anticardiolipin) can deposit in several tissues (Jog and James, 2017). The production of cytokines such as type 1 IFN activates B and T cells and propagates the signal to produce more IFN by DC. This upregulation of the type 1-IFN pathway is critical in the severity and progression of SLE (Connelly et al, 2018).

Common symptoms include extreme fatigue, painful or swollen joints, muscle pain, sensitivity to the sun, unexplained fever, skin rashes most commonly on the face, mouth ulcers, pale or purple fingers or toes from cold or stress (Raynaud's syndrome), and kidney insufficiency (NIH, NIAMS, 2018). SLE is characterized by periods of remission and relapse and may present with various constitutional and organ-specific symptoms.

Medical Management

General treatment of SLE includes sun protection, diet and nutrition, smoking cessation, and exercise, whereas organ-specific treatments include use of steroids, NSAIDs, DMARDs, and biologics. Pharmacologic treatment includes the cytotoxic agents cyclophosphamide and azathioprine; their combination with corticosteroids must be employed early if there is major organ involvement in order to prevent or minimize irreversible damage.

The hallmark of SLE is B-cell activation and the production of harmful autoantibodies. Therefore B-cell depletion and cytokine or Treg cells targeted therapies, alone or combined with cytotoxic drugs, have been used to treat SLE. There are more than 20 biologic therapies used for SLE. They have different immune targets, such as B cells, T cells, and myeloid cells and their cytokines, known to contribute to lupus pathogenesis (Davis and Reimold, 2017).

Hydroxychloroquine (Plaquenil, an antimalarial drug) has potential benefits for dermatologic manifestations, arthritis, preventing lupus flares, reducing thrombosis in APS, atherosclerotic risk, and type 2 diabetes risk. Steroid hormones, azathioprine and MTX and mycophenolate mofetil, are some of the DMARDs used to control SLE manifestations (Davis and Reimold, 2017).

Medical Nutrition Therapy

Because kidney insufficiency is common in SLE, total protein intake may need to be reduced (see Chapter 34). SLE patients tend to have higher consumption of carbohydrates and low intake of dietary fiber and omega-3 (EPA and DHA) and omega-6 fatty acids. The latter has been negatively associated with increased disease activity, altered serum lipid profiles, and increased carotid plaque presence (Lourdudoss et al, 2016). In addition, SLE patients often have inadequate intakes of calcium, fruits, and vegetables and high consumption of oils and fats (Aparicio-Soto et al, 2017).

Photosensitivity, sunlight avoidance, the use of sun protection, and low dietary intake, in combination with medications prescribed to treat the symptoms of the disease, may be responsible for the observed low levels of vitamin D (Dall'Ara et al, 2018). Decreased conversion of 25-hydroxy vitamin D to its active form, calcitriol (1,25-dihydroxy vitamin D₃), is possible because of renal impairment common in SLE, putting additional stress on vitamin D metabolism.

Vitamin D deficiency has been associated with higher ANA levels in healthy subjects and in treatment-naive SLE patients, suggesting it might be a trigger for autoantibody production. Vitamin D supplementation may be beneficial to patients with high anti-dsDNA positivity, possibly reducing clinical flares (Aparicio-Soto et al, 2017; Franco et al, 2017).

Vitamin D supplementation in patients with SLE is recommended because increased vitamin D levels seem to ameliorate inflammatory and blood markers and show a tendency toward subsequent clinical improvement. General international recommendations have established that vitamin D supplementation with 800 to 1000 IU/day or 50000 IU/month is safe for most individuals and can ensure levels of vitamin D within the optimal range (Aparicio-Soto et al, 2017; Dall'Ara et al, 2018).

Vitamin A has also shown beneficial effects, alone or in combination with low-dose immunosuppressive drugs, in lupus nephritis and cytokine modulation in both mouse models and patients with SLE (Aparicio-Soto et al, 2017). The most likely mechanism of action for vitamin A in SLE is via IL-17 and transforming growth factor (TGF β), cytokine regulation, and possibly others like IL-6 (Handono et al, 2016).

An adequate intake of dietary fiber is recommended in SLE because of the beneficial effects of fiber in decreasing cardiovascular risk, promoting gut mobility, and reducing serum levels of inflammation markers such as CRP, cytokines, and homocysteine (Aparicio-Soto et al, 2017).

Complementary Integrative Therapies

More than an estimated 50% of patients with SLE have used CIM to reduce symptoms and manage their health. Supplements of N-acetyl cysteine and turmeric reduce SLE activity and, together with mind-body methods (cognitive-behavioral therapy and other counseling interventions), improve mood and quality of life of SLE patients (Greco et al, 2013). A small study showed short-term turmeric supplementation can decrease proteinuria, hematuria, and systolic blood pressure in patients suffering from relapsing or refractory lupus nephritis (Khajehdehi et al, 2012). No systematic reviews have been performed for the application of integrative medicine for lupus nephritis on patients with SLE (Choi et al, 2018).

SPONDYLARTHRIIDES

The most important clinical features of this group of diseases are inflammatory back pain, asymmetric peripheral oligoarthritis (predominantly of the lower limbs), and enthesitis (inflammation at the site where the tendon attaches to the bone). Conventional medical treatment is based mainly on the use of NSAIDs (ibuprofen, COX-2 inhibitors) and DMARDs (sulfasalazine); patients with persistently active disease are also treated with blocking agents (TNF, IL-6). Physiotherapy is of major importance in the general approach to patients with any of these spondylarthritides. Nutritional therapy must emphasize keeping a healthy body weight, as well as increasing the consumption of foods rich in antioxidants and with antiinflammatory activities (see Box 38.2 and Appendix 22).

Ankylosing spondylitis (AS) is the major subtype of the spondylarthritides. AS (from Greek *ankylos*, fused; *spondylos*, vertebra; *-itis*, inflammation) affects joints in the spine and the sacroiliac joint in the pelvis and can cause eventual fusion of the spine. AS most often

develops in young adult men and it lasts a lifetime. Enthesitis, inflammation of the site where ligaments and tendons insert into the bone, accounts for much of the pain and stiffness of AS. This inflammation eventually can lead to bony fusion of the joints, where the fibrous ligaments transform to bone, and the joint permanently grows together. Other joints also can develop synovitis, with lower limb joints more commonly involved than upper-limb joints. Pain in the low back and buttocks are usually the first symptoms of AS. In contrast to mechanical low back pain, low back pain and stiffness in AS patients are worse after a period of rest or on waking up in the morning and improve after exercise, a hot bath, or a shower. Progressive stiffening of the spine is usual, with ankylosis occurring after some years of disease in many, but not all, patients. A majority of patients have mild or moderate disease with intermittent exacerbations and remissions and maintain some mobility and independence throughout life. Complete fusion results in a complete rigidity of the spine, a condition known as bamboo spine.

Polymyalgia rheumatica (PMR) means “pain in many muscles,” and is a syndrome with pain or stiffness, usually in the neck, shoulders, and hips. It may be caused by an inflammatory condition of blood vessels such as temporal arteritis (inflammation of blood vessels in the face, which can cause blindness if not treated quickly). Most PMR sufferers wake up in the morning with pain in their muscles; however, there have been cases in which the patient has developed the pain during the evenings. Treatment for PMR includes the use of corticosteroids (prednisone) alone or with an NSAID (ibuprofen) to relieve pain, exercises to strengthen the weak muscles, and a healthy diet (antiinflammatory diet) (see Appendix 22).

Polymyositis (PM), which means “inflammation of many muscles,” is a type of chronic inflammation of the muscles (inflammatory myopathy) and is more common in adult women. Symptoms include pain with marked weakness or loss of muscle mass in the muscles of the head, neck, torso, and upper arms and legs. The hip extensors are often severely affected, leading to particular difficulty in ascending stairs and rising from a seated position. Early fatigue while walking is caused by weakness in the upper leg muscles. Sometimes the weakness presents itself as an inability to raise from a seated position without help or an inability to raise one’s arms above one’s head. Dysphagia or other problems with esophageal motility occur in as many as one third of patients; foot drop in one or both feet can be a symptom of advanced PM.

Treatment for PM includes corticosteroids, specialized exercise therapy, and a whole-foods antiinflammatory diet tailored to individual needs. Patients with dysphagia may benefit by changing the consistency of foods (softened, increased moisture) and a referral to a speech language therapist for further assessment.

CLINICAL CASE STUDY

Linda is a 33-year-old Mexican female, team manager at a service company and mother of two. She is an active smoker with periodontal disease. Six months ago, she presented with chronic additive symmetric polyarthritis, involving the wrists, hands, knees, and toes. Linda has morning stiffness for about an hour, her symptoms improve with movement and worsen with rest. She has taken several NSAIDs with no major improvement. At examination, the doctor noted inflammation in the joints.

Laboratory tests showed mild normocytic normochromic anemia, elevated erythrocyte sedimentation rate, and high C-reactive protein. She was positive for rheumatoid factor and antibodies to cyclic citrullinated peptide (ACPA).

Marginal erosions in the metacarpophalangeal joints were found by x-ray imaging.

Linda was diagnosed with rheumatoid arthritis. Based on polyarthritis, positivity of antibodies and erosions, it was determined to be a severe case, and she was started on disease-modifying antirheumatic drugs (DMARDs) methotrexate (MTX) and corticosteroids.

Nutrition Assessment

Patient is 33-year-old Mexican woman with a recent diagnosis of rheumatoid arthritis. Anthropometric Data

CLINICAL CASE STUDY—cont'd

Ht 5'8" (1.73 m); Wt 152 lb (69 kg) (lost 6 lb [4%] over past 2 months)
 Body mass index (BMI) = 23
 Biochemical data: Hb 10.5 g/dL

Food and Nutrition History

Diet reflects reliance on convenience foods and highly processed take-out fast foods with inadequate intake of antiinflammatory fruits, vegetables, whole grains, and omega 3 fatty acids.

Decline in food preparation due to difficulty in shopping and cooking. Pt reports having a lower than normal appetite due to stress and pain.

Caloric intake: 1600 kcal/day (80% of estimated need)

Estimated energy requirement (EER): 2070 kcal (30 kcal/kg) and 82 g protein (1.2 g/kg body weight [BW] for acute phase).

Nutrition Diagnostic Statements

- Inadequate energy intake related to reduced appetite from stress and pain as evidenced by consuming an estimated 80% of caloric needs and involuntary weight loss of 4% in 2 months (NI-1.4) (NC-3.2).
- Impaired ability to prepare foods/meals related with pain and swelling in hands and wrist joints as evidenced by patient's report.
- Undesirable food choices related to food and nutrition knowledge deficit about the relationship between whole foods antiinflammatory diet and the progression of autoimmune disease as evidenced by a reliance on highly

processed convenience foods and low intake of omega-3 fatty acids, fruits, vegetables, and whole grains.

- Altered nutrition-related laboratory values (Hemoglobin) related to drug-nutrient interaction with MTX and inadequate iron intake, as evidenced by anemia diagnosis.

Interventions

- Ensure adequate energy, protein, and iron intake (2000 kcals, 80 g protein)
- Whole foods, iron-rich diet with an emphasis on vegetables, whole grains, oily fish, and antiinflammatory herbs and spices (turmeric)
- Education about whole foods based on convenience foods and adaptive utensils that may make food preparation easier
- Omega-3 fatty acid supplementation (2,000 to 3000 mg daily). Folic acid (due to MTX) and iron supplementation as prescribed by her physician
- Advice to cease smoking and perform moderate intensity physical activity

Monitoring and Evaluation

- Monthly weight measurements; although Linda's BMI is currently adequate in spite of her weight loss, it is important to stop weight loss due to her autoimmune condition.
- Repeat iron laboratories in 3 months
- Evaluate energy, protein, and iron intake. If arthritis is not active, adjust protein to 1 g/kg BW.

Medical Nutrition Therapy for Neurologic Disorders

Maggie Moon, MS, RDN

Ashley Contreras-France, MA, MS, CCC-SLP

KEY TERMS

absence seizure (petit mal)	embolic stroke	otorrhea
adrenomyeloleukodystrophy (ALD)	epidural hematoma	paraplegia
adrenomyeloneuropathy	epilepsy	paresthesia
Alzheimer's disease (AD)	Frazier Free Water Protocol	Parkinson's disease (PD)
amyotrophic lateral sclerosis (ALS)	Glasgow Coma Scale	partial seizures
anosmia	Guillain-Barré syndrome (GBS)	peripheral nervous system (PNS)
aphasia	hemianopsia	peripheral neuropathy
apraxia	hemiparesis	refractory epilepsy
areflexia	hydrocephalus	rhinorrhea
aspiration	hyperosmia	seizure
aspiration pneumonia	intracranial pressure (ICP)	speech-language pathologist (SLP)
basilar skull fractures	intraparenchymal hemorrhage	spinal cord injury (SCI)
central nervous system (CNS)	International Diet Standardisation Initiative (IDDSI)	stroke (cerebrovascular accident)
chronic inflammatory demyelinating polyneuropathy (CIDP)	ketogenic diet	subarachnoid hemorrhage (SAH)
concussion	Lewy bodies	subdural hematoma
contusion	medium-chain triglyceride (MCT) oil	syndrome of inappropriate antidiuretic hormone secretion (SIADH)
cortical blindness	motor strips	tetraplegia
deglutatory dysfunction	multiple sclerosis (MS)	thromboembolic event
diffuse axonal injury	myasthenia gravis (MG)	thrombotic stroke
Disability Adjusted Life Year (DALY)	myelin	tonic-clonic (grand mal) seizure
dysarthria	myelopathy	transient ischemic attack (TIA)
dysosmia	neglect	traumatic brain injury (TBI)
dysphagia	neuromuscular junction	Wernicke-Korsakoff syndrome (WKS)

The nervous system is essential to daily existence, health, and well-being: from breathing to how we perceive the world around us, to how we think and store memories, to movement and coordination. It is also involved in sleep, healing, stress responses, hunger, thirst, digestion, and more. That is why this chapter starts with the basic anatomy and physiology of the central nervous system (CNS) and how good nutrition supports its health.

Conversely, poor nutrition can also have an impact on the brain (Table 39.1). In addition, medical nutrition therapy supports the medical management of neurologic disorders from trauma (e.g., sports injury, surgery), as well as other diseases and conditions (e.g., Alzheimer's, epilepsy, Parkinson's) (Table 39.2).

Though relatively rare, neurologic disorders affect hundreds of millions of people globally (World Health Organization [WHO], 2016a). Neurologic disorders, when combined, make up the world's number one cause of years lost to disability, also known as **Disability Adjusted Life Years (DALY)** (GBD 2015 Neurological Disorders Collaborator Group, 2017). The measure of DALY includes the years people live with a disability as well as their shortened lifespan. Grouped together, neurologic disorders are the second leading cause of death, and the

number of those deaths has risen by 36.7% in just 25 years (1990–2015). This number is expected to grow as the aging population grows.

To meet this growing demand, dietetics professionals need to understand the fundamental nutrition required for a healthy nervous system, and be equipped with current evidence and best practices for the neurologic conditions in which nutrition has the most potential impact. Many elements of nutrition care for neurologic diseases and conditions are similar regardless of the origin of the disease process. For example, it is important to know how to develop a diet appropriate for varying degrees of dysphagia, as it is the most common issue complicating nutrition therapy for neurologic disorders and international guidelines have recently been updated. For an overview, see Box 39.1.

THE NERVOUS SYSTEM

There are two main components of the nervous system: the **central nervous system (CNS)**, which includes the brain and spinal cord, and the **peripheral nervous system (PNS)**, which includes the nerves that extend from the spinal cord to the rest of the body (i.e., neck, chest, abdomen, arms, legs, muscles, and internal organs). The CNS and PNS

TABLE 39.1 Neurologic Diseases of Nutritional Origin

Disease	Deficient Nutrient	Physiologic Effect	Treatment
Protein-calorie deprivation	Protein and calories	Impaired cognitive and intellectual function	Protein foods, adequate calories
Wet beriberi	B ₁ Thiamin	Peripheral or central neurologic dysfunction	Thiamin, food and/or supplement as needed
Pellagra	B ₃ Niacin	Memory loss, hallucinations, dementia	Niacin, food and/or supplement as needed
Pernicious anemia	Vitamin B ₁₂ cobalamin	Lesions occur in myelin sheaths of optic nerves, cerebral white matter, peripheral nerves	Monthly vitamin B ₁₂ injections, oral vitamin B ₁₂ supplements
Wernicke-Korsakoff syndrome	B ₁ Thiamin	Encephalopathy, involuntary eye movements, impaired movement, amnesia	Eliminate alcohol; thiamin food or supplement, adequate hydration
Magnesium deficiency	Magnesium	Muscle spasms, anxiety, headache, insomnia, cramps	Magnesium in food/supplements
Zinc deficiency	Zinc	Taste and smell loss, hallucinations, depression, brain defects during pregnancy	Zinc in food/supplements
B ₂ deficiency	B ₂ Riboflavin	Burning, itching of eyes, sensitivity to light, burning sensations around mouth, peripheral nerve damage	Riboflavin, food and/or supplement as needed. Keep food sources away from heat and light.
B ₅ deficiency	B ₅ Pantothenic acid	Rare but can lead to fatigue, burning sensations on hands and feet, and headaches	Pantothenic acid, food and/or supplement as needed
B ₆ deficiency	B ₆ Pyridoxine	Abnormal touch sensations, mania, convulsions, abnormal EEG readings	Pyridoxine, food and/or supplement as needed. Eliminate alcohol
B ₉ deficiency	B ₉ Folic acid	Peripheral nerve problems, memory disorder, convulsions; neural tube defects	Folate in food and supplements/Folic Acid in supplements
Hypocalcemia and tetany seizures	Vitamin D	When combined with low calcium can lead to seizures	Vitamin D, food and/or supplement as needed. Sensible sun exposure.
Cretinism	Iodine	Stunted physical and mental growth	Seafood, fortified salt, supplement
Wilson's disease	Excessive copper	Mental and movement problems; genetic disorder	Low copper diet, including supplements

EEG, Electroencephalography.

TABLE 39.2 Nutritional Considerations for Neurologic Conditions

Medical Condition	Relevant Nutrition Therapy
Adrenoleukodystrophy	Lorenzo's oil may lower VLCFA levels.
Dementia	Recommend antiinflammatory diet such as MIND diet or Mediterranean diet. Minimize distractions at mealtime. Initiate smell or touch of food. Guide hand to initiate eating. May require verbal cueing for sequential bites. Provide nutrient-dense foods, omega-3 fatty acids.
Amyotrophic lateral sclerosis	Intervene to prevent malnutrition and dehydration. Possibly ketogenic diet. Monitor dysphagia progression. Antioxidant use (vitamins C, E, selenium, methionine) is well tolerated, but not proven.
Epilepsy	Provide ketogenic diet (see Appendix 19, Ketogenic Diets)
Guillain-Barré syndrome	Attain positive energy balance with high-energy, high-protein tube feedings. Assess dysphagia. Discuss safe food handling to prevent recurrence.
Migraine headache	Coffee is therapeutic. Coenzyme Q ₁₀ , riboflavin, feverfew, butter bur, and chiropractic services may possibly be effective. B ₆ , B ₁₂ , and folic acid are potentially prophylactic. Possibly avoid tyramine-containing foods (e.g., aged cheese, wine), which can be trigger foods. Possibly avoid tomatoes, citrus, chocolate, spinach, aged meats and cheeses (histamine in or released by these foods may trigger, maintain, or aggravate headache). Consider a supervised elimination diet to identify individualized food triggers. Maintain adequate dietary and fluid intake. Keep extensive records of symptoms and foods.

Continued

TABLE 39.2 Nutritional Considerations for Neurologic Conditions—cont'd

Medical Condition	Relevant Nutrition Therapy
Myasthenia gravis	Provide nutritionally dense foods at beginning of meal. Small, frequent meals are recommended. Limit physical activity before meals. Place temporary feeding tube in advanced disease.
Multiple sclerosis	Recommend antiinflammatory diet. Increase omega-3 intake, especially from marine sources. Decrease saturated fat intake. Evaluate health and especially vitamin D status of patient. Nutrition support may be needed in advanced stages. Distribute fluids throughout waking hours; limit before bed.
Parkinson's disease (see Appendix 19, Ketogenic Diets)	Focus on drug-nutrient interactions with dietary protein and vitamin B ₆ . Minimize dietary protein at breakfast and lunch. Recommend antiinflammatory diet.
Pernicious anemia	Patient will need B ₁₂ injections through medical management. Provide diet liberal in HBV protein. Provide diet supplemented with Fe ⁺ , vitamin C, and B complex vitamins (especially B ₁₂ and folate).
Spinal trauma	Assess site of trauma and degree of impairment Possibly provide enteral or parenteral nutrition support. Provide high-fiber diet, adequate hydration to minimize constipation. Provide healthful diet to meet nutrient needs (e.g., Mediterranean diet, DASH diet, MIND diet).
Stroke	Mediterranean, DASH, or MIND diet. Assess possible dysphagia. Enteral nutrition via tube feeding may be needed if motor functions are poor.
Wernicke-Korsakoff syndrome	Provide thiamin-rich foods and supplementation. Provide adequate hydration. Eliminate alcohol. Dietary protein may have to be restricted.

DASH, Dietary Approaches to Stop Hypertension; Fe⁺, iron; HBV, high biologic value; MIND, Mediterranean-DASH intervention for neurodegenerative delay; VLCFA, very-long-chain fatty acid.

BOX 39.1 Issues Complicating Nutrition Therapy

Nutrition assessment requires taking a detailed patient history. The diet history and mealtime observations are used to assess patterns of normal chewing, swallowing, and rate of ingestion. Weight loss history establishes a baseline weight; a weight loss of 10% or more is indicative of nutritional risk. Assessment for nutrients involved in neurotransmitter synthesis is particularly important in these patients. It is important to ask about all supplements and medications to determine food-drug interactions or side effects that will impact adequate nourishment. Nutrition diagnoses common in the neurologic patient population include the following:

- Chewing difficulty
- Increased energy expenditure
- Inadequate energy intake
- Inadequate fluid intake
- Physical inactivity
- Poor nutritional quality
- Difficulty with independent eating
- Swallowing difficulty
- Underweight
- Elimination problems
- Inadequate access to food or fluid

Meal Preparation

Confusion, dementia, impaired vision, or poor ambulation may contribute to difficulty with meal preparation, thus hindering oral food and beverage intake. Assistance with shopping and meal planning are frequently necessary. Food manufacturers are facilitating the management of modified textures through use of the International Dysphagia Diet Standardisation Initiative (IDDSI) framework for easy identification. Further, the growing use of food delivery decreases the cognitive burdens associated with grocery shopping and meal planning.

Eating Difficulties and Inadequate Access to Food or Fluid

With chronic neurologic diseases, a decline in function may hinder the ability for self-care and nourishment. Access to food and satisfying basic needs may depend on the involvement of family, friends, or professionals. With acute neurologic situations such as seizures, trauma, stroke, or Guillain-Barré syndrome (GBS), the entire process of eating can be interrupted abruptly. The patient may require enteral nutrition for a time until overall function improves, and adequate oral intake is resumed (see Chapter 13).

Eating Issues: Presentation of Food to the Mouth

The patient with neurologic disease may be unable to eat independently because of limb weakness, poor body positioning, hemianopsia, limb apraxia,

BOX 39.1 Issues Complicating Nutrition Therapy—cont'd

confusion, or neglect. Tremors in Parkinson's disease (PD), spastic movements, or involuntary movements that occur with cerebral palsy, Huntington's disease, or tardive dyskinesia may further restrict dietary intake. The affected region of the central nervous system (CNS) determines the resulting disability (see Table 39.3).

If limb weakness or paralysis occurs on the dominant side of the body, poor coordination resulting from a new reliance on the nondominant side may make eating difficult and unpleasant. The patient may have to adjust to eating with one hand or using the nondominant hand. An occupational therapist can facilitate strategies and provide adaptive equipment to support self-feeding. **Hemiparesis** is weakness on one side of the body, usually both limbs and sometimes the face, that causes the body to slump toward the affected side; it may increase a patient's risk of aspiration.

Hemianopsia is blindness for one half of the field of vision. Patients must learn to recognize that they no longer have a normal field of vision and must

compensate by turning the head. **Neglect** is a failure to respond to stimuli on the weakened or paralyzed side of the body; this occurs when the right parietal side of the brain suffers an insult. The patient ignores the affected body part, and the perception of the body's midline is shifted. This phenomenon may occur after insult to the left side of the brain, resulting in right-sided neglect. However, right-sided neglect is less frequent, less severe, and more likely to resolve than left-sided neglect (Myers, 2009). Hemianopsia and neglect can occur together and severely impair the patient's function. Patients may eat only half of the contents of a meal because they recognize only half of it (Fig. 39.1).

Another potential deterrent to independent eating is apraxia because the person is unable to carry out an action and follow directions. Demonstration may make it possible for the action to occur; however, judgment may be affected as well and can result in the performance of dangerous tasks. This makes it unsafe to leave the patient alone.

work together to control voluntary actions (e.g., muscle movement) and involuntary activity (e.g., breathing, temperature regulation, heart beat).

A careful history of the patient's signs and symptoms can help determine where CNS lesions may originate. Through this process, the lesion can be localized to muscle, nerve, spinal cord, or brain as part of the medical diagnosis. Nerve tracts coming to and from the brain cross to opposite sides in the CNS (Fig. 39.2). Therefore a lesion on the

cortex that affects the right arm is found on the left side of the brain. Fig. 39.3 shows the segments of the brain.

Symptoms of muscle weakness, loss of coordination, and impaired range of motion are the most quantifiable clinical signs of nervous system disease. The neurons in the motor strip (upper motor neurons) receive input from all parts of the brain and project their axons all the way to their destinations in the spinal cord. Axons connect to the spinal cord motor neurons (lower motor neurons). These neurons extend from the spinal cord to muscles without interruption. The location of a lesion in the nervous system often can be deduced clinically by observing stereotypical abnormalities and function of either upper or lower motor neurons (Table 39.3).

TABLE 39.3 Basic Functions of Cranial Nerves

Number	Nerve Function
Olfactory (I)	Smell
Optic (II)	Vision
Oculomotor (III)	1. Eye movement 2. Pupil constriction
Trochlear (IV)	Eye movement
Trigeminal (V)	1. Mastication 2. Facial heat, cold, touch 3. Noxious odors 4. Input for corneal reflex
Abducens (VI)	Eye movement
Facial (VII)	1. All muscles of facial expression 2. Corneal reflex 3. Facial pain 4. Taste on anterior two thirds of tongue
Vestibulocochlear (VIII)	Hearing and head acceleration and input for oculocephalic reflex
Glossopharyngeal (IX)	1. Swallowing 2. Gag reflex 3. Palatal, glossal, and oral sensation
Vagus (X)	1. Heart rate, gastrointestinal activity, sexual function 2. Cough reflex 3. Taste on posterior third of tongue
Spinal accessory (XI)	1. Trapezius 2. Sternocleidomastoid muscle
Hypoglossal (XII)	Tongue movement

Fig. 39.1 A, Vision with hemianopsia (half of the visual field is absent). Food photography credit: Courtesy Maggie Moon, MS, RDN.

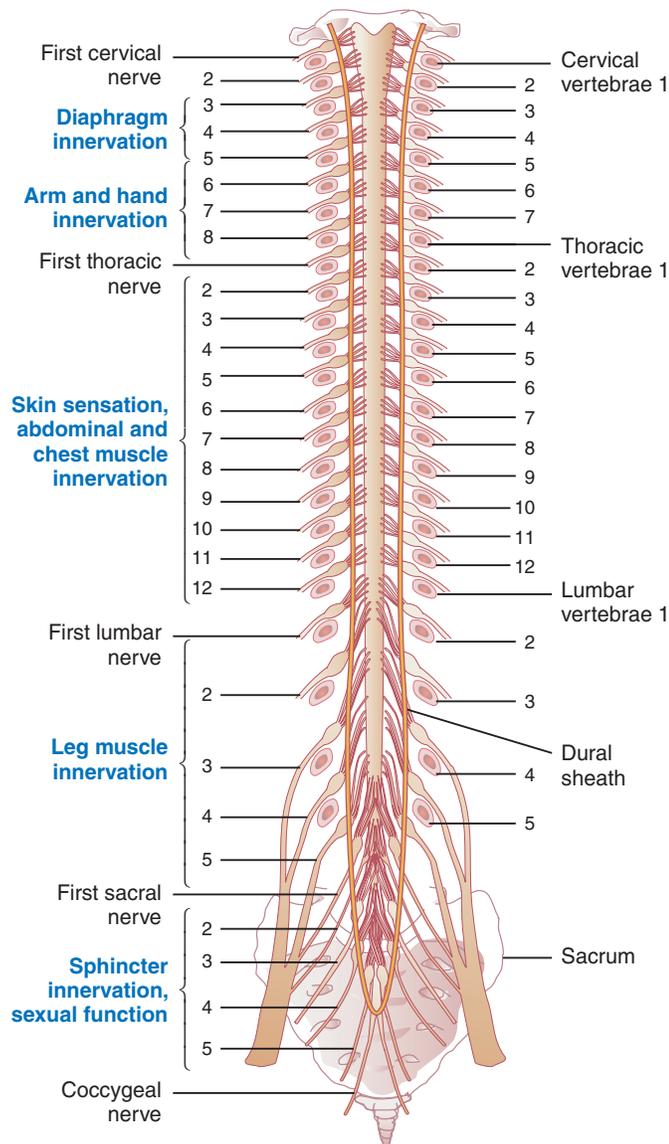

Fig. 39.2 Spinal cord lying within the vertebral canal. Spinal nerves are numbered on the left side; vertebrae are numbered on the right side; body areas supplied by various levels are in blue.

Locations and Signs of Mass Lesions

Eating and drinking require complex coordination within many parts of the nervous system. Therefore a problem at any location within the nervous system can affect the ability to meet nutritional requirements (Table 39.4).

- **Frontal lobe lesions:** The frontal lobes in the brain are the source of the most complex activities and commonly offer the most complex presentations. Psychiatric manifestations such as depression, mania, or personality change may indicate a tumor or other frontal lobe mass, either right or left. Frontal lobes are larger, and the posterior portions of the frontal lobes contain the **motor strips**, which control muscle movement. Lesions that develop in the central frontal lobe may present as motor apraxia, an impairment of motor planning (Duffy, 2013). A person with **apraxia** may not be able to perform purposeful movements such as independent eating despite a willingness to do so.
- **Skull base lesions:** Lesions or tumors near the skull base can lead to changes in smell and vision because olfactory and

optic nerves track along the bottom of these frontal lobes. Changes to sense of smell include **anosmia** (absence of smell), **hyperosmia** (increased sensitivity of smell), or **dysosmia** (distortion of normal smell).

- **Temporal lobe lesions:** Temporal lobes control memory and speech, and lesions in this part of the brain are seen in Alzheimer's dementia, stroke, and seizures. A right parietal lobe mass or insult may result in chronic inability to focus attention to the body's left side, a condition known as **neglect**. Because language centers are located near the junction of the left temporal, parietal, and frontal lobes, pathologic conditions in this region may cause **aphasia**, the inability to process language.
- **Occipital lobe lesions:** The occipital lobes are reserved for vision, and dysfunction here may bring about **cortical blindness** of varying degrees. In this condition the people are unaware that they cannot see.
- **Cerebellum and brainstem lesions:** Lesions of the cerebellum and brainstem may obstruct the ventricular system where it is the narrowest. This obstruction may precipitate life-threatening **hydrocephalus**, a condition of increased **intracranial pressure (ICP)** that may quickly result in death due to increased accumulation of fluid in the brain. Other signs of hydrocephalus include trouble with balance, walking and coordination, marked sleepiness, and complaints of a headache that is worse on awakening. Lesions in the brainstem may infiltrate any of the cranial nerves that innervate structures of the face and head, including the eyes, ears, jaw, tongue, pharynx, and facial muscles. These lesions have consequences for nutrition, because the patient is often unable to eat without risk of aspiration of food or liquids into the lungs. Tumors or other lesions in the medulla oblongata (the lower half of the brainstem) may infiltrate respiratory and cardiac centers with grim consequences.
- **Spinal cord lesions:** Lesions in the spinal cord are much less common than brain tumors and ordinarily cause lower motor neuron signs at the level of the lesion and upper motor signs in segments below the level of the lesion. **Spinal cord injury (SCI)** is the most common pathologic condition in this region. Other examples of spinal cord abnormalities are **multiple sclerosis (MS)**, **amyotrophic lateral sclerosis (ALS)**, tumor, syrinx (fluid-filled neurologic cavity), chronic meningitis, vascular insufficiency, and mass lesions of the epidural space. Injuries to the cervical and thoracic regions of the spinal cord may result in respiratory dysfunction requiring assisted ventilation which presents challenges for intake.
- **Pituitary gland and hypothalamus lesions:** Lesions of the pituitary gland and hypothalamus often manifest systemically; for example, electrolyte and metabolic abnormalities secondary to adrenocortical, thyroid, and antidiuretic hormone dysregulation. Because of the proximity to the visual pathways, changes may occur in visual field or acuity. The **syndrome of inappropriate antidiuretic hormone secretion (SIADH)** is often a complication; volume status and hyponatremia are part of the medical diagnosis (see Chapter 5). Because the hypothalamus is the regulatory center for hunger and satiety, lesions here may present as anorexia or overeating.
- **Peripheral nerve and neuromuscular junction lesions:** Disorders of peripheral nerves and the neuromuscular junction affect one's ability to maintain proper nutrition from fluctuating weakness and easy fatigability in voluntary muscle movements. Disorders such as **Guillain-Barré syndrome (GBS)** or **myasthenia gravis (MG)** may counteract the efforts to maintain nutritional balance. While respiratory and limb muscles are obviously affected, the impact of weakness on oral, pharyngeal, and laryngeal muscles presents challenges for safe intake of food and drink.

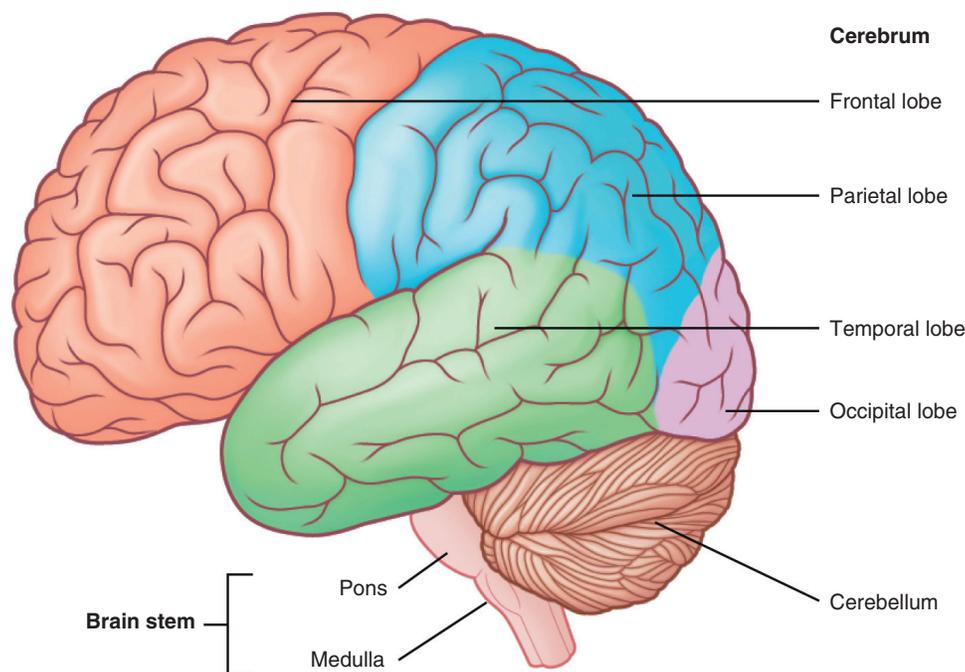

Fig. 39.3 Parts of the brain. Trauma or disease in one area may affect speech, vision, movement, or eating ability. (From Scully C: *Medical problems in dentistry*, ed 6, 2010, Churchill Livingstone.)

TABLE 39.4 Common Impairments with Neurologic Diseases

Site in the Brain	Impairment	Results
Cortical lesions of the parietal lobe (perception of sensory stimuli)	Sensory deficits	Fine regulation of muscle activities impossible if the patient is unable to perceive joint position and motion and tension of contracting muscles
Lesions of the nondominant hemisphere	Hemi inattention syndrome (neglect)	Patient neglects the affected side of the body
Optic tract lesions (usually of the middle cerebral artery or the artery near the internal capsule)	Visual field cuts	Patient reads one half of a page, eats from only half of the plate, etc. (see Fig. 39.1)
Loss of subcortically stored pattern of motor skills	Apraxia	Inability to perform a previously learned task (e.g., walking, rising from a chair), but paralysis, sensory loss, spasticity, and incoordination are not present
No identification with a particular brain disorder or a specifically located lesion	Language apraxia	Inability to produce meaningful speech, even though oral muscle function is intact and language production has not been affected; may produce groping oral movements in attempts at production
Lesion of Broca area	Nonfluent aphasia	Thought and language formulation are intact, but the patient is unable to connect them into fluent speech production; word-finding deficits (anomia) are common
Lesion of Wernicke area	Fluent aphasia	Flow of speech and articulation seem normal, but language output makes little or no sense; characterized by deficits in auditory comprehension and the presence of jargon, or nonwords that follow the language conventions
Extensive brain damage	Global aphasia	Language expression and reception are severely impaired
Brainstem lesions, bilateral hemispheric lesions, cerebellar disorders, cranial nerve lesions, and diffuse neurologic diseases	Dysarthria	Inability to produce intelligible words due to impairments in respiration, phonation, articulation, resonance, and prosodic systems

Nutrition and Lifestyle Factors for a Healthy Nervous System

The healthy nervous system, like the body it is housed in, requires optimal consumption of the right macronutrients, micronutrients, and phytonutrients, as well as adequate water intake. There is no specialized diet for maintaining a healthy CNS, and an eating pattern that has appropriate portions of a variety and balance of healthful

foods applies as it does to the general population. However, certain compounds are of active interest in the research community, including curcumin, choline, polyphenols, and omega-3 fatty acids (Fig. 39.4).

The brain consumes up to 20% of the energy needed to maintain the body's resting metabolic rate, far outpacing it being only 2% of total body weight. About 75% of the brain is water, and 60% of the remaining brain matter is made of lipids. The brain is especially sensitive to oxidative stress and inflammation, and does not have access to

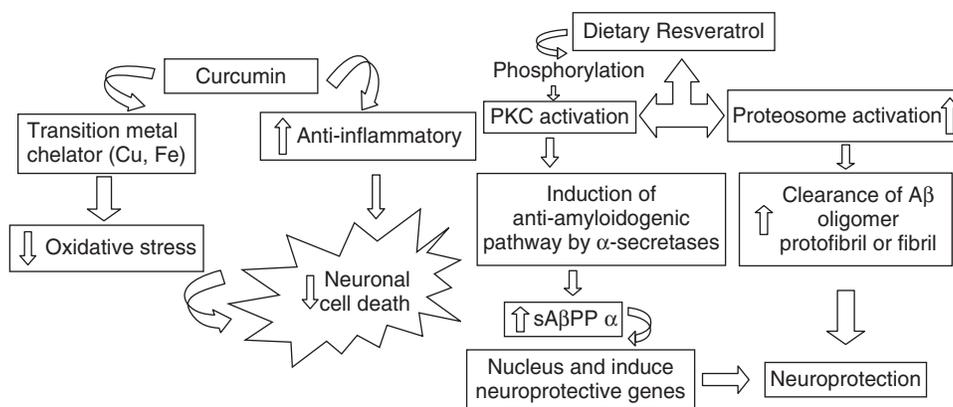

Fig. 39.4 The role of curcumin and resveratrol in neuroprotection. Left: Curcumin has multiple biologic effects: it chelates transition metals (iron and copper) and acts as an antioxidant and antiinflammatory molecule, protecting from oxidative stress. Right: Resveratrol favors phosphorylation in protein kinase C, activating the nonamyloidogenic pathway of A β PP cleavage, and this leads to reduction in A β formation. sA β PP α , a product of A β PP cleavage, gets translocated to the nucleus and modulates the genes. All these events favor neuronal cell survival. A β , Amyloid beta; PKC, protein kinase C; sAPP β , secreted fragment of amyloid protein precursor beta. (From Ramesh BN, et al: Neuronutrition and Alzheimer's disease, *J Alzheimer's Dis* 19:1123, 2010. With permission from IOS Press.)

as many endogenous antioxidant enzymes as other areas of the body, which is why dietary antioxidants are important for brain health, even in small amounts (Morris, 2012).

Nonnutritive lifestyle factors that improve nervous system health include adequate sleep for rest and repair, exercise for maintaining neural connections related to memory and learning, social engagement, and a constant supply of oxygen.

DYSPHAGIA

The nutritional management of patients with neurologic disease is complex. Severe neurologic impairments often compromise the mechanisms and cognitive abilities needed for adequate nourishment. A common result is **dysphagia** (difficulty swallowing), and the ability to obtain, prepare, and present food to the mouth can be compromised. Modified food textures are often required for the individual with swallowing problems. The **International Dysphagia Diet Standardisation Initiative (IDDSI)** has created a system for naming, describing, and testing various texture modifications for liquids and solids (Steele et al, 2015). However, not all institutions have adopted the new system and are still operating under the National Dysphagia Diet system (Box 39.2).

Early recognition of signs and symptoms, implementation of an appropriate care plan to meet the nutritional requirements of the individual, and counseling for the patient and family members on dietary choices are essential. Regular evaluation of the patient's nutrition status and disease management are priorities, with the ultimate goal of improving outcomes and the patient's nutritional quality of life. Active coordination with swallowing professionals, including **speech-language pathologists (SLP)** and occupational therapists (OT), aids in achieving this outcome.

Dysphagia often leads to malnutrition because of inadequate intake. Symptoms of dysphagia include drooling, choking, or coughing during or following meals; inability to suck from a straw; a "gurgly," or wet, voice quality; holding pockets of food in the buccal recesses or sublingual cavity (of which the patient may be unaware); absent gag reflex; and chronic respiratory infections. Patients with intermediate

or late-stage Parkinson's disease, MS, ALS, dementia, or stroke are likely to have dysphagia.

A swallowing evaluation by an SLP is important in assessing and treating swallowing disorders. The SLP is often consulted for individual patients following traumatic brain injury (TBI), stroke, or cancers of the head and neck, and for those at risk of **aspiration**, or the inhalation of foreign material, such as food and liquid, into the lungs. **Aspiration pneumonia** may result from the bacteria in saliva that is carried into the lungs; a common misconception is that pneumonia results from the food and liquid (Coyle, 2018). Coordination with an SLP for the management of other conditions that result in poor swallowing coordination may also be necessary for incorporating compensatory strategies or diet texture modifications. Many registered dietitian nutritionists (RDNs) have acquired additional training in swallowing therapies to help coordinate this evaluation process.

Phases of Swallowing

Proper positioning for effective swallowing should be encouraged (i.e., sitting upright, and in some cases, a chin down position). Concentrating on the swallowing process can also help reduce choking. Initiation of the swallow begins voluntarily but is completed reflexively. Normal swallowing allows for safe and easy passage of food from the oral cavity through the pharynx and esophagus into the stomach by propulsive muscular force, with some benefit from gravity. The process of swallowing can be organized into three phases, as shown in Fig. 39.5.

Oral Phase

During the preparatory and oral phases of swallowing, food is placed in the mouth, where it is combined with saliva, chewed if necessary, and formed into a bolus by the tongue. The tongue pushes the food to the rear of the oral cavity by gradually squeezing it backward against the hard and soft palate in a stripping action and creating negative pressure in the anterior oral cavity. Adequate muscle bulk in the buccal muscles supports fixing the lateral portion of the tongue, the movement of the soft palate to seal off the nasopharynx, and the allowance for respiration during the oral phase of the swallow. Increased ICP or

BOX 39.2 Development of Dysphagia Diets**Transitional Phasing Out of National Dysphagia Diet (NDD)**

Not all facilities have transitioned to the new International Dysphagia Diet Standardisation Initiative (IDDSI) system, and some still use NDD. As such, it is important to be aware of both during this transition period. Below, find an overview of the NDD system.

Texture Modifications**Level 3: Dysphagia Advanced (Previously: Mechanical Soft)**

- Soft-solid foods. Include easy-to-cut whole meats, soft fruits and vegetables (i.e., bananas, peaches, melon without seeds, tender meat cut into small pieces and well moistened with extra gravy or sauce).
- Crusts should be cut off bread.
- Chopped or cut into small pieces.

EXCLUDES hard, crunchy fruits and vegetables, sticky foods, and very dry foods. NO nuts, seeds, popcorn, potato chips, coconut, hard rolls, raw vegetables, potato skins, corn, etc.

Level 2: Dysphagia Mechanically Altered (Previously: Ground)

- Cohesive, moist, semisolid foods that require some chewing ability.
- Includes fork-mashable fruits and vegetables (i.e., soft canned or cooked fruits with vegetables in pieces smaller than ½ inch).
- Meat should be ground and moist. Extra sauce and gravy should be served.

EXCLUDES most bread products, crackers, and other dry foods. No whole grain cereal with nuts, seeds, and coconut. No food with large chunks. Most food should be ground texture.

Level 1: Dysphagia Puree

- Smooth, pureed, homogenous, very cohesive, pudding-like foods that require little or no chewing ability.
- No whole foods.
- Includes mashed potatoes with gravy, yogurt with no fruit added, pudding, soups pureed smooth, pureed fruits and vegetables, pureed meat/poultry/fish served with sauces/gravies, and pureed desserts without nuts, seeds, or coconut. AVOID scrambled, fried, or hard-boiled eggs.

Fluid Modifications

Thin liquids: includes water, soda, juice, broth, coffee, and tea. This also includes foods like Jello, ice cream, and sherbet that melt and become thin in the mouth.

Nectar-thick liquids: are pourable and the consistency of apricot nectar.

Honey-thick liquids: slightly thicker than nectar and can be drizzled; consistency of honey.

Pudding-thick liquids: should hold their shape, and a spoon should stand up in them; they are not pourable and are eaten with a spoon.

Adapted from National Dysphagia Diet Task Force: *National Dysphagia Diet: standardization for optimal care*, Chicago, IL, 2002, American Dietetic Association.

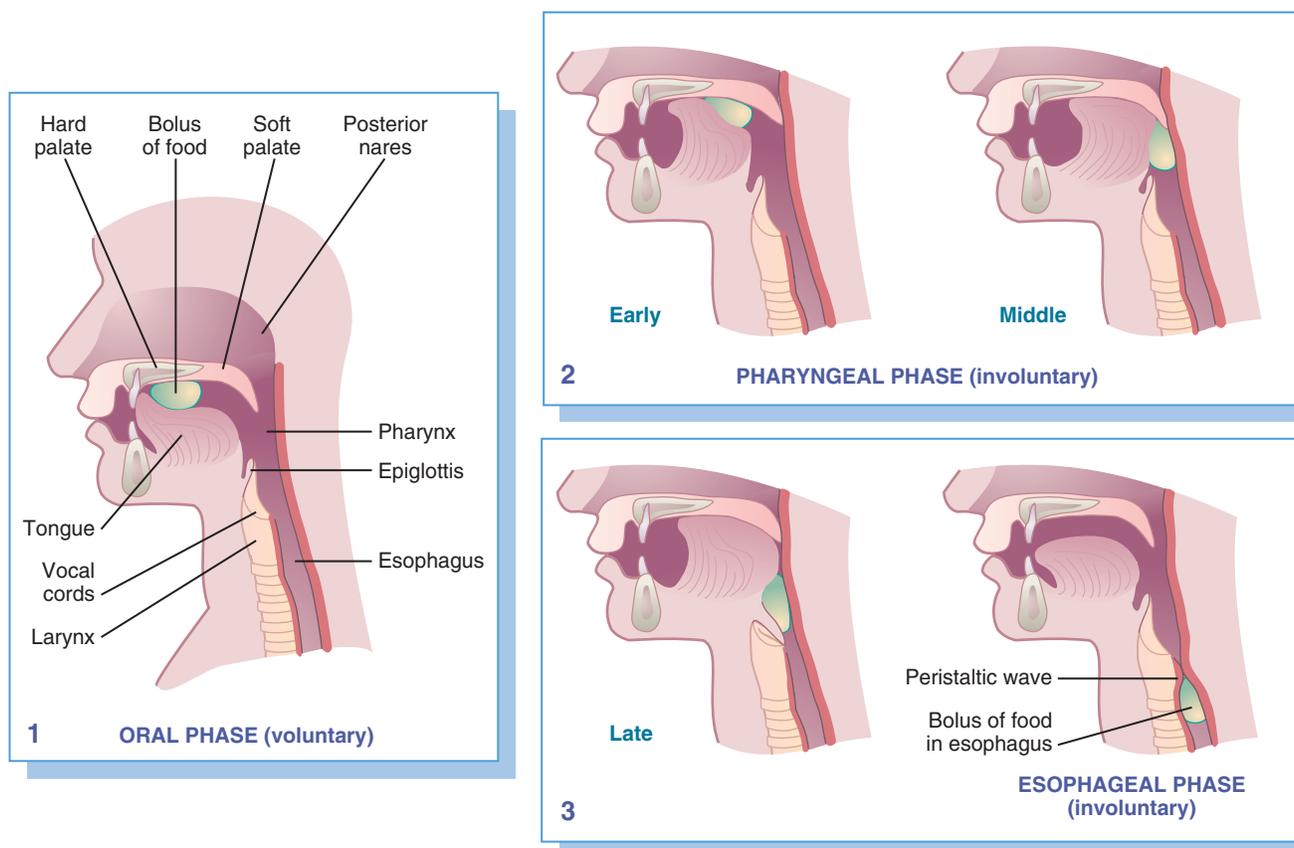

Fig. 39.5 Swallowing occurs in three phases: Voluntary or oral phase: Tongue presses food against the hard palate, forcing it toward the pharynx. Involuntary, pharyngeal phase: Early: wave of peristalsis forces a bolus between the tonsillar pillars. Middle: soft palate draws upward to close posterior nares, and respirations cease momentarily. Late: vocal cords approximate, and the larynx pulls upward, covering the airway and stretching the esophagus open. Involuntary, esophageal phase: Relaxation of the upper esophageal (hypopharyngeal) sphincter allows the peristaltic wave to move the bolus down the esophagus.

intracranial nerve damage may result in weakened or poorly coordinated tongue movements. Weakened lip muscles result in the inability to completely seal the lips, form a seal around a cup, or suck through a straw. Patients are often embarrassed by drooling and may not want to eat in front of others. The patient may have difficulty forming a cohesive bolus and moving it through the oral cavity. Food can become pocketed in the buccal recesses, especially if sensation in the cheek is lost or facial weakness exists.

Pharyngeal Phase

The pharyngeal phase is initiated when the bolus is propelled past the faucial arches. Four events must occur in rapid succession during this phase. The soft palate elevates to close off the nasopharynx and prevent oropharyngeal regurgitation. The hyoid bone and larynx elevate, causing the epiglottis to flip downward while the vocal cords adduct to protect the airway. The pharynx sequentially contracts while the cricopharyngeal sphincter relaxes, allowing the food to pass into the esophagus. Breathing resumes with exhalation at the end of the pharyngeal phase. Symptoms of poor coordination during this phase include gagging, choking, and nasopharyngeal regurgitation. Individuals with dysphagia may initiate swallow during inhalation, increasing the risk for aspiration.

Esophageal Phase

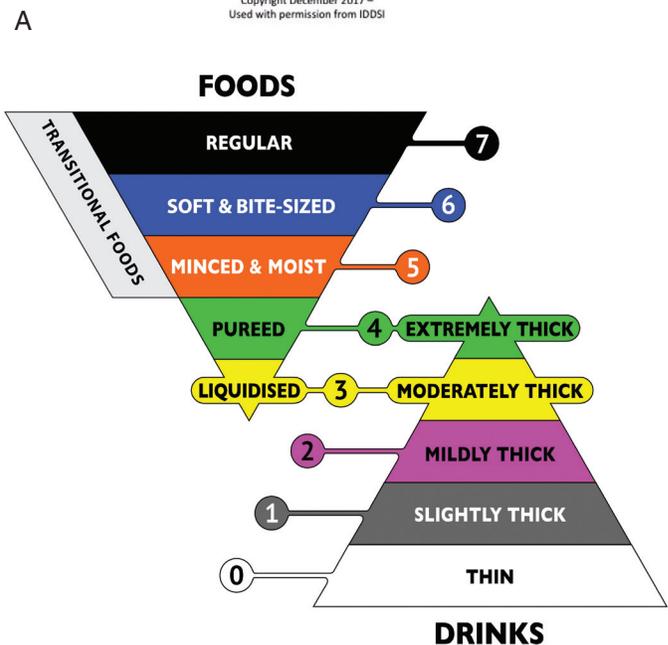

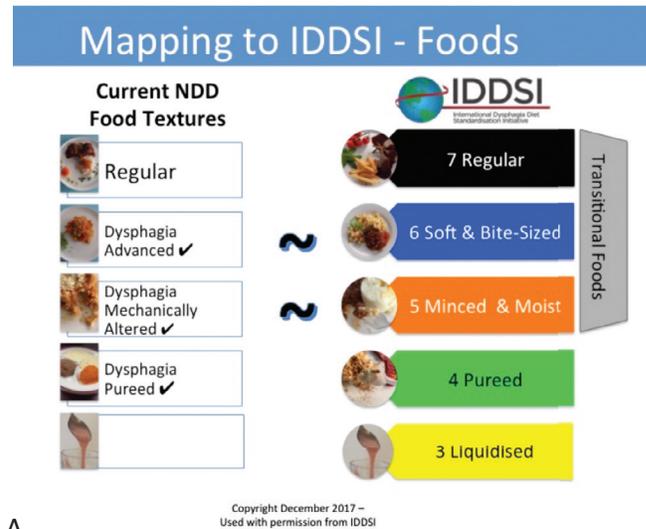

The final or esophageal phase, during which the bolus continues through the esophagus into the stomach, is completed involuntarily. Normal esophageal transit takes 8 to 20 seconds for the peristaltic wave to push the bolus through the lower esophageal sphincter. Difficulties that occur during this phase are generally the result of a mechanical obstruction, but neurologic disease cannot be ruled out. For example, impaired peristalsis can arise from a brainstem infarct.

Medical Nutrition Therapy

Weight loss, anorexia, and dehydration are key concerns with dysphagia. Observation during meals allows the nurse or RDN to screen informally for signs of dysphagia and bring them to the attention of the health care team. Environmental distractions and conversations during mealtime increase the risk for aspiration and should be curtailed. Reports of coughing and unusually long mealtimes are associated with tongue, facial, and masticator muscle weakness. Changing the consistency of foods served may be beneficial while simultaneously keeping the diet palatable and nutritionally adequate. A soft, blended, or pureed consistency may reduce the need for oral manipulation and conserve energy while eating though this may compromise palatability.

In 2002 the Academy of Nutrition and Dietetics (AND) published the National Dysphagia Diet (NDD), which was developed through consensus of a panel of dietitians, SLPs, and scientists. The NDD is prescribed by an SLP that evaluates the individual's ability to safely swallow both food textures and liquids. Standard levels of dysphagia from severe to mild were designated with assigned diet texture modifications for each level to promote the safety of swallow (Fig. 39.6). The traditional levels of dysphagia severity range from mild to severe (see Box 39.2).

More recently, a collaborative group of dietitians, SLPs, food scientists, physicians, OTs, engineers, nurses, and food service professionals recognized a professional deficiency in the language and implementation of modified diet textures for the management of dysphagia. These individuals created a nonprofit international organization known as the IDDSI which tested and created norms for each dysphagia diet texture modification. The findings of this organization are supported by both the AND and the American

Speech-Language-Hearing Association. As such, international implementation standards are in process to support the medical necessity of implementation.

In November 2015 IDDSI created a new framework which utilizes current evidence to create diet texture specifications that are cross-cultural, through the lifespan, and applicable in all care settings (Steele et al, 2015). The framework consists of eight levels. Solids are defined across levels three through seven: liquidized, pureed, minced and moist, soft and bite-sized, and regular (Cichero et al, 2013) (see Table 39.5).

TABLE 39.5 International Dysphagia Diet Standardisation Initiative (IDDSI) Framework

Level	Name & Description	Testing Methods
0	Thin <ul style="list-style-type: none"> Flows like water Can drink through nipple, cup, or straw 	Flows through a 10 mL slip tip syringe completely within 10 seconds without any residue
1	Slightly Thick <ul style="list-style-type: none"> Thicker than water, requiring more effort Flows through a straw, syringe, or nipple Found in infant formula 	Flows through a 10 mL slip tip syringe leaving 1-4 mL in the syringe after 10 seconds
2	Mildly Thick <ul style="list-style-type: none"> Flows off a spoon Sippable, but requires effort to drink through a straw 	Flows through a 10 mL slip tip syringe leaving 4-8 mL in the syringe after 10 seconds
3	Liquidized/Moderately Thick <ul style="list-style-type: none"> Can be drunk from a cup Effort is required for using a straw Cannot be molded on a plate, nor eaten with a fork No chewing required No lumps, fibers, or particles present 	<ul style="list-style-type: none"> Flows through a 10 mL slip tip syringe leaving >8 mL in the syringe after 10 seconds Easily pours from a spoon when tilted; does not stick to spoon Fork prongs do not leave a clear pattern on the surface
4	Pureed/Extremely Thick <ul style="list-style-type: none"> Eaten with a spoon though a fork is possible Cannot be drunk from a cup Will maintain molding on a plate Falls off a spoon when tilted and holds shape No lumps Not sticky 	<ul style="list-style-type: none"> Fork tines make a clear pattern on the surface Will not flow through the fork tines though may form a small tail Will hold shape on a spoon
5	Minced & Moist <ul style="list-style-type: none"> Eaten with a fork or spoon Can be scooped or shaped No separate thin liquid Small lumps visible <ul style="list-style-type: none"> 2 mm for pediatrics 4 mm for adults Lumps mash with tongue pressure only 	<ul style="list-style-type: none"> When pressed with a fork, particles easily separated Scooped sample sits in a pile and does not flow through fork tines Holds shape on a spoon
6	Soft & Bite-Sized <ul style="list-style-type: none"> Can be mashed down with pressure from a fork A knife is not required to cut this food Chewing is required before swallowing No separate thin liquid Bite-sized pieces <ul style="list-style-type: none"> 8 mm for pediatric 15 mm for adults 	<ul style="list-style-type: none"> Pressure from a fork on side can cut pieces When pressed down, the bite will squash and change shape; it does not return to original shape
7	Regular <ul style="list-style-type: none"> Normal, everyday foods Sample size is not restricted Hard, tough, chewy, fibrous, stringy, dry, crispy, crunchy, or crumbly textures permitted Mixed consistency foods and liquids 	No testing
Transitional Foods	Foods that start as one texture but change into another when moisture is applied, or temperature changes occur <ul style="list-style-type: none"> Cheetos™ puffs Ice cream 	After moisture or temperature introduced, the bite becomes deformed with fork pressure and cannot recover its shape

Table created by Ashley Contreras-France, MA, MS, CCC, SLP, adapted from IDDSI, 2017.

It is important to be aware of both the NDD and IDDSI standards while health care facilities transition fully to IDDSI.

Liquids

Swallowing liquids of thin consistency such as juice or water is the most difficult swallowing task because of the timely coordination and

control required. Liquids are easily aspirated into the lungs and may pose a life-threatening event because **aspiration pneumonia** may ensue. Aspiration occurs when any material, including saliva, goes below the level of the vocal folds. The development of aspiration pneumonia is contingent on the condition of the individual's pulmonary system, the volume and pH of the aspirated bolus, and the potential pathogens

present. Of greatest concern is the bacteria present within the oral cavity as this creates the greatest risk for aspiration pneumonia (Coyle, 2018). Therefore oral care is often prescribed as a primary component of aspiration precautions and pneumonia prevention.

If a patient has difficulty consuming thin liquids, meeting fluid needs can become a challenge. Dry milk powder as a thickener alters the taste and might raise protein content too high for children, especially with limited free water. Commercial thickeners now have xanthan gum or modified food starches as ingredients. Benefits of xanthan gum include the following: it is tasteless, holds its thickening level over time, is easy to mix, and can be used on the ketogenic diet as it does not contain any carbohydrate or calories. Xanthan gum is not recommended for children less than 1 year of age because it has been implicated in the development of necrotizing enterocolitis (NEC) (Beal et al, 2012). Modified food starches add calories and continue to thicken over time, so it is more difficult to be accurate in the level of thickening.

The thickening of fluids should be prescribed with careful assessment of risk. Risks associated with thickening fluids include dehydration, drink aversion, and difficulty clearing aspirated fluids. Clinical studies suggest that patients with dysphagia have more difficulty clearing a thickened liquid from the respiratory system than a thinner liquid (Carlaw et al, 2012). Modifications in fluids were addressed in the NDD report, and the four terms used to identify the viscosity level of fluids are thin, nectar-thick, honey-thick, and spoon-thick (McCullough et al, 2003). These levels of thickness have since been redefined within the IDDSI framework under levels zero through four: thin, slightly thick, mildly thick, moderately thick, and extremely thick (Cichero et al, 2013) (see Table 39.5).

Infant cereals, pudding, or yogurt blend well into fluids, provide calories and protein, and are less expensive than commercial thickeners. Stage 2 baby fruits or applesauce can be added to juice to create a nectar or honey consistency, maintain a good flavor, and add calories, and they are less expensive than commercial supplements.

It is difficult to maintain adequate fluid intake with thickened liquids, especially if drinking skills are poor. Mild chronic dehydration resulting from limited water intake can cause fatigue and malaise. Encouraging soft or blended fruits and vegetables provides, a good source of free water. A systematic assessment, such as the Dehydration Risk Appraisal Checklist, may be beneficial to alert providers of the patient's elevated risk for dehydration, especially for those with modified diets (Bulgarelli, 2015). Determination of dehydration risk facilitates coordination with all professionals as to the considerations of downgrade in liquid textures for reduction of aspiration risk versus complex medical risks associated with dehydration resulting from thickened liquids. The decision, therefore, should be made as a team with documented risk levels.

The **Frazier Free Water Protocol**, which allows for drinking water in those who otherwise require thickened liquids, is being increasingly used in long-term care. This protocol is based on the following assumptions:

1. Aspiration of water poses little risk to the patient if oral bacteria associated with the development of aspiration pneumonia can be minimized.
2. Allowing free water decreases the risk of dehydration.
3. Allowing free water increases patient compliance with swallowing precautions and improves quality of life.
4. Good oral hygiene is a key ingredient of the water protocol and offers other benefits to swallow function.

A key component for implementation of the Frazier Free Water Protocol is based on the understanding that aspiration does not always lead to pneumonia. Therefore the prescribed oral care regimen serves to decrease overall risk as it serves to reduce oral bacteria, a likely cause for the development of pneumonia (Carlaw et al, 2012).

Liquid intake is a concern in those with neurogenic bladder and urinary retention, a common management issue in patients with a **myelopathy** (a pathologic condition of the spinal cord) or an SCI. This predisposes the individual to urinary tract infections (UTIs). Alternately, myelopathy and SCI may result in urinary urgency, frequency, or incontinence. To minimize these problems, distributing fluids evenly throughout the waking hours and limiting them before bedtime may help. Some patients limit fluid intake severely to decrease urgency or frequent urination. This practice increases the risk of UTI and is not recommended.

One nontraumatic cause of myelopathy and neurogenic bladder is MS, an unpredictable and severe progressive disease of the CNS. Individuals with MS have a higher incidence of UTIs.

Milk is considered a liquid with unique properties. Some people associate consumption of milk with symptoms of excess mucus production; however, research evidence does not support this belief. When the dysphagic patient reports increased phlegm after milk consumption, it may actually be a consequence of poor swallowing ability rather than mucus production.

Textures

As chronic neurologic disease progresses, cranial nerves become damaged, leading to neurologic deficits often manifested by dysphagia or elimination of entire food groups. Nutrition intervention should be individualized according to the type and extent of dysfunction. Vitamin and mineral supplementation may be necessary. If chewable supplements are not handled safely, liquid forms may be added to acceptable foods.

Presented with small, frequent meals, the patient may eat more. Swallowing can also be improved by carefully selecting various tastes, textures, and temperatures of foods. Juices can be substituted for water and provide flavor, nutrients, and calories. Thermal and gustatory stimulation may aid in triggering a swallow response; therefore cold food items may be better tolerated. Carbonation combined with citrus helps with the sensory issues by "awakening" the mouth. Sauces and gravies lubricate foods for ease in swallowing and can help prevent fragmentation of foods in the oral cavity. Moist pastas, casseroles, and egg dishes are generally well tolerated. Avoid foods that crumble easily in the mouth, because they can increase choking risk. Alcoholic beverages and alcohol-containing mouth washes should be avoided because they dry out the oral membranes.

Enteral Tube Nutrition

Patients with acute and chronic neurologic diseases may benefit from nutrition support. Enteral tube nutrition does not minimize the risk for aspiration pneumonia. In fact, in individuals post stroke, aspiration pneumonia was the most common complication. Aspiration precautions should be maintained in the patient with dysphagia even in the presence of enteral tube nutrition and no oral intake.

In most instances the gastrointestinal tract function remains intact, and enteral nutrition is the preferred method of administering nutrition support. One noted exception occurs after SCI, in which ileus, an obstruction in the ileum, is common for 7 to 10 days after the insult, and parenteral nutrition may be necessary. Although a nasogastric (NG) tube can be a short-term option, a percutaneous endoscopic gastrostomy (PEG) tube, commonly known as a G-tube, or gastrostomy-jejunostomy (PEG/J) tube, commonly known as a GJ-tube, is preferred for long-term management. These should be considered for patients whose swallowing is inadequate (see Chapter 12). A benefit of the PEG or PEG/J is in the reversibility should swallow function return.

Malnutrition itself can produce neuromuscular weakness that negatively affects quality of life; it is a prognostic factor for poor survival. In the acutely ill but previously well-nourished individual who is

unable to resume oral nourishment within 7 days, nutrition support is used to prevent decline in nutritional health and aid in recovery until oral intake can be resumed. Conversely, in the chronically ill, nutrition support is an issue that each patient must eventually address because it may result in prolonged therapy. However, adequate nutrition can promote health and may be a welcome relief to an overburdened patient.

NEUROLOGIC DISEASES OF NUTRITIONAL ORIGIN

Most neurologic symptoms arising from primary nutritional deficiency or excess can be corrected with increased or decreased food or supplement intake (see Table 39.1). For example, dietary deficiencies of vitamin B₁₂, folate, thiamin, and niacin—or excessive long-term intake (12 months or more) of vitamin B₆ supplements (but not food)—can directly result in neurologic symptoms that can be reversed through dietary changes and supplements when addressed early. Though, with **Wernicke-Korsakoff syndrome (WKS)**, the severe and acute thiamin deficiency and its neurologic effect occur secondary to alcoholism. In this case the primary cause of alcoholism should be addressed, as well as repletion of thiamin.

Emerging neurologic disorders that may have nutritional origins stem from gluten sensitivity. Numerous reports of patients with neurologic dysfunction related to gluten sensitivity have been reported since 1966 including ataxia, headache, and seizures (Hadjivassiliou et al, 2010), with up to 60% of patients with gluten ataxia showing evidence of cerebellar atrophy (Hadjivassiliou et al, 2015). Symptoms of gluten sensitivity typically are focused on gut function; however, most patients who present with neurologic manifestations of gluten sensitivity have no gastrointestinal symptoms. Celiac disease is common in people with autism with and without gastrointestinal symptoms.

NEUROLOGIC DISORDERS FROM TRAUMA

Cerebrovascular Accident (Stroke)

Stroke (cerebrovascular accident) occurs either when the brain's blood supply is suddenly interrupted (i.e., ischemic stroke, which accounts for 87% of all strokes [American Heart Association [AHA], 2017]), or when a blood vessel in the brain bursts (hemorrhagic stroke). Both of these situations cause brain cells to die within minutes, either due to loss of oxygen and nutrients or bleeding around the brain, respectively.

Severe strokes are often preceded by **transient ischemic attacks (TIAs)**, brief attacks of cerebral dysfunction of vascular origin with no persistent neurologic defect. Stroke is responsible for about one in every 20 deaths in the United States (Centers for Disease Control and Prevention [CDC], 2017a), and stroke is a leading cause of death and a common cause of serious, long-term disability in the United States (AHA, 2017). Advanced age is the most significant risk factor for stroke. Among modifiable risk factors, hypertension and smoking are the major contributors (see Chapter 32). Other factors include poor diet, obesity, coronary heart disease, diabetes, physical inactivity, excessive alcohol intake, and genetics. About 80% of strokes are preventable (CDC, 2018a). The high costs of stroke in the United States, estimated at \$34 billion a year, include the disability-related costs of health care services, medicines, and missed days at work (AHA, 2017).

Pathophysiology

Embolic stroke occurs when a cholesterol plaque is dislodged from a proximal vessel, travels to the brain, and blocks an artery, most commonly the middle cerebral artery (MCA). In patients with

dysfunctional cardiac atria, clots may be dislodged from there and embolize. In **thrombotic stroke** a cholesterol plaque within an artery ruptures, and platelets subsequently aggregate to clog an already narrowed artery. Most strokes are incited by a **thromboembolic event**, which may be aggravated by atherosclerosis, hypertension, diabetes, and gout (see *Pathophysiology and Care Management Algorithm: Neurological Diseases*).

Intracranial hemorrhage occurs in only 13% of strokes but is often fatal immediately. Intracranial hemorrhage occurs more commonly in individuals with hypertension. In **intraparenchymal hemorrhage**, a vessel inside the brain ruptures. A variation of intraparenchymal hemorrhage is a lacunar (deep pool) infarct. These smaller infarcts occur in the deep structures of the brain such as the internal capsule, basal ganglia, pons, thalamus, and cerebellum. Even a small lacunar infarct can produce significant disability because the brain tissue in the deep structures is so densely functional. A second type of intracranial hemorrhage is **subarachnoid hemorrhage (SAH)**. SAH occurs commonly as a result of head trauma but more often as a result of a ruptured aneurysm of a vessel in the subarachnoid space.

Medical Management

A thromboembolic stroke is more likely to occur when the patient is fully conscious, but the onset of motor or sensory changes occurs suddenly. Hemorrhage is suspected when the patient presents with headache, decreased level of consciousness, and vomiting, all of which occur within minutes to hours. As with all neurologic disease, the clinical presentation depends on the location of the abnormality. An infarct of a particular cerebrovascular territory can be suspected by seeking out various neurologic deficits. An MCA occlusion produces paresis, with sensory deficits of limbs on the opposite side of the body because this artery supplies the motor and sensory strips. If the left MCA is occluded, **aphasia**, or loss of language or expression, may be present. Individuals often receive rehabilitative services, such as physical therapy, occupational therapy, and speech-language pathology, in a skilled nursing facility for short-term daily intervention with transition to intermittent long-term periodic management.

In the past, treatment for embolic stroke was supportive; it focused on prevention of further brain infarction and rehabilitation. Use of thrombolytic, “clot-busting” drugs reverses brain ischemia by lysing the clots. Initiation of therapy needs to occur within 6 hours of the onset of symptoms. Use of aspirin may be of some value in preventing further cerebrovascular events, but its effectiveness varies from one patient to another.

Controlling ICP while maintaining sufficient perfusion of the brain is the treatment for intracranial hemorrhage. This may include surgical evacuation of large volumes of intracranial blood and severe functional consequences, and therefore intracranial hemorrhage has a longer period of convalescence than ischemic stroke.

Postevent, more than two out of three stroke survivors use rehabilitation services, including physical and occupational therapy, for which updated guidelines from the AHA and American Stroke Association were issued in 2016 (AHA, 2016). Survivors may be admitted to a long-term care facility if their activities of daily living are severely impaired.

Medical Nutrition Therapy

Lifestyle and behavior changes that include diet are key components to primary prevention of stroke (Meschia et al, 2014). The landmark PREDIMED randomized controlled trial (RCT) showed how a Mediterranean diet supplemented with tree nuts or extra virgin olive oil reduced cardiac events, including stroke (Estruch et al, 2018). See Appendix 23 on the Mediterranean diet.

Efforts should be directed toward maintaining the overall health of the patient. For example, foods that support cellular repair and improved inflammatory markers include nuts, low-fat dairy, whole grains, and antioxidant-rich fruits and vegetables. In particular, a diet high in omega-3 fatty acids has been shown in some studies to provide a protective benefit against stroke, and current dietary recommendations to eat seafood twice per week helps meet omega-3 intake goals. Keep in mind that omega-3 fatty acid supplements have not shown the

same benefit, and are contraindicated for anyone taking a blood thinner such as warfarin or aspirin (National Institutes of Health [NIH], National Center for Complimentary and Integrative Health [NCCIH], 2013). See Table 39.6 for additional information on nutrition and stroke (Iacoviello et al, 2018).

Eating difficulties and resulting behavioral problems are determined by the extent of the stroke and the area of the brain affected. Dysphagia, an independent predictor of mortality, commonly

TABLE 39.6 Nutrition Guidance to Reduce Stroke Risk

Guidance and Rationale	
Recommended	
Mediterranean-type diet	<ul style="list-style-type: none"> • Antiinflammatory, antioxidant, antiatherogenic, and antithrombotic • Diet pattern associated with lower morbidity and mortality from stroke
DASH diet	<ul style="list-style-type: none"> • Largely plant-based plus dairy products with low salt Intake • Associated with reduced risk of stroke
Plant-based diets	<ul style="list-style-type: none"> • Large amounts of vegetable dietary sources compared with animal sources • Pattern overlaps with other patterns that lower stroke risk
Fruits and vegetables	<ul style="list-style-type: none"> • 5-9 servings a day • Ensures adequate intake of dietary fibers, minerals (potassium, magnesium), vitamins (e.g., folic acid), and other nutrients • Reduction of blood pressure and improvement of microvascular function • Dose-dependent inverse association with reduced risk of total, ischemic, and hemorrhagic stroke
Nuts	<ul style="list-style-type: none"> • 20-30 g/day for heart health and reduced risk of stroke • Improves markers of oxidation, inflammation, and endothelial function
Whole-grain cereals	<ul style="list-style-type: none"> • Adequate intake for heart health recommended • Improvement of blood pressure, body weight, insulin resistance, lipid profile, and subclinical inflammation (limited evidence for a reduced risk of stroke at higher intakes)
Legumes	<ul style="list-style-type: none"> • Intake needed to support heart health recommended • No association between legumes intake and stroke risk
Olive oil	<ul style="list-style-type: none"> • Use extra virgin olive oil as main fat • Polyphenols, tocopherols, and monounsaturated fatty acids • Reduced risk of stroke with higher intakes of extra virgin olive oil
Chocolate	<ul style="list-style-type: none"> • Moderate intake of dark chocolate is associated with reduced risk of total stroke • Increased high-density lipoprotein (HDL), decreased low-density lipoprotein (LDL) oxidation, improved endothelial function, and reduced blood pressure
Fish	<ul style="list-style-type: none"> • Fatty and semifatty fish twice a week for heart health • PUFA, vitamins D and B, potassium, calcium, and magnesium contained in fish may have favorable vascular effects • Reduced risk of total and ischemic stroke with higher fish consumption; no consistent association with hemorrhagic stroke
Milk and dairy products	<ul style="list-style-type: none"> • Regular intake of low-fat milk and dairy products recommended • Possibly mediated by high content of calcium, magnesium, potassium, and bioactive peptides • Lower risk of ischemic and hemorrhagic stroke observed with regular moderate consumption of low-fat milk and dairy products
Coffee	<ul style="list-style-type: none"> • Moderate regular intake recommended and associated with lower risk of total and ischemic stroke • Contains polyphenols, chlorogenic acid, caffeine, niacin, and lignans
Tea	<ul style="list-style-type: none"> • Moderate intake recommended, especially green tea • Favorable health effects of antioxidants, catechins, L-theanine • Higher tea consumption is associated with reduced risk of total, ischemic, and hemorrhagic strokes
Alcohol	<ul style="list-style-type: none"> • Moderate intake of 1 drink/day for women; 2 drinks/day for men may reduce risk • Evidence of a J-shaped relationship between ethanol intake and stroke risk • Moderate consumption is associated with improved lipid profile, reduction in platelet aggregation, beneficial effects on inflammation, antiatherogenic and antithrombotic effects, and regulation of endothelial function and blood pressure • Alcohol abuse associated with increased risk of total, ischemic, and hemorrhagic stroke
Dietary calcium	<ul style="list-style-type: none"> • Adequate dietary intake recommended • Possible beneficial effects of low-fat dairy products on blood pressure and systemic inflammation, particularly in overweight individuals
Magnesium	<ul style="list-style-type: none"> • Adequate dietary intake recommended • Beneficial effects on blood pressure, insulin resistance, and blood lipids

TABLE 39.6 Nutrition Guidance for Stroke Risk—cont'd

Guidance and Rationale	
Potassium	<ul style="list-style-type: none"> • Meet DRI recommendations • Blood pressure—lowering effect • Evidence of an inverse association between potassium intake and risk of stroke, likely more favorable for ischemic rather than hemorrhagic stroke
Folates	<ul style="list-style-type: none"> • Adequate dietary intake recommended as it has been associated with lower risk of stroke, especially ischemic • Beneficial effect likely independent of homocysteine
Vitamin C	<ul style="list-style-type: none"> • Adequate dietary intake recommended • Prevention of endothelial dysfunction, antiinflammatory and antihypertensive role • Both higher dietary and blood levels of vitamin C have been associated with reduced risk of stroke
Vitamin D	<ul style="list-style-type: none"> • Correct for deficiency, indicated by a plasma concentration of 25-hydroxycholecalciferol below 50 nmol/L (20 ng/mL) • Favorable role on blood pressure, insulin sensitivity, renin-angiotensin system, endothelial function, proliferation of vascular smooth muscle cells, regulation of parathyroid hormone levels • Low blood levels of vitamin D are associated with increased stroke incidence
Dietary fiber	<ul style="list-style-type: none"> • Adequate dietary intake of at least 25 g/day through plant foods recommended to reduce blood pressure levels, improve insulin resistance, lipid profile fibrinolysis, inflammation, and endothelial function • Dietary fiber intake is associated with reduced risk of stroke: effect more pronounced for ischemic stroke and for women
Low-glycemic load carbohydrates	<ul style="list-style-type: none"> • A low-glycemic load diet is recommended • Vascular injury induced by a chronic increase in blood glucose and postprandial insulinemia, oxidative stress, and a subclinical systemic inflammation with production of oxidized lipoproteins and AGEs • A high dietary GL is associated with the risk of stroke while total CHO intake and GI are not
Dietary fats	<ul style="list-style-type: none"> • Intake of MUFA-rich and PUFA-rich foods recommended, especially to replace saturated fats and refined carbohydrates
Protein	<ul style="list-style-type: none"> • Adequate dietary intake recommended without specific sufficient evidence in support of any association between dietary protein intake and stroke
Eggs	<ul style="list-style-type: none"> • No recommendation available as no association with either ischemic or hemorrhagic stroke was documented
Avoid	
Western diet	<ul style="list-style-type: none"> • A typical Western diet that is high in meat, saturated fats, and refined carbohydrates and low in whole grains, fruits, vegetables, legumes, nuts, seeds, and fiber is associated with multiple chronic diseases including stroke
Meat and processed meat	<ul style="list-style-type: none"> • Limit meat to 1-2 times per week; limit processed meat as much as possible • Likely linked to the unfavorable effects of SFA content, high heme, lipid peroxidation, and high salt content of processed meat on blood pressure • High intake of meat and processed meat is associated with a higher risk of total and ischemic stroke
Calcium supplement	<ul style="list-style-type: none"> • Extreme caution when prescribing calcium supplements, unless needed to correct proven deficits. Calcium supplements may increase the risk of myocardial infarction and stroke especially in post menopausal women
Sodium	<ul style="list-style-type: none"> • Reduce to 2 g/day or below (5 g of salt) • Strong relationship between higher salt intake and risk of elevated blood pressure and stroke
Supplements of folates, B ₆ , B ₁₂ , Vitamin A, Vitamin E	<ul style="list-style-type: none"> • The use of antioxidant vitamin supplements for the prevention of stroke is not indicated • Association between dietary or plasma levels of vitamin B₆/vitamin B₁₂ with stroke risk is uncertain • Vitamin B₆/vitamin B₁₂/folate supplements are not beneficial for the prevention of stroke • No association between vitamin A intake and stroke risk • Both higher dietary and supplemented vitamin E intakes are associated with increased risk of hemorrhagic stroke
Dietary fats	<ul style="list-style-type: none"> • Foods rich in SFA should be limited and trans fatty acids (TFA) should be avoided • Reduction or substitution of SFAs with PUFAs or MUFAs is associated with reduced stroke risk.
PUFA supplements	<ul style="list-style-type: none"> • Evidence from intervention studies of primary and secondary prevention of stroke failed to find any association between omega-3 fatty acid supplementation and either ischemic or hemorrhagic stroke
Sweetened beverages	<ul style="list-style-type: none"> • Limit due to unfavorable effect on LDL-cholesterol, VLDL, blood glucose, and insulin associated with increased risk of total and ischemic stroke

AGEs, Advanced glycation end products; CHO, cholesterol; DASH, Dietary Approaches to Stop Hypertension; GI, gastrointestinal; GL, glycemic load; MUFA, monounsaturated fatty acid; PUFA, polyunsaturated fatty acids; SFA, saturated fatty acid; VLDL, very-low-density lipoprotein.

Iacoviello L, Bonaccio M, Cairella G, et al: Diet and primary prevention of stroke: Systematic review and dietary recommendations by the ad hoc Working Group of the Italian Society of Human Nutrition, *Nutr Metab Cardiovasc Dis* 28:309–334, 2018.

accompanies stroke and contributes to complications and poor outcomes from malnutrition, pulmonary infections, disability, increased length of hospital stay, and institutional care. In some instances, enteral nutrition via a tube feeding is required to maintain nutritional health until oral alimentation can be resumed. As motor functions improve, eating and other activities of daily living are part of the patient's rehabilitation process and necessary for resuming independence. Malnutrition predicts a poor outcome and should be prevented.

HEAD TRAUMA OR NEUROTRAUMA

Traumatic brain injury (TBI) refers to any of the following, alone or in combination: brain injury, skull fractures, extraparenchymal hemorrhage—epidural, subdural, subarachnoid—or hemorrhage into the brain tissue itself, including intraparenchymal or intraventricular hemorrhage. In the United States TBI is a major cause of death and disability, affiliated with 30% of all injury-related deaths, or 153 people each day (Taylor et al, 2017). For people ages 65 and older, the leading cause of TBI-related death was falls; for those 64 years of age and younger, preventable causes ranged from assault to car accidents to intentional self-harm.

Morbidity is high, and headache is one of the most common complaints. It is difficult to accurately predict neurologic recovery. Despite intensive intervention, long-term disability occurs in a large portion of severe head injury survivors.

Pathophysiology

Brain injury can be categorized as three types: concussion, contusion, and diffuse axonal injury. A **concussion** is a brief loss of consciousness, less than 6 hours, with no damage found on computed tomography (CT) or magnetic resonance imaging (MRI) scans. Microscopic studies have failed to find any evidence of structural damage in areas of known concussion, although evidence of change in cellular metabolism exists. A **contusion** is characterized by damaged capillaries and swelling, followed by resolution of the damage. Large contusions may dramatically increase ICP and may lead to ischemia or herniation. Contusions can be detected by CT or MRI scans. **Diffuse axonal injury** results from the shearing of axons by a rotational acceleration of the brain inside the skull. Damaged areas are often found in the corpus callosum (the bridge between the two hemispheres) and the upper, outer portion of the brainstem. The variation in cognitive changes present with TBI reflect the physical trauma to the brain. However, mild TBI will not show any physical trauma to neurologic structures but manifest complex cognitive presentations in behavior and processing (Hovda, 2017).

Skull fractures of the calvarium and the base are described in the same manner as other fractures. Displacement refers to a condition in which bones are displaced from their original positions. *Open* or *closed* describes whether a fracture is exposed to air. Open fractures dramatically increase the risk of infection (osteomyelitis), and open skull fractures carry an increased risk for meningitis because the dura mater is often violated.

Epidural and **subdural hematomas** are often corrected by surgical intervention. The volume of these lesions often displaces the brain tissue and may cause diffuse axonal injury and swelling. When the lesion becomes large enough, it may cause herniation of brain contents through various openings of the skull base. Consequent compression and ischemia of vital brain structures often rapidly lead to death.

Medical Management

The body's response to stress from TBI results in production of cytokines (interleukin-1, interleukin-6, interleukin-8, and tumor necrosis factor) and inflammation (see Chapter 7). These are elevated in the body after head injury and are associated with the hormonal changes

that negatively affect metabolism and organ function (see Chapter 37). Inflammatory cytokines tend to cause organ demise; tissue damage has been observed in the gut, liver, lung, and brain. Overall, the molecular basis of functional recovery is poorly understood.

Clinical findings of brain injury often include a transient decrease in level of consciousness. Headache and dizziness are relatively common and not worrisome unless they become more intense or are accompanied by vomiting. Focal neurologic deficits, progressively decreasing level of consciousness, and penetrating brain injury demand prompt neurosurgical evaluation.

Skull fractures underneath lacerations often can be felt as a “drop off” or discontinuity on the surface of the skull and are readily identifiable by CT scan. **Basilar skull fractures**, bone breaks at the skull base, are manifested by **otorrhea** (fluid leaking from the ear) or **rhinorrhea** (salty fluid dripping from the nose or down the pharynx). Other signs include raccoon eyes and Battle's sign—blood behind the mastoid process. Basilar skull fractures may precipitate injuries to cranial nerves, which are essential for chewing, swallowing, taste, and smell.

Hematomas are neurosurgical emergencies because they may rapidly progress to herniation of brain contents through the skull base and to subsequent death. These lesions may present similarly, with decreased level of consciousness, contralateral hemiparesis, and pupillary dilation. These lesions damage brain tissue by gross displacement and traction. Classically the **epidural hematoma** presents with progressively decreasing consciousness after an interval of several hours during which the patient had only a brief loss of consciousness. Subdural hematoma usually features progressively decreasing consciousness from the time of injury.

Sequelae most often include epilepsy and postconcussive syndrome, a constellation of headache, vertigo, fatigue, and memory difficulties. Treatment for these patients can be highly complex, but the two goals of any therapeutic intervention are to maintain cerebral perfusion and to regulate ICP. Perfusion and pressure control have implications for nutrition therapy.

Medical Nutrition Therapy

The intersection of nutrition and TBI is complex, and in some cases adequate evidence does not exist to answer questions about best nutritional support. However, the updated Brain Trauma Foundation guidelines (Carney et al, 2017) provide two key nutrition-related recommendations for improved clinical outcomes:

- Feed patients to replace basal caloric needs within 5 to 7 days postinjury to decrease mortality.
- Use transgastric jejunal feeding to reduce the incidence of ventilator-associated pneumonia.

Hypermetabolism contributes to increased energy expenditure. Correlations between the severity of brain injury as measured by the **Glasgow Coma Scale** (Fig. 39.7) and energy requirements have been shown. The Glasgow Coma Scale is based on a 15-point scale for estimating and categorizing the outcomes of brain injury based on overall social capability or dependence on others.

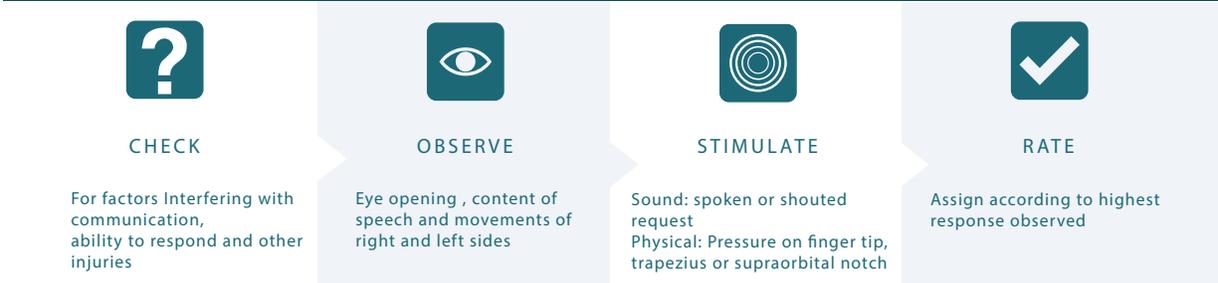

The previous edition of the guidelines (Brain Trauma Foundation, 2007) indicate that nitrogen needs are higher at 14 to 25 g/day for a fasting patient with severe head injury, compared with just 3 to 5 g/day in a normal fasting person. This is due to protein degradation caused by inflammation-associated hypercatabolism, and evidenced by profound urinary urea nitrogen excretion. If a patient continues to fast, they can lose up to 10% of lean mass in a week. For context, 30% weight loss increases mortality rate.

In patients medicated with barbiturates, metabolic expenditure may be decreased to 100% to 120% of basal metabolic rate. This

decreased metabolic rate in pharmacologically paralyzed patients suggests that maintaining muscle tone is an important part of metabolic expenditure. See Chapter 37 for guidelines on care of the critically ill patient with head trauma.

Choline and its derivative citicoline support cell membrane integrity, the impairment of which is a suggested part of the pathophysiology of TBI. Recent research found citicoline significantly improves the recovery of patients with TBI (Secades, 2016). Therefore supplementation with citicoline and increasing dietary intake of choline may be supportive. Common supplementation of citicoline in the literature is 500 to 1000 mg/day. Good dietary sources of choline ($\geq 10\%$ daily value [DV]) include eggs, beef, soybeans, chicken,

cod, shiitake mushrooms, and red potatoes (skin on). Foods with a smaller but still significant amount of choline ($\geq 5\%$ DV) include wheat germ, kidney beans, quinoa, low-fat milk, nonfat yogurt, cooked Brussels sprouts, cooked broccoli, nonfat cottage cheese, and white tuna fish.

Experimental dietary interventions of natural plant compounds exist in animal models of young mice and rats in blunt force trauma models. Of these, the most studied with common food sources and a promising trend of positive results include allicin, baicalein, crocin, curcumin, ellagic acid, epigallocatechin gallate, formononetin, gallic acid, ginseng, luteolin, quercetin, resveratrol, and rutin (Table 39.7; see Fig. 39.6).

TABLE 39.7 Role of Dietary Compounds in Traumatic Brain Injury (TBI)

# Studies	Compound	Impact	Food Sources
1	Allicin Compound that gives garlic its aroma	In mild TBI, 50 mg/kg 2-4 hrs posttrauma was the therapeutic window and most effective dose for improving oxidative stress, neuroinflammation, apoptosis, and TBI-related declines in neuroscores. Possible mechanism is by activating nitric oxide synthase (NOS).	Garlic, onions, shallots, green onions, chives, leeks
1	Crocin Bioactive compound in saffron	In moderate cortical impact TBI, a 20 mg/kg dose 30 minutes preinjury decreased the severity of motor skills damage, brain edema 24-hours post injury, and modest reduction in neuroinflammatory markers.	Saffron (<i>Crocus sativus L.</i>)
7	Curcumin polyphenol	In a lateral fluid percussion (LFP) injury model, a diet with 500 ppm curcumin was provided for either 4 weeks prior (moderate improvement in spatial learning and memory, as measured by Morris Water Maze [MWM], reduced oxidative stress, increased brain-derived neurotrophic factor [BDNF], and protected mitochondria and synaptic proteins); or 2 weeks postinjury (greater impact on improved oxidative stress, mitochondrial homeostasis, and MWM performance). In a secondary injury cascade (SIC) of cortical contusion model, both 50 or 100 mg/kg injection pretreatment led to improved locomotor behavior. Posttreatment was not measured. In moderate to severe injury, dosing immediately before (75 or 150 mg/kg) or 30-minutes postinjury (300 mg/kg) significantly reversed some of the SIC, neuroinflammation, and edema. However, the cortical lesion size was not affected, so there was no neuroprotection. In another severe cortical injury model, 100 mg/kg curcumin postinjury improved neuroscores at 24 hours postinjury with small but significant reductions in edema, inflammation, and indicators of damaged and dying neuronal cells.	Turmeric (<i>Curcuma longa L.</i>); strong antiinflammatory and antioxidant potential
1	Ellagic acid Polyphenol antioxidant	In a mild to moderate diffuse injury model, 100 mg/kg for 7 days before injury led to improved learning and memory, as measured by a passive avoidance task, reduced blood-brain barrier (BBB) permeability and inflammatory cytokines, and improved signs of long-term synaptic strengthening in the hippocampus. The mechanism is unknown, but ellagic acid is generally known to have antiinflammatory, antioxidant, and immunomodulatory characteristics.	Found in various fruits and nuts including black raspberry (38 mg/100 g), blackberry (44 mg/100 g), cloudberry (15 mg/100 g), pomegranate juice (17 mg/100 mL), raw chestnut (735 mg/100 g), walnut (29 mg/100 g), Japanese walnut (16 mg/100 g)
3	Epigallocatechin gallate (EGCG) polyphenol	In three studies of very mild TBI, a 4-week pretreatment with 0.1% solution of EGCG in the drinking water improved neuronal survival and cognitive performance in MWM postinjury, supported by significantly reduced lipid peroxidation, DNA damage, and a proapoptotic protein. Pretreatment had stronger benefits than limited postinjury treatment. The proposed mechanism is the antioxidant properties of EGCG.	Freshly brewed green tea (27 mg/100 mL), oolong tea (18 mg/100 mL), black tea (9 mg/100 mL). For an alternate source, pecans offer 2 mg/100 g. Bottled teas offer 2-9 mg/100 mL.

TABLE 39.7 Role of Dietary Compounds in Traumatic Brain Injury (TBI)—cont'd

# Studies	Compound	Impact	Food Sources
1	Formononetin Phytoestrogen isoflavone	In one mild to moderate closed-head TBI model, 10 or 20 mg/kg was injected 5 days postinjury and improved neuroscores and reduced brain edema, supported by increased antioxidant enzyme levels and reduced lipid peroxidation.	Roasted soybeans (6 mg/100 g)
1	Gallic acid Phenolic acid	In severe TBI, 100 mg/kg by mouth for 7 days prior and 2 days post injury significantly improved neuroscore and learning and memory behaviors as measured by passive avoidance tests.	Found in various fruits, vegetables, seeds, and nuts: Raw chestnuts (480 mg/100 g) and cloves (458 mg/100 g) are among the highest sources. Green chicory leaf (26 mg/100 g), red chicory leaf (15 mg/100 g), dried sage and oregano (5 mg/100 g), black tea (5 mg/100 mL), blackberry and cloudberry (4-5 mg/100 g), vinegar (3 mg/100 mL), and dried dates (2 mg/100 g) Root of <i>Panax ginseng</i>
4	Ginseng	In moderate TBI models, a component of ginseng, ginseng total saponins (GTS), was tested at varying doses twice a day for 14 days postinjury, and the best benefit was at 20 mg/100 g for improving neuroscores starting within 6 hours of injury, hippocampal CA3 region neuron protection and reduced cortical neuron death, supported by signs of reduced oxidation and inflammation. However there was no change in brain edema or lesion volume at 24 hours. Another ginseng-derived compound, ginsenoside Rb1 (GS-Rb1), reduced brain infarction and edema and improved neuroscores when given at 20-40 mg/kg immediately postinjury. For severe TBI, oral intake of total ginseng at 100 or 200 mg/kg eliminated oxidative stress and neuroinflammation when provided daily starting at 14 days postinjury. After 9 days, animals performed better in spatial learning and memory, as measured by MWM.	
4	Luteolin Flavone in a variety of vegetables such as broccoli and celery, and aromatic plants such as mint	In moderate to severe TBI, 10, 30, and 50 mg/kg given 30-minutes postinjury all decreased edema, and the 10 and 30 mg/kg dose improved grip strength and reduced oxidative stress and apoptosis. With 30 mg/kg there was a significant reduction in BBB opening, cell damage, and inflammation. With a 15-day pretreatment of 20 mg/kg reduced TBI-induced Alzheimer's disease.	Dried Mexican oregano (56 mg/100 g), fresh common thyme (40 mg/100 g), fresh common sage (33 mg/100 g), raw globe artichoke (42 mg/100 g), dried lemon verbena (5 mg/100 g). Black olives and dried rosemary (3 mg/100 g)
2	Quercetin Bioflavonoid found in many vegetables and fruits	In severe TBI, 30 mg/kg was given immediately posttrauma and for 3 following days, resulting in improved MWM scores at 4-weeks postinjury.	Black elderberry (42 mg/100 g), dried Mexican oregano (42 mg/100 g), capers (33 mg/100 g), cloves (28 mg/100 g), dark chocolate (25 mg/100 g), raw shallots (2 mg/100 g)
6	Resveratrol Polyphenol with high levels in grapes, nuts, and red wine	In moderate TBI, 100 mg/kg immediately postinjury significantly reduced oxidative stress and edema at 24-hours posttrauma, decreased lesion size at 14 days. In moderate to severe TBI, 100 mg/kg immediately after injury and for 2 following days resulted in improved balance and learned memory behavior as measured by beam balance and MWM at 5 days posttrauma. Another study using the same treatment found resveratrol significantly reduced edema, enhanced motor coordination, and MWM navigation. These findings were supported by reduced inflammation and neuron protection.	Raw lingonberry (3 mg/100 g), muscadine red wine (3 mg/100 mL), European cranberry (2 mg/100 g), raw redcurrant (2 mg/100 g)
2	Rutin A flavonol glycoside of quercetin found widely in plants	In severe TBI, 20, 40, or 80 mg/kg doses were given 14 days posttrauma for an additional 2 weeks, resulting in near-preinjury cognition levels and decreased inflammation, lipid peroxidation, and increases in markers for antioxidants.	Buckwheat, citrus fruit, but found widely in plants, apples, other fruits and vegetables

Chart created by Maggie Moon, MS, RDN, adapted from data in Scheff and Ansari, 2017.

The omega-3 fatty acids docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) have antioxidant, antiinflammatory, and antiapoptosis properties, leading to neuron protection in the damaged brain (Dyall, 2015). Studies have shown that short-term implementation of a ketogenic diet acutely postinjury improves structural and functional outcome in TBI in animals and shows potential in humans (McDougall et al, 2018) (see Appendix 19).

Immune-enhancing nutrition formulas are available for critically ill head-injured patients; the formulas are enhanced with glutamine, arginine, and omega-3 fatty acids. Data to support their use has not been consistent. One recent human clinical trial did show increased markers of antioxidants and decreased inflammatory markers (Rai et al, 2017); an earlier preliminary human study found increased prealbumin levels and some benefit of decreased infection in those patients using the immune-enhanced formula (Painter et al, 2015).

SPINE TRAUMA AND SPINAL CORD INJURY

Spine trauma encompasses many types of injuries, ranging from stable fractures of the spinal column to catastrophic transection of the spinal cord. A complete **spinal cord injury (SCI)** is defined as a lesion in which there is no preservation of motor or sensory function more than three segments below the level of the injury. With an incomplete injury there is some degree of residual motor or sensory function more than three segments below the lesion.

Pathophysiology

The spinal cord responds to insult similarly to the brain. Bleeding, contusion, and shorn axons appear first, followed by a multiyear remodeling process consisting of gliosis and fibrosis.

The location of the SCI and the disruption of the descending axons determine the extent of paralysis. **Tetraplegia** (formerly known as quadriplegia) exists when the injury to the spinal cord affects all four extremities. When the SCI location results in only lower extremity involvement, it is called **paraplegia**.

Medical Management

SCIs have numerous clinical manifestations, depending on the level of the injury. Complete transection results in complete loss of function below the level of the lesion, including the bladder and sphincters. After the patient is stabilized hemodynamically, the doctor evaluates the degree of neurologic deficit. Patients with suspected SCI are usually immobilized promptly in the field. Complete radiographic evaluation of the spinal column is obligatory in multitrauma and unconscious patients.

In the awake patient, clinical evidence of spine compromise is usually sufficient to determine the need for further workup. CT and MRI are used to more accurately delineate bony damage and spinal cord compromise. A dismal 3% of patients with complete spinal cord insults recover some function after 24 hours. Failure to regain function after 24 hours predicts a poor prognosis for reestablishment of function in the future. Incomplete spinal cord syndromes may have somewhat better outcomes.

Morbidity and mortality rates associated with SCI have improved dramatically, particularly in the last two decades. Advances in acute-phase care have reduced early mortality and prevented complications frequently associated with early death, such as respiratory failure and pulmonary emboli. Today, fewer than 10% of patients with SCI die of the acute injury.

Medical Nutrition Therapy

Technologic advances in enteral and parenteral feeding techniques and formulas have played a role in maintaining the nutrition status of these

patients (see Chapter 12). Although the metabolic response to neurotrauma has been studied extensively, the acute metabolic response to SCI has not, but it is similar to other forms of neurotrauma during the acute phase. Initially paralytic ileus may occur but often resolves within 72 hours postinjury.

In the acute phase, calorie estimates should be based on energy expenditure measured by indirect calorimetry. Metabolic activity is decreased due to muscle denervation. Actual energy needs are at least 10% lower than predicted levels. If indirect calorimetry is unavailable, consider the Harris-Benedict formula, using admission weight, injury factor of 1.2, and activity factor of 1.1. Acute protein needs are 2 g/kg of ideal body weight (Academy of Nutrition and Dietetics, 2009) (see Chapter 2).

Because DHA and EPA have antioxidant, antiinflammatory, and antiapoptosis properties, patients may benefit from fish oil supplementation (Dyall, 2015).

For those who survive the injury but are disabled for life, there are significant alterations in lifestyle, as well as the possibility of secondary complications. In general, the number and frequency of complications, such as the impaired ability to prepare food and self-feed, and the presence of constipation, pressure ulcers, changes in weight status, and pain vary but will involve nutrition management (Box 39.3). Evidence-based practice guidelines for SCI were released in 2010 by the Academy of Nutrition and Dietetics. While updated guidelines do not exist as of 2018, opportunities for future research to improve the guidelines have been proposed (DiTucci, 2014). Individuals with SCI have significantly higher fat mass and lower lean mass. Loss of muscle tone caused by skeletal muscle paralysis below the level of injury contributes to decreased metabolic activity, initial weight loss, and predisposition to osteoporosis. The higher the injury, the lower the metabolic rate, which results in lower energy requirements. Guidelines for accepted weights adjusted for paraplegia and tetraplegia are as follows:

Weight adjustment from ideal body mass index (BMI)

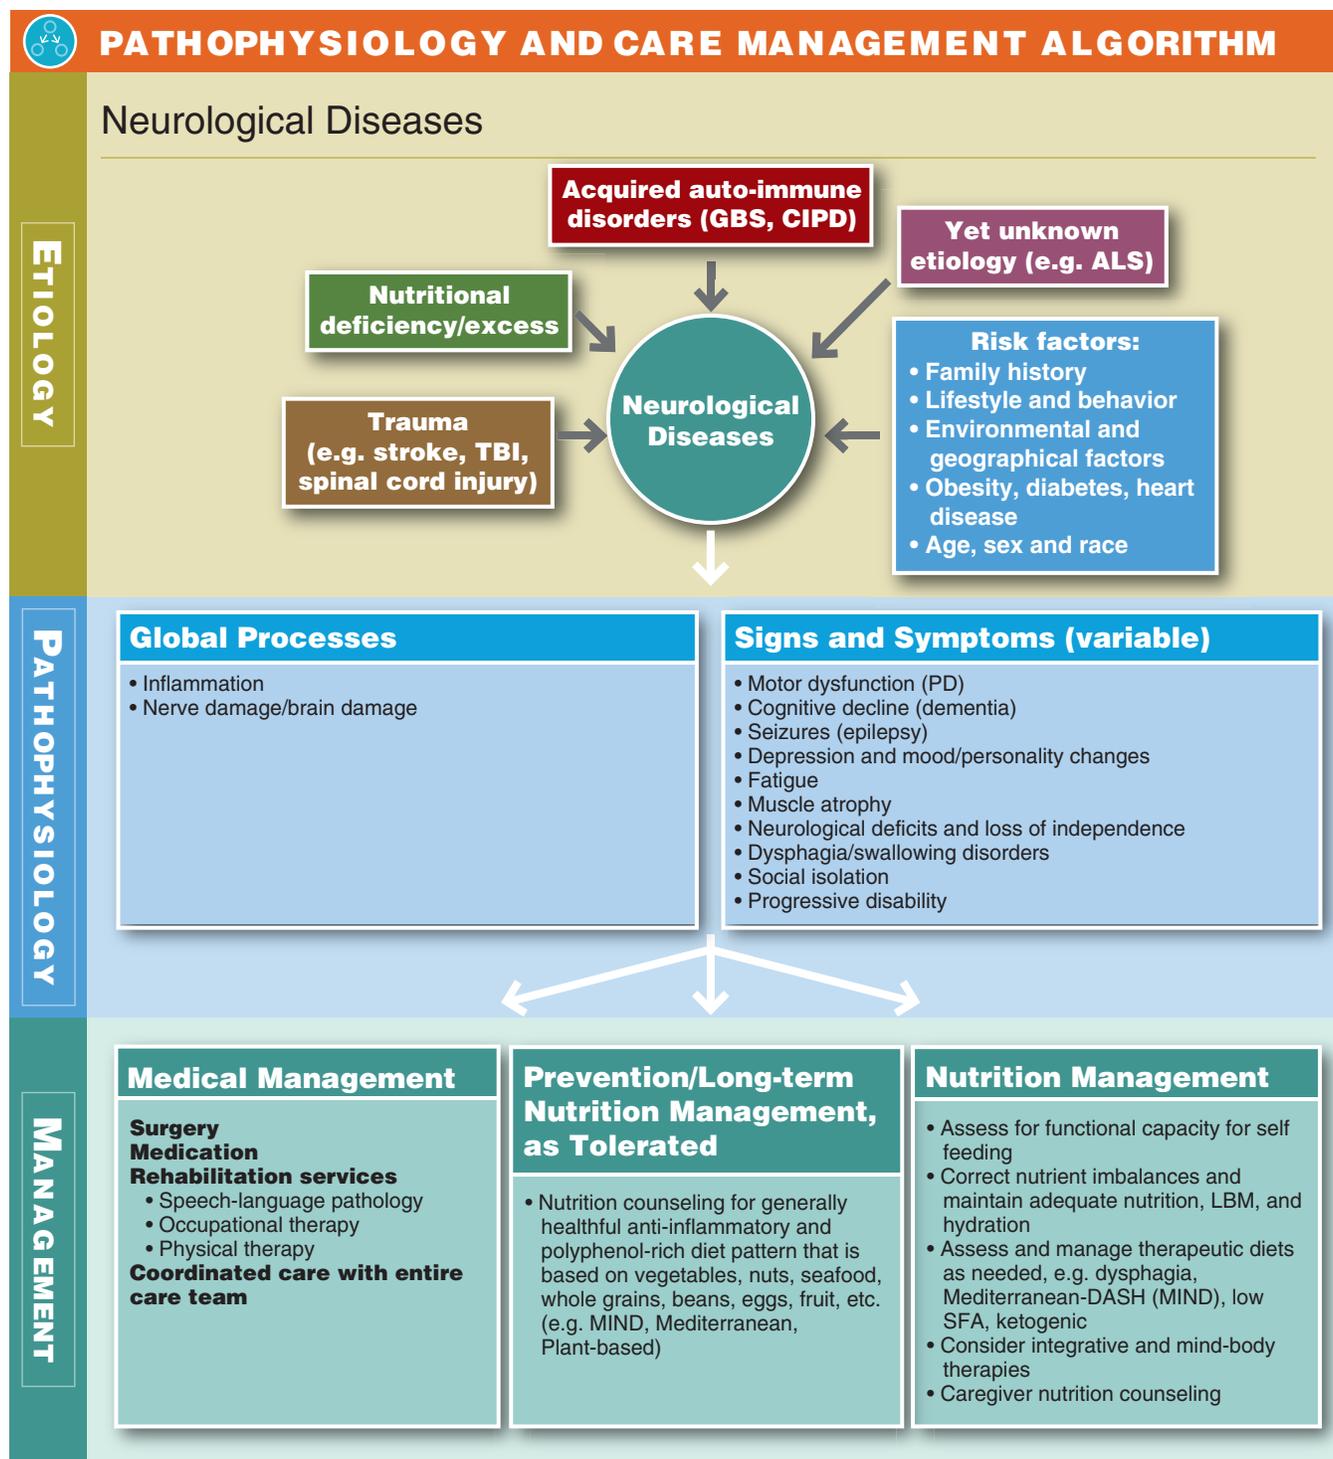

Paraplegic	Reduce by 10 to 15 lb
Tetraplegic	Reduce by 15 to 20 lb

Tetraplegic patients have lower metabolic rates than paraplegic patients, proportional to the amount of denervated muscle in their arms and legs, caused in part by the loss of residual motor function. In the rehabilitation phase, tetraplegics may require approximately 25% to 50% fewer calories than conventional equations predict. Thus these patients have the potential to become overweight. It has been proposed that obesity may slow the eventual rehabilitation process by limiting functional outcome. In the rehabilitation phase, estimated energy needs are approximately 22.7 kcalories per kg body weight (quadriplegia), and 27.9 kcalories per kg body weight (paraplegia). Protein needs range from 0.8 to 1 g/kg body weight as long as there are no pressure ulcers or infections (Academy of Nutrition and Dietetics, 2009).

SCI is associated with osteopenia and osteoporosis as a result of bone mineralization losses secondary to immobilization, and the prevalence of long-bone fractures increases. Adequate intake of vitamin D and calcium should be planned without excessive daily intakes.

NEUROLOGIC DISEASES

Neurologic diseases are relatively rare, and their exact causes are largely unknown. Many are being actively studied, and the science that informs our understanding will continue to rapidly evolve in the next

several decades. What we do know is that neurologic diseases can significantly impact nutritional status.

Adrenomyeloleukodystrophy

Pathophysiology

Adrenomyeloleukodystrophy (ALD) is a rare congenital enzyme deficiency that affects the metabolism of very-long-chain fatty acids (VLCFAs). This leads to accumulation of VLCFAs, particularly hexacosanoic acid (C26:0) and tetracosanoic acid (C24:0) in the brain and

adrenal glands. The incidence is 1 in 21,000 male births and 1 in 14,000 female births (Hung et al, 2013). While ALD more commonly presents in young males, it should be considered in women with chronic myelopathy or **peripheral neuropathy**, especially with early fecal incontinence (Engelen et al, 2014); there have also been cases of men presenting with ALD as late as their mid-30s (Chen et al, 2018).

ALD is an X-linked recessive disorder characterized by myelopathy, peripheral neuropathy, and cerebral demyelination. The adult variant, **adrenomyeloneuropathy**, has chronic distal axonopathy of spinal

BOX 39.3 Key Guidelines for Managing Spinal Cord Injury

If the patient with spinal cord injury (SCI) is in the acute phase, the registered dietitian nutritionist (RDN) should assess energy needs by indirect calorimetry (IC).

Initial weight loss during the acute phase of injury may lead to weight gain in the chronic phase because of body mass redistribution.

Patients with SCI have reduced metabolic activity because of denervated muscle. Actual energy needs are at least 10% below predicted needs.

Because of decreased energy expenditure and caloric needs, secondary to lower levels of spontaneous physical activity and a lower thermic effect of food, adults in the chronic phase of SCI are often overweight or obese and therefore at risk for diabetes and cardiovascular disease.

Persons of all ages with SCI appear to be at high risk for cardiovascular disease, atherogenesis, and undesirable blood lipid values. Modifiable risk factors such as obesity, inactivity, dietary factors, and smoking must be addressed. Physical activity, including sports, swimming, electrically stimulated exercise, and body-weight supported treadmill training, may result in improvements in blood lipid parameters. Dietary intervention using the current evidence-based guide for lipid disorders should be provided by an RDN.

Nutrition care provided by the RDN as part of a multidisciplinary team results in improved nutrition-related outcomes in the acute care, rehabilitation, and community settings. SCI patients experience improvements in nutrient deficiencies, nutrition problems associated with social isolation and mobility issues, overweight and obesity, bowel management, swallowing, and nutrition-related chronic diseases.

Cranberry juice may be beneficial for prevention of urinary tract infections. One cup (250 mL) daily can be recommended, unless the patient has diabetes.

A minimum of 1.5 L of fluid is recommended per day. Therapeutic diets of high fiber and adequate water intake alone often do not suffice for treatment of constipation; a routine bowel preparation program may be required. For chronic bowel dysfunction, 15 g of fiber seems more beneficial than higher levels (20 to 30 g).

Maintenance of nutritional health is important because poor nutrition is a risk factor for infection and pressure ulcer development. Regular assessment of nutritional status, the provision of adequate nutritional intake, and the implementation of aggressive nutritional support measures are indicated. Reduced pressure ulcer development occurs in patients who maintain a normal weight, higher activity levels, and better serum levels of total protein, albumin, prealbumin, zinc, vitamin D, and vitamin A. Thus sufficient intake of calories, protein, zinc, and vitamins C, A, and B-complex is warranted.

When pressure ulcers are present, use 30 to 40 kcal/kg of body weight/day and 1.2 g to 1.5 g of protein/kg body weight/day (see Chapter 20). Fluid requirements should be at least 1 mL fluid per kcal provided; increase if air-fluidized beds are used and when losses are increased for any reason.

Academy of Nutrition and Dietetics Evidence Analysis Library: Spinal Cord Injury (SCI) Guideline, 2009.

cord and peripheral nerves marked by cerebral inflammatory demyelination; head trauma is an environmental factor that is detrimental in those people genetically at risk. The mental and physical deterioration progresses to dementia, aphasia, apraxia, dysarthria, and blindness.

Medical Management

Clinical manifestations usually occur before age 7, with average age of onset between 5 and 12 years, and may manifest as adrenal insufficiency or cerebral decompensation.

Dysarthria (impairment of the neuromuscular system for the production of speech) and dysphagia may interfere with oral alimentation. Bronzing of the skin is a late clinical sign. With adrenal insufficiency, replacement of steroids is indicated, which may improve neurologic symptoms and prolong life. Numerous therapies have been directed at the root of the disorder but have been disappointing. The selective use of bone marrow transplant is one current therapy; gene therapy holds promise for the future.

Medical Nutrition Therapy

Nutritional therapy by dietary avoidance of VLCFAs does not lead to biochemical change because of endogenous synthesis. A specialty altered fatty acid product, Lorenzo's oil (C18:1 oleic acid and C22:1 erucic acid), lowers the VLCFA level, likely through inhibition of elongation activities (Morita et al, 2018). Although the clinical course is not significantly improved, a slower decline in function may result.

Dementia

More than 16 million people are providing unpaid care for dementia patients (CDC, 2018b). Dementia is one of the top 10 causes of death in the United States where it is the sixth leading cause of death among adults and the fifth leading cause of death among older adults aged 65 years and older, and risk increases with age. The mortality rates may be even higher as it has been demonstrated that dementia is underreported on death certificates. The annual hard costs of treating dementia in 2018 was approximately \$277 billion, with an additional \$232 billion equivalent spent in unpaid hours of care from family and friends (CDC, 2018c). **Alzheimer's disease (AD)** is the most common form of dementia. See Chapter 40 for more on AD.

Pathophysiology

The primary risk factor for dementia is aging. Additional risk factors include diabetes, high blood pressure, smoking cigarettes, and a family history of dementia.

Medical Treatment

Expert international groups collaborated with the Alzheimer's Association and National Institute on Aging to update criteria and guidelines for diagnosing dementia and mild cognitive impairment (MCI) (Albert et al, 2011; Jack et al, 2011; McKhann et al, 2011; Sperling et al, 2011). Key updates to the prior 1984 guidelines include:

- Three stages of dementia where it had previously only identified the final stage of dementia:
 1. Early preclinical asymptomatic stage: marked by amyloid buildup and other nerve cell changes
 2. MCI: includes memory or other thinking problems unusual for a person's age and education that do not interfere with independent living
 3. Dementia: memory loss, difficulty finding words, and visual/spatial problems that interfere with independent living
- Definition of AD expanded beyond memory loss to include other aspects of cognition such as word-finding ability and judgment, which may be impaired earlier
- Better differentiation between AD and other dementias and disorders that may increase risk for AD, such as vascular disease, that were not previously recognized or understood
- Identification of potential biomarkers of underlying brain disease that can be used for research purposes (not clinical); these simply did not exist in 1984 when confirmation of diagnosis was only possible by autopsy

Most medical management is targeted to improving the quality of life for those with the condition and their caregivers, including

maintaining mental function, managing behavioral issues, and delaying symptoms. Preliminary and observational evidence suggests that the risk of developing dementia can be reduced through lifestyle factors (see Chapter 40).

A review paper on the pros and cons of medical marijuana suggest that cannabis may diminish adverse effects of conditions such as ALS, MS, AD, and Parkinson's disease, but that chronic cannabis may lead to cognitive impairments (Suryadevara et al, 2017).

Medical Nutrition Treatment

Potential Risk Reduction

Preliminary research suggests an eating pattern called the Mediterranean-DASH intervention for neurodegenerative delay (MIND) diet may help slow cognitive decline and reduce the risk of developing AD (see Chapter 40). It is based on established heart-healthy eating patterns and enhanced with foods specifically for brain health. Two large prospective studies suggest that this diet may slow cognitive decline by 7.5 years and reduce the risk of AD by up to 53% (Morris et al, 2015a, 2015b).

A literature review on nutrition in cognitive function and brain aging in the elderly determined that the MIND diet substantially slowed cognitive decline over and above the Mediterranean and DASH diets individually, though all are healthy eating patterns (Gardener and Rainey-Smith, 2018). A phase 3 RCT began in 2017 to test the effects of a 3-year MIND diet intervention, with an estimated completion date in April 2021. One of the underlying mechanisms may be related to polyphenol content (Figueira et al, 2017) (Table 39.8).

Public Health Approaches to Promoting Health and Independence for an Aging Population

Clinicians can participate in public health efforts and improve patient outcomes by training caregivers through the REACH OUT program, which trains caregivers of people with dementia, including AD. Participants had improved health and less depression, and those in their care were less likely to be left unsupervised, wander, or have access to dangerous objects. Information on how to implement a community-based program for dementia caregivers with examples, tips, resources, websites, and references in a step-by-step guide is available (National Association of Chronic Disease Directors, 2009).

Clinical Approaches

In early stages, the goal of nutrition therapy is maintenance of membrane integrity and correction of existing nutritional deficiencies. A person with preclinical or early dementia may have olfactory and taste dysfunction that may reduce appetite. RDNs can guide caregivers to make meal times simple and social, and to encourage eating.

In the MCI phase, the goal of nutrition therapy is to manage nutrition in the context of behavioral changes, monitor for weight loss and signs of dysphagia, and consider the need for oral nutritional supplements to fill deficiencies. When dementia progresses to a severe stage, the goal is to provide appropriate therapy for dysphagia as needed, correct weight loss, monitor for signs of pulmonary aspiration risk, and consider finger foods and high calorie drinks when intake at meals decreases (Pivi et al, 2017).

TABLE 39.8 The Mediterranean-DASH Intervention for Neurodegenerative Delay (MIND) Diet

Food	Frequency	Food Sources
Olive oil	Daily, main fat	Extra virgin olive oil
Wine	Daily, 5 oz glass only	Red wine
Whole grains	3x/day	Amaranth, barley, brown rice, buckwheat, bulgur, corn, farro, oatmeal, sorghum, quinoa, wheat berry, whole wheat, wild rice
Vegetables	Daily	Asparagus, cauliflower, carrot, onions, bell peppers, celery, cucumber, sweet potato, garlic, mushrooms, green beans
Leafy green vegetables	Near daily, 6x/week	Arugula, broccoli, lettuces, spinach, cabbage, kale, Swiss chard, collard greens, mustard greens, watercress, bok choy
Nuts	5x/wk	Almonds, cashews, pecans, pistachios, walnuts
Beans	3-4x/wk, every other day	Black beans, black-eyed peas, cannellini beans, chickpeas, great northern beans, kidney beans, lima beans, pinto beans
Berries	2x/wk	Wild blueberries, highbush blueberries, strawberries, raspberries, pomegranate, blackberry, gooseberry, cranberry, cloudberry, lingonberry, boysenberry, huckleberry, bilberry, goji berry, currants, mulberry, acai
Poultry	2x/wk	Chicken, turkey
Seafood	1x/wk	Salmon, arctic char, sardines, rainbow trout, mussels, oysters, barramundi, crab, squid
Red meat	Less than 4x/week	Beef, bison, pork, lamb
Cheese	Less than once a week	Cheddar, mozzarella, parmigiano-reggiano, feta, brie, Camembert, provolone, Swiss cheese, Gouda, Gorgonzola, manchego, Emmental
Butter and stick margarine	Less than 1 tablespoon per day	Inclusive of fats with a large percentage of saturated fat or trans fats: butter, margarine, ghee, and coconut oil (would include trans fatty acids if they were not already banned)
Pastries and sweets	Less than 5 times a week	Éclair, croissant, pie, baklava, donut, bear claw, cannoli, cinnamon roll, samosa, empanada, cronut, danish, dutch baby pancake, macaron, mooncake, pain au chocolat, pan dulce, candy, chocolate, gummies, fudge, jelly beans, sour candy
Fried/fast foods	Less than one serving per week	French fries, fried chicken, mozzarella sticks, hushpuppy, fried shrimp, fried green tomatoes, fried clams, arancini, churro, jalapeno poppers, onion rings, bacon, fried calamari rings, chicken fingers

Severe dementia causes complications of immobility, swallowing disorders, and accompanying risk of malnutrition that raises the risk of acute problems that can lead to death (e.g., pneumonia). However, note that there is a lack of evidence for using a feeding tube for people with advanced dementia, and the practice is declining.

European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines for nutrition in dementia provide 26 recommendations (Volkert et al, 2015). Screening for malnutrition and closely monitoring body weight are recommended. For patients with inadequate intake who are in crisis caused by a potentially reversible condition, artificial nutrition may be appropriate for mild to moderate—but not severe or terminal stage—dementia. Supplements of single nutrients are not recommended unless there is a deficiency, and supplements in general would only be to improve nutrition status, not to treat or prevent cognitive decline. However, the clinician should use best judgment when compounds, such as curcumin, are generally safe and possibly effective (Table 39.9).

There is preliminary research regarding the antioxidant and anti-inflammatory properties of the polyphenol curcumin, found naturally in turmeric or in supplement form. High-dose animal and in vitro studies suggest a therapeutic role through improved glucose homeostasis, lipid metabolism, endothelial function, insulin immunosupport and inhibiting amyloid plaque aggregation. While it shows promise, adequate human studies have been less convincing to date, and more research is needed. However, in amounts normally found in food, this is a safe and possibly helpful compound to include in a therapeutic diet. Note that bioavailability tends to be low, but is improved 2000 times in the presence of piperine (naturally found in black pepper), which suppresses rapid processing in the liver and urinary extraction of curcumin (Kim and Clifton, 2018).

In addition to nutrition care, integrative patient-centered approaches to care are low-cost, low-risk, and helpful to people with dementia (Anderson et al, 2017), including:

- Support groups for social engagement and relieving social isolation
- Aerobic exercise, which has been shown to improve spatial memory, executive functioning and brain connectivity, as well as improve activities of daily living (ADL) and cognition, through reducing inflammation and supporting neurogenesis
- Cognitive training and stimulation for improved word associations (e.g., names of things) and money tasks (e.g., making change)
- Stress-reducing mind-body interventions such as meditation and mindfulness, which have been shown to improve logical memory, working memory, verbal fluency, attention, sleep, mood, cerebral blood flow, and agitation. Reflective exercise such as yoga and tai chi may help improve cognitive function through similar mechanisms as aerobic exercise. Guided imagery has been shown to improve cognitive function and mood. These activities promote relaxation through psychoneuroimmunological pathways that can be dysregulated in people with dementia.

Amyotrophic Lateral Sclerosis

Etiology

Amyotrophic lateral sclerosis (ALS), also known as Lou Gehrig's disease, is a progressive and fatal neurodegenerative disorder affecting the motor neurons in the CNS. ALS involves a progressive denervation, atrophy, and weakness of muscles; hence the name amyotrophy. ALS affects about 5 in 100,000 people in the United States (Mehta et al, 2018), with 1.9 new cases each year per 100,000 people. Global cases are projected to increase by 69% by 2040 primarily due to aging (Arthur et al, 2016). The hereditary form accounts for 5% to 10% of cases, but the remaining 90% to 95% of cases have no clear cause. Whites, males, non-Hispanics, people aged 60 years and older, and

TABLE 39.9 ESPEN Guidelines on Nutrition in Dementia: Interventions to Support Adequate Food Intake

Potential Cause of Malnutrition	Reasonable Intervention
Mastication problems	Oral care Dental treatment Texture modification
Swallowing problems	Swallowing evaluation Swallowing training Texture modification
Xerostomia	Check medication for adverse side effects, remove or change medication if possible Ensure adequate fluid intake Use mouth rinse and gel
Restricted mobility, immobility	Physiotherapy Group exercise Resistance training Help with shopping and cooking Meals on wheels
Psychiatric disorders (e.g., depressive mood, depression, anxiety)	Adequate medical treatment Eating with others/shared meals Pleasant meal ambience/eating environment Group activities, occupational therapy
Acute disease, (chronic) pain	Adequate medical treatment
Adverse effects of medications (e.g., xerostomia, nausea, apathy)	Coordinate care regarding medications, manage side effects (i.e., moist foods, easy to digest, and enjoyable foods)
Social problems (e.g., lacking support, family conflict)	Help with shopping, cooking, and eating Meals on wheels, shared meals Resolve conflicts
Difficulties in shopping, preparing meals, and/or eating regularly	Help with shopping Domestic help Meals on wheels Person who is present at mealtimes
Forgetting to eat	Supervision during meals Verbal prompting, encouragement
Decreasing ability to remember eating, to recognize food, and to eat independently	Feeding assistance Increased time spent by nurses during feeding Energy-dense meals
Behavioral problems, wandering	Emotional support Specific behavioral and communication strategies
Dysphagia	Texture modification in coordination with SLP

those with a family history are more likely to develop ALS. One study found obesity (BMI >30) was a significant predictor for younger-age onset of ALS (Hollinger et al, 2016).

The cause of ALS is not clear. Thus there is no cure, and survival is typically 3 to 5 years after disease onset. However, in a very unique

case, renowned physicist Stephen Hawking (1942–2018) lived with ALS for 55 years. Risk factors related to occupation, trauma, diet, or socioeconomic status are not consistent, although environmental toxins have been suspected to play a role (Su et al, 2016). One of the first clues that ALS may involve an environmental factor was obtained on the island of Guam, where an unusually high proportion of people over the past century have developed symptoms similar to ALS as they age. Studies are ongoing but thus far without proof of cause.

Pathophysiology

The pathologic basis of weakness in ALS is the selective death of motor neurons in the ventral gray matter of the spinal cord, brainstem, and in the motor cortex. Clinical manifestations are characterized by generalized skeletal muscular weakness, atrophy, and hyperreflexia (NIH, GARD, 2018). The typical presentation is:

- Signs of lower motor neuron deficits: weakness, wasting, fasciculation (muscle twitching)
- Signs of upper motor neuron deficits: hyperactive tendon reflexes, Hoffman signs, Babinski signs, or clonus (muscle contractions)

Muscle weakness begins in the legs and hands and progresses to the proximal arms and oropharynx. As these motor nerves deteriorate, almost all of the voluntary skeletal muscles are at risk for atrophy and complete loss of function. The loss of spinal motor neurons causes the denervation of voluntary skeletal muscles of the neck, trunk, and limbs, resulting in muscle wasting, flaccid weakness, involuntary twitching (fasciculations), and loss of mobility.

Progressive loss of function in cortical motor neurons can lead to spasticity of jaw muscles, resulting in strained speech and dysphagia. The onset of dysphagia is usually insidious. Swallowing difficulties usually follow speech difficulties. Discussions regarding eventual need for enteral nutrition often coincide with the introduction of augmentative and alternative communication systems as the speech and swallow function decline (Coyle, 2018). Although some weight loss is inevitable given the muscle atrophy, consistent or dramatic loss may be an indicator of chewing difficulties or dysphagia. Eye movement and eye blink are spared, as are the sphincter muscles of the bowel and bladder; thus incontinence is rare. Sensation remains intact and mental acuity is maintained.

Medical Management

No currently known therapy cures the disease. In 2017 the Food and Drug Administration (FDA) approved a second drug for ALS called

edaravone. Both riluzole and edaravone help slow the progression of ALS (Mehta et al, 2018). Edaravone's documented benefit is among early ALS patients with rapid disease progression, though it is approved in the United States for all ALS patients (Dorst et al, 2018). It was initially developed and approved in Japan, and is being considered for approval in Europe as of mid-2018. Treatment with a high dose of methylcobalamin (B₁₂) is being studied to preserve muscle integrity (NIH, 2014). The ketogenic diet has shown positive results in disease amelioration in mouse models (Yang and Fan, 2017). Although mechanical ventilation can extend the life of patients, most decline this option. Quality of life is poor in advanced ALS and supportive comfort measures are primarily used.

Medical Nutrition Therapy

There are decreases in body fat, lean body mass, muscle power, and nitrogen balance and an increase in resting energy expenditure as death approaches. Hypermetabolic status and increased resting energy expenditure measurements have been noted. Hypercaloric enteral diets were demonstrated to be safe and well tolerated in a small phase 2 RCT (Wills et al, 2014). A study of 148 ALS patients found survival time was associated with early intake of a higher fat and protein diet (Kim et al, 2018).

The relationship between dysphagia and respiratory status is important. As ALS progresses, a progressive loss of function in bulbar and respiratory muscles contributes to oral and pharyngeal dysphagia. This results in the need for nutrition support, generally via gastrostomy tube. In late stages, when respiratory muscles are impaired, feeding tube placement is associated with more risk. For that reason, early feeding tube placement is recommended.

The clinician should become familiar with common clinical findings in ALS to prevent secondary complications of malnutrition and dehydration. The functional status of each patient should be monitored closely so that timely intervention with the appropriate management techniques can be started. Oropharyngeal weakness affects survival in ALS by placing the patient at continuous risk of aspiration, pneumonia, and sepsis and by curtailing the adequate intake of energy and protein. These problems can compound the deteriorating effects of the disease. The Amyotrophic Lateral Sclerosis Severity Scale often is used to assess the functional level of swallowing, speech, and upper and lower extremities. Once the severity of deficits has been identified, appropriate interventions can be implemented (see *Focus On: Dysphagia Intervention for Amyotrophic Lateral Sclerosis [ALS]*).

FOCUS ON

Dysphagia Intervention for Amyotrophic Lateral Sclerosis (ALS)

Strand and colleagues (1996) outlined dysphagia intervention on a continuum of five stages that correlate to the amyotrophic lateral sclerosis (ALS) severity scale. They include the following:

Normal Eating Habits (ALS Severity Scale Rating 10-9)

Early assessment and intervention are critical for maintaining nutritional health in ALS. This is the appropriate time to begin educating the patient, before the development of speech or swallowing symptoms. Hydration and maintenance of nutritional health are critical at this stage. Fluid intake of at least 2 qt/day is important. Dehydration contributes to fatigue and thickens saliva. For patients with spinal ALS, emphasis on fluids is important because they may intentionally limit fluid intake because of difficulties with toileting. The diet history is helpful to assess patterns of normal chewing, swallowing, and the rate of ingestion. Weight loss history establishes a baseline weight. A weight loss of 10% or more is indicative of nutritional risk.

Early Eating Problems (Severity Scale Rating 8-7)

At this point patients begin to report difficulties eating; reports of coughing and unusually long mealtimes are associated with tongue, facial, and masticator muscle weakness. Dietary intervention begins to focus on modification of consistency, avoidance of thin liquids, and use of foods that are easier to chew and swallow.

Dietary Consistency Changes (Severity Scale Rating 6-5)

As symptoms progress, the oral transport of food becomes difficult as dry, crumbly foods tend to break apart and cause choking. Foods that require more chewing (e.g., raw vegetables or steak) are typically avoided. As dysphagia progresses, ingestion of thin liquids, especially water, may become more problematic. Often the patient has fatigue and malaise, which may be associated with a mild chronic dehydration resulting from a decreased fluid intake. Dietary intervention should change food consistency (see Appendix 20) to reduce the need for oral manipulation and to conserve energy. Small, frequent meals

Continued

FOCUS ON—cont'd

also may increase intake. Thick liquids that contain a high percentage of water, as well as attempts to increase fluid intake, must be emphasized to maintain fluid balance. Popsicles, gelatin, ice, and fresh fruit are additional sources of free water. Liquids can be thickened with a modified cornstarch thickener. Swallowing can be improved by emphasizing taste, texture, and temperature. Juices can be substituted for water to provide taste, nutrients, and calories. A cool temperature facilitates the swallowing mechanism; therefore cold food items may be better tolerated; heat does not provide the same advantage. Carbonation also may be better tolerated because of the beneficial effect of texture. Instructions for preventing aspiration should be addressed: Safe swallowing includes sitting upright with the head in a chin-down position. Concentrating on the swallowing process can also help reduce choking. Avoid environmental distractions and conversation during mealtime; however, families should be encouraged to maintain a normal mealtime routine. As dysphagia progresses, the limitation of food consistencies may result in the exclusion of entire food groups. Vitamin and mineral supplementation may be necessary. If chewable supplements are not handled safely, liquid forms may be added to acceptable foods. Fiber also may have to be added along with fluids for constipation problems.

Tube Feeding (Severity Scale Rating 4-3)

Dehydration will occur acutely before malnutrition, which is a more chronic state. This may be an early indication of the need for nutrition support. Weight

loss from muscle wasting and dysphagia eventually leads to placement of a percutaneous endoscopic gastrostomy (PEG) tube for nutrition and protection against aspiration caused by dysphagia. Enteral nutrition support is preferred because the gastrointestinal tract should be functioning properly. Given the progressive nature of ALS, placing feeding tubes when there are signs of dysphagia and dehydration is better than initiating this therapy later, after the patient has become overtly malnourished or when respiratory status is marginal. The decision of whether to place a feeding tube for nutrition support is part of the decision-making process each patient must face. Adequate nourishment can maintain health of the individual longer and may be a welcome relief for the patient. The purpose of nutrition support should be to enhance the quality of life. Long-term access should be considered via a PEG or percutaneous endoscope jejunostomy tube (see Chapter 12).

Nothing by Mouth (Severity Scale Rating 2-1)

The final level of dysphagia is reached when patients can neither eat orally nor manage their own oral secretions. Although saliva production is not increased, it tends to pool in the front of the mouth as a result of a declining swallow response. Once the swallowing mechanism is absent, mechanical ventilation is required to manage saliva flow. Tube feeding is permanent at this stage.

Epilepsy

Epilepsy is a chronic condition characterized by unprovoked, recurring seizures. **Seizures** are caused by abnormal electrical activity of a group of neurons. According to the latest available estimates from 2015 data, an estimated 1.2% of the total U.S. population has active epilepsy, which translates to 3.4 million people including 3 million adults and 470,000 children (CDC, 2017b).

Pathophysiology

Most seizures begin in early life, but a resurgence occurs after age 60. The first occurrence of a seizure should prompt investigation into a cause. A clinical workup usually reveals no anatomic abnormalities, and the cause of the seizure may remain unknown (idiopathic). Seizures before age 2 are usually caused by fever, developmental defects, birth injuries, or a metabolic disease (see Chapters 42 and 43). The medical history is the key component for suggesting further avenues of diagnostic investigation and potential treatments, especially in children. An electroencephalogram can help delineate seizure activity. It is most helpful in localizing partial complex seizures.

Medical Management

The dramatic **tonic-clonic (grand mal) seizure** is the most common image of a convulsive seizure, yet numerous classifications of seizures, each with a different and often less dramatic clinical presentation, exist. A generalized tonic-clonic seizure typically involves the entire brain cortex from its beginning phases. After such a seizure the patient wakes up slowly and will be groggy and disoriented for minutes to hours. This is termed the postictal phase and is characterized by deep sleep, headache, confusion, and muscle soreness.

The **absence seizure (petit mal)** is also generalized in nature. Patients with absence seizures may appear to be daydreaming during an episode, they recover consciousness within a few seconds and have no postictal fatigue or disorientation.

Partial seizures occur when there is a discrete focus of epileptogenic brain tissue. A simple partial seizure involves no loss of consciousness, whereas a complex partial seizure is characterized by a

change in consciousness. Failure of partial seizure control may prompt consideration of seizure surgery. A localized focus resected from non-essential brain renders a patient seizure free in 75% of cases.

Determining the seizure type is key to implementing effective therapy. Antiepileptic drugs control seizures in 70% of people; however, these drugs can have undesirable side effects. Use of just one antiseizure medication is recommended initially, resorting to combination therapies only when needed. If seizures are not well controlled after a trial of two antiseizure drugs, the likelihood of control from an additional medication or combination of medications is minimal.

Medications used in anticonvulsant therapy may alter the nutrition status of the patient (see Appendix 13). For example, phenobarbital has been associated with decreased cognitive function (memory and attention) in children, perhaps because it depletes folate; further, an animal study showed widespread apoptosis in the developing brain after phenobarbital exposure (Kim and Ko, 2016). It occasionally is considered for use after failure of other antiepileptic drugs. Phenobarbital, phenytoin, and valproates interfere with intestinal absorption of calcium by interfering with vitamin D metabolism in the kidneys. Long-term therapy with these drugs may lead to osteomalacia in adults or rickets in children, and vitamin D supplementation is recommended. Folic acid supplementation interferes with phenytoin metabolism; thus it contributes to difficulties in achieving therapeutic levels.

Phenytoin, valproates, and phenobarbital are bound primarily to albumin in the bloodstream. Decreased serum albumin levels limit the amount of drug that can be bound. This results in an increased free drug concentration and possible drug toxicity even with a standard dose.

Absorption of phenobarbital is delayed by the consumption of food; therefore administration of the drug must be staggered around mealtimes if it is used. Continuous enteral feeding slows the absorption of phenytoin, thus necessitating an increase in the dose to achieve a therapeutic level. Stopping the tube feeding 1 hour before and 1 hour after the phenytoin dose was common practice in the past but is no longer recommended. The phenytoin dose should be adjusted based on the tube feeding.

Marijuana is being explored for its anticonvulsant properties, especially for treatment-resistant epilepsy (O'Connell et al, 2017; Reddy, 2017), though a number of neurologic adverse effects have been reported, highlighting the need to weigh risks and benefits (Solimini et al, 2017).

Medical Nutrition Therapy

The classic **ketogenic diet**, which has been in existence since the 1920s, is a well-established nonpharmacologic treatment for epilepsy. A 2018 consensus statement advocates for implementing a ketogenic diet in hard-to-manage epilepsy even before medical intractability, defined as failure of two or more antiseizure medications (see Appendix 19 on the ketogenic diet).

While the exact mechanisms are not clearly understood, therapeutic benefits may be due to neuronal metabolism, neurotransmitter function, neuronal membrane potential, and neuron protection against reactive oxygen species (Zhang et al, 2018). Two mouse models suggest the way the gut microbiota is altered by ketogenic diet therapy correlates to seizure protection (Olson et al, 2018) (Box 39.4).

It is absolutely contraindicated when a patient has a metabolic disorder that limits fat metabolism or carnitine production, and may be relatively contraindicated when there are certain issues that need to be addressed before initiating a ketogenic diet.

Originally designed using ratios of 4:1 or 3:1 (grams of fat to non-fat) to achieve strong and consistent ketosis, less restrictive versions are now available that can also be effective. The modified ketogenic diet uses lower ratios (e.g., 1:1 and 2:1), and modified Atkins and the low glycemic index treatment (LGIT) are also available for those who may benefit from a less restricted approach (Roehl and Sewak, 2017).

Glucose Transporter Type I Deficiency Syndrome (Glut-1 DS) and pyruvate dehydrogenase deficiency (PDHD) are two genetically inherited disorders that typically include seizures and are treatable with ketogenic diet therapy. The diet also has been effective for other inherited disorders in which seizures are also typical: glycogen storage diseases, nonketotic hyperglycinemia, and respiratory chain defects. The common feature of each of these conditions is the failure of the brain to derive adequate fuel from glucose. Ketones provided by ketogenic diet therapy offer an alternative fuel source which improves symptoms, preserves neurons, and can prevent further decline.

Short-term side effects include fatigue, headaches, nausea, emesis, constipation, hypoglycemia, or acidosis, especially in the first few weeks on the diet (Kossoff et al, 2018; Roehl and Sewak, 2017). An oral

citrate or sodium bicarbonate can help buffer acidosis, or the dietary fat ratio can be decreased to improve tolerability and palatability. Ensuring adequate fiber and fluid can help manage gastrointestinal distress and improve compliance with the ketogenic diet.

Although the diet is restrictive and requires continued effort, ketogenic diets are effective in reducing seizure frequency by 50% or more in about half of patients who are otherwise resistant to drug therapy and considered to have **refractory epilepsy**.

Improvement in seizure control can take up to 3 months after diet has been implemented. Antiepileptic drugs are not stopped but may be reduced before initiation, if medication toxicity occurs, or after it has been established that the diet therapy is effective.

The majority of the diet is composed of fresh meats, eggs, cheese, fish, heavy whipping cream, butter, oils, nuts, and seeds. Vegetables and fruits are added in small amounts, within the current diet prescription. A carbohydrate-free multiple vitamin and mineral supplement is necessary to ensure that the diet is nutritionally complete. However, additional vitamins and minerals are often necessary, including calcium, vitamin D, and selenium. All prescription and over-the-counter medications (e.g., pain relievers, cold remedies, mouthwash, toothpaste, and lotions) must be scrutinized for sugar content to minimize carbohydrate. It is important that the diet be strictly followed; the smallest amount of extra carbohydrate can cause a breakthrough seizure. Weight and height should be monitored, because a rapid rate of weight gain can decrease ketosis and reduce effectiveness. The RDN should work closely with the patient throughout the course of therapy to ensure nutritional adequacy and optimal seizure control.

Attention to the patient's health status, growth, and development is required during the course of therapy. For the child whose epilepsy is controlled by diet, complying with the diet is much easier than dealing with devastating seizures and injuries.

As clinical and scientific research evolves, improvements in which diet to use, how long to use it, and specific guidelines for certain epilepsies will emerge. Some patients may benefit from a simple diet initially then graduate to the more restrictive ketogenic therapy based on their seizure outcome results. Others may start off with the most restrictive ketogenic therapy and transition to a less restrictive one for long-term maintenance (see Fig. 39.8 and Appendix 19).

Guillain-Barré Syndrome (GBS) and Chronic Inflammatory Demyelinating Polyneuropathy (CIDP)

GBS and **chronic inflammatory demyelinating polyneuropathy (CIDP)** are acute and chronic, respectively, acquired immune-mediated inflammatory disorders of the PNS. They are rare autoimmune disorders that damage the nerves, causing muscle weakness, and in severe cases, paralysis. The incidence of GBS is approximately 1 in 100,000, or about 3000 to 6000 people each year in the United States (CDC, 2017c). It is also called acute inflammatory demyelinating polyneuropathy and Landry's ascending paralysis. Similarly, there are 1 to 2 new cases of CIDP per 100,000 people in the United States each year (GBS-CIDP Foundation International, 2018). CIDP is sometimes called chronic relapsing polyneuropathy and is considered the chronic form of GBS.

Etiology

In 60% of GBS cases the disorder follows an infection, surgery, or an immunization. Some of the more common organisms are *Campylobacter jejuni* (responsible for up to 40% of cases in the United States) and *Mycoplasma* spp. It can also develop after flu, cytomegalovirus, Epstein-Barr virus, and Zika virus infection. In very rare cases, it can develop in the days and weeks following a vaccination. Despite an association with infections, GBS and CIDP are not contagious.

BOX 39.4 Gut Microbiota In Neurologic Conditions

The gut microbiota communicates with the central nervous system through the gut-brain axis. Gut microbiota dysbiosis is seen in neurologic diseases. Exactly how these are connected is not yet fully understood, but emerging science on the gut microbiome suggests a role in neurologic diseases. The gut and brain communicate via three basic mechanisms: direct neuronal communication, endocrine signaling mediators, and the immune system. Dietary habits can affect intestinal microbial composition, and microbiome dysbiosis may be one factor in the development of multiple sclerosis (MS) (Chu et al, 2018). People with Parkinson's disease and Alzheimer's disease also suffer from gut microbiota dysbiosis, though whether it is a cause or effect of the condition is not clearly understood (Parashar and Udayabanu, 2017; Westfall et al, 2017). Dietary factors can theoretically modulate chronic activation of inflammatory response in aging, a risk factor for many neurologic conditions (Erro et al, 2018). There is not enough evidence to support clinical recommendations at this time, but this is an active area of research. In the meantime, greater intake of fermented foods, polyphenols, and dietary fiber are generally safe ways to support a healthy microbiome.

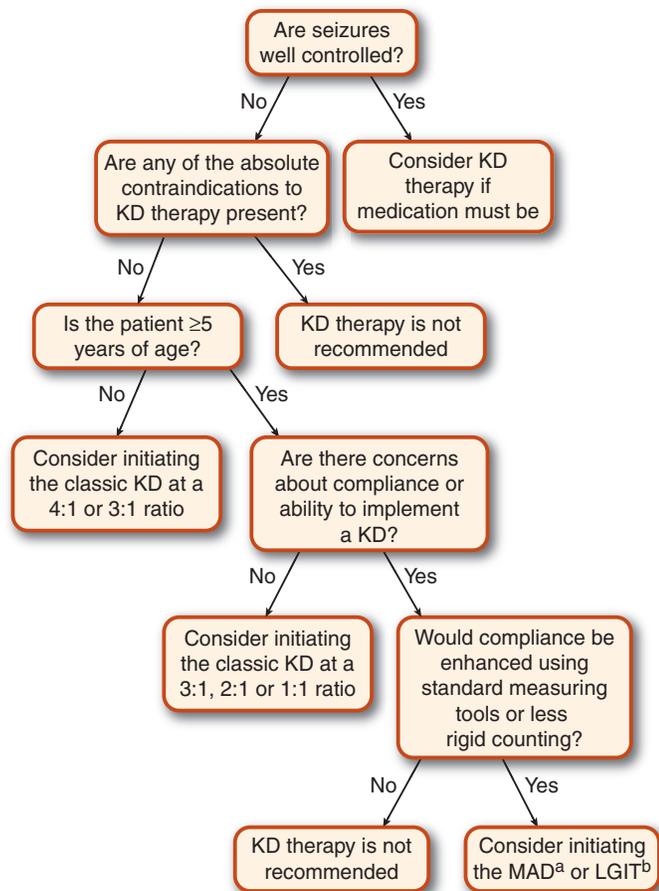

Fig. 39.8 Ketogenic diet (KD) therapy initiation decision tree. ^aMAD, Modified Atkins diet. ^bLGIT, low glycemic index treatment. (From *Journal of the Academy of Nutrition and Dietetics* 2017 117, 1279–1292. With permission from Elsevier).

Several pathologic varieties exist related to which segment of the immune system is inflicting nerve damage. The clinical course of GBS is similar regardless of subtype, although GBS after a *Campylobacter* infection tends to be more severe. Gluten sensitivity has been reported in some cases as a cause of GBS. The cause of CIDP is similar to GBS; however, the illness follows a longer course (Eldar and Chapman, 2014).

Pathophysiology

Relatively symmetric weakness with **paresthesia** (numbness and tingling) usually begins in the legs and progresses to the arms and face, potentially leading to paralysis. Chest muscles are affected in 20% to 30% of people with GBS, making it difficult to breathe (WHO, 2016b). In severe cases, the ability to speak and swallow is compromised, which is life-threatening and requires hospitalization. Most people fully recover within a few months of diagnosis and treatment, even from severe cases, though about 30% continue to experience some muscle weakness years after the first GBS symptom (NIH, Genetic and Rare Diseases [GARD] Information Center, 2017).

The loss of function in affected nerves occurs because of demyelination. **Myelin** is the specialized fatty insulation that envelops the conducting part of the nerve, the axon. In GBS, the immune system mounts an attack against the body's own myelin. Presumably myelin shares a common characteristic with the pathogen from the antecedent infection; thus the immune system cannot differentiate what is foreign (pathogen) from what is native (myelin). When the nerve is

demyelinated, its ability to conduct signals is severely impaired, resulting in neuropathy.

Medical Management

GBS reveals itself in a matter of days. The most common sequence of symptoms is **areflexia** (absence of reflexes), followed by proximal limb weakness, cranial nerve weakness, and respiratory insufficiency. These symptoms normally peak by 2 weeks but may progress up to 1 month. Medical diagnosis is ordinarily made on clinical grounds, but nerve conduction studies are also beneficial. Before the clinical course is apparent, myelopathic disorders must be considered.

Because of the precipitous progression, vital capacity and swallowing function may rapidly deteriorate such that intensive care is sometimes necessary. Intubation and respiratory support should be instituted early in respiratory decline to avoid the need for resuscitation. Any endotracheal tube intubation lasting longer than 7 to 10 days increases the risk for laryngeal injury; this factor increases the risk of dysphagia. A systematic review of documented incidence of dysphagia following endotracheal intubation found that the highest rates of dysphagia (62%, 56%, and 51%) were in patients intubated for more than 24 hours (Skoretz et al, 2010).

Plasmapheresis, the exchange of the patient's plasma for albumin, is often helpful to reduce the load of circulating antibodies. Intravenous immunoglobulin or steroids have been shown to help.

Medical Nutrition Therapy

GBS progresses quickly. During the acute stage, the metabolic response of GBS is similar to the stress response that occurs in neurotrauma. Energy needs assessed by indirect calorimetry may be as high as 40 to 45 kcal/kg and protein needs are twice the usual amount. Supportive nutritional care should be offered to attenuate muscle wasting.

For a small percentage of patients, oropharyngeal muscles may be affected, leading to dysphagia and dysarthria. In this situation, a visit by the RDN at mealtime can be a valuable way to observe difficulties the patient may have with chewing or swallowing. Specific difficulties warrant evaluation by a swallowing specialist. The SLP can evaluate the degree of dysphagia and make appropriate dietary recommendations pertaining to texture. As the patient recovers, it is important to discuss safe food handling and future prevention of *C. jejuni* infection.

Myasthenia Gravis

Myasthenia gravis (MG) is the most well-known auto-immune disorder of the neuromuscular junction. The **neuromuscular junction** is the site on the striated muscle membrane where a spinal motor neuron connects. Here the signal from the nerve is carried to the muscle via a submicron-size gap: a synapse. The molecule that carries the signal from the nerve ending to the muscle membrane is acetylcholine (Ach), and acetylcholine receptors (AchRs) populate the muscle membrane. These receptors translate the chemical signal of Ach into an electrical signal that is required for contraction of muscle fibers. MG is one of the most well-characterized autoimmune diseases, a class of disorders in which the body's immune system raises a response to AchRs.

The prevalence of MG is approximately 14 to 20 per 100,000 people in the United States, or about 36,000 to 60,000 cases (Myasthenia Gravis Foundation of America, 2015). It is underdiagnosed and true prevalence is likely higher. Males are more affected than females, with symptoms appearing most commonly after age 50.

Pathophysiology

In MG the body unwittingly makes antibodies to AchR. These antibodies are the same that fight off colds. The AchR antibodies bind to

AchR and make them unresponsive to Ach. There is no disorder of nerve conduction and no intrinsic disorder of muscle. The characteristic weakness in MG occurs because the signal of the nervous system to the muscle is garbled at the neuromuscular junction. Patients with MG commonly have an overactive thymus gland. This gland resides in the anterior thorax and plays a role in the maturation of B-lymphocytes, the cells that are charged with synthesizing antibodies.

Relapsing and remitting weakness and fatigue, varying from minutes to days, characterize MG. The most common presentation is diplopia (double vision) caused by extraocular muscle weakness, followed by dysarthria, facial muscle weakness, and dysphagia. Dysphagia or swallowing disorders (resulting from fatigue after mastication) may cause malnutrition. Less commonly, proximal limb weakness in the hips and shoulders may be present. Severe diaphragmatic weakness can result in respiratory difficulty. Sensory nerves are not involved.

Medical Management

Anticholinesterases are medicines that inhibit acetylcholinesterase, thus serving to increase the amount of Ach in the neuromuscular junction. Removal of the thymus results in symptomatic improvement in most patients. Corticosteroids are immunosuppressive. Additional immunosuppressant drugs can reverse symptoms while in use, though each comes with side effects: azathioprine, cyclosporine, cyclophosphamide, mycophenolate mofetil, methotrexate, and eculizumab—a first-in-its-kind therapy for patients unresponsive to at least two immunotherapies for at least a year; it was approved by the FDA in October 2017. Plasma exchange is a short-term strategy for rapidly declining patients, to quickly strengthen patients before surgery and as intermittent therapy for those who are unresponsive to all other treatments. Intravenous immune globulin improves 50% to 100% of patients within a week and lasting several weeks or months; the mechanism is unknown (*Myasthenia Gravis Foundation of America, 2015*).

Medical Nutrition Therapy

Chewing and swallowing often are compromised in MG. Because this compromise is due to fatigue, it is important to provide nutritionally dense foods at the beginning of meals before the patient fatigues. Small, frequent meals that are easy to chew and swallow are helpful. Difficulties holding a bolus on the tongue have been observed, suggesting that foods that do not fall apart easily may be better tolerated, for example IDDSI level 5, minced and moist. For patients treated with anticholinesterase drugs, it is crucial to time medication with feeding to facilitate optimal swallowing.

Physical activity should be limited before mealtime to ensure maximum strength to eat a meal. It is also important not to encourage food consumption once the patient begins to fatigue because this may contribute to aspiration. If and when respiratory crisis occurs, it is usually temporary. Nutrition support via tube feeding may be implemented in the interim to assist in maintaining vital functions of the patient until the crisis subsides. Once extubated, a swallow evaluation using a videofluoroscopic swallow study (VFSS) is appropriate to assess the degree of **deglutitory dysfunction** (swallowing irregularity) or risk of aspiration associated with an oral diet.

Multiple Sclerosis

Multiple sclerosis (MS) is a chronic inflammatory disorder of the CNS and is one of the most common causes of nontraumatic disability among young and middle-aged adults, more women than men and more common among people of Northern European ancestry (*National Multiple Sclerosis Society, 2018a*).

MS affects approximately 2.5 million worldwide. In the United States the National Multiple Sclerosis Society estimates that nearly 403

per 100,000 people are affected, representing nearly a million people, which is more than double previous estimates. This is according to preliminary results presented in October 2017 (*National Multiple Sclerosis Society, 2017*). MS symptoms can start anywhere between 10 and 80 years of age, but onset is usually between 20 and 40 years, with a mean of 32 years. Although MS is more frequently seen in European Americans than African Americans, the latter group appears to accumulate disability more quickly, suggesting more destructive tissue injury in this population. The prevalence of MS varies by geographic location and generally increases the further one travels from the equator in either hemisphere. It remains unclear whether this altered incidence represents an environmental influence, genetic difference, or variable surveillance (*Hersh and Fox, 2018*).

MS affects the CNS and is characterized by destruction of the myelin sheath, which protects nerve axons, which transmit electrical nerve impulses. Multiple areas of optic nerves, spinal cord, and brain undergo sclerosis, whereby myelin is replaced with sclera or scar tissue. No single test can ascertain whether a patient has MS; however, diagnostic criteria (revised McDonald criteria) were developed for use by practicing clinicians (*Thompson et al, 2018*).

The signs and symptoms of MS are easily distinguished, and they recur over the natural history of this disease. In the worst scenario, MS can render a person unable to write, speak, or walk. Fortunately, the majority of patients are only mildly affected.

Pathophysiology

The precise cause of MS remains undetermined. A familial predisposition to MS has been noted in a minority of cases. Geographic latitude and diet are implicated. Epidemiologic studies have linked the incidence of MS to geographic location and sunshine exposure. Studies have shown that people born in an area with a high risk of MS who then migrate to an area with a lower risk before the age of 15 assume the risk of their new area. Such data suggest that exposure to some environmental agent before puberty may predispose a person to develop MS.

There is growing evidence that higher sunlight exposure—and therefore vitamin D production—reduces the risk of MS, and poor levels of vitamin D have been linked to increased risk, suggesting a protective effect for vitamin D. The degree of sunlight exposure catalyzes the production of vitamin D in the skin. Vitamin D produced by the skin is eventually metabolized to vitamin D₃, which is a selective immune system regulator and may inhibit MS progression (*Zahoor and Haq, 2017*).

Given the current evidence of the potential benefits of vitamin D, it appears to be reasonable and safe to consider vitamin D supplementation adequate to achieve optimal levels in patients with MS, though the mechanism is not yet clearly understood (*Rosen et al, 2016*).

The evidence is also growing that smoking plays an important role in MS. Studies have shown that smoking increases a person's risk of developing MS and is associated with more severe and rapid disease progression. Fortunately, the evidence also suggests that stopping smoking—whether before or after the onset of MS—is associated with a slower progression of disability (*National Multiple Sclerosis Society, 2015*).

Obesity in childhood and adolescence, especially among females, has been shown to increase risk of developing MS later in life. There is some data of early adulthood obesity and increased risk as well, and obesity in the already diagnosed may exacerbate inflammation (*Novo and Batista, 2017*).

Various viruses and bacteria are being studied for their role in developing MS. For example, previous infection with Epstein-Barr virus (EBV) appears to increase the risk of developing MS. Human herpes virus 6 (HHV-6) is being studied related to triggering relapses. This is

an area of active research. The theories that have been disproven include living with a dog or other small pet, having allergies, exposure to heavy metals, experiencing physical trauma, and exposure to aspartame ([National Multiple Sclerosis Society, 2018b](#)).

Four disease courses have been identified by the National Multiple Sclerosis Society:

1. Clinically isolated syndrome (CIS): an isolated episode lasting at least 24 hours that looks like MS but does not yet meet full criteria of diagnosis. People may or may not go on to develop MS.
2. Relapsing-remitting MS (RRMS): the most common type of MS (about 85% of new cases), RRMS is characterized by intermittent neurologic symptoms during attacks (relapses) followed by periods of remission during which the disease does not appear to progress (remissions).
3. Secondary progressive MS (SPMS): most people with RRMS eventually develop SPMS, in which disability progresses over time.
4. Primary progressive MS (PPMS): accounts for about 15% of people with MS, in which neurologic function declines from the onset of symptoms.

Medical Management

Fluctuating symptoms and spontaneous remissions make MS treatments difficult to evaluate. Medical intervention attempts to reduce exacerbation of symptoms, also called flares, manage daily manifestations of disease process, and slow, possibly halt, disease course ([National Multiple Sclerosis Society, 2018](#)). Initially, recovery from relapses is nearly complete, but over time, neurologic deficits remain. Therefore measures to maximize recovery from initial attacks or exacerbations, prevent fatigue and infection, and use all available rehabilitative measures to postpone the bedridden stage of disease are imperative. Rehabilitative services are standard practice for the management of weakness, spasticity, tremor, incoordination, and other symptoms.

Drugs for spasticity can be initiated at a low dose and cautiously increased until the patient responds. Physical therapy for gait training and range-of-motion exercises may be implemented. Steroid therapy is used in treating exacerbations; adrenocorticotropic hormone (ACTH) and prednisolone are the drugs of choice. However, treatment is not consistently effective and tends to be more useful in cases of less than 5 years' duration. Side effects of short-term steroid treatment include increased appetite, weight gain, fluid retention, nervousness, and insomnia. Reduced cerebrospinal fluid and serum levels of vitamin B₁₂ and folate have been noted in MS patients who receive high-dose steroids. Methotrexate also may be used with ACTH, causing anorexia and nausea.

A 2014 guideline from the American Academy of Neurology provides a summary of evidence-based guidance on complementary and integrative medicine in MS including conclusions related to marijuana use for pain, spasticity, and reduced urinary frequency ([American Academy of Neurology, 2014](#)).

Medical Nutrition Therapy

The role of diet in MS requires continued prospective and clinical trials to fully illuminate. To date, there are preclinical models, epidemiologic studies, and a limited number of prospective studies that provide early direction on which specific dietary components and dietary patterns may have an impact.

In two epidemiologic studies of about 9000 total patients with MS, healthier eating habits were associated with lower levels of disability, and better mental health–related quality of life ([Sand, 2018](#)). While there are mixed data on high-fat (ketogenic) versus low-fat (Swank or McDougall) diets, longer terms studies seem to favor a diet lower in saturated fat.

- A pilot short-term trial of 60 RRMS patients suggests ketogenic and fasting-mimicking diet (FMD) of 3 days a week on a very-low-calorie diet had higher health-related quality of life at 3 months compared with controls.
- In the 1950s Dr. Swank started to follow a small group of 144 MS patients for more than 3 decades, and those who complied with a low-saturated-fat diet (<20 g/day) experienced significantly less disability and had lower mortality rates than those who did not. However, this study lacked randomization or controls for potential confounders, so it is more directional.
- A small study found the very-low-fat vegan McDougall diet (10% calories from fat) had neutral results (no differences in clinical relapses), but was only powered to find a much bigger shift and so there is now a larger trial underway to test its impact on fatigue.
- A prospective 2-year study in more than 200 pediatric MS patients found that saturated fat tripled the risk of relapse for every 10% increase in energy intake from saturated fat.
- A very small study of 10 subjects found that a Paleolithic diet in combination with dietary supplements, exercise program, electrical stimulation, and meditation significantly improved fatigue in PPMS patients.

Observational data suggest that the specific dietary components that may reduce the risk of MS include fish, marine sources of omega-3 fatty acids, vitamin D, fruits and vegetables, and whole grains. Preclinical studies suggest a high-salt diet may worsen disease progression, but human studies have found both positive and neutral associations, making sodium and MS a topic to watch in the scientific literature ([Sand, 2018](#)).

Though very little work has been done to date on the Mediterranean diet and MS, the preliminary evidence on foods and nutrients that may positively impact MS suggests it is worth studying. A pilot clinical trial of a modified Mediterranean diet in MS is in progress.

The National Multiple Sclerosis Society published a guide to vitamins, minerals, and herbs in 2015 that can be useful when working with an MS patient ([National Multiple Sclerosis Society, 2015](#)) ([Table 39.10](#)).

The RDN's evaluation of the patient to maximize nutritional intake is imperative. Vitamin D status should be assessed by measuring 25-hydroxy vitamin D. Evidence suggests high serum vitamin D may decrease the risk of MS and risk of relapse and new lesions, and supplementation may be warranted ([Bagur et al, 2017](#)). There is now some evidence that an antiinflammatory diet (see Chapter 7 and Appendix 22) can be of use in treating MS. This is an active area of research.

As the disease progresses, neurologic deficits and dysphagia may occur as the result of damaged cranial nerves. Thus, diet consistency may have to be modified along the IDDSI continuum of regular (level 7) to pureed (level 4) foods, even progressing to thickened liquids (levels 2 or 3) to prevent aspiration ([IDDSI, 2017](#)). Impaired vision, dysarthria, and poor ambulation make meal preparation difficult. In this situation, reliance on meal delivery services, prepackaged, single-serving, or convenience foods often permits independent preparation of meals. Given the chronic nature of this debilitating disease, patients may require enteral nutrition support.

Neurogenic bladder is common, causing urinary incontinence, urgency, and frequency. To minimize these problems, distributing fluids evenly throughout the waking hours and limiting them before bed is helpful. Some patients severely limit fluid intake to decrease urination frequency, which unintentionally increases the risk of UTIs. UTIs and recurrent falls are common in patients with MS and are associated with MS relapse ([Zelaya et al, 2017](#)).

Neurogenic bowel can cause either constipation or diarrhea, and incidence of fecal impaction is increased in MS. A diet that is high in

TABLE 39.10 Supplemental Vitamins, Minerals, and Herbs Used in MS

Vit/Min/Herb	Relation to MS	Risks	Food Sources	Role of RDN
Vitamin D Evidence suggestive not conclusive	Higher blood levels associated with lower risk of developing MS For those with MS, low levels associated with increased risk of MS relapses and developing new MRI lesions and increased levels of disability	High doses may increase risk of kidney stones in some people	Fish, fortified dairy and plant-based alternatives, breakfast cereals. Also produced in the skin in response to sunlight.	Guide patients to choose food first and sensible sun exposure; for supplements, D3 supplement form preferred over D2; and stay under UL
AOX vitamins A, C, E	Preliminary evidence suggests damage caused by free radicals may be involved in the disease process	Safety of supplement AOX in MS not clearly established; theoretical risk of stimulating the immune system and MS has an overactive immune system part of the disease process, not good to stimulate. Given the theoretical benefits and risks, food sources are safest and supplements can be tested in moderation under care.	A wide variety of fruits and vegetables. A: eggs, fish, carrots, sweet potato, spinach, mangos, broccoli, salmon, pistachios. C: citrus, tomatoes, broccoli, kiwi, bell peppers, strawberries, cauliflower, peas, brussels sprouts, cantaloupe, spinach. E: almonds, hazelnuts, peanut butter, spinach, broccoli, sunflower seeds, safflower oil, sunflower oil, peanuts, corn oil, soybean oil.	Encourage food sources over supplements
B ₆	No clear link, but patients reportedly take for help with energy	High doses can cause numbness, tingling or pain at doses as low as 50–100 mg/d	B ₆ : chickpeas, yellowfin tuna, salmon, chicken breast, fortified cereals, turkey, banana, bulgur, cottage cheese, winter squash, rice, nuts, onions, spinach, tofu, watermelon.	DRI level from food and dietary supplements. Do not exceed the UL
B ₁₂	People with MS have low B ₁₂ more than general population; no evidence that normal B ₁₂ levels in MS patient and then supplementation does anything to improve MS	N/A	Eggs, meat, poultry, shellfish, dairy products	Supplement if necessary, especially if serum B ₁₂ is low or methylmalonic acid (MMA) level is elevated.
Selenium	Observational data that selenium levels are lower in people with MS than general population; but in animal study selenium supplementation worsened an MS-like disease	Theoretically may increase the immune response	Seafood, beans, whole grains, low-fat meats, dairy	Get selenium from foods; if using supplements, avoid exceeding the UL
Calcium	Old hypothesis with very little evidence supporting it that MS was linked to high intake of milk in childhood with sudden drop off in teen years Could help generally with bone health and this population tends to be at risk for osteoporosis		Dairy, eggs, green leafy vegetables, bone-in anchovies, calcium-made tofu	Encourage food sources at the DRI level or supplementation if dietary adequacy is not achieved.
Zinc	Data is equivocal; may activate immune system; may worsen an animal model of MS	High dose can cause copper deficiency leading to copper-deficiency myelopathy, which causes symptoms that mimic MS	Zinc Oysters, beef, crab, fortified cereal, beans, chicken, yogurt, cashews, chickpeas, oatmeal, milk, almonds, kidney beans, peas, flounder	Food and supplemental forms not exceeding the RDA

Continued

TABLE 39.10 Supplemental Vitamins, Minerals, and Herbs Used in MS—cont'd

Vit/Min/Herb	Relation to MS	Risks	Food Sources	Role of RDN
Ginkgo Biloba	One small study shows it may help improve MS fatigue; inhibits platelet activating factor to decrease activity of certain immune cells, theoretically could help MS; two human studies: one suggested benefit, the larger showed no benefit to prevent relapses or cognitive dysfunction	May inhibit blood clotting so avoid on bleeding disorder or blood-thinning, or surgery; may interact with medications	Ginkgo	Discuss with health care team
St. John's Wort	No published data on effects on immune system that could concern MS patients. Typically used for depression.	Interactions with medications for MS	St. John's wort	Check for drug nutrient interactions and consult care team about interventions for depression
Valerian	Not studied in MS population; used to help with sleep as MS patients may have difficulty sleeping and fatigue; valerian could decrease time to sleep	May increase effects of sedating drugs prescription	Valerian root	Check for drug nutrient interactions
Asian ginseng Panax ginseng	One small MS study reports improvement in fatigue; inconsistent results in general population studies	May stimulate immune system		Too little evidence to gauge effectiveness
Cranberry	May help prevent UTI, a common issue in MS	May interact with warfarin/Coumadin	Cranberry juice, sauce, fresh	Monitor blood glucose with diabetes, check for drug nutrient interactions
Marijuana, most specifically cannabidiol (CBD)	Acts on CNS in ways that may reduce MS symptoms and slow disease activity		Recommendation from AAN summary of evidence: https://www.nationalmssociety.org/Treating-MS/Complementary-Alternative-Medicines/Marijuana	Work in accordance with legal regulations, but consider for medicinal use

AAN, American Academy of Neurology; CNS, central nervous system; MRI, magnetic resonance imaging; MS, multiple sclerosis; RDA, recommended dietary allowance; UL, tolerable upper intake level; UTI, urinary tract infection.

fiber with additional prunes and adequate fluid can moderate both problems.

Parkinson's Disease

Parkinson's disease (PD) is a progressive, disabling, neurodegenerative disease, first described by James Parkinson in 1817. PD is characterized by motor system dysfunction, seen as trembling in the hands, arms, legs, jaw, and face; rigid or stiff limbs and trunk; bradykinesia or slow movement; and impaired balance and coordination. These signs are due to the loss of dopamine-producing brain cells (NIH, National Institute of Neurological Disorders and Stroke [NINDS], 2018).

Although the natural history of this disease can be remarkably benign in some cases, approximately 66% of patients are disabled within 5 years and 80% are disabled after 10 years (Yao et al, 2013). MCI or dementia may affect up to 80% of people with PD (Goldman et al, 2018).

PD is one of the most common neurologic diseases in North America, costing an estimated \$25 billion a year in the United States (Parkinson's Foundation, 2018). About 1 million people in the United States live with PD, and about 60,000 will be diagnosed each year. Prevalence by state is available at Parkinson's Foundation. The

incidence is similar across socioeconomic groups, although PD is less common in African Americans and Asians compared with European Americans. It most commonly occurs between the ages of 40 and 70, and affects men 1.5 times more than women. Risk increases slightly if there is family history of PD or ongoing exposure to herbicides and pesticides.

Pathophysiology

PD is caused by the progressive impairment or deterioration of dopaminergic neurons in an area of the brain known as the substantia nigra, which sits within the midbrain, beneath the cerebral cortex, functionally part of the basal ganglia. When functioning normally, these neurons produce the vital neurotransmitter dopamine. The cause of PD is unknown, but several factors appear to play a role. The presence of **Lewy bodies**, which are clumps of specific substances within brain cells, are microscopic markers of PD. Researchers believe these Lewy bodies hold an important clue to the cause of PD. Lewy bodies are proteins found in abundance in the brainstem area that deplete the neurotransmitter dopamine.

The role of endogenous toxins from cellular oxidative reactions has emerged because aging has been associated with a loss of

dopamine-containing neurons and an increase in monoamine oxidase, an enzyme that removes dopamine from the brain (Gaweska and Fitzpatrick, 2011). When metabolized (enzymatic oxidation and autooxidation), dopamine produces endogenous toxins (hydrogen peroxide and free radicals), causing peroxidation of membrane lipids and cell death. In the presence of an inherited or acquired predisposition, severe oxidative injury can lead to substantial loss of dopaminergic neurons similar to that observed in PD.

Several other environmental factors also have been implicated as causal factors of PD. The connection between smoking and a lowered risk for PD has been evaluated for therapeutic potential in epidemiologic and basic research studies, but clinical results remain inconsistent (Ma et al, 2017). In older patients, drug-induced PD may occur as a side effect of neuroleptics or metoclopramide (see Appendix 13).

Recent epidemiologic studies have shown a link between PD and environmental factors including drinking well water, rural living, farming, diet, and exposure to agricultural chemicals (Pan-Montojo and Reichmann, 2014). PD has also been linked to exposure to different metals and industrial compounds. Many studies performed in the 1990s identified manganese, lead, copper, iron, zinc, aluminium, or amalgam. Higher incidence of PD has been reported in manganese miners. It was shown that manganese, a component of various pesticides, also reproduces PD symptoms after long and chronic exposure (between 6 months and 16 years). Remarkably, some populations have witnessed a decreasing prevalence of certain types of neurodegenerative diseases that coincide with the disappearance of an environmental factor unique to these populations (Pan-Montojo and Reichmann, 2014). A meta-analysis of observational studies found that 5 and 10 years of pesticide exposure were associated with 5% and 11% increased risk of developing PD (Yan et al, 2018).

Nutrient-related findings are biologically plausible and support the hypothesis that oxidative stress may contribute to the pathogenesis of PD (Czlonkowska and Kurkowska-Jastrzębska, 2011). The relationships of folate, elevated plasma homocysteine levels, and caloric deficits are being evaluated.

Medical Management

The five clinical signs—resting tremor (e.g., limbs, head, and presence of pill rolling), rigidity (e.g., resistance to passive range of motion), bradykinesia (e.g., slow initiation of movement), akinesia (e.g., festinating gait, masked face, reduced limb movement), and postural abnormalities (e.g., stooped and poor adjustment to tilting or falling)—remain the criteria for medical diagnosis. In the 1960s, L-dopa (a precursor to dopamine) was introduced for controlling PD symptoms of bradykinesia, rigidity, and tremor, and it remains the most effective pharmacologic agent to treat PD today (Lees et al, 2015). Sinemet is a combination of levodopa and carbidopa, which enhances levodopa, helping to lower the effective dosage and reduce side effects. Saffinamide is sometimes added to the regimen when new symptoms appear. Types of medications include dopamine precursors, inhibitors of levodopa breakdown, dopamine agonists, inhibitors of dopamine breakdown (monoamine oxidase [MAO]-B inhibitors), and anticholinergic. A full list of Parkinson's medications approved in the United States and common side effects are available at the website for the American Parkinson Disease Association.

Pharmacotherapy agents, surgical interventions, and physical therapy are the best adjunctive therapies.

Medical Nutrition Therapy

The primary focus of nutrition intervention is to optimize dietary intake, particularly to maintain muscle mass for strength and

mobility. One cross-sectional study of more than 1000 individuals suggests a diet pattern rich in vegetables, fruits, nuts, fish, and olive oil was associated with a slower rate of PD progression (Mischley et al, 2017).

Nutrition intervention should also focus on drug-nutrient interactions, especially between dietary protein and L-dopa. Side effects of medications for PD include anorexia, nausea, reduced sense of smell, constipation, and dry mouth. To diminish the gastrointestinal side effects of L-dopa, it should be taken with meals. Foods that contain natural L-dopa such as broad beans (fava beans) should be avoided. For some patients, dyskinesia may be reduced by limiting dietary protein at breakfast and lunch and including it in the evening meal. Table 39.11 presents a sample menu for this diet.

TABLE 39.11 Dietary Protein Redistribution with L-Dopa Therapy

	Amount of Protein (g)
Breakfast	
½ C oatmeal	2
1 orange	0.5
1 C Rice Dream beverage	0.5
Egg replacer (unlimited)	0
Low-protein bread toast	0
Olive oil (unlimited)	0
Fruit (unlimited)	0
Coffee or tea (unlimited)	0
Lunch	
½ C vegetable soup	2
1 C tossed salad	1
Salad dressing (unlimited)	0
1 banana	1
Low-protein pasta (unlimited)	0
Olive oil (unlimited)	0
Juice, coffee, tea, or water	0
Afternoon Snack	
Fruit-only smoothies (unlimited)	0
100% juice (up to half of total daily fruit)	0
Total	7
Dinner	
4 oz (at least) fish, chicken, pork, beef	28 or more
1 C stuffing	4
Gravy	0
½ C peas	2
¾ C yogurt	8
1 C milk	8
Evening Snack	
1 oz cheese or deli meat	7
4 crackers	2
Water, herbal tea, or 100% juice	0
Daily total	73 or more

Fiber and fluid adequacy lessen constipation, a common concern for people with PD. Pyridoxine (vitamin B₆) has a possible efficacy-lowering interaction with L-dopa. Decarboxylase, the enzyme required to convert L-dopa to dopamine, depends on pyridoxine. The nutrient-drug interaction does not occur when carbidopa is used in combination with levodopa (Sinemet), which it commonly is, so likelihood of occurrence is low (Hansten and Horn, 1997). Interactions between pyridoxine and aspartame should be considered as well. In addition, manganese should be carefully monitored to avoid excesses above dietary reference intake (DRI) levels. The high demand for molecular oxygen, the enrichment of polyunsaturated fatty acids in membrane phospholipids, and the relatively low abundance of antioxidant defense enzymes are all relevant factors (Sun et al, 2008). Antiinflammatory and neuroprotective effects come from phenolic compounds, such as resveratrol from grapes and red wine, curcumin from turmeric, and epigallocatechin from green tea (Sun et al, 2008). Sufficient intake of vitamin D₃ and omega-3 fatty acids should be recommended.

In a small clinical study seven volunteers with PD agreed to maintain a ketogenic diet for 1 month. Five had improvement in their postdiet test scores (Hashim and Vanitallie, 2014). An 8-week pilot RCT of 38 PD patients tested a low-fat versus ketogenic diet (Phillips et al, 2018), and both groups significantly improved motor symptoms. However, at least in the short term of 8 weeks, the ketogenic group had greater improvements in nonmotor symptoms. Although these studies are preliminary in nature, they raise awareness for the potential role of ketogenic diet therapy in this disease.

A yearlong study of 257 patients with PD and 198 controls found that those who were more compliant with a Mediterranean diet had later age-at-onset of PD (Alcalay et al, 2012); these findings match large epidemiologic studies (Gao et al, 2007).

As the disease progresses, rigidity of the extremities can interfere with the patient's ability to eat independently. Rigidity interferes with the ability to control the position of the head and trunk, necessary for eating. Eating is slowed; mealtimes can take up to an hour. Simultaneous movements such as those required to handle a knife and fork become difficult. Tremors in the arms and hands may make consuming liquids independently impossible without spilling. Perception and spatial organization can become impaired. Dysphagia is often a late complication. Patients may be silent aspirators, that is the individual will aspirate without a cough response, a change to voicing, or a latent protective behavior such as a throat clear, which affects nutrition status and increases the risk for aspiration pneumonia.

Experimental treatment procedures are an active area of study. Deep brain stimulation, other surgical interventions, and efforts with stem cell research continue in hope of a cure. Over the counter and complementary therapies are also common, and the Parkinson's Foundation maintains a summary of these, including two of the most common: coenzyme Q₁₀ and St. John's Wort. A common supplement is coenzyme Q₁₀, which has been used safely in studies lasting up to 5 years (Natural Medicines Database, 2018a). Data are mixed on coenzyme Q₁₀ and PD, but appear to either neutralize or improve activities of daily living and slow functional decline for early Parkinson's. A large clinical trial was stopped midstudy in 2011 due to lack of improvement in delaying early PD progression (Parkinson Study Group QE3 Investigators, 2014). St. John's Wort is another popular supplement that may be effective for mild to moderate depression (Natural Medicines Database, 2018b).

CLINICAL CASE STUDY

Michael is a 67-year-old white man who is a lifelong resident of Sherman Oaks, CA, a suburb of Los Angeles. He was a high school football star and now runs a small landscaping business and volunteers as a local football coach. He enjoys taking walks in a park that is next to a large freeway. Sometimes he will go on an easy hike in the nearby hills with his wife, Lisa. They are happily married and both love Mexican food (especially chips and salsa, tacos, and margaritas) and music by the Beatles.

Michael was diagnosed with Parkinson's disease 3 years ago, after Lisa noticed that his hands were shaking at rest. She noted that he had been complaining about having to move more slowly at work and at football practices, too.

Michael is coming in for a regular check-up appointment. He has been taking Sinemet (mix of levodopa and carbidopa) and Neupro (rotigotine) to control his symptoms. His symptoms are well managed, but he's experienced some nausea and dizziness on these medications that he just lives with because they keep him functional. He also takes coenzyme Q₁₀, St. John's Wort, and a high potency multivitamin with 75 mg pyridoxine.

He is 6'0" and currently weighs 160 lb. He was 180 lb at his last visit 3 months ago. Lisa thinks he's lost a little weight, but isn't sure. He's always been fit and lean. What she has noticed is that they don't talk as much during meals anymore and that it takes him a long time to finish his food. After speaking with the couple for a while, Lisa remembers one time recently when she'd made his favorite banana bread and the whole house smelled amazing, but he didn't notice. Her feelings had been hurt. She admits that sometimes he loses interest and doesn't seem to have the energy to finish his meals. When she encourages him to eat, he can be either apathetic or irritable.

Nutrition Diagnostic Statements

- Inadequate energy intake related to PD progression, hyposmia, and decreased appetite, as evidenced by recent weight loss of 12% in 3 months (severe), decreased food intake, and fatigue.
- Difficulty swallowing related to PD progression as evidenced by slow eating pace.
- Environmental factors to consider are long-term exposure to car pollution and herbicides from his landscaping work.

Nutrition Care Questions

1. What dietary advice do you have for Michael and his caregiver?
2. What changes in Michael's diet and lifestyle would you recommend?
3. What other evaluations does Michael need?
4. What possible food-drug interactions could be occurring?
5. What strategies can Michael use to decrease his exposure to car pollution and herbicides?

Medical Nutrition Therapy in Psychiatric and Cognitive Disorders

Christina Troutner, MS, RDN

KEY TERMS

addiction	dementia	major depressive disorder (MDD)
advanced glycation end products (AGEs)	depression	mild cognitive impairment (MCI)
adverse childhood experience (ACE)	dopamine	MIND diet
alpha-linolenic acid (ALA)	<i>Diagnostic and Statistical Manual of</i>	neurotransmission
alpha-lipoic acid	<i>Mental Disorders (DSM-5)</i>	norepinephrine
alcoholism	docosahexaenoic acid (DHA)	schizophrenia
Alzheimer's disease (AD)	eicosapentaenoic acid (EPA)	schizoaffective disorder
amygdala	enteric nervous system (ENS)	serotonin
anxiety	epinephrine	serotonin syndrome
arachidonic acid (ARA)	fibromyalgia syndrome (FMS)	synaptic plasticity
bipolar disorders	glutamate	vascular dementia
chronic fatigue syndrome (CFS)	leaky gut (intestinal hyperpermeability)	

Most illnesses reflect widespread disorders in many parts of the body and are a mix of physical and psychological factors. For example, heart attacks are more common in those with higher levels of hostility (Varghese et al, 2016; Izawa et al, 2011), schizophrenia and autism have been associated with food sensitivities (Jackson et al, 2012; Teitelbaum et al, 2011), and bipolar disorder may be linked to disruption in energy metabolism (Nierenberg et al, 2013). Unfortunately, conditions may be labeled as psychological from a mindset that views the condition as “less real” than other illnesses. This is especially common until a biologic marker or laboratory test is available for an illness. For example, multiple sclerosis was previously called “hysterical paralysis,” thought to be caused by an oedipal complex, and lupus was once considered to be a neurosis until tests for these conditions were developed. **Chronic fatigue syndrome (CFS)** and **fibromyalgia (FMS)**, once thought to be psychosomatic, are now accepted as legitimate physiologic conditions.

As this shift occurs, the artificial and unhealthy boundary between mental and physical illnesses is fading, being replaced with a more accurate reality that treatment in general is most effective when it treats the whole person, recognizing that physiologic imbalances are important to consider in many mental health disorders. The psychological consequences of suboptimal nutritional intake may occur before the physical signs. These include irregular eating habits and unhealthy food choices and can be assessed

through careful dietary intake analysis, a nutrition-focused physical examination and biochemical assessment.

The brain weighs approximately 3 lb (1.4 kg). Nerve cells (neurons) gather and transmit electrochemical signals via axons and dendrites. Neurons are the gray matter of the brain; dendrites and axons are the white matter. The cerebrum is the largest part of the brain divided into two halves, which are divided into four lobes, in each hemisphere: (1) the frontal lobes involved with speech, thought, learning, emotion, and movement; (2) the parietal lobes, which process sensory information such as touch, temperature, and pain; (3) the occipital lobes, dealing with vision; and (4) the temporal lobes, which are involved with hearing and memory. The central nervous system consists of the brain and the spinal cord, which connect to the peripheral nervous system, and extends throughout the body (Fig. 40.1).

The brain is approximately 80% fat. The fatty acid composition of neuronal cell membrane phospholipids reflects their intake in the diet. The degree of a fatty acid's unsaturation determines its three-dimensional structure and thus membrane fluidity and function. The ratio between omega-3 and omega-6 polyunsaturated fatty acids (PUFAs) influences various aspects of serotonergic and catecholaminergic neurotransmission. Beyond their role in brain structure, essential fatty acids (EFAs) are involved in the synthesis and functions of neurotransmitters and in the molecules of the immune system. Nutrition can impact multiple functions in most parts of the brain (Box 40.1).

Nerve cells communicate through the release of molecules of neurotransmitters from the transmitting (releasing) end of one nerve cell, through the synapse between them, to the receiving end (receptors) of

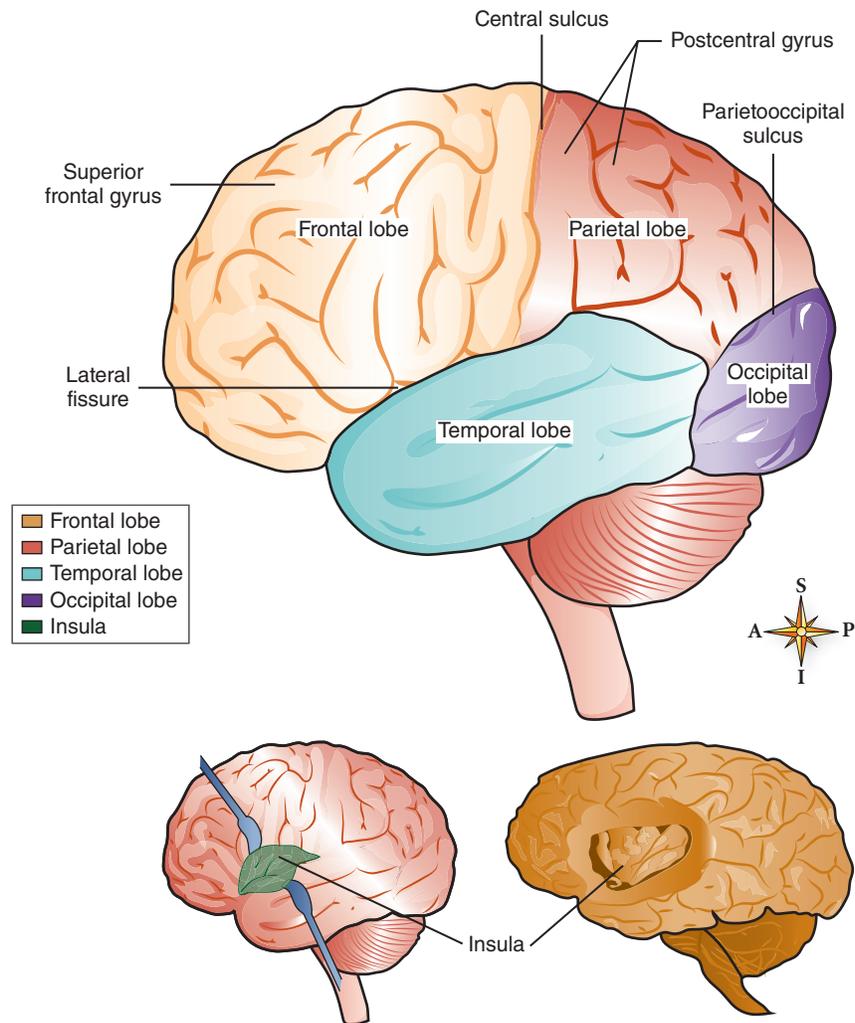

Fig. 40.1 The human brain.

BOX 40.1 How Nutrients Affect Mental Health

Nutrients can affect mental health through a variety of actions:

1. Support the normal development of the brain and central nervous system.
2. Serve as precursors and cofactors for neurotransmitter production.
3. Provide an energy source for the brain.
4. Influence genetic transcription.
5. Support mood and sense of well-being.

Reference: Leyse-Wallace R: *Nutrition and mental health*, Boca Raton, Fla, 2013, Taylor and Francis Inc., CRC Press.

a nearby neuron. There are numerous neurotransmitters, including **serotonin**, acetylcholine, dopamine, **norepinephrine**, **epinephrine**, and **glutamate**.

One of the most important contributions of nutrition to mental health is maintaining the structure and function of the neurons and neurotransmitters in the nervous system. The production of neurotransmitters requires adequate amounts of nutrients. Among these nutrients are amino acids (tryptophan, tyrosine, and glutamine), minerals (zinc, copper, iron, iodine, selenium, magnesium),

and B vitamins (B₁, B₂, B₃, B₆, B₁₂, folate). Suboptimal intake of any of these nutrients can impair the production of neurotransmitters and lead to a deterioration of mental health (Table 40.1)

THE ENTERIC NERVOUS SYSTEM

Due to its extensive network of neurons, the gut is often called the **enteric nervous system (ENS)** or the second brain, which functions autonomously. The ENS contains about 100 million neurons—fewer than the brain, but more than the spinal cord. Acetylcholine, serotonin, and norepinephrine are major neurotransmitters in the ENS. Neural activity in the gut is triggered by receptors that respond to mechanical, thermal, osmotic, and chemical stimuli. Bidirectional information continually passes between the gut and CNS, therefore neurologic and gastrointestinal conditions may have gut and brain components (Sharkey and Savidge, 2014).

The gastrointestinal tract is colonized by more than 10 trillion bacteria, more than there are cells in the body. These bacteria and their byproducts influence brain function and behavior. Gastrointestinal infections with unhealthy microbiota can influence brain function by causing increased intestinal wall permeability, also called **leaky gut (intestinal hyperpermeability)**, which is discussed further in

TABLE 40.1 Neurotransmitters: Precursors and Urinary Metabolites

Neurotransmitter	Precursors	Required Cofactors	Urinary Metabolite
Norepinephrine	Phenylalanine and tyrosine	Copper, S-adenosyl-L-methionine (S-AdoMet), vitamin C	Vanilmandelate (VMA)
Norepinephrine to epinephrine	Phenylalanine and tyrosine	Copper, S-AdoMet, vitamin C	Vanilmandelate (VMA)
Dopamine	Phenylalanine and tyrosine	Tetrahydrobiopterin (BH ₄), vitamin B ₆	Homovanillate (HVA)
Serotonin	Tryptophan	Tetrahydrobiopterin (BH ₄), vitamin B ₆	5-Hydroxyindoleacetate (5-HIAA)

NEW DIRECTIONS

Brain-Derived Neurotrophic Factor (BDNF)

Brain-derived neurotrophic factor, also known as *BDNF*, is a protein found in the brain and the peripheral nerves. It plays a role in the growth, differentiation, and maintenance of nerve cells. In the brain, BDNF binds to receptors in the synapses between neurons, increasing voltage and improving signal strength. The synapses can change and adapt over time in response to experience, a characteristic called synaptic plasticity. The BDNF protein helps regulate synaptic plasticity, which is important for learning and memory.

Inside the cells, BDNF activates genes that increase production of more BDNF and other important proteins, as well as serotonin, the neurotransmitter vital for learning and self-esteem. Low levels of BDNF have been associated with depression and even suicide.

The BDNF protein is found in regions of the brain that control eating, drinking, and body weight and likely contributes to the management of these functions.

Certain common genetic variations (polymorphisms; see Chapter 5) in the BDNF gene have been associated with an increased risk of developing psychiatric disorders such as bipolar disorder, schizophrenia, anxiety, and eating disorders.

A particular polymorphism in the *BDNF* gene alters the amino acid sequence in the protein, replacing valine with methionine at position 66 (written as Val66Met or V66M), which impairs the protein's ability to function. Many studies report an association between the Val66Met polymorphism and psychiatric disorders; however, some studies have not supported these findings. It is still unclear how changes in the *BDNF* gene are related to these disorders.

Emerging evidence suggests that moderate aerobic exercise can enhance BDNF expression, which supports the association between exercise and improvements in cognitive function and memory (Wang and Holsinger, 2018).

Chapters 25 and 27. Intestinal wall permeability can result from a host of bowel infections and medications and is associated with many illnesses such as Crohn's disease, celiac disease, multiple sclerosis, and irritable bowel syndrome. See Chapter 27 for more information on these conditions.

BLOOD GLUCOSE REGULATION

Fluctuations in blood glucose can amplify aberrant moods and behavior (Young and Benton, 2014). Rapid and abrupt increases in blood glucose can trigger rapid and excessive release of insulin. This is often followed by a rapid drop in blood glucose as insulin drives the glucose into the cells. The body compensates by raising levels of the compounds epinephrine and cortisol, both of which can trigger marked emotional changes and erratic behavior. The effects of insulin persist well beyond the presence of sugar in the gastrointestinal tract. The natural response is to consume more sugar as it provides immediate relief of the symptoms of low blood glucose; this is the beginning of emotional swings as blood glucose goes up and down.

The habit of eating carbohydrate-rich foods during stress may be physiologically rewarding, as it may raise the level of serotonin in the brain, causing a soothing effect (Wurtman and Wurtman, 2018). With the average American consuming about 100 lb of sugar yearly (U.S. Department of Agriculture, Agricultural Research Service, 2018), this is becoming a major health problem. On the other hand, adequate carbohydrate intake—45% to 65% of total calories, optimally from whole grains and fiber-rich vegetables and fruits—is important for maintaining healthy blood glucose levels, which may protect against mood disturbance and support feelings of well-being (Breyer et al, 2016).

Reducing refined carbohydrates and sugar intake can decrease these blood glucose fluctuations considerably. Consuming adequate protein and healthy fats can also contribute to stabilization of

blood sugar levels, often with dramatic clinical and emotional improvement from balancing these three macronutrients (Owen and Corfe, 2017).

THE ROLE OF NUTRIENTS IN MENTAL FUNCTION

Omega-3 Fatty Acids

Omega-3 PUFAs are the preferred fatty acids in the brain and nervous system. From conception through maturity, the essential omega-3 fatty acids **icosapentaenoic acid (EPA)** and **docosahexaenoic acid (DHA)** make unique and irreplaceable contributions to overall brain and nervous system functioning. Clinical research has shown effective and promising roles for EPA and DHA in various psychiatric conditions (Box 40.2) (see *Focus On: Abbreviations for Fatty Acids*).

FOCUS ON

Abbreviations for Fatty Acids

ALA	Alpha (α) linolenic acid
ARA	Arachidonic acid
CLA	Conjugated linoleic acid
DGLA	Dihomo-gamma (γ)-linolenic acid
DHA	Docosahexaenoic acid
EFA	Essential fatty acid
EPA	Eicosapentaenoic acid
GLA	Gamma-linolenic acid
HUFA	Highly unsaturated fatty acid
LA	Linoleic acid
LCFA	Long-chain fatty acids
MUFA	Monounsaturated fatty acids
PUFA	Polyunsaturated fatty acids

BOX 40.2 Some Conditions for Which EPA and DHA May Have Benefit

Alzheimer's disease, dementia, and cognitive function
 Age-related macular degeneration
 Anxiety
 Attention-deficit/hyperactivity disorder (ADHD)
 Bipolar disorder
 Depression
 Postpartum depression
 Rheumatoid arthritis
 Schizophrenia
 Suicidal ideation

DHA, Docosahexanoic acid; EPA, eicosapentaenoic acid.
 Reference: Office of Dietary Supplements, National Institutes of Health. *Omega-3 Fatty Acids* (website). <https://ods.od.nih.gov/factsheets/Omega3FattyAcids-Consumer/>.

Alpha-linolenic acid (ALA), a plant-based source of omega-3 fat with 8 carbons and 3 double bonds (18:3), is found in the oil of some seeds and nuts (e.g., flax, chia, sunflower, soybean, and walnuts). **Eicosapentaenoic acid (EPA)** is a 20-carbon omega-3 fatty acid with 5 double bonds (20:5), and **docosahexaenoic acid (DHA)** is a 22-carbon fatty acid with 6 double bonds (22:6). EPA and DHA occur naturally in fatty fish and seafood.

ALA serves as a precursor for EPA and DHA, but the conversion of ALA to EPA is approximately 5% to 10%, and conversion of ALA to DHA is even lower (<3%). Health status, other nutritional factors, and genetic variations, particularly in the *FADS1* gene, may influence the conversion rate. Studies have suggested possible differences in conversion rates between vegetarians and carnivores (Welch et al, 2010). Most nutrition and mental health experts do not recommend reliance on ALA as a source of EPA or DHA.

Arachidonic acid (ARA), a 20-carbon omega-6 fatty acid with 4 double bonds (20:4), serves as a precursor to the eicosanoids prostaglandins, thromboxanes, and leukotrienes, which are involved with inflammation, vasoconstriction, and a multitude of metabolic regulations, and also influence mood (see Chapter 7).

Although specific mechanisms remain unclear, clinical research has shown the importance of sufficient EPA intake for general mental health, and particularly as an adjunctive treatment for depression (Grosso et al, 2016). In general, EPA works better when ingested with DHA. They occur together naturally in deep sea fish and seafood. Higher intakes of fish are associated with a decreased risk of depression, particularly in women (Yang et al, 2018). DHA is preferred and selectively stored in brain and nerve cells, and DHA makes up much of the mass of brain tissue. It is required for normal brain growth, development, and maturation and is involved with **neurotransmission** (brain cells communicating with each other), lipid messaging, genetic expression, and cell membrane synthesis. DHA also provides vital structural contributions; DHA is concentrated in the phospholipids of brain cell membranes.

Oily fish such as salmon, sardines, and tuna are high in EPA and DHA, with the freshest fish having the highest levels. Some canned tuna also has significant amounts and may be more practical for those who cannot get fresh fish. Omega-3 levels of canned albacore tuna are higher than “chunk light” canned tuna, and the tuna should be water and not oil packed, because otherwise the omega-3 oils, which are fat soluble, will be lost when the oil is poured off (see Appendix 26).

During Pregnancy and Lactation

Experts recommend that pregnant women consume at least 200 to 300 mg DHA during pregnancy for optimal development of the infant nervous system. The role of DHA and EPA in pregnancy and lactation is discussed in Chapter 14. Up to 10% of pregnant women may experience depression, and there is considerable interest in finding effective alternatives to prescription medication. Several pilot trials using EPA and DHA from fish oil have been conducted in depressed pregnant women and women with postpartum depression. One dose-ranging study reported measurable improvements in women who consumed as little as 500 mg of combined EPA and DHA.

Research on DHA and EPA intakes by pregnant women and the impact on child cognition has been conflicting. A study that followed more than 9000 pregnant women and their children for 8 years reported lower intelligence quotient and social development in the children of those women who consumed fewer than 12 ounces of fish a week while pregnant. In other words, the children of the women who ate fish two or more times a week during their pregnancy fared better emotionally and mentally (Hibbeln and Davis, 2009). However, a study with the Maastricht Essential Fatty Acid Birth (MEFAB) cohort, with 292 mother-child pairs, showed that there was no association between maternal fatty acid status during pregnancy and child cognition (Brouwer-Brolsma et al, 2017). DHA supplements—as an alternative to DHA from food sources—can be costly and often do not provide the same benefit (Gould et al, 2017). Some concern has been raised about high mercury levels in fish during pregnancy (see Chapter 14). Pregnant women can opt for fish lower in mercury, such as salmon, tuna (canned, light), cod, and catfish. Mercury-free omega-3 fatty acid supplements are also available.

During Childhood

Depression among children is increasing. At the same time, the few studies measuring consumption of EPA and DHA in children report very low average intakes.

Some clinical trials using EPA and DHA supplements from fish oil in children with attention-deficit disorder (ADD) or attention-deficit/hyperactivity disorder (ADHD) have reported benefit, but not all. The difference in findings may be due to many variables, including study design, dose, age of supplementation, the background diet, genetics, and teacher or family dynamics (Gillies et al, 2012). However, it has been shown that children with ADD, ADHD, behavior problems, or who are overweight tend to have lower levels of EPA and DHA in their blood (Milte et al, 2015; Antalis et al, 2006) (see Chapter 43 for further discussion of ADD and ADHD).

During Adulthood

According to the World Health Organization (WHO) major depression is a leading cause of disability around the world (WHO, 2018). The intake of seafood has been shown to be inversely related to the incidence of depression in populations around the world. Increases in homicide occurrence have been associated with less seafood consumption. In active-duty military men, risk of suicide death was 62% greater with lower DHA status (Lewis et al, 2011). When EPA, DHA, and multivitamins were given to prison inmates, antisocial behavior, including violence, fell significantly compared with those on placebo. In another study, teens who had previously attempted suicide made fewer suicide attempts when given EPA and DHA (Hallahan et al, 2007).

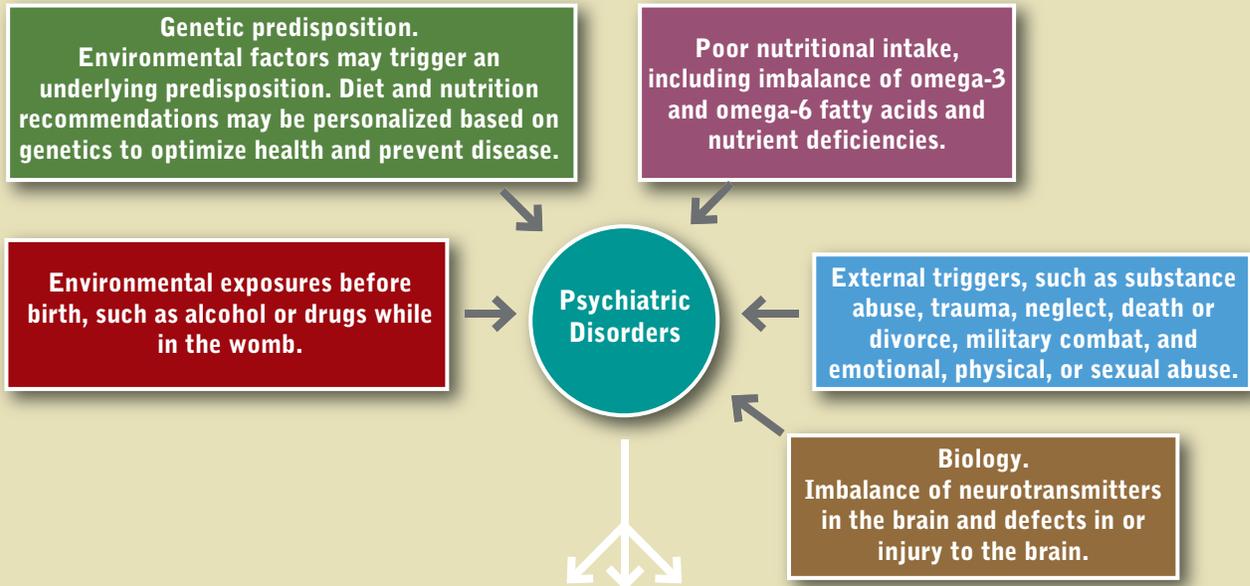

With much of the brain composed of the fatty acids found in fish oil (DHA), it is not surprising that fish oil has been shown to be helpful in many conditions. These include depression and schizophrenia

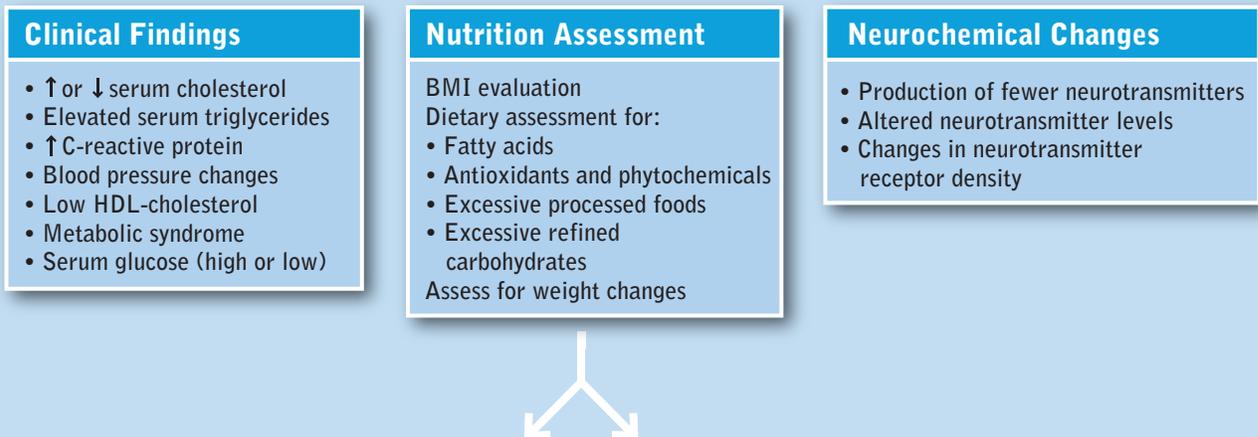

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Psychiatric Disorders

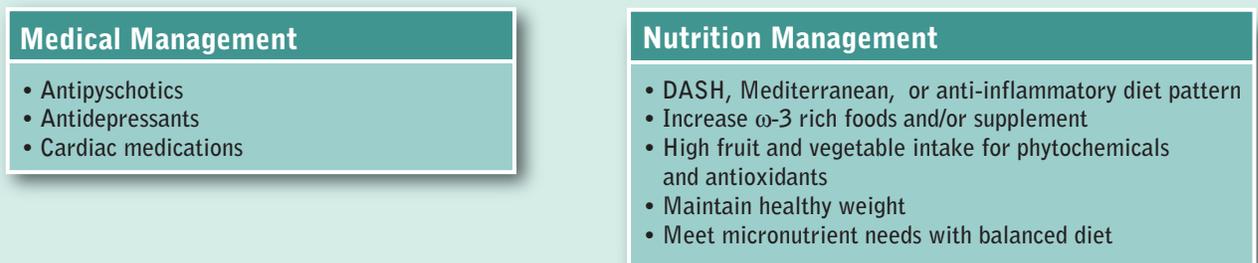

ETIOLOGY

PATHOPHYSIOLOGY

MANAGEMENT

Medical Management

- Antipsychotics
- Antidepressants
- Cardiac medications

Nutrition Management

- DASH, Mediterranean, or anti-inflammatory diet pattern
- Increase ω -3 rich foods and/or supplement
- High fruit and vegetable intake for phytochemicals and antioxidants
- Maintain healthy weight
- Meet micronutrient needs with balanced diet

unresponsive to drug treatment alone. EPA was also found to be beneficial in treating the depression associated with bipolar illness (manic depressive illness) (Sarris et al, 2012).

During Adulthood

Research suggests that individuals who consume more fish and seafood during their lifetime have better cognitive function later in life.

Higher blood levels of DHA have been associated with better cognitive function in middle adulthood. Omega-3 fatty acids may have substantial benefits in reducing the risk of cognitive decline in older people (Molfinio et al, 2014).

Consumption of a Mediterranean-type diet has also been associated with a decreased rate of cognitive decline with age. It is not clear which aspect of this whole diet approach is responsible for

this effect, although it is possible that it is not a single nutrient but the combined effects of the overall diet that produces this benefit. The Mediterranean diet is high in antioxidants and nutrients such as choline and phosphatidylcholine, known to be important for brain function.

Long-chain omega-3 PUFAs, along with other nutrients, have the potential to prevent and reduce comorbidities in older adults. They reduce inflammation, blood lipids, platelet aggregation, and blood pressure. Different mechanisms contribute to these effects, including supporting cell membrane function and composition, eicosanoid production, and gene expression.

The position of the Academy of Nutrition and Dietetics (AND) includes a recommendation for children and adults to eat fish at least twice a week, aiming for intake of 8 ounces or more. The latest recommendation of the International Society for the Study of Fatty Acids and Lipids, released in 2004, is consumption of a daily minimum of 500 mg combined of EPA and DHA. With caveats inherent for ecologic, nutrient disappearance analyses, a healthy dietary allowance for omega-3 fatty acids for current U.S. diets was estimated at 3.5 g/day for a 2000-kcal diet. Higher intakes may be especially helpful in neurologic and psychiatric disorders because of the key roles these omega-3 PUFAs play in the brain.

Omega-3 Supplements

For those who do not eat optimal amounts of omega-3 fats, supplements can be useful. In nature 1000 mg of fish oil contains approximately 180 mg EPA and 120 mg DHA; the remainder is other oils and fatty acids. Therapeutic amounts of EPA and DHA start with around 400 mg of each. Supplement companies sell concentrates of varying dosages, so it is important to read the label. It is also important to make sure the label indicates that the fat is free of heavy metals such as mercury and contaminants such as organophosphates.

Vitamins

Vitamins are critical for energy production as well as many other reactions, and deficiencies can cause serious cognitive and mood problems. Insufficient vitamin intake is defined as intake of an amount below the reference daily vitamin intake amounts, but vitamin deficiency means development of clinically relevant, measurable disorders or characteristic deficiency symptoms due to insufficient intake. Nonetheless, any person with insufficient vitamin intake is also at risk for development of a subclinical functional vitamin deficiency (see Chapter 5).

Mild nutritional deficiencies from poor diet can cause behavioral and cognitive dysfunction, as can increased needs from altered metabolism resulting from genetic mutations (see Chapter 6). Obtaining the levels of micronutrients shown in studies to change brain function often requires a pharmacologic, rather than a dietary reference intake (DRI) level of supplementation, and cannot be reasonably achieved by diet alone. Described below are the function of selected vitamins and minerals involved in psychiatric conditions.

Studies have identified genetic mutations that alter the production and function of serotonin, dopamine, and other neurotransmitters. For example, the methylenetetrahydrofolate reductase (MTHFR) test can reveal alleles (C > T and A > C substitutions) that influence folate metabolism and can lead to a decrease in the production of serotonin and dopamine, as well as an increase in homocysteine levels resulting from an impaired metabolic pathway. People with these genetic single nucleotide polymorphisms (SNPs) (see Chapter 6) with active illness may require folate supplementation in a methylated (5-methyltetrahydrofolate [MTHF]) form. Elevated methylmalonic acid levels suggest

the need for B₁₂ supplementation, especially in the presence of elevated serum homocysteine levels (see Appendix 31 for food sources of folate and vitamin B₁₂).

Thiamin (Vitamin B₁)

Thiamin diphosphate (TDP), the most bioactive form of thiamin, is an essential coenzyme in glucose metabolism and the biosynthesis of neurotransmitters, including acetylcholine, γ -aminobutyrate, glutamate, aspartate, and serotonin. Norepinephrine, serotonin, and glutamate, as well as their receptors, are potential targets for antidepressant therapies. The degradation rate of TDP, bound to its dependent enzymes, is directly proportional to the available amount of its main substrate, carbohydrate. Body stores of B₁ fall rapidly during fasting. Low TDP concentrations and impaired thiamin-dependent enzymatic activities have been detected in the brains of patients with Alzheimer's disease (AD), Parkinson's dementia (PD), and other neurodegenerative diseases (Zhang et al, 2013).

Wernicke encephalopathy (WE) is a potentially reversible, yet serious neurologic manifestation caused by vitamin B₁ (thiamin) deficiency. It is commonly associated with heavy alcohol consumption but is also reported with the excessive vomiting of hyperemesis gravidarum and vomiting after bariatric surgery. Most patients present with the triad of ocular signs (nystagmus), ataxia, and confusion (see Chapter 28).

Guidelines by the European Federation of Neurological Societies (EFNS) recommend that patients with alcoholism or the conditions mentioned above receive thiamin, 200 mg tid, administered intravenously (IV), before starting any carbohydrate or glucose intake, and that, if directed by a physician, it be continued until there is no further improvement in signs and symptoms. For nonalcoholic patients with thiamin deficiency, an IV dose of thiamin, 100 to 200 mg once daily, may be sufficient (Galvin et al, 2010).

Learning disorders and behavioral problems in young children (sometimes to the point of hospitalization) improved with a high-dose thiamin supplement (Fattal et al, 2011). People with AD were shown to have lower serum thiamin levels than those with other types of dementia (Lu'o'ng and Nguyen, 2011). It has been suggested that the measurement of blood thiamin metabolites may be used as an inexpensive and noninvasive diagnostic tool for distinguishing AD from vascular and frontotemporal dementia (Pan et al, 2015). Some medications may interact with thiamin.

Riboflavin (Vitamin B₂)

Biochemical signs of riboflavin depletion appear within a few days of dietary deprivation. Poor riboflavin status interferes with iron absorption and contributes to the etiology of anemia when iron intakes are low. Riboflavin is involved in determining circulating concentrations of homocysteine and may exert some of its effects by reducing the metabolism of other B vitamins, notably folate and vitamin B₆, which are of particular interest in psychiatric disorders. In those with frequent migraines, supplementing with 400 mg of riboflavin a day decreased migraine frequency by 50% to 69% after 6 weeks of use (Markley, 2012).

Niacin (Vitamin B₃)

Niacin is a key component of the molecule NADH, which is important for production of the neurotransmitter dopamine. Nicotinamide, the amide form of niacin, plays an important role in neuronal development and in protecting neurons from traumatic injury, stroke, and ischemia (Fricker et al, 2018). One of the signs of pellagra, the niacin-deficiency disease, is dementia. Pellagra can be a cause of delirium during alcohol withdrawal (Oldham and Ivkovic, 2012). Acute pellagra

resembles sunburn in its first stages. Psychiatric manifestations are fairly common but are easily overlooked due to their nonspecific nature. Examples include irritability, poor concentration, anxiety, fatigue, restlessness, apathy, and depression.

Vitamin B₁₂

The symptoms of vitamin B₁₂ deficiency may include agitation, irritability, confusion, disorientation, amnesia, impaired concentration and attention, and insomnia. Mental symptoms may also include stupor, apathy, negativism, memory and judgment disorders or even psychoses, depression, and dementia (Gröber et al, 2013). Catatonia is also described as a psychiatric form of vitamin B₁₂ deficiency. Psychiatric disorders that may be diagnosed in patients having B₁₂ deficiency include depression, bipolar disorder, panic disorder, psychosis, phobias, and dementia.

A vitamin B₁₂ deficiency may express itself in a wide variety of neurologic manifestations such as paresthesias, coordination disorders, reduced nerve conduction velocity, and progressive brain atrophy in the elderly. Cobalamin contributes to hematopoiesis, myelin synthesis, and synthesis of epithelial tissue.

Seventy-five to ninety percent of persons with a clinically relevant B₁₂ deficiency have neurologic disorders, and in about 25% of cases these are the only clinical manifestations of the B₁₂ deficiency. Levels less than 200 ng/L are sure signs of a B₁₂ deficiency, but a functional B₁₂ deficiency may also be present at levels under 450 ng/L.

Moderately elevated concentrations of homocysteine (>10 μmol/L) have been associated with an increased risk of dementia, notably AD, in many cross-sectional and prospective studies. Raised plasma concentrations of homocysteine are associated with regional and whole-brain atrophy, not only in AD but also in healthy elderly people. Determination of methylmalonic acid and homocysteine are particularly recommended in cases of diagnostically unclarified B₁₂ deficiency.

Possible nutrient-drug interactions occur with antibiotics, anticonvulsants, colchicine, metformin, and N₂O. Proton pump inhibitors reduce gastric acid secretion and thus the intestinal release of vitamin B₁₂ from foods (see Appendix 13).

Hydroxycobalamin, methylcobalamin, and cyanocobalamin are suitable for treatment. The lowest dose of oral cyanocobalamin required to normalize mild vitamin B₁₂ deficiency is more than 200 times the recommended dietary allowance of approximately 3 mcg daily (i.e., >500 mcg per day). For deficiency resulting from absorption disorders, doses of 500 to 2000 mcg/day are required.

In a randomized and double-blind interventional study (VITA-COG study) involving 168 older adults with mild cognitive impairment (age >70 years), oral supplementation of vitamin B₁₂, folate, and vitamin B₆ over a period of 24 months slowed the progression of brain atrophy and reduction of cognitive performance by 53.3% (Gröber et al, 2013).

In a study of people being treated for depression, participants with higher levels of vitamin B₁₂ tended to get a greater benefit from antidepressants (Moore et al, 2012).

Folate

Folate deficiency is associated with depression, cognitive decline, and dementia. The NHANES 2010 data examined relations between folate and vitamin B₁₂ status biomarkers for mental as well as physical conditions. These conditions included lead and neurobehavioral test performance, anemia and cognitive function, hypothyroidism, and gene-nutrient interactions.

Folate deficiency has been identified as a risk factor for schizophrenia through epidemiologic, biochemical, and gene association studies. Folate plus vitamin B₁₂ supplementation can improve negative symptoms of schizophrenia. Negative symptoms imply the lack of something, such as social contacts, initiative, energy, motivation, or display of emotion, but treatment response is influenced by genetic variation in folate absorption. These findings support a personalized medicine approach for the treatment of negative symptoms (Roffman et al, 2013).

Folate deficiency may be the result of decreased intake, or increased needs caused by common genetic defects (see MTHFR discussion above). Consequences of inadequate intake are compounded when there is an increased folate requirement, such as during pregnancy, lactation, premature birth, and chronic hemolytic anemias, for example sickle cell anemia and thalassemias (see Chapter 31). Conditions associated with increased cell turnover such as leukemias, aggressive lymphomas, and tumors associated with a high proliferative rate can also cause increased folate demand.

Folate may help cognitive function by decreasing homocysteine levels, improving vascular health, and attenuating antioxidant responses thus inflammatory status (Enderami et al, 2018). However, research is not conclusive. An observational study that included 2900 healthy seniors with high blood levels of homocysteine showed that neither supplementation of folic acid nor vitamin B₁₂ improved cognitive performance (van der Zwaluw et al, 2014).

In addition, low folate is associated with AD, with higher folate levels associated with 50% reduction in the risk of developing AD (Luchsinger et al, 2007; Chen et al, 2015). Not all studies have shown a protective effect, however, and one study showed a U-shaped curve, with very high folate levels associated with higher homocysteine levels and a greater risk for developing AD (Faux et al, 2011).

Total homocysteine (tHcy), a nonspecific indicator of inadequate folate status, accumulates with folate inadequacy but is relatively stable across normal folate ranges (Yetley and Johnson, 2011). Folate biomarkers (serum, plasma, and red blood cell folate) increase in response to folate in a dose-response manner (Duffy et al, 2014).

Vitamin D

Vitamin D affects hundreds of genes in the human body and is recognized as an important nutrient for brain health as well as for bone and skeletal health. Clinical research has associated vitamin D deficiency with the presence of mood disorders, all cause dementia including AD, as well as increased risk for major and minor depression in older adults (Littlejohns et al, 2014; Stewart and Hirani, 2010). Supplementing with vitamin D, however, has shown mixed results (Bertone-Johnson et al, 2012; Kjærgaard et al, 2012).

Vitamin D has a crucial role in proliferation, differentiation, neurotrophism, neuroprotection, neurotransmission, and neuroplasticity of cells. Vitamin D exerts its biologic function not only by influencing cellular processes directly, but also by influencing gene expression. The brain has vitamin D receptors, which help provide protection against, and even aid in reversal of, neurocognitive decline. In a study that combined vitamin D with the AD medication memantine, the combination therapy was associated with improvement compared with memantine or vitamin D alone (Annweiler et al, 2012).

Serum levels of vitamin D are most often tested by assessing circulating levels of 25(OH)D, which is the combined product of skin synthesis from sun exposure and dietary sources (see Chapter 5 and Appendix 38). Currently, no “official” agreement has been reached regarding blood levels of 25(OH)D that indicate deficiency, insufficiency,

and sufficiency of vitamin D, especially related to brain health. For example, serum levels of 25(OH)D may be low despite a person having an adequate diet or sufficient sun exposure, because of conversion to other forms such as 1,25(OH)D. Many practitioners favor 25(OH)D serum levels of at least 30 ng/mL or 75 nmol/L, although for depression levels of 60 to 80 ng/mL may be beneficial.

The best sources of vitamin D are (1) exposure of the skin to sunlight (the amount of time necessary for an individual to produce adequate vitamin D is dependent on skin type and ultraviolet [UV] index), (2) foods such as oily fish and egg yolks, and (3) vitamin D–fortified foods, such as cow's milk, soy milk, other fortified milks, and fortified cereals. The recommended advice regarding sun exposure is to “avoid sunburn—not sunshine” (see Appendix 38).

Minerals

Iron

Iron deficiency results in poor brain myelination and impaired monoamine metabolism. Glutamate and γ -aminobutyric acid homeostasis is modified by changes in brain iron status. Such changes not only produce deficits in memory, learning capacity, and motor skills but also result in emotional and psychological problems (Kim and Wessling-Resnick, 2014).

Iron deficiency is associated with apathy, depression, and fatigue. Iron deficiency anemia in children is associated with a significantly increased risk of psychiatric disorders, including mood disorders, autism spectrum disorder, ADHD, and developmental disorders (Chen et al, 2013) (see Chapters 31 and 43). At 10 years of age, children given iron supplements from 6 months to 12 months of age smiled and laughed more and needed less prompting to complete a social stress task. However, there were no differences in behaviors such as anxiety, depression, or social problems. Benefits in affect and response to reward may improve performance at school and work, mental health, and personal relationships (Lozoff et al, 2014). Anemia is a late sign of iron deficiency, and therefore a normal blood count in no way precludes its presence.

Iron plays a critical role in dopaminergic signaling. Atypical antipsychotic medications, increasingly used in children and adolescents, modulate brain dopamine. In a study of 115 children who had taken risperidone (an antipsychotic medication commonly used for schizophrenia) for 2.5 ± 1.7 years, 45% had iron depletion and 14% had iron deficiency. Iron status was inversely associated with weight gain during risperidone treatment. It was also inversely associated with the antipsychotic prolactin concentration, which was nearly 50% higher in the iron-deficient group (Calarge and Ziegler, 2013). Nutrition assessment should include evaluation of iron status. Prolactinemia is a challenging side effect of risperidone therapy, especially in males, that may be improved when iron status is normalized.

Selenium

The essential trace mineral selenium is a constituent of selenoproteins, which have important structural and functional roles. Known as antioxidants, they act as a catalyst for the production of active thyroid hormone and are needed for the proper functioning of the immune system. Deficiency has been linked to adverse mood states and depression (Conner et al, 2015; Rayman, 2000). One study found that low dietary selenium intake was associated with an approximate tripling of the likelihood for developing de novo major depression disorder (MDD) (Pasco et al, 2012).

Selenium is available in multivitamin/multimineral supplements and as a stand-alone supplement, often in the forms of selenomethionine or selenium-enriched yeast (grown in a high-selenium

medium). An optimal dose for supplementation is ~ 55 mcg per day for adults, which is equivalent to the recommended dietary allowance (RDA) (Akbaraly et al, 2010). Selenium poisoning from very large intakes is a concern (Nuttall, 2006) (see Appendix 45 on selenium).

Zinc

Zinc imbalance can result not only from insufficient dietary intake but also from impaired activity of zinc transport proteins and zinc-dependent regulation of metabolic pathways. It is known that some neurodegenerative processes are connected with altered zinc homeostasis, and it may influence the state of PD, AD, depression, ADHD, aging-related loss of cognitive function, and possibly psychotic symptoms (Petrilli et al, 2017; Tyszka-Czochara et al, 2014; Grabrucker et al, 2011). Zinc may play a role in regulating the production of dopamine in the brain. Mechanisms of action by which zinc reduces depressive symptoms include (1) decreasing dopamine reuptake (by binding to the dopamine receptor), (2) increasing the conversion of the thyroid hormone T4 to T3, and (3) promoting excitatory neurotransmitter function.

A study of older adults in Australia using a food-frequency questionnaire found those with the highest zinc intake had a 30% to 50% reduction of odds of developing depression. They also reported no association between the zinc-to-iron ratio and developing depression (Vashum et al, 2014). Children with ADHD had lower blood levels of zinc, ferritin, and magnesium than children without ADHD, but they had normal copper levels (Mahmoud et al, 2011).

Amino Acids

In addition to being the building blocks for the key neurotransmitters serotonin (from tryptophan), dopamine, and norepinephrine (both from tyrosine), amino acids are also critical precursors for the antioxidants glutathione (made from glutamine, glycine, and N-acetyl cysteine [NAC]). Amino acid sufficiency can be measured either through plasma or urinary amino acids or by urinary organic acid testing, which measures byproducts of the particular neurotransmitter pathways (see Table 40.1). As more of the neurotransmitters are found in the gut than in the brain, these tests may be helpful but are not absolute indicators of brain neurotransmitter levels or adequacy. Amino acid levels can be low due to inadequate protein intake.

The role of serotonin and dopamine in depression is widely known and it is targeted by many medications, but the role of antioxidants gets less attention, despite its importance. For example, NAC has been shown to be helpful in a wide array of psychiatric conditions, including addiction, compulsive disorders, schizophrenia, and bipolar disorder (Dean et al, 2011). Antioxidant-rich foods, such as dark leafy greens, yellow and orange vegetables, berries, and nuts, can also be incorporated in the diet.

Phytochemicals

New research suggests that plant-based foods rich in bioactive phytochemicals are important to normal brain function and mental health. Promising phytochemicals include three subclasses of flavonoids: flavanols, anthocyanins, and flavanones. These phytochemicals have antioxidant activity, but their more important contributions may be in protecting and preserving brain cell structure and metabolism through a complex cascade of cellular mechanisms, including signaling, transcription, phosphorylation, and gene expression (Spencer, 2010). Foods such as berries, citrus fruits, green tea, and some spices contain phytochemicals, as well as essential vitamins and minerals. Curcumin, derived from turmeric,

may be especially neuroprotective, being associated with lower risks of PD and AD.

There is evidence that numerous other plant-based molecules have nutritional and possibly pharmacologic effects in the brain, and the mechanisms are sometimes unknown. These molecules appear to affect brain health through antioxidant, antiinflammatory, and nutrigenomic influences. Other mechanisms are also plausible. Examples of these foods include onion, ginger, turmeric, oregano, sage, rosemary, and garlic. In a study on sulforaphane treatment of autism spectrum disorder (ASD) by Singh et al (2014), participants receiving sulforaphane, a broccoli seed extract, had improvement in social interaction, abnormal behavior, and verbal communication. Sulforaphane, which showed negligible toxicity, was selected because it upregulates genes that protect aerobic cells against oxidative stress, inflammation, and

DNA damage, all of which are prominent and possibly mechanistic characteristics of ASD (see Chapter 43). It is plausible that benefits could also be obtained by including more cruciferous vegetables, like broccoli, Brussels sprouts, and cabbage, in the diet (Panjwani et al, 2018).

Nutritional Supplements

People experiencing cognitive and mood dysfunction or psychosis often have difficulty maintaining a healthy diet despite guidance (Davison and Kaplan, 2011). When optimal nutrient levels are not obtained through the diet, a multivitamin may be a reasonable solution.

There are hundreds of psychiatric disorders, which fall into general categories as shown in Table 40.2.

TABLE 40.2 Medical Nutrition Therapy (MNT) for Psychiatric Disorders

A psychiatric diagnosis is based on symptoms observed or reported. A psychoanalytic diagnosis involves the etiology and meaning of symptoms. *The Diagnostic and Statistical Manual of Mental Disorders*, fifth edition (DSM-5), is used by both groups of mental health professionals.

There are hundreds of psychiatric disorders, which fall into the 13 categories below.

MNT therapy for psychiatric disorders requires a nutritional assessment, which takes into account the following:

1. Increase or decrease in appetite
2. Increase or decrease in activity level and therefore calorie requirements
3. Use of medications which cause dry mouth, thirst, constipation, and fluctuations in weight
4. Decrease in ability to concentrate, understand, and follow directions
5. Altered nutritional needs due to use of alcohol, drugs, or tobacco
6. Possible decrease in ability for self-care such as adequate income, shopping, meal preparation
7. History of comorbid conditions that may have resulted in suboptimal or deficient nutritional intake
8. Use of food or nutrition supplements as the “magic answer” in therapy

Psychiatric

Disorder	Description	Examples	Nutrition Strategies
Adjustment disorders	A group of symptoms, such as stress, feeling sad or hopeless, and physical symptoms that can occur after a stressful life event. Difficulty coping can result in a stronger reaction than expected for the type of event that occurred.	Sadness, hopelessness, worry, anxiety, excessive crying.	Small, concrete steps and goals. Assess physical symptoms and changes (fatigue, diarrhea, activity level, etc.)
Anxiety disorders	Worry and fear are constant and overwhelming and can be crippling. Anxiety can cause such distress that it interferes with a person's ability to lead a normal life.	Includes generalized anxiety disorder, panic disorder, obsessive-compulsive disorder, social anxiety disorder, post-traumatic stress disorder (PTSD), and specific phobias.	Reassurance and verbal reward for successes. Gradual changes. Use healthy comfort foods. Support blood sugar stability.
Associative disorders	Escape from reality in ways that are involuntary and unhealthy; experience of disconnection and lack of continuity between thoughts, memories, surroundings, actions, and identity.	Symptoms include amnesia and not remembering previous alternate identities.	Support healthy food choices that provide balanced nutrition. Emphasize colorful foods and including all food groups. Omit foods with negative associations.
Eating disorders	A group of serious conditions in which preoccupation with food and weight results in focus on little else. Eating disorders can cause serious physical problems and can even be life-threatening (see Chapter 22).	Includes anorexia nervosa, bulimia, and binge-eating disorders.	Support good food choices already in place. Enlist individual in goal-setting. Encourage use of multivitamin/mineral supplement. Include moderate activity level and social eating.

TABLE 40.2 Medical Nutrition Therapy (MNT) for Psychiatric Disorders—cont'd

Psychiatric Disorder	Description	Examples	Nutrition Strategies
Impulse control disorders (ICDs)	Repetitive or compulsive engagement in a specific behavior (e.g., gambling, hair-pulling) despite adverse consequences, diminished control over the problematic behavior, and tension, or urge state before engagement in the behavior.	Includes pathologic gambling, kleptomania, pyromania, and intermittent explosive disorder. Criteria for other ICDs (compulsive shopping, problematic Internet use, compulsive sexual behavior, and compulsive skin picking) are currently under consideration.	Steer away from overfocus on a single goal. Encourage variety in food choices. Moderate a regular schedule of meals and snacks.
Mood disorders	A general emotional state or mood that is distorted or inconsistent with the circumstances.	Includes: Major depressive disorder —prolonged and persistent periods of extreme sadness Bipolar I and II disorders —also called manic depression or bipolar affective disorders Seasonal affective disorder (SAD) —a form of depression associated with fewer hours of daylight Cyclothymic disorder —emotional ups and downs; less extreme than bipolar disorder Premenstrual dysphoric disorder —mood changes and irritability that occur during a woman's premenstrual phase and go away with the onset of menses Persistent depressive disorder (dysthymia) —a long-term (chronic) form of depression Disruptive mood dysregulation disorder —chronic, severe, and persistent irritability in children, often includes frequent temper outbursts that are inconsistent with the child's developmental age	Inquire about history of weight changes. Ensure adequate folate, B ₁₂ , and omega-3 fatty acid intake. Encourage regular, simple meals and snacks that help maintain healthy blood sugar levels. Detailed planning. Social eating if possible. Bipolar: Assess for consistent fluid and sodium intake. Include plan for social activity and exercise.
Personality disorders	A class of mental disorders characterized by long-term rigid patterns of thought and behavior that deviate markedly from the expectations of the culture. They can cause serious problems and impairment of function.	Includes: behavioral pattern that causes significant distress or impairment in personal, social, or occupational situations. Similar situations do not affect most people's daily functioning to the same degree.	Flexible/variety of food and beverage choices (provide options to give the patient freedom to choose). Flexible eating times.
Psychotic disorders	Serious illnesses that affect the mind and alter a person's ability to think clearly, make good judgments, respond emotionally, communicate effectively, understand reality, and behave appropriately.	Includes: Schizophrenia —symptoms such as hallucinations and difficulty staying in touch with reality. Often unable to meet the ordinary demands of daily life. Schizoaffective disorder —symptoms of schizophrenia and a mood disorder.	Social eating. Simple meals. Give shopping guidelines and healthy snack ideas. Assess for potential metabolic syndrome. Assess for excess supplement use or water intake.
Sexual dysfunction	Inability to fully enjoy sexual intercourse; disorders that interfere with a full sexual response cycle rarely threaten physical health, but can take a heavy psychological toll, bringing on depression, anxiety, and debilitating feelings of inadequacy.		Support adequate nutrition for healthy physical function. Mediterranean diet may be supportive for vascular function.

Continued

TABLE 40.2 Medical Nutrition Therapy (MNT) for Psychiatric Disorders—cont'd

Psychiatric Disorder	Description	Examples	Nutrition Strategies
Sexual disorders	Disorders involving sexual functioning, desire, or performance, must cause marked distress or interpersonal difficulty to rate as disorder.	Diagnosis made only when the situation persists, caused at least in part by psychological factors; could occur occasionally or be caused by a temporary factor such as fatigue, sickness, alcohol, or drugs.	Healthy balanced diet to support physical function.
Sleep disorders	Disorders involving changes in sleeping patterns or habits. Signs and symptoms include excessive daytime sleepiness, irregular breathing or increased movement during sleep, difficulty sleeping, and abnormal sleep behaviors.	Includes insomnia, sleep apnea, restless leg syndrome, and narcolepsy.	Food record with times of eating to increase awareness and presence of night eating syndrome. Meet iron requirements.
Somatoform disorders	A group of disorders characterized by thoughts, feelings, or behaviors related to somatic (physical) symptoms, and are excessive for any medical disorder that may be present.	May accompany anxiety disorders and mood disorders, which commonly produce physical symptoms. Somatic symptoms improve with successful treatment of the anxiety or mood disorder.	Review physical symptoms and changes in frequency and severity (abdominal pain, diarrhea, constipation). Eating for comfort.
Substance disorders	Distinct, independent, co-occurring mental disorders, in that all or most of the psychiatric symptoms are the direct result of substance use.	Symptoms of substance-induced disorders go from mild anxiety and depression (the most common across all substances) to full-blown manic and other psychotic reactions (much less common). Psychotic symptoms can be caused by heavy and long-term amphetamine abuse. Dementia (problems with memory, concentration, and problem solving) may result from using substances directly toxic to the brain, which commonly include alcohol, inhalants like gasoline, and amphetamines.	Calculate calories from alcohol, mg of caffeine intake; % of calories from sugar and sweets to increase client awareness and track progress. Moderate goals. Gradual changes. Encourage use of vitamin/mineral supplements (and thiamin in particular for alcoholism). Assess history of irregular food intake and weight changes.

ADDICTION AND SUBSTANCE ABUSE

Addiction is defined as the persistent compulsive use of a substance known by the user to be physically, psychologically, or socially harmful. Addiction to alcohol, or **alcoholism**, and other substances results in compulsive and relapsing behavior. Addiction may be accompanied by depression or anxiety.

Successful treatment requires attention to the contribution of nutrition in the perpetuation of and recovery from addiction. Addictions may result in poor appetite, craving for sugar and sweets, constipation, and lack of motivation to prepare meals. Poor nutritional status may result from primary malnutrition from insufficient food or nutrient intake, or secondary malnutrition due to alteration in absorption, digestion, metabolism, or excretion of nutrients.

Addiction involves numerous neurotransmitters. The master pleasure molecule, which links and involves most forms of addiction, is **dopamine**. Its production is triggered by use of heroin, amphetamines, marijuana, alcohol, nicotine, cocaine, and caffeine or the activities of gambling or sex. Compulsive eating behavior may be linked to the same reward system. Other neurotransmitters demonstrated to be

involved in addiction include serotonin and glutamate. Nutritional derangements associated with addiction may be severe and can perpetuate addiction, or intensify addiction-related health problems, and make recovery a more difficult process.

Screening for Alcoholism

A moderate intake is defined as no more than two drinks a day for men or one drink a day for women ([Centers for Disease Control and Prevention \[CDC\], 2014](#)). Individuals with intakes larger than this should be assessed using a validated screening tool for alcoholism. One such tool is the Alcohol Use Disorders Identification Test (AUDIT) developed by the WHO and available at their website.

The CAGE questionnaire was commonly used as a screening and evaluation tool for alcoholism ([Box 40.3](#)) but has been largely replaced by the AUDIT screening instrument due to its improved sensitivity and specificity. The AUDIT tool is a simple way to screen and identify people at risk of alcohol problems ([Box 40.4](#)).

Pathophysiology

In some research on alcohol consumption, light drinking has been shown to be good for the heart and circulatory system and protective

against type 2 diabetes and gallstones. However, no level of alcohol consumption has been shown to improve health and reduce all-cause mortality (Burton et al, 2018), thus the only way to minimize health loss is with zero consumption. Heavy drinking is a major cause of preventable death in most countries; it is implicated in about half of fatal traffic accidents in the United States. Heavy drinking can damage the liver and heart, harm an unborn child, increase the

chances of developing breast and some other cancers, contribute to depression and violence, and interfere with relationships. When alcohol begins to create problems, and especially when one denies these issues or cannot change the course of them, alcohol addiction must be considered.

Nutrient deficiencies can exacerbate these negative consequences of chronic alcohol consumption:

1. Deficiency of vitamin B₁ can trigger confusion and psychosis (called Wernicke encephalopathy; see Chapter 28)
2. Magnesium deficiency may aggravate withdrawal symptoms such as delirium tremens (DTs) and cardiac arrhythmias. Red blood cell (RBC) magnesium levels are more useful in assessment than serum magnesium levels, which may remain normal even with severe magnesium deficiency. Because magnesium deficiency is so common in alcoholics, deficiency should be presumed to be present.
3. Malnutrition, malabsorption, gastritis, and chronic diarrhea (see Chapters 26 and 27)
4. Hepatitis and cirrhosis (see Chapter 28)
5. Cardiomyopathy (see Chapter 32)
6. Bone marrow disorders
7. Neuropathy, which is also associated with B₁₂ deficiency, and dementias

BOX 40.3 CAGE Questionnaire for Assessing Alcohol Use

Have you ever felt you should **C**ut down on your drinking?
 Have people **A**nnoyed you by criticizing your drinking?
 Have you ever felt bad or **G**uilty about your drinking?
 Have you ever had a drink first thing in the morning to steady your nerves or to get rid of a hangover (**E**ye opener)?

Item responses on the CAGE are scored 0 or 1, with a higher score as an indication of alcohol problems. A total score of 2 or greater is considered clinically significant.

Ewing JA: Detecting alcoholism. The CAGE questionnaire, *JAMA* 252:1905, 1984.

BOX 40.4 Alcohol Use Disorders Identification Test (AUDIT) Instrument

1. How often do you have a drink containing alcohol?
 - (1) Never (skip to questions 9 and 10)
 - (2) Monthly or less
 - (3) 2 to 4 times a month
 - (4) 2 to 3 times a week
 - (5) 4 or more times a week
2. How many drinks containing alcohol do you have on a typical day when you are drinking?
 - (1) 1 or 2
 - (2) 3 or 4
 - (3) 5 or 6
 - (4) 7, 8, or 9
 - (5) 10 or more
3. How often do you have six or more drinks on one occasion?
 - (1) Never
 - (2) Less than monthly
 - (3) Monthly
 - (4) Weekly
 - (5) Daily or almost daily
4. How often during the last year have you found that you were not able to stop drinking once you had started?
 - (1) Never
 - (2) Less than monthly
 - (3) Monthly
 - (4) Weekly
 - (5) Daily or almost daily
5. How often during the last year have you failed to do what was normally expected from you because of drinking?
 - (1) Never
 - (2) Less than monthly
 - (3) Monthly
 - (4) Weekly
 - (5) Daily or almost daily
6. How often during the last year have you been unable to remember what happened the night before because you had been drinking?
 - (1) Never
 - (2) Less than monthly
 - (3) Monthly
 - (4) Weekly
 - (5) Daily or almost daily
7. How often during the last year have you needed an alcoholic drink first thing in the morning to get yourself going after a night of heavy drinking?
 - (1) Never
 - (2) Less than monthly
 - (3) Monthly
 - (4) Weekly
 - (5) Daily or almost daily
8. How often during the last year have you had a feeling of guilt or remorse after drinking?
 - (1) Never
 - (2) Less than monthly
 - (3) Monthly
 - (4) Weekly
 - (5) Daily or almost daily
9. Have you or someone else been injured as a result of your drinking?
 - (1) No
 - (2) Yes, but not in the last year
 - (3) Yes, during the last year
10. Has a relative, friend, doctor, or another health professional expressed concern about your drinking or suggested you cut down?
 - (1) No
 - (2) Yes, but not in the last year
 - (3) Yes, during the last year

Add up the points associated with answers. A total score of 8 or more indicates harmful drinking behavior.

Medical Management

The science of treating addictions has evolved considerably. Treatment has progressed from viewing addiction as a character flaw or sign of weakness to thinking of addiction as a chronic brain disorder that results from genetic and environmental inputs.

Any patient or client with active substance abuse issues may be presumed to have nutritional deficiencies. It may be useful to do nutritional testing, especially to document the more dangerous conditions such as thiamin deficiency (see Chapter 5). However, in an acute setting it is critical and may even be lifesaving to presume that B vitamin and magnesium deficiencies are present and treat them rather than wait for laboratory results.

Medical Nutrition Therapy

Medical nutritional therapy for addictions should be individualized, taking into account the current nutritional status of the patient. Some may be homeless and clearly malnourished, whereas others may have less visible deficiencies. Special attention must be given to B vitamins, magnesium, and amino acid deficiencies (see Chapter 5). When possible, the best approach is to evaluate each patient for deficiencies through blood work and then replete as needed or assume poor nutritional status and provide a broad multivitamin/mineral supplement and a diet containing high-quality protein and fats. When gastritis or other intestinal problems are evident, these must be treated to allow for adequate digestion and absorption of nutrients.

Providing adequate levels of amino acids, B vitamins, minerals, and omega-3 fatty acids generally stabilizes function in a patient dealing with addiction of any kind. As seen with many psychiatric disorders, magnesium and NAC are also very helpful in addiction recovery (Bondi et al, 2014; McClure et al, 2014).

Finally, educating addicts about brain function and nutrition enhances their ability to participate successfully in a recovery program, and empowers them to make healthy choices while also understanding the mechanism of addiction (Box 40.5).

ANXIETY

Anxiety disorders are the most common mental illness in the United States (National Institute of Mental Health [NIMH], 2017). According

BOX 40.5 Summary of Medical Nutrition Therapy for Substance Abuse

If warranted by history, assess for high-risk alcohol consumption.
 Assess appetite, GI function including nausea, and potential changes in food consumption.
 Assess oral health, missing teeth, and chewing ability.
 Start multivitamin-mineral supplement; recommend use for 6 months.
 Recommend supplement of omega-3 fatty acids: 800 to 1000 mg/day.
 Recommend biochemical assessment of thiamin, iron, folic acid, magnesium, selenium.
 Recommend 25% to 30% of calories in diet from high quality protein.
 Nutritionally adequate diet (moderate intake of up to 300-450 mg caffeine, moderate use of desserts to mediate withdrawal, moderate fiber and adequate fluid intake, inclusion of dairy foods).
 Recommend nutrition education group as early as possible during withdrawal.

Reference: Weiss, D: *Nutrition interventions in addiction recovery: the role of the dietitian in substance abuse treatment*. Webinar, September 25, 2013.

to the CDC, the prevalence rates for anxiety disorder in developed countries range from 13.6% to 28.8% of the population and are higher in developed nations than in developing nations. The underlying etiology of anxiety is not well understood. Different forms of anxiety include generalized anxiety disorder (GAD), panic disorder, obsessive compulsive disorder (OCD), posttraumatic stress disorder (PTSD), and social anxiety disorder (see Table 40.2). Common to all these disorders are heightened and poorly controlled emotional, somatic, and neurologic symptoms triggered by a specific type of circumstance or situation, such as an **adverse childhood experience (ACE)**, death or divorce, substance abuse, military combat, and emotional, physical, or sexual abuse or, in the case of GAD, not related to any specific trigger.

Etiology

At one level, **anxiety** expressed as a heightened awareness of one's surroundings and of potential danger can be seen as an evolutionary advantage in terms of dealing with threats. However, when this mechanism becomes pervasive and debilitating, it moves into the realm of pathology.

There is a clear genetic component to anxiety. The stress of an ACE can also constitute a significant etiologic factor for anxiety that may impact the individual into and throughout adulthood. It is felt that the anxiety and panic response becomes "hard-wired" at an early age that create hormonal and brain patterns that become entrenched.

Pathophysiology

The structure in the brain thought to generate anxiety is the **amygdala** (the threat center), which processes fear-related stimuli and then signals other parts of the brain (especially the locus ceruleus) to fire and release norepinephrine; corticotropin-releasing factor (CRF), which ultimately stimulates elevated cortisol levels; and other excitatory components of the sympathetic nervous system. Glutamate is being recognized as playing an increasing role in anxiety disorders (as well as in depression) and is a target for pharmacologic and nonpharmacologic treatment (European College of Neuropsychopharmacology, 2013).

Difficult life circumstances that provoke stress can exacerbate underlying anxiety disorders and may be helpful to address with counseling. These can include marital and relationship stress, job stress, grief, and physiologic stressors such as sleep disorders, menopause, thyroid disease, and food allergies. Hormonal imbalances, including high or low thyroid, low progesterone, and high or low testosterone levels, can also trigger anxiety. Anxiety can be a presenting complaint of perimenopause and of high or low cortisol levels, reflecting adrenal gland dysfunction.

Anxiety provokes physical and emotional symptoms, including rapid heart rate, shallow breathing, diaphoresis, hypervigilance, and sleep disorders. It can be difficult at first to diagnose anxiety because patients present with multiple somatic complaints, and only after somatic pathology is ruled out can a diagnosis of anxiety disorder be established.

Medical Management

The primary pharmacologic therapy for anxiety disorders includes benzodiazepines, selective serotonin reuptake inhibitors (SSRIs), and norepinephrine reuptake inhibitors. Medications used primarily for other conditions can be useful in the treatment of anxiety, such as gabapentin, buspirone, and antipsychotic medications. Each of these can be effective but not for everyone. Each of these treatments carries the potential for side effects.

Medical Nutritional Therapy

Nutritional therapies that target the underlying metabolic causes of anxiety can be effective. Blood sugar imbalance or being hungry can trigger anxiety and should be suspected if anxiety symptoms are worse in the late morning or afternoon (i.e., after several hours without food). Eating smaller, balanced meals and maintaining routine meal-times is recommended.

Nutritional deficiencies may be present, especially of vitamin D (Armstrong et al, 2007), B vitamins, and magnesium. Magnesium deficiency can cause anxiety, and anxiety also can cause increased magnesium losses. In hospitalized patients, parenteral magnesium (e.g., 2 g IV over 1 hour, then 1 g per hour for 1 to 3 days) significantly decreased severe anxiety and agitation in agitated psychiatric inpatients. A multivitamin with 100 mg magnesium and high-dose B vitamins was shown to decrease anxiety in a placebo-controlled study. Treatment with B vitamins has also been shown to improve anxiety whether or not deficiency was present (Gaby, 2011). Box 40.6 presents medical nutrition therapy (MNT) and herbal support for anxiety management.

A recent study that included 445 healthy females showed that higher intake of fermented foods that contain probiotics such as yogurt, kefir, pickles, and other lactofermented vegetables may be protective against social anxiety symptoms and neuroticism (Hilimire et al, 2015). Participants were asked to think about their food intake over the past 30 days and indicate how many of certain fermented foods they consumed. “High” and “low” consumption groups were calculated as one standard deviation below and above the mean (9.91 ± 24.51). High consumption of fruits and vegetables as well as exercise frequency were also negatively correlated with social anxiety.

Dietary intake that supports the synthesis of neurotransmitters may also help alleviate anxiety. For example, deficiencies in L-tryptophan, L-phenylalanine, or L-tyrosine, the important building blocks of serotonin, are associated with anxiety (Alramadhan et al, 2012).

Integrative therapies such as meditation, mindfulness, and yoga may also be helpful.

BIPOLAR DISORDER

This is also called bipolar affective disorder and was previously called manic depressive disorder. “Mood Disorders” in the *DSM-IV* has been replaced with separate sections for depressive disorders and bipolar disorders. Bipolar disorder is placed between the psychotic disorders and the depressive disorders in the *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)*, “in recognition of its place as a bridge between the two diagnostic classes in terms of symptomatology, family history and genetics” (Parker, 2014). The criteria for the major psychotic disorders and mood disorders are largely unchanged in the *DSM-5*.

Bipolar disorder is a disorder in which people experience episodes of an elevated or agitated mood known as mania alternating with episodes of depression. The NIMH reports the 12-month prevalence of bipolar disorder in the U.S. adult population is approximately 2.8% and the lifetime prevalence is about 4.4%. The average age of onset is 25 years (NIMH, 2017). There is a genetic component, but other factors, including hormones, neurotransmitter abnormalities, and stress, are likely to be factors in triggering this illness.

BOX 40.6 Medical Nutrition Therapy for Management of Anxiety

- Assess for vitamin D, magnesium, and B vitamin, and essential fatty acid status (see Chapter 5).
Eliminating caffeine for 3 to 4 weeks is recommended to see if anxiety decreases. Warn about withdrawal symptoms for 7 to 10 days, including headaches. Cutting intake in half every 4 to 7 days may avoid this. Switching from coffee to green tea can also be helpful as it has less caffeine and contains theanine, a calming amino acid. Anxiety may be triggered by low doses of caffeine (the amounts in decaffeinated coffee); a switch to caffeine-free teas may be necessary.
- Ensure regular meals with protein and low glycemic carbohydrates to promote stable blood sugar.
- Consider adding in a multivitamin (MVI) if dietary intake does not meet the dietary reference intake (DRI) for folate, B₁₂, zinc, magnesium, and vitamin D.

Integrative Therapies for Anxiety

- **GABA:** Deficiency of the neurotransmitter gamma-aminobutyric acid (GABA) is associated with anxiety, with GABA being a primary counterbalance for excitatory neurotransmitters (Möhler, 2012).
- **Inositol:** Inositol can be helpful in treating anxiety and panic disorders and is very safe. In high doses it may be valuable in controlling several other mental health disorders, including panic disorder, obsessive compulsive disorder, agoraphobia, and depression.
- **Kava:** Kava has a long history of use for treatment of anxiety at doses of 120–280 mg kavalactones. Safe for short term use (4–8 weeks). Caution in those with liver disease (Sarris, 2018).
- **Lavender:** The smell of lavender is calming, so keeping a vase full of lavender flowers (even dried) around or using a lavender oil spray can be helpful.

In addition, taking a lavender capsule can be calming and reduce the need for tranquilizers (Woelk and Schläfke, 2010).

- **Magnolia:** Magnolia bark has a long history of use in traditional Chinese formulas that relieve both anxiety and depression without the feeling of sedation (Talbot et al, 2013).
- **Passionflower extract:** Doses of 100 to 500 mg 1 to 4 times per day can be helpful (Movafegh et al, 2008).
- **Theanine:** Theanine is derived from green tea. Doses of 200 mg 1 to 2 times per day are helpful (Unno et al, 2013). L-theanine is involved in the formation of the calming neurotransmitter GABA and also stimulates the release of serotonin and dopamine.

Pathophysiology

Symptoms occur with different levels of severity. At milder levels of mania, known as hypomania, individuals appear energetic, excitable, and may be highly productive. As mania becomes more severe, individuals begin to behave erratically and impulsively, and may have great difficulty with sleep. Behavior may include alcohol abuse, sexual indiscretion, and excessive spending. Eating disorders are a potential comorbidity. The manic phase may result in difficulty in planning and preparing food.

During the depressed phase, 25% to 50% of patients attempt suicide. At the most severe level, individuals can experience psychosis. **Bipolar disorder** has recently been subdivided into bipolar I (involving cycles of severe mood episodes from mania to depression) and bipolar II (in which milder episodes of mania are mixed with bouts of severe depression) (see Table 40.2). Some individuals experience a mixed state in which features of mania and depression are present at the same time. Manic and depressive episodes last from a few days to several months.

Medical Management

A number of medications are used with varying degrees of success. Medical treatment of bipolar disease is complex and requires frequent monitoring by skilled clinicians. Lithium, a classic treatment, is considered benign when used as lithium orotate at low doses (e.g., 5 mg a day), but when used at high doses as lithium carbonate can cause marked toxicity, including hypothyroidism, renal toxicity, and tremor. Lithium carbonate has a narrow therapeutic index; there is not a large difference between a toxic and therapeutic dose, and blood levels must be closely observed. Other medications used to treat bipolar disorder are mood stabilizers, benzodiazepines, and antipsychotic medications.

The presence of MTHFR reductase genetic mutations should be determined. Some genetic mutations associated with a higher risk of bipolar disorder respond to nutritional treatments of methyl folate (5-MTHF) and methylated B₁₂.

Medical Nutritional Therapy

Lithium and sodium are similar in chemical binding; therefore a stable, moderate, intake of salt (sodium) is necessary to help stabilize lithium levels. Providing dietary guidance based on the Dietary Approaches to Stop Hypertension (DASH) diet may be helpful (see Appendix 17).

Many people starting a course of lithium experience significant dose-dependent weight gain, often resulting in noncompliance with medication. Other side effects that may affect nutritional status include increased thirst, nausea, vomiting, and diarrhea. The usual daily intake of lithium from the diet is 0.65 to 3.1 mg/day (Kapusta et al, 2011).

New information relates bipolar disorder to mitochondrial dysfunction, which leads the possibility of treating bipolar disease with mitochondrial modulators such as coenzyme Q₁₀, NAC, acetyl-L-carnitine (ALCAR), S-adenosyl-L-methionine (SAMe), **alpha-lipoic acid**, creatine monohydrate, and melatonin (Forester et al, 2015; Nierenberg et al, 2013). This suggests disruption of brain energy metabolism and its relationship to mood disorders and psychiatric disease.

Adequate intake of omega-3 fatty acid may also be important in treatment of bipolar disorder and can be obtained in the diet from deep sea fish or a supplement (Saunders et al, 2016).

Iron excess is also associated with an increased risk of bipolar disorder, so screening of serum ferritin level is warranted to ensure that it

is within normal range (Serata et al, 2012). Evaluation in general for mineral and trace element deficiencies is warranted.

As with other mood and psychiatric disorders, the presence of celiac disease or gluten sensitivity should be considered (Dickerson et al, 2011). In nonceliac gluten sensitivity (NCGS), serum and intestinal signs may be absent, but clinical symptoms are reported, and clear within a few days of starting a gluten-free diet. Emerging scientific literature contains several reports linking gluten sensitivity states with neuropsychiatric manifestations including autism, schizophrenia, and ataxia (Genius and Lobo, 2014).

DEMENTIA AND ALZHEIMER'S DISEASE

Mild cognitive impairment (MCI) is an intermediate stage between the expected cognitive decline of normal aging and the more serious decline of dementia. It can involve problems with memory, language, thinking, and judgment that are greater than normal age-related changes.

Dementia represents a serious loss of cognitive ability characterized by memory loss. It may be stable and nonprogressive, as may occur after brain injuries, or it may be progressive, resulting in long-term decline due to damage or disease in the body. Two of the most common causes are **Alzheimer's disease (AD)** and vascular disease (called multiinfarct dementia). Other less frequent causes are PD and Lewy body dementia.

Three and a half million Americans have **vascular dementia** caused by poor circulation to the brain and multiple ministrokes that are also called transient ischemic attacks (TIAs). It is the second leading cause of dementia in Western countries. This syndrome can result from (1) atherosclerotic vascular disease, (2) an embolism usually from the heart due to vascular or arrhythmic disease, (3) poorly controlled hypertension, or (4) an increased tendency to clotting for reasons either inherited or acquired. Recognition of vascular dementia with AD is often delayed until the syndrome is far into its course. Vascular dementia should be considered if the progression of the cognitive dysfunction has progressed in discrete steps, each representing another ministroke.

AD affects an estimated 5.8 million Americans (Alzheimer's Association, 2019). AD is the sixth leading cause of death in the United States and prevalence is increasing at a faster rate than other chronic diseases. For example, whereas deaths from heart disease decreased by 8.9% between 2000 and 2017, deaths from AD increased by 145% (Fig. 40.2). Data from the Framingham Heart Study showed the lifetime risk for AD is about 1 in 10 for men and 1 in 5 for women. See Fig. 40.3 for details. Late-onset AD or LOAD accounts for the large majority of AD cases whereas early-onset, occurring in people ages 30 to 60 years, represents less than 5%. Like other chronic diseases, AD develops as a result of multiple factors. AD appears to be more prevalent in Western countries.

The most proven risk factor for AD is advanced age. Other non-modifiable risk factors that are associated with higher risk include a positive family history of AD, the presence of the APOE-e4 allele and other genetic risk variants, female gender, and Down's syndrome. Modifiable risk factors include cardiovascular disease risk factors such as hypertension, diabetes, obesity during midlife, and smoking; high amounts of alcohol use; traumatic brain injury; and low educational level. Recent research also links the oxidative stress of air pollution to AD risk (Chen et al, 2017).

Currently AD is incurable. As drug trials for treatment of AD have proven mostly unsuccessful, researchers are turning their focus to prevention as a promising strategy for combating this disease. The pathophysiological changes in the brain associated with AD begin 20 or more years before symptoms appear, providing opportunity for

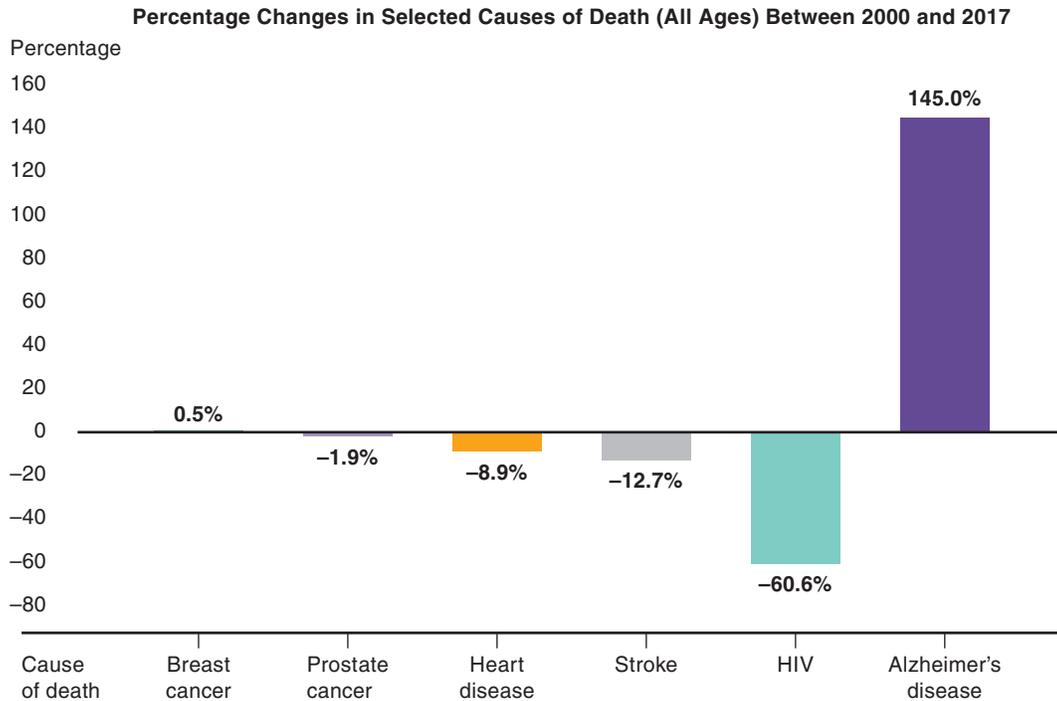

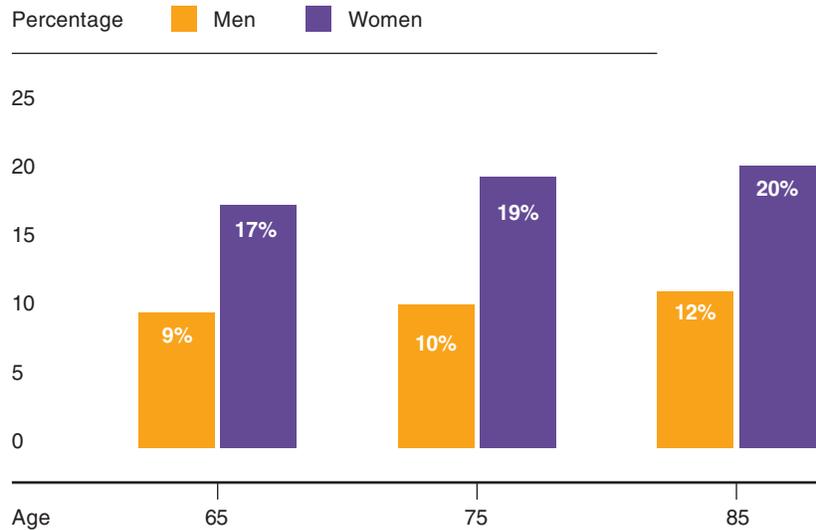

Fig. 40.2 Percentage change in causes of death (all ages) 2000 to 2017. Adapted from Alzheimer's Association, Factors and Figures Report.

Created from data from Seshadri et al.

Fig. 40.3 Estimated lifetime risk for Alzheimer's by age and sex, from the Framingham Study. Adapted from Seshadri, et al: Lifetime risk of dementia and Alzheimer's disease: the impact of mortality on risk estimates in the Framingham Study. *Neurology* 49(6), 1997. <https://n.neurology.org/content/49/6/1498>

lifestyle modification for slowing the progression of and/or preventing AD. Factors that may be protective against AD include physical activity, social engagement, and cognitive training. The role of diet and nutrition in AD prevention and treatment is an active and promising area of research.

Pathophysiology

AD is associated with loss of neurons, characterized by microscopic changes in the brain that include deposition of amyloid plaques, tau

proteins, and neurofibrillary tangles. The only definitive test for diagnosing AD is a brain biopsy, which, appropriately, is not done. For evaluating dementia the American Academy of Neurology recommends structural neuroimaging, which may include computed tomography (CT) or magnetic resonance imaging (MRI), and screening for depression, vitamin B₁₂ deficiency, and hypothyroidism. A recent study demonstrated potential use of a blood test for 10 lipids (eight phosphatidylcholines and two acetyl-L-carnitines) as the best combination lipid blood test panel. A sample of peripheral blood predicted with

more than 90% accuracy the development of either amnesic MCI or AD within a 2- or 3-year time frame (Mapstone et al, 2014).

Medical Management

Only half of people with dementia seen by physicians in general practice receive even the basic workup discussed earlier. In only 35% is the correct cause of the dementia determined, and these workups are generally conducted in higher level (secondary care) hospital settings.

A study of autopsies showed that in half the people who had been diagnosed with AD, AD was not seen on their brain biopsy. Rather, they had other causes of dementia that were missed (White, 2011). Although problematic, this also suggests that by looking for and treating nutritional and other issues, function may be improved—sometimes markedly.

Even small changes in brain function can make the difference between being able to care for oneself versus not recognizing one's children. People with dementia can have marked day-to-day fluctuations in cognition. Several types of treatment, including nutritional support and attention to adequate hydration, may significantly improve cognitive function.

It is critical that the practitioner always consider the possible presence of a treatable condition when evaluating a patient for dementia. Examples of treatable and even reversible causes of cognitive decline and memory loss include hormonal imbalances, brain tumors, infections, nutritional deficiencies (e.g., folate and vitamin B₁₂), and the side effects of numerous medications.

It is also important to distinguish between normal fluctuations in mental function and dementia. AD is not when one keeps forgetting where one left the keys, it is when one forgets how to use the keys. Hospitalization can result in poor sleep, loss of routine and familiar surroundings, loss of freedom to make choices, treatment with strong psychoactive medications, and poor diet (e.g., being kept repeatedly nothing by mouth [NPO] for tests, or dietary restrictions from acute illness). This can trigger disorientation that can be confused with dementia. Getting the person into familiar surroundings as quickly as possible, off psychoactive medications, and eating a nutritious diet are important keys to treatment. Other factors may also optimize cognitive function (Box 40.7).

BOX 40.7 Optimizing Cognition in DEMENTIA

Drugs: Wean the person off drugs that are not essential. Being on 10-15 drugs (polypharmacy) is not uncommon in the elderly and can result in abnormal behavior. Anticholinergic medications are especially problematic.

Emotional: Rule out depression and encourage adequate sleep. Nutritional support with favorite foods and comfort foods. Often sweets are preferred.

Metabolic: Levels of hormones should be corrected when possible. Making sure that the person is getting at least the 150 mcg recommended dietary allowance (RDA) of iodine a day is important for maintaining optimal thyroid function (Carcaillon, 2013; Tan et al, 2008) (see Chapter 30).

Ears and eyes: Hearing and vision loss can mimic dementia.

Nutrition: Optimize nutritional intake.

Tumors and other brain lesions: A magnetic resonance imaging (MRI) or computed tomography (CT) scan is appropriate if one is diagnosed with dementia.

Infections: Silent urine and sinus infections can impair mental function.

Anemia, diabetes, and other overt medical problems should be assessed for and treated.

Carcaillon L, et al: Low testosterone and the risk of dementia in elderly men: impact of age and education, *Alzheimers Dement* 10(Suppl 5):S306, 2014; Tan ZS, et al: Thyroid function and the risk of Alzheimer disease: the Framingham study, *Arch Intern Med* 168:1514, 2008.

The medical management of vascular dementia involves decreasing or eliminating further vascular insults to the brain. Treatment may include using aspirin, cholesterol, and blood pressure–lowering agents, and medically managing heart disease when present.

The medical therapies available for AD do not cure nor reverse the disease, though they may help reduce the severity of symptoms and/or slow progression of AD. Therapies are currently limited to (1) acetylcholinesterase inhibitors such as donepezil (Aricept) and rivastigmine tartrate (Exelon), aimed at maintaining levels of acetylcholine in the brain, and (2) memantine (Namenda), an N-methyl-D-aspartate (NMDA) receptor antagonist aimed at reducing glutamate activity, which is excitatory and destructive of brain tissue. Some benefit can be gained from combining these two classes of drugs. Although these medications are generally well tolerated and can modestly slow progression, they often do little to improve symptoms day to day.

Medically managing diabetes and insulin resistance is critical to delaying progression of dementia of any type. Hyper- and hypoglycemia, as well as unchecked insulin resistance, can cause damage to brain structures (Northam and Cameron, 2013) (see *New Directions: Insulin Resistance in AD and the SNIFF Study* [Schiöth et al, 2012]).

NEW DIRECTIONS

Insulin Resistance in AD and the SNIFF Study

Severe insulin resistance in some areas of the brain is present in AD. Brain tissue is one of the few tissues outside of the pancreas that produces insulin, and glucose is the fuel brain cells commonly use. If insulin resistance is present, glucose cannot enter brain cells and the cells essentially starve and cannot function, unless they switch to using ketones for fuel. This suggests that treatment of insulin resistance and metabolic syndrome may be useful in the prevention of or slowing the progression of AD (Willette et al, 2015).

This makes exercise, avoiding excess sugar and saturated fats, and increasing fiber intake especially important. Even just 4 weeks of cutting back on sugar and saturated fats was associated with increased insulin sensitivity and decreased amyloid (Hanson et al, 2013). Intranasal insulin at 10 or 20 IU two times/day is currently being tested in an Alzheimer's randomized controlled trial (the Study of Nasal Insulin to Fight Forgetfulness [SNIFF] study) (Claxton et al, 2015; Morris et al, 2014).

Increasing the level of ketones in the blood and brain may also be considered. The brain can use ketones as fuel, and the metabolism of ketones does not require insulin (Paoli et al, 2014). The role of ketones and ketogenic agents in prevention and management of AD continues to be researched (Sharma et al, 2014; see Appendix 19).

The “4 As” of AD—amnesia, aphasia, apraxia, and agnosia—point to the sequential changes in brain function, behavior, and performance that impair the individual and ultimately can make adequate nutritional intake difficult to maintain (Box 40.8). Specific techniques that take into account the brain deficits must be implemented to improve the ability to eat and enjoy food. An occupational therapist can offer assistance in a dining needs assessment.

Medical Nutritional Therapy

Recent evidence has emerged supporting the connection between dietary intake and cognitive health, particularly in regard to the aging population. A healthier diet during middle-age years (adequate amounts of B vitamins, antioxidants, PUFAs, and phytonutrients [Valls-Pedret et al, 2012]) has been associated with better cognitive function later in life. The **MIND Diet** or Mediterranean-DASH intervention for neurodegenerative delay has been found to substantially

BOX 40.8 The 4 As of Alzheimer's Dementia

Amnesia: The inability to use or retain memory, including short-term and long-term memory.

The person may constantly repeat questions such as “Where am I?” and “Who are you?” and “When are we going to eat?” or accuse the caregiver of stealing or being an imposter. This type of behavior can continue for hours at a time. This occurs due to damage to the frontal lobes and the hippocampus. This is usually the first area of change noticed by others. At this level of amnesia, the person with dementia does not look ill, so the confusion and inability to remember can appear to be purposeful and is often interpreted as just “annoying” behavior.

NUTRITIONAL IMPACT: May forget to eat, or not trust the caretaker involved in meal preparation or service.

Aphasia: The inability to use or understand language.

The loss of the ability to speak and write is called *expressive aphasia*. An individual may forget words he or she has learned and will provide a lengthy description of an item because he or she cannot find the right word. The individual may call family members by the wrong names. With *receptive aphasia*, an individual may be unable to understand spoken or written words or may read and not understand a word of what is read. Sometimes an individual pretends to understand and even nods in agreement; this is to cover up aphasia. Although individuals may not understand words and grammar, they may still understand nonverbal behavior (i.e., smiling).

NUTRITIONAL IMPACT: May not articulate wants, needs, or requests when it comes to eating.

Apraxia: The inability to use or coordinate purposeful muscle movement or coordination.

In the early stages the person may reach for an item and miss it, have difficulty catching a ball, or clapping hands. The floor may appear to be moving to this person and balance becomes affected, increasing the risk for falls and injury. In time, this loss of ability to move affects the activities of daily living (sleeping, ambulating, toileting, grooming, hygiene, dressing, and eating). In the end stage, the person is not able to properly chew or swallow food, increasing the risk of choking or aspiration. This is linked to damage to parietal lobes (pain, touch, temperature and pressure, sensory perception) and the cortex (skilled movement) and the occipital lobes.

NUTRITIONAL IMPACT: Physically unable to eat, chew, or swallow.

Agnosia: The inability to recognize people or use common objects.

The person may become lost in a familiar place because he or she doesn't recognize the items that alert us to our surroundings. He or she may confuse a fork with a spoon, a toothbrush with a hairbrush, or toothpaste with denture cream. Eventually the ability to recognize objects is lost completely. The person may also confuse a son with a husband or a father or an uncle, or a daughter may be confused with a mother or an aunt or a grandmother. This process is associated with increased damage to the frontal lobes, the occipital lobes (visual association, distance and depth perception), and the temporal lobes.

NUTRITIONAL IMPACT: May not be able to use normal eating utensils or may even forget how to feed himself or herself.

Reference: Alzheimer's Foundation of America: About Alzheimer's (website). <http://www.alzfdn.org/AboutAlzheimers/symptoms.html>, 2014.

slow cognitive decline with aging (Morris et al, 2015; see Appendices 17 and 23).

Three parameters of cognition (delayed recall, learning ability, and memory) were significantly associated with Hb A1c levels in the range of 4.3% to 6.5%, illustrating the effect of even moderate blood glucose levels (American Academy of Neurology, 2015; Kerti et al, 2013).

The metabolic consequences of a high fructose intake and a deficiency of omega-3 fatty acids on cognitive abilities was associated with insulin action, signaling mediators, and lower cognitive scores. Insulin is a vasodilator and its function is blunted in insulin-resistant individuals, which decreases cerebral circulation (Agrawal and Gomez-Pinilla, 2012; Barrett et al, 2009). Insulin resistance, the impairment of the insulin receptor signaling cascade in the hippocampus, may be accompanied by decreasing regional blood flow and reduced memory. Vasoprotective effects that include improved cerebral blood flow have been shown to be associated with a whole food-based diet (Presley et al, 2011).

Research has demonstrated that dietary factors can influence risk for AD due to their effects on vascular function, neuronal function, and **synaptic plasticity**, which is the ability of synapses to strengthen or weaken over time. Key nutrients that are being investigated for their involvement in AD pathogenesis and brain health overall include the B-vitamins folate, B₁₂, and B₆; choline; folate; iron; potassium; vitamins A, E, and D; omega-3 fatty acids, saturated fat; and cholesterol. Flavanols, polyphenols, caffeine/coffee, and curcumin are also being examined for their roles. Several of these are discussed below.

Historically, folate has been considered an important nutrient for the prevention and treatment of AD. A long-term study using data from the Baltimore Longitudinal Study of Aging, which was begun in 1958 and included more than 1400 participants, found that the participants who had intakes at or above the 400 mcg RDA for folate had a 55% reduction in the risk of developing AD (Corrada et al, 2005).

Most people who reached that level did so by taking folate supplements, which suggests that many people do not get the recommended amounts of folate in their diets. In another study adding folate at 1 mg a day to the anticholinesterase medications used in AD resulted in improved functional status (Connelly et al, 2008). Overall, multivitamins were shown to result in improvement in immediate free recall memory (Grima et al, 2012). A multivitamin, preferably with higher than RDA doses of vitamin B₁ and 400 to 1000 mcg/day of folate, is recommended. More recent studies have focused on folate's role in decreasing inflammation as the key factor in treating AD (Chen et al, 2016).

High folate levels in the presence of low vitamin B₁₂ status worsens the enzymatic functions of vitamin B₁₂, which can lead to hyperhomocysteinemia and elevated methylmalonic acid (MMA), and both are associated with cognitive impairment and decline. In a study of 10,413 older individuals (age ≥ 60 years) in the 1999–2002 NHANES, it was shown that levels of cognitive impairment increased by 4.7-fold in people with high folate levels (>32.6 nmol/L) and low vitamin B₁₂ (<19.3 nmol/L) (Selhub et al, 2007).

Inadequate levels of vitamin B₁₂ can affect the risk for cognitive decline, AD, and dementia. This problem is exacerbated by the fact that approximately 10% to 15% of elderly individuals are B₁₂ deficient (<200 pmol/L) with reduced ability to absorb vitamin B₁₂. An analysis of 549 individuals from the Framingham Heart Study cohort showed plasma B₁₂ levels between 187 and 256.8 pmol/L was predictive of cognitive decline (Morris et al, 2012). B₁₂ deficiency is known to damage the myelin sheaths that cover cranial, spinal, and peripheral nerves, which may be correlated with atrophy of gray matter brain regions especially vulnerable to AD pathogenesis. A recent study showed that supplementation of 0.8 mg/day folate, 0.5 mg/day vitamin B₁₂, and 20 mg/day vitamin B₆ over two years significantly slowed brain atrophy in these regions in individuals with MCI and raised levels of plasma

tHcy at baseline when compared to those without the supplementation regimen (Douaud et al, 2013).

Vitamin E is vital for maintaining the integrity of cell membranes. Deficiency leads to poor transmission of nerve impulses and nerve damage. Deterioration of neuronal membranes is central to AD. Adequate vitamin E may help slow progression of AD, but only when needs are met through the diet, not supplements (Morris et al, 2002). Most vitamin E supplements are synthetic alpha tocopherols, which not only increase risk of vitamin E deficiency, but do not help AD. The high levels of alpha tocopherol (more than 100 IU/day) can induce a relative deficiency of the other tocopherols. In addition, high dose vitamin E has a pro-oxidative effect, which is linked to increased mortality and incidents of heart failure. Therefore, supplementation with vitamin E, especially at doses more than 100 IU is not recommended, unless a natural mixed tocopherol is used (Usoro and Mousa, 2010).

Iron accumulation in the brain, after tau tangles and the accumulation of beta amyloid plaques, is the third hallmark of AD. Given that at any given moment the brain is using about 20% of the body's entire supply of oxygen (and up to 50% when "thinking hard") iron becomes critical for brain health. It is also released in the breakdown and repair process of myelin sheaths. In this sense, the more myelin sheath breakdown, the greater the accumulation of iron. Iron is also involved in several of the molecular steps leading to the protein deposits, beta-amyloid plaques, and tau characteristic of AD. It has been shown that brain regions most affected by AD have higher levels of ferritin, the storage form of iron in the body. Excessive levels of iron in the brain can promote free radical damage, lipid peroxidation, and cellular death. Iron levels in brain gray matter regions increase with age and are higher in people with age-related neurodegenerative disorders.

The link between iron and AD has been corroborated by nutritional genomic research examining polymorphisms of genes that participate in iron metabolism, transportation, and storage. For example, a risk variant in the transferrin (TF) gene, which leads to defective binding of iron during transport, leads to higher levels of iron and is also a genetic determinant of AD (Wang and Holsinger, 2018) while risk variants in the HFE gene, which lead to hemochromatosis, can increase risk for AD and an earlier age of onset of AD (Lehmann et al, 2006). About 15% of people carry the TF risk variant, which is associated with a 10% to 20% increased risk of AD.

Though iron is implicated in AD neuropathology, the effect of dietary intake of iron within recommended ranges and risk of AD is not clear (Cherbuin et al, 2014). In some regions of the world where consumption of red meat, the richest source of heme iron, in the diet is less, lower incidence of AD is reported. This area of study requires further investigation. Recommendations stand to limit consumption of excessive iron in the diet. If taking a multivitamin, choose one without iron.

Whereas high intakes of saturated fat and cholesterol in the diet are associated with higher risk of cardiovascular disease, the links to AD are not as clear, which may be due, in part, to the individual's APOE genotype. In a meta-analysis of 12 observational studies it was shown that in 4 of the 12 studies, saturated fat increased AD risk while one study showed an inverse relationship (Barnard et al, 2014).

Interestingly, though high cholesterol levels in the periphery increase risk for heart disease and may be associated with AD, cholesterol levels in the brains of AD patients are reduced. Cholesterol balance in the brain is a key parameter for controlling beta amyloid plaque production and clearance. Increasing levels of cholesterol and LDL are generally associated with increased risk of AD though this association is only seen in non-APOE-e4 carriers (Hall et al, 2006). An individual's APOE genotype may have significant influence on dietary recommendations of these nutrients for AD risk reduction.

APOE is a major cholesterol carrier in the brain, mediating lipid transport from one tissue to one cell type or another (and in the brain, primarily neurons). There are three isoforms of APOE: e2, e3, and e4. E2, which is relatively rare, may provide protection against AD; e3, which is most common, presents a neutral risk; e4, which is present in 10% to 15% of the population, increases risk of AD. The isoform type affects the following differently: amyloid plaque aggregation and clearance in the brain, lipid transport, glucose metabolism, neuronal signaling, neuroinflammation, and mitochondrial function. The e4 isoform is less efficient in beta amyloid plaque clearance; thereby its presence can exacerbate the neurotoxicity triggered by plaque accumulation among other deleterious effects.

Each person carries two isoforms of APOE. Those who inherit one copy of e4 have a three-fold higher risk of developing AD, and those with two copies have an 8- to 12-fold higher risk in comparison to those who do not carry a copy of e4. Efforts are being made to understand if dietary modification of cholesterol or saturated fat can modulate the effect of APOE-e4 in the brain and thus risk of AD (Hanson et al, 2013). More research is warranted in this area.

There is growing evidence in the literature that the microbiome composition, species, identity and combinations, density, and distribution of these bacteria may influence how well we age (Mohajeri et al, 2018). As innate immunity predominates over time certain bacteria proliferate, triggering an inflammatory response such as from tumor necrosis factor-alpha (TNF- α). Adequate intake of dietary fiber, fermented foods, and plant-based foods to support a healthy microbiome should be encouraged.

The integrity of the blood-brain barrier (BBB) becomes more difficult to maintain as the bacterial load and sustained TNF- α response occurs. In conditions such as AD, genetic polymorphisms that favor jawbone decay result in increased periodontal pocket depth. This provides the perfect environment for oral anaerobes most closely associated with AD. These conditions in combination with predisposing genetic polymorphisms may increase the propensity for bacteria or endotoxins to gain access to the brain, triggering neuropathology and altering brain function (Shoemark and Allen, 2015). Thus good oral hygiene is important for general wellness of this population.

Advanced glycation end products (AGEs) are implicated in the initiation and progression of Alzheimer-type dementia (Cai et al, 2014). AGEs, also known as glycotoxins, are a diverse group of highly oxidant compounds created through a nonenzymatic reaction between reducing sugars and free amino groups of proteins, lipids, or nucleic acids. The formation of AGEs is a part of normal metabolism, but excessively high levels of AGEs in tissues and the circulation can become pathogenic. AGEs promote oxidative stress and inflammation by binding with cell surface receptors or cross-linking with body proteins, altering their structure and function. In addition to AGEs that form within the body, AGEs also exist in foods. AGEs in foods are formed during dry cooking of food, particularly baking, roasting, and frying. The fat in meat, with beef having generally the most, tends to be richest in AGEs of all foods. AGEs are absorbed and contribute significantly to the body's AGE pool (Uribarri et al, 2010).

Low levels of the omega-3 EFA DHA are present in those with dementia. Increasing omega-3 fat or fish oil intake (from deep sea fish or a supplement if necessary) is more likely to be helpful in those with mild cognitive defects than in those with severe AD (Freund et al, 2014).

AD is 70% less common in India than in the United States, and this is thought to be due to a diet high in turmeric, the source of the bioactive compound curcumin, which is the spice that makes Indian curries yellow (Rigacci and Stefani, 2015). Research has shown that curcumin may combat the buildup of beta amyloid plaques involved in AD

BOX 40.9 Medical Nutrition Therapy for Alzheimer's Disease

A Mediterranean-style diet like that used in the MIND study may slow cognitive decline. A multivitamin supplement containing at least 400 mcg of folate, 1000 IU of vitamin D, and 500 mcg of B₁₂. If the serum vitamin B₁₂ level is under 300 pg/mL or serum homocysteine or methylmalonic acid are elevated, a trial of vitamin B₁₂ injections is reasonable.

Iron deficiency may be present despite technically normal ferritin (a key laboratory measure for iron) levels. Especially if anemia, cognitive dysfunction, or restless leg syndrome are present, it is reasonable to keep the ferritin level at least 60 mcg/L (ng/mL). Using the standard ferritin cutoffs of 12 and 20 mcg/L (ng/mL) (in females and males respectively) to diagnose iron deficiency is ill advised, as ferritin levels can be higher than this in as many as 92% of people with severe iron deficiency based on bone marrow biopsy.

pathogenesis (Reddy et al, 2018). A shortcoming of supplementing curcumin is that it is poorly absorbed. Piperine, however, which is the major active component of black pepper, can increase the bioavailability of curcumin by 2000%. The supplement Meriva is a formulation of both compounds thus providing curcumin in a highly absorbable form. Combining curcumin and vitamin D was also associated with increased amyloid clearance by macrophages (Masoumi et al, 2009; Box 40.9). Curcumin may be generally neuroprotective, also showing benefit in Parkinson's disease (PD) (Pan et al, 2012).

Several prospective studies have shown that intake of specific foods and food groups may influence risk for cognitive decline and AD. In the MIND diet, greater intakes of dark leafy greens, other vegetables, berries, and nuts and seeds rich in monounsaturated and polyunsaturated fatty acids have been shown to be protective in AD and are emphasized whereas red meats, cheeses, and fried foods are limited.

MNT for Advanced Dementia

Advanced dementia almost always results in a decline food intake. Forgetting how to eat and lack of hunger queues can create a challenge for

adequate nutrition. It is not uncommon for patients with advanced dementia to develop very different food preferences than what they had earlier in life. As brain function deteriorates, swallowing ability can also be affected, and some people, due to dysphagia, require a texture modified diet (see Chapter 39 and Appendix 20). Providing assistance during meals can become necessary. See Chapter 19 on caring for older adults.

DEPRESSION

Major depressive disorder (MDD) is a common and costly disorder affecting about 6.7% or 16 million Americans. It is usually associated with severe and persistent symptoms, leading to social role impairment and increased mortality, making it the leading cause of disability worldwide (Fig. 40.4) (WHO, 2018). Though rigorously studied, still little is understood of the condition and no definitive cause has been identified. In addition, about one third of people do not respond adequately to available treatments. As is the case for most cognitive disorders, depression affects more women than men. The percent of those who suffer from depression also varies by ethnicity (Fig. 40.5).

There are multiple factors contributing to the development of depression, including genetics, nutrition, environmental stressors, hormonal disruption especially in the hypothalamic-pituitary-adrenal (HPA) axis, and alterations in neurotransmitter biology and function (the monoamine deficiency theory). In addition, people with certain genetic predispositions may be more susceptible to depression following chronic stress (Sutton et al, 2018).

In efforts to better understand the genetic etiology of MDD and develop treatments in particular for the one third of drug nonresponders, a meta-analysis was conducted in 2018 based on the DNA of 135,000 people with reported depression and 350,000 healthy people. The analysis uncovered 44 genetic risk factors linked to MDD (Wray et al, 2018). Though most were associated with targets of current antidepressant medications, this study marked a critical first step for understanding the genetic architecture of depression and possible avenues for treatment. A higher body mass index (BMI) was also linked to MDD.

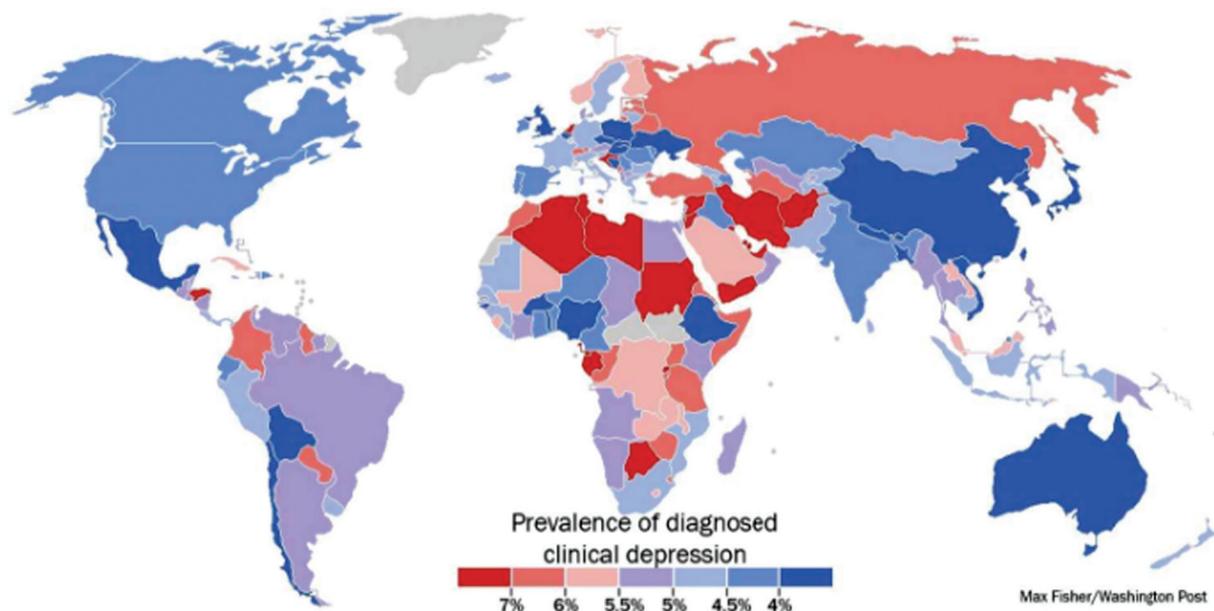

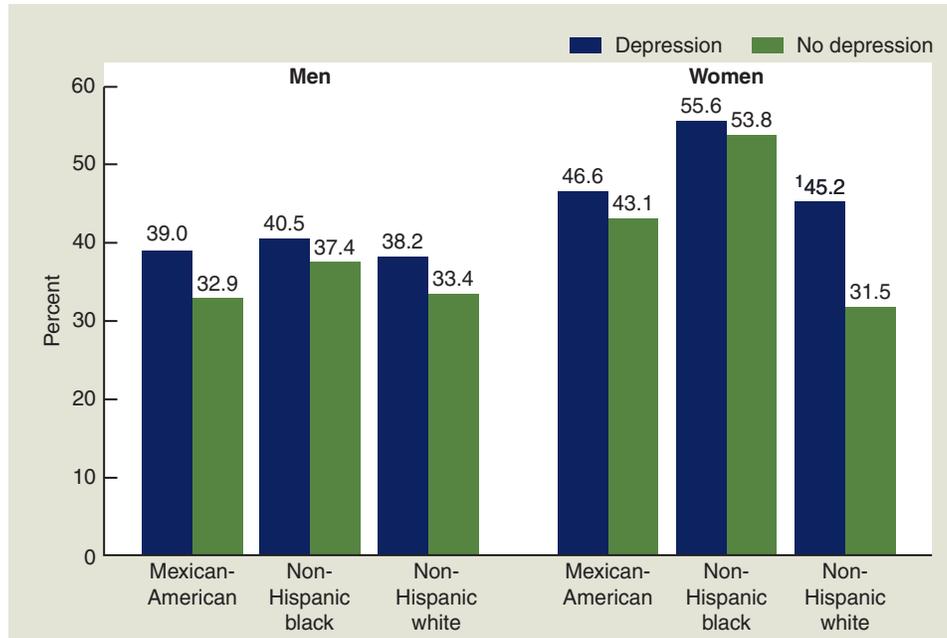

Fig. 40.4 Prevalence of diagnosed clinical depression by country. Source: <https://www.washingtonpost.com/news/worldviews/wp/2013/11/07/a-stunning-map-of-depression-rates-around-the-world>

¹Significantly different from no depression.

NOTES: Estimates were age-adjusted by the direct method to the 2000 U.S. census population using the age groups 20–39, 40–59, and 60 and over. Depression is defined as moderate to severe depressive symptoms. Access data table for Figure 3 or https://www.cdc.gov/nchs/data/databriefs/db167_table.pdf#3

SOURCE: CDC/NCHS, National Health and Nutrition Examination Survey, 2005–2010.

Fig. 40.5 Age-adjusted percentage of adults aged 20 and over who were obese, by sex, race/ethnicity, and depression status. United States 2005–2010. Source: <https://www.cdc.gov/nchs/products/databriefs/db167.htm>

This range of factors and the relative contribution of each to the development of depression in an individual is likely an important reason for the variability of individual response to specific therapies. Thus viewing depression as a heterogeneous condition is useful and demands that the health care provider consider each patient's individuality (see Table 40.2 and Box 40.10).

BOX 40.10 Diagnostic Criteria for Major Depression

- Depressed mood or a loss of interest or pleasure in daily activities for more than 2 weeks.
- Mood representing a change from the person's baseline.
- Impaired function: social, occupational, educational.
- Specific symptoms, at least five of these nine, present nearly every day:
 1. Depressed mood or irritable most of the day, nearly every day, as indicated by subjective report (e.g., feels sad or empty) or observation made by others (e.g., appears tearful)
 2. Decreased interest or pleasure in most activities, most of each day
 3. Significant weight change (5%), or change in appetite
 4. Change in sleep: insomnia or hypersomnia
 5. Change in activity: psychomotor agitation or retardation
 6. Fatigue or loss of energy
 7. Guilt/worthlessness: feelings of worthlessness or excessive or inappropriate guilt
 8. Concentration: diminished ability to think or concentrate, or more indecisiveness
 9. Suicidality: Thoughts of death or suicide, or has suicide plan

American Psychiatric Association (APA): *Diagnostic and Statistical Manual of Mental Disorders*, ed 5, Arlington, VA, 2013, American Psychiatric Association.

Pathophysiology

The monoamine deficiency theory of depression suggests that a deficiency of the monoamines serotonin, dopamine, and norepinephrine, or altered monoamine receptor function in the central nervous system, is the main pathophysiologic factor in depression. This theory has provided a target for the most common pharmacologic methods of treating depression.

In addition to the dietary decrease in fish oils and omega-3 fatty acids already discussed, other factors contribute to depression, including nutritional and hormonal deficiencies. In depression not responsive to antidepressants, a good response is seen using the T3 thyroid hormone despite normal thyroid tests. No significant improvement was seen with T4, the thyroid hormone most often used (Posternak et al, 2008). T3 has also been shown to be helpful in resistant bipolar depression (Kelly and Lieberman, 2009). Testosterone deficiency in men causes depression. Symptoms suggestive of depression can arise in the perimenopausal state, and appropriate therapy including bioidentical hormone therapy can be a useful in addressing this (Joffe, 2011).

As discussed earlier, epidemiologic research has identified associations between lower seafood consumption and increased rates of depression around the world. Dozens of clinical studies using EPA and DHA omega-3 supplements for depression have been conducted, and results are mixed but generally positive (Grosso et al, 2016).

Medical Management

Standard treatment of MDD includes pharmacotherapy as outlined in Box 40.11. Current pharmacologic therapy of depression is inconsistently effective (Garland, 2004). It has been nearly three decades since a new drug has been identified for treatment of MDD. Recent research,

BOX 40.11 Common Medications Used to Treat Depression

- Selective serotonin reuptake inhibitors (SSRIs), such as fluoxetine, paroxetine, and sertraline among others
- Serotonin norepinephrine reuptake inhibitors, such as duloxetine and venlafaxine
- Norepinephrine-dopamine reuptake inhibitor-bupropion
- Ketamine
- **Older therapies including monoamine oxidase inhibitors and tricyclic antidepressants can be useful but are generally second-line therapies**

however, has found that ketamine may ease symptoms for 60% to 70% of those who are resistant to the treatments currently available (Ioanescu and Papakostas, 2017). Clinical trials are underway to investigate two drugs with similar molecular mechanisms of ketamine.

Although a variable moderate percentage of depressed patients receive some benefit from pharmacologic therapy, a majority will not achieve full remission (see *New Directions: Can Genes Help Determine Psychopharmacologic Therapy?*)

NEW DIRECTIONS

Can Genes Help Determine Psychopharmacologic Therapy?

Saliva-based genetic tests for genetic and biological markers can indicate the potential response to different psychiatric drugs. Analysis by a psychopharmacologist can help clinicians more quickly find effective treatment for patients with a range of psychiatric conditions, including depression, bipolar disorder, schizophrenia, anxiety disorders, obsessive compulsive disorders (OCD), and attention-deficit/hyperactivity disorders (ADHD).

Medical Nutritional Therapy

Though it has proved difficult to fundamentally link one specific or a series of nutritional deficiencies or one dietary pattern to MDD, there is somewhat a chicken and egg problem that is presented when using observational research to examine the relationship between nutrition and MDD (and other psychiatric disorders). Is it the disease that leads one to eat less healthfully or does an unhealthy diet potentiate the disease?

A Mediterranean diet–like eating pattern has also been examined in relation to MDD. Studies have shown that diets rich in fruits, vegetables, olive oil, fish, whole grains, low-fat dairy, and antioxidants and low in animal foods may protect against the development of depressive symptoms later in life and decrease risk of MDD (Pagliai et al, 2018; Ylilauri et al, 2017).

Clinical trials examining specific dietary components have shed light on the role of nutrition in MDD risk and development.

Curcumin appears to be a promising treatment for depression due to its antiinflammatory effects (Ng et al, 2017). Effectiveness of common curcumin is decreased because of poor absorption; supplements that provide curcumin with piperine enhance bioavailability.

Low serum zinc levels have been consistently shown in depressed individuals versus healthy controls (Swardfager et al, 2013) and predispose people to treatment-resistance in depression. Repletion of zinc levels may augment otherwise ineffective therapies (Ranjbar et al, 2014). Mechanisms of action by zinc in reducing depressive symptoms include (1) decreasing dopamine reuptake (by binding to the dopamine

receptor), (2) increasing the conversion of T4 to T3, and (3) promoting excitatory neurotransmitter function.

Nutritional approaches to augmenting serotonin and serotonin receptor response include the use of St. John's Wort, tryptophan, 5-hydroxytryptophan (5-HTP), and vitamin D. SAMe can be an effective additive therapy to treat major depressive disorders. It is important to coordinate care with a medical doctor or psychiatrist before recommending these supplements. Caution must be used in treating depression with St. John's Wort, tryptophan, and 5-HTP in patients being treated with serotonergic drugs, such as SSRIs, serotonin-norepinephrine reuptake inhibitors (SNRIs), or tramadol to avoid triggering **serotonin syndrome** (see *Focus On: Serotonin Syndrome*). St. John's Wort also has a high risk of drug nutrient interactions (see Chapter 11).

FOCUS ON

Serotonin Syndrome

If brain serotonin levels go too high, the result is serotonin syndrome. Serotonin syndrome encompasses a wide range of clinical findings.

- Mild symptoms may consist of increased heart rate, anxiety, sweating, dilated pupils, tremor or twitching, and hyperresponsive reflexes.
- Symptoms of moderate elevation include hyperactive bowel sounds, high blood pressure, and fever.
- Severe symptoms include increases in heart rate and blood pressure that may lead to shock.
- Most often, excess serotonin occurs from combining serotonin raising medications (typically selective serotonin reuptake inhibitors [SSRIs]). It may also come from adding 5-hydroxytryptophan (5-HTP), tryptophan, or herbs (e.g., St. John's Wort, Panax, ginseng, nutmeg, or yohimbe) to high doses of medications which raise serotonin. Treatment is to cut back or stop these adjunctive treatments. Abruptly stopping antidepressants can cause severe withdrawal, so, except in severe situations, dosing is usually lowered rather than stopped completely (Undurruga and Baldessarini, 2012).

Although many clinicians are trained to think that the only presentation of serotonin syndrome is a febrile rigid state requiring emergency medical care, in milder forms patients are simply agitated and have muscle spasms. There is no way to diagnose this other than by clinical suspicion and altering the therapy to reduce serotonin levels and note if symptoms resolve.

In those with vitamin B₁₂ or folate deficiency and especially coexisting with an MTHFR methylation mutation or elevated homocysteine levels, optimizing B₁₂ and folate levels may help improve depression (Bhatia and Singh, 2015). It can be helpful to evaluate patients with longstanding mood disorders, especially those with a family history of mood disorders, for a genetic methylation mutation of either COMT (catechol-O-methyl transferase) or MTHFR (see Chapter 6). These mutations are involved in inactivation of catecholamine neurotransmitters and are implicated in schizophrenia, OCD, ADHD, and depression as well as vascular disease, thrombotic stroke, homocystinuria, and homocysteinemia.

FATIGUE, CHRONIC FATIGUE SYNDROME (CFS), AND FIBROMYALGIA SYNDROME (FMS)

Although research has shown that fatigue, chronic fatigue syndrome (CFS), and fibromyalgia syndrome (FMS) are physical conditions, discussion of them is included here because cognitive dysfunction

(often called “brain fog”) is a frequent symptom, and CFS and FMS are often poorly understood. Disorders such as CFS and FMS have a confusing array of diverse symptoms. Some experts believe that CFS and fibromyalgia are variations of the same process; they are discussed here as a single condition (CFS/FMS). Overt fibromyalgia affects approximately 2% of the population (Wolfe et al, 2013), and another approximately 2% have a milder intermediate form.

Women are affected twice as often as men. CFS/FMS can be caused by, and have overlapping symptoms with, autoimmune disorders such as systemic lupus erythematosus (SLE) or hypothyroidism. Viral pathogens, immune dysregulation, central nervous system dysfunction, musculoskeletal disorders, mitochondrial dysfunction, nutrient deficiencies, and other systemic abnormalities and allergies have been proposed as contributing factors in CFS/FMS.

Pathophysiology

Research suggests mitochondrial and hypothalamic dysfunction are common denominators in the syndromes of CFS/FMS (Cordero et al, 2010). Dysfunction of hormonal, sleep, and autonomic control (all centered in the hypothalamus), and energy production can explain the large number of symptoms and why most patients have a similar set of complaints.

Because the hypothalamus controls sleep, the hormonal and autonomic systems, and temperature regulation, it has very high energy

BOX 40.12 Effects of Insufficient, High-Quality Sleep

Alteration in moods: irritability, anger, greater risk for depression
 Lessened ability to cope with stress
 Decreased ability to learn
 Decreased memory
 Poor insight
 Impaired judgment
 Increased pain
 Immune dysfunction

Source: <http://www.webmd.com/sleep-disorders/excessive-sleepiness-10/emotions-cognitive>

needs for its size, so it malfunctions early in a shortage of energy. In addition, inadequate energy stores in a muscle results in muscle shortening (think of writer’s cramp) and pain, which is further accentuated by the loss of deep sleep (Box 40.12). The paradox of severe fatigue combined with insomnia, lasting more than 6 months, indicates the likelihood of a CFS-related process. If a patient also has widespread pain, fibromyalgia is probably present as well (see *Focus On: Fibromyalgia Diagnostic Criteria*).

FOCUS ON

Fibromyalgia Diagnostic Criteria

- Widespread pain index (WPI) ≥ 7 and symptom severity (SS) scale score ≥ 5 , or WPI 3 to 6 and SS scale score ≥ 9 .
- Symptoms have been present at a similar level for at least 3 months.
- The patient does not have a disorder that would otherwise explain the pain.

WPI (Widespread Pain Index)

Check each area below that you’ve had pain in over the last week. Score 1 point for each you check and enter the total score in the blank space provided.

- | | | |
|--------------------------|------------------------------------|--------------|
| • Shoulder girdle, left | • Hip (buttock, trochanter), left | • Jaw, left |
| • Shoulder girdle, right | • Hip (buttock, trochanter), right | • Jaw, right |
| • Upper arm, left | • Upper leg, left | • Chest |
| • Upper arm, right | • Upper leg, right | • Abdomen |
| • Lower arm, left | • Lower leg, left | • Upper back |
| • Lower arm, right | • Lower leg, right | • Lower back |
| | | • Neck |

_____ Total WPI (score 1 point for each item checked above)

SS (Symptom Severity)

- a. Rate each of the three symptoms below according to the severity you’ve experienced over the past week using the scale shown.

0 = No problem

1 = Slight or mild problems, generally intermittent

2 = Moderate, considerable problems, often present and/or at a moderate level

3 = Severe: pervasive, continuous, life-disturbing problems

_____ Fatigue

_____ Waking unrefreshed

_____ Cognitive symptoms (“brain fog”)

- b. Rate each symptom below that you’ve experienced during the previous 6 months. Score 1 point for each you check.

0 = No problem

1 = Slight or mild problems, generally intermittent

2 = Moderate, considerable problems, often present and/or at a moderate level

3 = Severe: pervasive, continuous, life-disturbing problems

_____ Fatigue

_____ Waking unrefreshed

_____ Cognitive symptoms (“brain fog”)

- c. Check each symptom below that you’ve experienced during the previous 6 months. Score 1 point for each you check.

- Headaches

- Pain or cramps in lower abdomen

- Depression

_____ Total SS (add the scores you entered in step a plus 1 point for each symptom you checked in step b)

Wolf F, Clauw DJ, Fitzcharles MA, et al: The American College of Rheumatology Preliminary Diagnostic Criteria for Fibromyalgia and Measurement of Symptom Severity, *Arthritis Care & Research*, (62)5, 600-610, 2010.

Diagnosis is based on the combination of chronic widespread pain and a symptom severity score based on the amount of fatigue, sleep disturbances, cognitive dysfunction, and other somatic symptoms. The diagnosis of fibromyalgia often overlaps with other chronic pain syndromes, including irritable bowel syndrome, temporomandibular disorders, and idiopathic low back pain. In CFS, chronic fatigue is the major symptom. It lasts 6 months or longer and is accompanied by

hypotension, sore throat, multiple joint pains, headaches, postexertional fatigue, muscle pain, and impaired concentration.

Medical Management

Standard medical therapy is aimed at addressing symptomatology but does not address the underlying metabolic, nutritional, and hormonal derangements. Medications such as low-dose Neurontin, Ambien,

Flexeril, or Desyrel are used to initiate and deepen sleep. Neurontin can also be helpful in reducing pain and restless leg syndrome. Three medications are approved by the Food and Drug Administration (FDA) for treatment of fibromyalgia: duloxetine (Cymbalta), milnacipran (Savella), and the anticonvulsant pregabalin (Lyrica). These can be helpful in some patients suffering from FMS but can have significant side effects.

There are no FDA-approved medications for CFS, and clinicians generally attempt to improve sleep quality in these patients and may attempt a trial of stimulants such as modafinil or amphetamines to improve daytime function. Although there is still much to learn, effective treatment is now available for the majority of these patients. Restoring adequate energy production through nutritional, hormonal, and sleep support, and eliminating the stresses that overuse energy (e.g., infections, situational stresses) restores function in the hypothalamic “circuit breaker” and also allows muscles to release, thus allowing pain to resolve. Massage therapy is an effective non-pharmacological treatment for muscle pain. A placebo-controlled study showed that with these measures, 91% of patients improve, with an average 90% improvement in quality of life, and the majority of patients no longer qualified as having FMS by the end of 3 months ($p < 0.0001$ vs. placebo) (Teitelbaum, 2012a).

The acronym SHINE, based on the integrated protocol used in the study, is a helpful way to structure treatment recommendations (Box 40.13).

Disordered Sleep

A common element of CFS/FMS is a sleep disorder. Many patients sleep solidly for only 3 to 5 hours a night with multiple awakenings. Even more problematic is the loss of deep stage three and four restorative sleep. Besides the standard medications for sleep improvement, natural sleep remedies can also be very helpful (Box 40.14).

BOX 40.13 SHINE Protocol for Treating Chronic Fatigue and Fibromyalgia

Sleep support
Hormonal support
Infection treatment
Nutritional support
Exercise as able

Teitelbaum JE: Effective treatment of chronic fatigue syndrome, *Integr Med* 10:44, 2012.

BOX 40.14 Natural Sleep Remedies and Recommended Dosages

- Herbal: Use singly or in combination, once a day at HS (see Chapter 12 for possible interactions).
Valerian (200-800 mg/day)
Passionflower (90-360 mg)
L-THEANINE (50-200 mg)
Hops (30-120 mg)
Lemon Balm Extract (20-80 mg)
- Melatonin: 0.5-5 mg at bedtime (0.5 mg is usually optimal for sleep, but higher doses may also decrease nighttime acid reflux).
- Two to three spritzes or sprays of lavender on the pillow at bedtime helps sleep. Lavender is also available in capsule form.

Source: Teitelbaum JE: Effective treatment of chronic fatigue syndrome, *Integrative Medicine* 10:44, 2012.

Other sleep disturbances must be ruled out. Sleep apnea is suspected if the patient snores, is overweight, is hypertensive, and has a shirt collar size more than 17 inches. Restless leg syndrome (RLS), more accurately called periodic limb movement disorder of sleep (PLMD), is also fairly common in CFS/FMS.

Thyroid function should also be evaluated (see Chapter 30).

Immune Dysfunction and Infections

Immune dysfunction is an integral part of CFS/FMS. Dozens of infections have been implicated in CFS/FMS, including viral, parasitic, and antibiotic-sensitive infections. Most of these infections are known as opportunistic infections, which means they will not survive in the presence of a healthy immune system. Many of them resolve on their own as the immune system recovers with the SHINE protocol (see Box 40.13).

General Pain Relief

Pain often resolves within 3 months of simply treating with the SHINE protocol (Teitelbaum, 2007). Nonsteroidal antiinflammatory drugs (NSAIDs) have been shown to be ineffective in fibromyalgia pain and can contribute to bleeding ulcers, and increased risk of heart attacks and strokes (Bhala et al, 2013; Trelle et al, 2010). Chronic use of acetaminophen depletes glutathione, a key antioxidant. The glutathione depletion from acetaminophen may be prevented by supplementing with NAC (500 to 1000 mg/day) (Woodhead et al, 2012).

Medical Nutritional Therapy

It is recommended that B₁₂, iron, total iron-binding capacity (TIBC), and ferritin levels be assessed, keeping in mind that elevated serum B₁₂ may be a sign of an MTHFR mutation and inadequate utilization of B₁₂. Measurement of erythrocyte magnesium and zinc may be helpful, although the laboratory tests are not reliable indicators of nutritional status. Due to a probably low-nutrient-density diet and possible increased nutrient needs, other possible nutrient deficiencies are likely. A multivitamin may be warranted if nutritional needs are not met through diet alone.

These patients often need to increase salt and water intake, especially in the presence of low blood pressure or orthostatic dizziness. Salt restriction is generally ill advised in these patients because of the adrenal dysfunction and orthostatic intolerance. Gluten avoidance may be helpful in a subset as well (Isasi et al, 2014; see Chapter 28).

SCHIZOPHRENIA

Schizophrenia is a severe mental disorder that presents as psychosis, often with paranoia and delusions. Diagnosis requires at least one of the symptoms to be delusions, hallucinations, or disorganized speech. A diagnosis of **schizoaffective disorder** requires that a person meet all of the criteria for schizophrenia and all of the criteria for an episode of bipolar disorder or depression, with the exception of impaired function (Parker, 2014).

Pathophysiology

The origins and causes of schizophrenia are not completely understood. Ultimately it may be understood as a heterogeneous disorder generated by a combination of biochemical, genetic, structural, nutritional, and environmental factors, including infections and toxins (Altamura et al, 2013). Heritability estimates for schizophrenia are about 80% (Gejman et al, 2010). Symptoms commonly begin to

appear in males during their late teens and early 20s and appear in females in their 20s or early 30s.

Medical Management

Pharmaceutical therapy revolves around the use of a combination of dopamine-blocking antipsychotic medications, antidepressants, and tranquilizers. Atypical antipsychotics, the newer, second-generation medications, are generally preferred because they pose a lower risk of serious side effects than do conventional medications.

Conventional, or typical, first-generation antipsychotic medications have frequent and potentially significant neurologic side effects, including the possibility of developing a movement disorder (tardive dyskinesia) that may or may not be reversible. Other treatments include psychosocial interventions such as the following:

- Individual therapy
- Social skills training
- Family therapy
- Vocational rehabilitation and supported employment.

Side effects of antipsychotics may include dry mouth, constipation, and increased appetite. Some antipsychotics should not be used with grapefruit and some other citrus fruits (see Chapter 8). Use of alcohol is contraindicated.

Medical Nutritional Therapy

People with severe mental illnesses (SMI) are more likely than other groups to be overweight, to smoke, and to have hyperglycemia and diabetes, hypertension, and dyslipidemia. Metabolic syndrome and other cardiovascular risk factors, as well as a reduced life expectancy, are common in people with schizophrenia (Vidović et al, 2013).

Schizophrenia appears to be associated with altered metabolism. A CT study showed that with equal total body fat and equal subcutaneous fat, there was three times the amount of visceral fat stored by schizophrenic patients. Reduced energy needs have been found in this population. The energy needs of these patients may be overestimated by the commonly used energy expenditure equations. The antipsychotic medications used are implicated in this decreased energy requirement. Weight gain after the start of antipsychotic medications is a common reason for patients to discontinue medication. Weight gains of 25 to 60 lb over the course of several years have been reported. Many patients are willing, able, and successful with weight management programs when they are offered. The most frequently used interventions included regular visits with a dietitian, a self-directed diet, and a stated treatment goal of weight loss. Behavioral group treatment has been shown successful in preventing weight gain and achieving weight loss.

Dietary factors that affect schizophrenia and depression are similar to those that predict illnesses such as coronary heart disease and diabetes. Low levels of membrane and erythrocyte EFAs have been observed, but do not appear to be related to dietary intake, but rather related to phospholipid metabolism. Supplements have been shown effective in raising the levels of EFAs in cell membranes and erythrocytes. A high intake of fish oil is also associated with a better prognosis, with the EPA fraction being more helpful than the DHA (Marano et al, 2013).

Evaluating for the presence of MTHFR mutations may also contribute to treatment (Zhang et al, 2013a). MTHFR and COMT polymorphisms may increase the predilection for schizophrenia, although the exact mechanism is currently unclear (Roffman et al, 2013). MTHFR defects and elevated plasma homocysteine

BOX 40.15 Medical Nutrition Therapy for Schizophrenia

Caution against use of grapefruit and/or grapefruit juice (can alter medication blood levels) and use of alcohol.

Assessment of blood levels for immunoglobulin A (IgA) and IgG transglutaminase antibodies to screen for celiac disease or gluten sensitivity even in the absence of gastrointestinal symptoms.

A gluten-free trial is critical if these are positive, and reasonable even if the tests are negative.

Recommend regular meal pattern and trial of a low glycemic, dairy free Mediterranean diet

Monitor weight: a 7% weight gain should trigger assessment for metabolic syndrome.

Refer to a behavioral weight management program as needed. In addition to nutrition-related material, program should include education regarding smoking, exercise, and alcohol consumption.

Assess diet for quality of fat intake; recommend optimal intake of essential fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) to replenish or maintain cell membrane and erythrocyte fatty acid status.

Relevant vitamin status includes genetic polymorphism of methylenetetrahydrofolate reductase (MTHFR) and adequacy of folate intake.

concentration have been suggested as risk factors for schizophrenia, but the results of epidemiologic studies have been inconsistent (Nishi et al, 2014).

The role of gluten and casein in schizophrenia has been suspected for more than 40 years, with an early blinded, controlled study showing that patients with schizophrenia on a gluten- and casein-free diet were released from the hospital significantly earlier (Niebuhr et al, 2011). Studies of individuals in the Clinical Antipsychotic Trials of Intervention Effectiveness (CATIE) show that 5.5% of those with schizophrenia have a high level of antitransglutaminase (antiTG) antibodies, a measure of gluten intolerance, compared with 1.1% of the healthy control sample (Jackson et al, 2012). Twenty-three percent of those with schizophrenia (age-adjusted) had antigliadin antibodies (AGA) compared with 3.1% in the comparison sample (Casella et al, 2011). It is strongly recommended that those with schizophrenia have blood levels checked for immunoglobulin A (IgA) and IgG transglutaminase antibodies to screen for celiac disease or gluten sensitivity even in the absence of gastrointestinal symptoms (Jackson et al, 2012a). AGA levels, although not as specific, are also recommended for adequate assessment. A gluten-free trial is critical if these are positive, and reasonable even if the tests are negative (see Chapter 27).

A meta-analysis aimed to determine the prevalence and extent of nutritional deficits in first-episode psychosis in schizophrenia reviewed 28 studies on 6 vitamins and 10 minerals. They concluded that deficits in vitamin D and folate previously observed in long-term schizophrenia appear to exist from illness onset and are associated with worse symptomology. No further conclusions could be made except that more and better studies are needed (Firth et al, 2017).

Schizophrenic patients who smoke have been found to have lower erythrocyte DHA and EPA compared with nonsmokers. Smoking status must be taken into account when studying EFAs in this population (Box 40.15).

CLINICAL CASE STUDY

Adele is a 52-year-old African American woman with a strong family history of Alzheimer's Disease (AD). She recently had genetic testing done and tested positive for APOE-4 genotype. She is on a statin drug for high LDL cholesterol and metformin for a new diagnosis of impaired fasting glucose. She is 5'7" and weighs 180 lbs and says her weight has been increasing slowly over the years. Because she has high cholesterol she tells you she does not eat eggs or butter and tries to eat only lean meats. She does not like fish or seafood and her main source of vegetables is salad which she tries to have most nights with dinner. Adele reports a strong craving for sweets and has a caramel latte on most days as there is a coffee stand in her office building where she works. She is trying to make the transition to whole grain breads and pasta but it is difficult because "no one in the house likes it that much". Because she is trying to lose weight she often skips lunch but then ends up overeating in the evening. She wants to exercise but hasn't in a while due to time limitations with work and family obligations. In addition to being concerned about her cholesterol and blood sugar she is now concerned about her recent test results and wants to discuss preventative measures for AD. After reading an article in the news, she wonders if she should be taking turmeric?

Nutrition Diagnostic Statements

- Undesirable food choices (NB 1.7) related to knowledge deficit about dietary factors that reduce risk of AD as evidenced by regular intake of high glycemic foods, low vegetable intake, elevated LDL cholesterol, and impaired fasting glucose.
- Physical inactivity (NB 2.1) related to busy lifestyle and time limitations as evidenced by report of no regular exercise, steady weight gain, and impaired fasting glucose.
- Excessive energy intake (NI-1.3) related to irregular meal patterns, compensatory overeating and preference for high glycemic foods as evidenced by steady weight gain and a BMI of 28.2.

Nutrition Care Questions

1. What diet changes can you discuss with Adele that are associated with decreasing risk of AD? Are these consistent with what she should be doing for her high cholesterol and high blood sugar?
2. Are there any dietary supplements that may be helpful for Adele?
3. How does exercise fit into the advice you would give her?

Pediatric Specialties

The unique, special role of nutrition in the pediatric population cannot be underestimated. Pediatricians, nurses, and dietitian nutritionists all recognize that unusual feeding problems or disorders can negatively influence growth and health, especially in the very young. This section addresses the specific pediatric conditions affecting the nutritional intake and growth velocity of infants and children. In some cases, adolescents are mentioned if relevant, but most of this section considers younger patients.

Whether in neonatal units, hospital pediatric units, out-patient clinics, long-term care units, or in-home care, children coping with genetic or acquired disorders need appropriate nutrition support in order to grow and thrive. More than ever, nutrition care in this specialty arena requires an understanding of the biochemical, physiologic, social, and economic challenges that our youngest patients face.

Medical Nutrition Therapy for Low-Birthweight Infants

Diane M. Anderson, PhD, RDN, FADA

KEY TERMS

apnea of prematurity	human milk fortifiers	oral care with colostrum
appropriate for gestational age (AGA)	infancy	osteopenia of prematurity
bronchopulmonary dysplasia (BPD)	infant mortality rate	perinatal period
carnitine	intrauterine growth restriction (IUGR)	postterm infant
extrauterine growth restriction (EUGR)	kangaroo care	premature (preterm) infant
extremely low birthweight (ELBW)	large for gestational age (LGA)	respiratory distress syndrome (RDS)
gastric gavage	low birthweight (LBW)	small for gestational age (SGA)
gestational age	necrotizing enterocolitis (NEC)	surfactant
glucose load	neonatal period	term infant
hemolytic anemia	neutral thermal environment	very low birthweight (VLBW)

The management of low birthweight (LBW) infants requiring intensive care is continually improving. With new technologies, enhanced understanding of pathophysiologic conditions of the **perinatal period** (from 20 weeks of gestation to 28 days after birth), current nutrition management principles, and regionalization of perinatal care, the mortality rate during **infancy**—the period from birth to 1 year of age—has decreased in the United States. In particular, the development and use of **surfactant**—a mixture of lipoproteins secreted by alveolar cells into the alveoli and respiratory air passages that contributes to the elastic properties of pulmonary tissue—have increased the survival of preterm infants, as has the use of antepartum corticosteroids. Most premature infants have the potential for long and productive lives (*Wilson-Costello and Payne, 2015*).

Nutrition can be provided to LBW infants in many ways, each of which has certain benefits and limitations. The infant's size, age, and clinical condition dictate the nutrition requirements and the way they can be met. Because of the complexities involved in the neonatal intensive care setting, a team that includes a registered dietitian nutritionist trained in neonatal nutrition should make the decisions necessary to facilitate optimal nutrition (*Ehrenkranz, 2014*). Neonatal nutritionists monitor compliance with standardized feeding guidelines; ensure that early, intense nutritional support is initiated; facilitate the smooth transition from parenteral to enteral nutrition; and monitor growth and individualized nutrition support to maintain steady infant growth. In regionalized perinatal care systems, the neonatal nutritionist also may consult with health care providers in community hospitals and public health settings.

INFANT MORTALITY AND STATISTICS

In 2016 the **infant mortality rate** in the United States decreased to 5.87 infant deaths per 1000 live births (*Xu et al, 2018*). More than

65% of these deaths occur in the neonatal period, with the leading causes being birth defects, prematurity, and LBW. The preterm birth rate was 9.85%, and the incidence of LBW was 8.17% (*Martin et al, 2018*). The incidence of premature and LBW infants has increased from 2014, which is due to the increased births of late premature infants (*Martin et al, 2017*). Late premature infants are infants born at 34 to 36 weeks' gestation (*Martin and Osterman, 2018*). Late premature infants may be near the size of the term infant but will have medical and clinical problems like all premature infants (*Williams and Pugh, 2018*).

PHYSIOLOGIC DEVELOPMENT

Gestational Age and Size

At birth, an infant who weighs less than 2500 g (5½ lb) is classified as having a **low birthweight (LBW)**; an infant weighing less than 1500 g (3⅓ lb) has a **very low birthweight (VLBW)**; and an infant weighing less than 1000 g (2¼ lb) has an **extremely low birthweight (ELBW)**. LBW may be attributable to a shortened period of gestation, prematurity, or a restricted intrauterine growth rate, which makes the infant **small for gestational age (SGA)**.

The **term infant** is born between the 37th and 42nd weeks of gestation. A **premature (preterm) infant** is born before 37 weeks of gestation, whereas a **postterm infant** is born after 42 weeks of gestation.

Antenatally, an estimate of the infant's **gestational age** is based on the date of the mother's last menstrual period, clinical parameters of uterine fundal height, the presence of quickening (the first movements of the fetus that can be felt by the mother), fetal heart tones, or ultrasound evaluations. After birth, gestational age is determined by clinical assessment. Clinical parameters fall into two groups: (1) a series of neurologic signs, which depend primarily on postures and tone and

(2) a series of external characteristics that reflect the physical maturity of the infant. The New Ballard Score examination is a frequently used clinical assessment tool (Ballard et al, 1991). An accurate assessment of gestational age is important for establishing nutritional goals for individual infants and differentiating the premature infant from the term SGA infant.

An infant who is **small for gestational age (SGA)** has a birth weight that is lower than the 10th percentile of the standard weight for that gestational age. An SGA infant whose intrauterine weight gain is poor, but whose linear and head growth are between the 10th and 90th percentiles on the intrauterine growth grid, has experienced asymmetric **intrauterine growth restriction (IUGR)**. An SGA infant whose length and occipital frontal circumference are also below the 10th percentile of the standards has symmetric IUGR. Symmetric IUGR, which usually reflects early and prolonged intrauterine deficit, is apparently more detrimental to later growth and development. Some infants can be SGA because they are genetically small, and these infants usually do well.

An infant whose size is **appropriate for gestational age (AGA)** has a birth weight between the 10th and 90th percentiles on the intrauterine growth chart. The obstetrician diagnoses IUGR when the fetal growth rate decreases. Serial ultrasound measurements document this reduction in fetal anthropometric measurements, which may be caused by maternal, placental, or fetal abnormalities. The future growth and development of infants who have had IUGR is diverse, depending on the specific cause of the IUGR and treatment. Some infants who suffered from IUGR are SGA, but many may plot as AGA infants at birth. Decreased fetal growth does not always result in an infant who is SGA.

An infant whose birth weight is above the 90th percentile on the intrauterine growth chart is **large for gestational age (LGA)**. Box 41.1 summarizes the weight classifications. Fig. 41.1 shows the classification of neonates based on maturity and intrauterine growth.

Characteristics of Immaturity

The premature or LBW infant has not had the chance to develop fully in utero and is physiologically different from the term infant (Fig. 41.2). Because of this, LBW infants have various clinical problems in the early **neonatal period**, depending on their intrauterine environment, degree of prematurity, birth-related trauma, and function of immature or stressed organ systems. Certain problems occur with such frequency that they are considered typical of prematurity (Table 41.1). Premature infants are at high risk for poor nutrition status because of poor nutrient stores, physiologic immaturity, illness (which may interfere with nutritional management and needs), and the nutrient demands required for growth.

Most fetal nutrient stores are deposited during the last 3 months of gestation; therefore the premature infant begins life in a compromised

BOX 41.1 Classification of Birthweight and Intrauterine Growth

Low birthweight <2500 g
Very low birthweight <1500 g
Extremely low birthweight <1000 g
Small for gestational age = Birthweight <10th percentile of standard for gestational age
Appropriate for gestational age = Birthweight between the 10th and 90th percentile of standard for gestational age
Large for gestational age = Birthweight >90th percentile of standard for gestational age

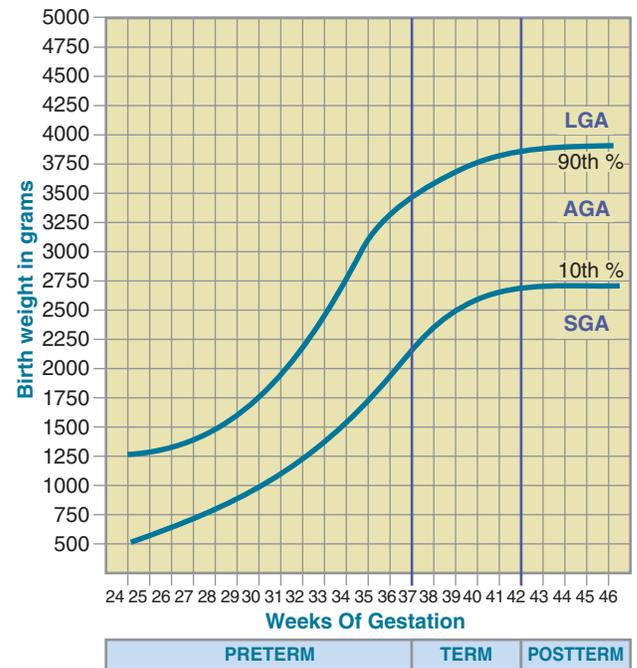

Fig. 41.1 Classification of neonates based on maturity and intrauterine growth (small for gestational age [SGA], appropriate for gestational age [AGA], or large for gestational age [LGA]). (From Battaglia FC, Lubchenco LO: A practical classification of newborn infants by weight and gestational age, *J Pediatr* 71:159, 1967.)

Fig. 41.2 A.R., born at 27 weeks of gestation; birth weight of 870 g (1 lb, 14 oz).

nutritional state. Because metabolic (i.e., energy) stores are limited, nutrition support in the form of parenteral nutrition (PN), enteral nutrition (EN), or both should be initiated as soon as possible. In the preterm infant weighing 1000 g, fat constitutes only 1% of total body weight; by contrast the term infant (3500 g) has a fat percentage of approximately 16%. For example, a 1000-g AGA premature infant has a glycogen and fat reserve equivalent to approximately 110 kcal/kg of body weight. With basal metabolic needs of approximately

TABLE 41.1 Common Problems Among Premature Infants

System	Problem
Respiratory	Respiratory distress syndrome, chronic lung disease (bronchopulmonary dysplasia)
Cardiovascular	Patent ductus arteriosus
Renal	Fluid and electrolyte imbalance
Neurologic	Intraventricular hemorrhage, periventricular leukomalacia (cerebral necrosis)
Metabolic	Hypoglycemia, hyperglycemia, hypocalcemia, metabolic acidosis
Gastrointestinal	Hyperbilirubinemia, feeding intolerance, necrotizing enterocolitis
Hematologic	Anemia
Immunologic	Sepsis, pneumonia, meningitis
Other	Apnea, bradycardia, cyanosis, osteopenia

From Eichenwald EC et al, editors: *Cloherty and Stark's Manual of neonatal care*, ed 8, Philadelphia, 2017, Wolters Kluwer.

TABLE 41.2 Expected Survival Time of Starved (H₂O Only) and Semistarved (D₁₀W) Infants

Birth Weight (g)	ESTIMATED SURVIVAL TIME (Days)	
	H ₂ O	D ₁₀ W
1000	4	11
2000	12	30
3500	32	80

Data from Heird WC, et al: Intravenous alimentation in pediatric patients, *J Pediatr* 80:351, 1972.
D₁₀W, Dextrose 10% in water; H₂O, water.

50 kcal/kg/day, it is obvious that this infant will rapidly run out of fat and carbohydrate fuel unless adequate nutrition support is established. The depletion time is even shorter for preterm infants weighing less than 1000 g at birth. Nutrient reserves also are depleted most quickly by tiny infants who have IUGR as a result of their decreased nutrient stores.

Theoretic estimates of survival time of starved and semistarved infants are shown in Table 41.2. These estimates assume depletion of all glycogen and fat and approximately one third of body protein tissue at a rate of 50 kcal/kg/day. The effects of fluids such as intravenously provided water (which has no exogenous calories) and 10% dextrose solution (D₁₀W) are shown. Currently, PN fluids are started on the day of birth to provide energy and protein for the VLBW infant. Early protein intake promotes positive nitrogen balance, normal plasma amino acid levels, and glucose tolerance.

The small premature infant is particularly vulnerable to undernutrition. Malnutrition in premature infants may increase the risk of infection, prolong chronic illness, and adversely affect brain growth and function. Premature infants fed premature infant formula or human milk demonstrate better growth and development than premature infants fed standard infant formula. Milk from the infant's own mother fed the first month of life has been linked to improved growth and development. Premature infants fed their own mother's milk have

improved neurodevelopment at 30 months of age and higher intelligence test scores at 8 years of age and have brains larger and more developed at 15 years of age ([American Academy of Pediatrics \[AAP\], 2012](#); [Isaacs et al, 2010](#)).

NUTRITION REQUIREMENTS: PARENTERAL FEEDING

Many critically ill preterm infants have difficulty progressing to full enteral feedings in the first several days or even weeks of life. The infant's small stomach capacity, immature gastrointestinal tract, and illness make the progression to full enteral feedings difficult (see *Pathophysiology and Care Management Algorithm: Nutrition Support of Premature Infants*). PN becomes essential for nutrition support, either as a supplement to enteral feedings or as the total source of nutrition. Chapter 12 offers a complete discussion of PN; only aspects related to feeding of the preterm infant are presented here.

Fluid

Because fluid needs vary widely for preterm infants, fluid balance must be monitored. Inadequate intake can lead to dehydration, electrolyte imbalances, and hypotension; excessive intake can lead to edema, congestive heart failure, and possible opening of the ductus arteriosus. Additional neonatal clinical complications reported with high fluid intakes include necrotizing enterocolitis (NEC), and bronchopulmonary dysplasia (BPD) (see Chapter 33).

The premature infant has a greater percentage of body water (especially extracellular water) than the term infant (see Chapter 3). The amount of extracellular water should decrease in all infants during the first few days of life. This reduction is accompanied by a normal loss of 10% to 15% of body weight and improved renal function. Failure of this transition in fluid dynamics and lack of diuresis may complicate the course of preterm infants with respiratory disease.

Water requirements are estimated by the sum of the predicted losses from the lungs and skin, urine, and stool, and the water needed for growth. A major route of water loss in preterm infants is evaporation through the skin and respiratory tract. This insensible water loss is highest in the smallest and least mature infants because of their larger body surface area relative to body weight, increased permeability of the skin epidermis to water, and greater skin blood flow relative to metabolic rate. Insensible water loss is increased by radiant warmers and phototherapy lights and decreased by humidified incubators, heat shields, and thermal blankets. Insensible water loss can vary from 50 to 100 mL/kg/day on the first day of life and increase up to 150 mL/kg/day, depending on the infant's size, gestational age, day of life, and environment. The use of humidified incubators can decrease insensible water losses and thereby reduce fluid requirements.

Excretion of urine, the other major route of water loss, varies from 1 to 3 mL/kg/hr ([Doherty, 2017](#)). This loss depends on the fluid volume and solute load presented to the kidneys. The infant's ability to concentrate urine increases with maturity. Stool water loss is generally 5 to 10 mL/kg/day, and 10 to 15 mL/kg/day is suggested as optimal for growth ([Dell, 2015](#)).

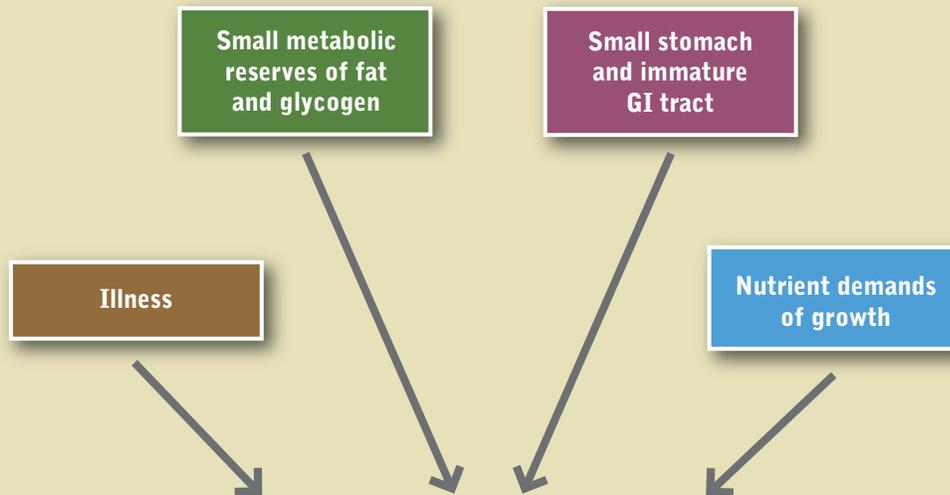

Because of the many variables affecting neonatal fluid losses, fluid needs must be determined on an individual basis. Usually fluid is administered at a rate of 60 to 100 mL/kg/day the first day of life to meet insensible losses and urine output. Fluid needs then are evaluated by assessing fluid intake and comparing it with the clinical parameters of urine output volume and serum electrolyte, creatinine, and urea nitrogen levels. Assessments of weight, blood pressure, peripheral perfusion, skin turgor, and mucous membrane moisture are performed daily. Daily fluid administration generally increases by 10 to 20 mL/kg/day.

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Nutrition Support of Premature Infants

ETIOLOGY

PATHOPHYSIOLOGY

High Nutritional Risk Status

MANAGEMENT

Neonatal Team Management

- Dietitian nutritionists
- Nurses
- Pharmacists
- Neonatologists

Nutrition Issues

- Parenteral nutrition (PN)
- Human milk + fortifiers
- Premature infant formulas
- Education of parents/caregivers on PN
- Growth
- Supplementation
 - Carnitine
 - Vitamin K injection
 - Possible iron
 - Possible vitamin D

By the end of the first week of life, preterm infants may receive fluids at a rate of 140 to 160 mL/kg/day. Fluid restriction may be necessary in preterm infants with patent ductus arteriosus (an opening between the pulmonary artery and the aorta), congestive heart failure, renal failure, or cerebral edema. However, more fluids are needed by preterm infants who are placed under phototherapy lights or a radiant warmer or when the environmental or body temperature is elevated.

Energy

The energy needs of preterm infants fed parenterally are less than those of enterally fed infants because absorption loss does not occur when nutritional intake bypasses the intestinal tract. Enterally fed preterm infants usually require 110 to 130 kcal/kg/day to grow, whereas parenterally fed premature neonates can grow well if they receive 90 to 100 kcal/kg/day (AAP, 2019; Embleton and Simmer,

TABLE 41.3 Comparison of Parenteral and Enteral Energy Needs of Premature Infants

	Parenteral	Enteral
Maintenance		
Gradually increase intake to meet energy needs by the end of the first week	30-50 kcal/kg/day	50 kcal/kg/day
Growth		
Meet energy needs as soon as the infant's condition is stable	90-100 kcal/kg/day	110-130 kcal/kg/day

2014). Energy and protein should be provided as soon as possible to prevent tissue catabolism (AAP, 2019; Embleton and Simmer, 2014). Two to 3 g/kg/day of protein with a total energy intake of 60-80 kcal/kg/day should be started within a few hours of birth to maximize nitrogen balance and blood amino acid levels (AAP, 2019; Embleton and Simmer, 2014).

Energy and protein intake should be increased as the infant's condition stabilizes and growth becomes the goal (Table 41.3). Many VLBW infants are born AGA but at discharge from the hospital weigh less than the 10th percentile for their postmenstrual age. This new SGA status is called **extrauterine growth restriction (EUGR)** or postnatal growth failure. EUGR may occur as a result of poor energy and protein intakes and the decreased growth associated with illness (Griffin et al, 2016).

Glucose

Glucose or dextrose is the principal energy source (3.4 kcal/g). However, glucose tolerance is limited in premature infants, especially in VLBW infants, because of inadequate insulin production, insulin resistance, and continued hepatic glucose release while intravenous glucose is infusing. Hyperglycemia is less likely when glucose is administered with amino acids than when it is infused alone. Amino acids exert a stimulatory effect on insulin release. Prevention of hyperglycemia is important because it can lead to diuresis and dehydration.

To prevent hyperglycemia in VLBW infants, glucose should be administered in small amounts. The **glucose load** is a function of the concentration of the dextrose infusion and the rate at which it is administered (Table 41.4). The administration of intravenous amino acids stimulates insulin production and the tolerance of intravenous glucose (Hay, 2018). The administration of exogenous insulin is avoided with premature infants (AAP, 2019). Insulin adheres to the intravenous tubing, which results in blood glucose fluctuations as a result of nonsteady insulin concentrations. Additional problems for the infant include hypoglycemia, decreased linear growth, the association of hypoglycemia with poor neurodevelopment, and death (Alsweiler et al, 2012). In general, preterm infants should receive an initial glucose load of 5 to 7 mg/kg/min, with a gradual increase to 11 to 12 mg/kg/min. The glucose load can be advanced by 1 to 2 mg/kg/min/day. Hypoglycemia is not as common a problem as hyperglycemia, but it may occur if the glucose infusion is decreased abruptly or interrupted.

Amino Acids

Protein guidelines range from 3.0 to 4.0 g/kg/day (AAP, 2019). Protein in excess of these parenteral requirements should not be administered because additional protein offers no apparent advantage, and increases the risk of metabolic problems (Hay, 2018). In practice preterm infants

TABLE 41.4 Guidelines for Glucose Load in Premature Infants

Initial Load (mg/kg/min)*	Daily Increments (mg/kg/min)	Maximum Load (mg/kg/min)
5-7	1-2	11-12

*Use the following formula to calculate glucose load: (% Glucose × mL/kg/day) × (1000 mg/g glucose) ÷ (1440 min/day). For example, (0.10 × 150 mL/kg/day) × (1000 mg/g glucose) ÷ (1440 min/day) = 10.4 mg/kg/min.

are usually given 2 to 3 g/kg/day of protein for the first few days of life, and then protein is provided as tolerated. Many nurseries stock starter PN, which is water, glucose, protein, and perhaps calcium and is available 24 hours a day. Infants then can be provided with protein immediately on admission to the nursery.

In the United States several pediatric PN solutions are available. The use of pediatric PN solutions results in plasma amino acid profiles similar to those of fetal and cord blood or to those of healthy infants fed breastmilk (van Goudoever et al, 2014). These solutions promote adequate weight gain and nitrogen retention. Standard amino acid solutions are not designed to meet the particular needs of immature infants and may provoke imbalances in plasma amino acid levels. For example, cysteine, tyrosine, and taurine levels in these solutions are low relative to the needs of the preterm infant, but the methionine and glycine levels are relatively high. Because premature infants do not effectively synthesize cysteine from methionine because of decreased concentrations of the hepatic enzyme cystathionase, a cysteine supplement has been suggested. Cysteine is insoluble and unstable in solution; thus it is added as cysteine hydrochloride when the PN solution is prepared.

In addition to plasma amino acid imbalances, other metabolic problems associated with amino acid infusions in preterm infants include metabolic acidosis, hyperammonemia, and azotemia. These problems can be minimized by using the crystalline amino acid products that are available and by keeping the protein load within the recommended guidelines (Table 41.5).

Lipids

Intravenous fat emulsions are used for two reasons: (1) to meet essential fatty acid (EFA) requirements and (2) to provide a concentrated source of energy. EFA needs can be met by providing 0.5 g/kg/day of lipids when giving the Intralipid® emulsion. Biochemical evidence of EFA deficiency has been noted during the first week of life in VLBW

TABLE 41.5 Guidelines for Administration of Parenteral Amino Acids for Premature Infants

Initial Rate (g/kg/day)*	Increments (g/kg/day)	Maximum Rate (g/kg/day)
2-3	Advance to meet needs	4

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition*, ed 8, Itasca, IL, 2019, American Academy of Pediatrics.

*Use the following formula to calculate protein load: % Protein × mL/kg/day = Protein g/kg/day.

For example: 2% amino acid parenteral solution provided at 150 mL/kg/day is 0.02 × 150 mL/kg/day = 3 g/kg/day.

TABLE 41.6 Guidelines for Administration of Parenteral Lipids for Premature Infants

Initial Rate (g/kg/day)*	Increments (g/kg/day)	Maximum Rate (g/kg/day)
2-3	1	3

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition*, ed 8, Itasca, IL, 2019, American Academy of Pediatrics.

*Use the following formula to calculate lipid load: % Lipid \times mL/kg/day = Lipid g/kg/day. For example, 0.20×15 mL/kg = 3 g/kg/day.

infants fed parenterally without fat. The clinical consequences of EFA deficiency may include coagulation abnormalities, abnormal pulmonary surfactant, and adverse effects on lung metabolism.

Lipids can be initiated at 2 to 3 g/kg/day and should be provided over 24 hours (AAP, 2019). Lipids can be advanced by 1 to 2 g/kg/day until a rate of 3 g/kg/day is reached (Table 41.6). Plasma triglycerides should be monitored because elevated triglyceride levels may develop in infants with a decreased ability to hydrolyze triglycerides. These infants usually have lower gestational age, lower birthweight, SGA status, infection, surgical stress, or liver disease. Monitoring of serum triglyceride levels is indicated, and a rate of less than 3 g/kg/day of fat may be required to keep serum triglyceride levels under 200 to 250 mg/dL (AAP, 2019). Once the infant is medically stable and additional energy is needed for growth, lipid loads can be increased slowly. Intralipids can be given to the infant with hyperbilirubinemia. At the present recommendation of 3 g/kg/day, given over 24 hours, the displacement of bilirubin from albumin-binding sites does not occur (AAP, 2014).

The total lipid load is usually 25% to 40% of nonprotein calories (AAP, 2019). (The lipid emulsions currently in use are described in Chapter 12.) In preterm infants 20% Intralipid® solutions providing 2 kcal/mL are recommended because plasma triglyceride, cholesterol, and phospholipid levels are generally lower with these than with the 10% emulsions. The 10% emulsions contain more of the phospholipid emulsifier per gram of lipid and this emulsifier decreases the breakdown of triglycerides.

Intralipid® intravenous fat emulsions are made from soybean oil and contain omega-6 fatty acids, linoleic acid, and arachidonic acid (ARA). These EFAs increase the production of inflammatory mediators and increase the infant's inflammatory state (Premkumar et al, 2014) (see Chapter 7). Omegaven® is a fish-oil base intravenous fat emulsion and contains omega-3 fatty acids: eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) and vitamin E. These omega-3 fatty acids are antiinflammatory and the antioxidant properties of vitamin E may be helpful in the treatment of PN-associated liver disease (PNALD) (Premkumar et al, 2014). PNALD can occur with infants who have been on PN for at least 14 days and may be due to a component of the PN and/or the lack of enteral feedings. Infection and prematurity are also risk factors for liver disease. The disease presents with elevated conjugated bilirubin. If not treated, severe liver disease can occur. Intralipid® also contains phytosterols which will decrease bile acid synthesis and flow, which can contribute to the development of PNALD. This fish-oil product is produced in Europe and has recently been approved to treat pediatric patients with PNALD by the Food and Drug Administration (FDA) for patients in the United States. The treatment dose is 1 g/kg/day of the Omegaven® product.

Clinical experience with the fish-oil base intravenous fat is positive with resolution of PNALD in most premature infants (Premkumar

et al, 2014). Investigations are needed to determine whether this product can be used to prevent PNALD, which presents with an elevated conjugated bilirubin. Another European fat emulsion, SMOFLipid® (soy oil, medium-chain triglyceride, olive oil, and fish oil), has become available in the United States and has just been approved for adult use by the FDA. SMOFLipid is used off label with the pediatric population. This blend of fat oils may also offer antiinflammatory properties (Vanek et al, 2012). Research must be completed on this product to determine whether it can prevent or treat PNALD and how infants grow on SMOFLipid® (Hojsak et al, 2016). EFA deficiency has been reported with 1 g/kg/day dosing with SMOFLipid, so 2 to 3 g/kg/day should be used with this product (Memon et al, 2019).

Carnitine is frequently added to PN solutions for premature infants. Carnitine facilitates the mechanism by which fatty acids are transported across the mitochondrial membrane, allowing their oxidation to provide energy. Because intravenous lipid does not contain carnitine and premature infants have limited ability to produce carnitine, carnitine supplementation may be helpful for preterm infants who are receiving only PN for 2 to 3 weeks (Hay et al, 2014). The recommended carnitine dose is up to 10 mg/kg/day (AAP, 2019).

Electrolytes

After the first few days of life, sodium, potassium, and chloride are added to parenteral solutions to compensate for the loss of extracellular fluid. To prevent hyperkalemia and cardiac arrhythmia, potassium should be withheld until renal flow is demonstrated. In general, the preterm infant has the same electrolyte requirements as the term infant, but actual requirements vary, depending on factors such as renal function, state of hydration, and the use of diuretics (Table 41.7). Very immature infants may have a limited ability to conserve sodium and thus may require increased amounts of sodium to maintain a normal serum sodium concentration. Serum electrolyte levels should be monitored periodically.

Minerals

Calcium and phosphorus are important components of the PN solution. Premature infants who receive PN with low calcium and phosphorus concentrations are at risk for developing **osteopenia of prematurity**. This poor bone mineralization is most likely to develop in VLBW infants who receive PN for prolonged periods. Calcium and phosphorus status should be monitored using serum calcium, phosphorus, and alkaline phosphatase activity levels (see Appendix 12). Alkaline phosphatase activity levels in premature infants are greater than the levels seen with adults. It is common to see levels up to 600 IU/L, which may reflect rapid bone growth (Abrams, 2017). When alkaline phosphatase activity levels of 800 IU/L or more persist, knee or wrist radiographs should be examined for rickets (Abrams, 2017).

TABLE 41.8 Guidelines for Administration of Parenteral Minerals for Premature Infants

Minerals	Amount (mg/kg/day)*
Calcium	60-80
Phosphorus	39-67
Magnesium	4.3-7.2

From American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition*, ed 8, Itasca, IL, 2019, American Academy of Pediatrics.

*These recommendations assume an average fluid intake of 120 to 150 mL/kg/day with 2.5 g of amino acids per 100 mL. The amino acid concentration prevents the precipitation of these minerals.

Elevation in alkaline phosphatase activity also may be seen with liver disease. Serum phosphorous may be low with rickets (Abrams, 2017).

Preterm infants have higher calcium and phosphorus needs than term infants. However, it is difficult to add enough calcium and phosphorus to parenteral solutions to meet these higher requirements without causing precipitation of the minerals. Calcium and phosphorus should be provided simultaneously in PN solutions. Alternate-day infusions are not recommended because abnormal serum mineral levels and decreased mineral retention develop.

Current recommendations for parenteral administration of additional calcium, phosphorus, and magnesium are presented in Table 41.8. The intakes are expressed at a volume intake of 120 to 150 mL/kg/day, with 2.5 g/100 mL of amino acids or protein. Lower fluid volumes or lower protein concentrations may cause the minerals to precipitate out of solution. The addition of cysteine hydrochloride increases the acidity of the fluid, which inhibits precipitation of calcium and phosphorus.

Trace Elements

Zinc should be given to all preterm infants receiving PN. If enteral feedings cannot be started by 2 weeks of age, additional trace elements should be added. However, the amount of copper or manganese should be reduced or omitted for infants with obstructive jaundice, and the amounts of selenium and chromium should be reduced or omitted in infants with renal dysfunction. Copper can be concentrated in the liver with cholestasis, and it is recommended to determine copper status by plasma copper levels or plasma ceruloplasmin levels (AAP, 2019; Domellof, 2014). Parenteral iron is not routinely provided because infants often receive blood transfusions soon after birth, and enteral feedings, which provide a source of iron, often can be initiated. If necessary, the dosage for parenteral iron is approximately 10% of the enteral dosage; guidelines range from 0.2 to 0.25 mg/kg/day (Domellof, 2014). Table 41.9 provides guidelines for trace minerals.

Vitamins

Shortly after birth all newborn infants receive an intramuscular (IM) injection of 0.3 to 1 mg of vitamin K to prevent hemorrhagic disease of the newborn from vitamin K deficiency. Stores of vitamin K are low in newborn infants, and there is little intestinal bacterial production of vitamin K until bacterial colonization takes place. Because initial dietary intake of vitamin K is limited, neonates are at nutritional risk if they do not receive this IM supplement.

Only intravenous multivitamin preparations currently approved and designed for use in infants should be given to provide the appropriate vitamin intake and prevent toxicity from additives used in adult

*Reduced or not provided for infants with obstructive jaundice.

Copper may have to be provided based on the infant's blood copper levels.

†Reduced or not provided for infants with renal dysfunction.

multivitamin injections. The AAP recommends 40% of the multivitamin for infusion (MVI)-pediatric 5-mL vial per kilogram of weight (AAP, 2019). The maximum dose of 5 mL is given to an infant with a weight of 2.5 kg (Table 41.10).

Respiratory distress syndrome (RDS) is a disease that occurs in premature infants shortly after birth because these infants are deficient in the lung substance surfactant. **Surfactant** is responsible for keeping the lung elastic while breathing; thus surfactant supplements are given to the infant to prevent RDS or to lessen the illness. Lipids and proteins are components of surfactant, and phospholipids are the major lipid. Choline is required for phospholipid synthesis, but choline supplementation does not increase the production of phospholipids (van Aerde and Narvey, 2006). Choline is a conditionally essential nutrient because the infant can synthesize choline (see Chapter 14 for a discussion of requirement for choline in pregnancy). Choline is added to premature infant formulas at the level contained in human milk. Human milk can be a good source of choline for the infant. The milk choline levels will reflect the mother's intake of choline (Zeisel et al, 2018). The upper level is extrapolated from the adult safe level of intake (Klein, 2002).

MVI, Multivitamin for infusion.

Maximum volume intake is 5 mL/day, which is achieved at 2.5 kg body weight.

*MVI-Pediatric/INFUVITE (5 mL) contains the following vitamins: 80 mg of ascorbic acid, 2300 USP units of vitamin A, 400 USP units of vitamin D, 1.2 mg of thiamin, 1.4 mg of riboflavin, 1 mg of vitamin B₆, 17 mg of niacin, 5 mg of pantothenic acid, 7 USP units of vitamin E, 20 mcg of biotin, 140 mcg of folic acid, 1 mcg of vitamin B₁₂, and 200 mcg of vitamin K.

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition*, ed 8, Itasca, IL, 2019, American Academy of Pediatrics.

Bronchopulmonary dysplasia (BPD) is a chronic lung disease that commonly develops in the premature infant as a result of RDS and the mechanical ventilation and oxygen used to treat it. Because of the role of vitamin A in facilitating tissue repair, and because of reports of preterm infants having low vitamin A stores, large supplemental doses of vitamin A have been suggested for the prevention of BPD. One report suggests that providing ELBW premature infants with IM injections of vitamin A at 5000 units/day three times per week during the first month of life decreases the incidence of BPD (Araki et al, 2018). Physicians may or may not use this supplementation. The decision will be based on the incidence of BPD in their nursery, the lack of proven additional benefits, the acceptability of using IM injections, and the availability of parenteral vitamin A (Darlow et al, 2016). See Chapter 33 for a discussion of BPD.

Apnea of prematurity is when the infant stops breathing for 20 seconds or longer. Apnea can be due to the infant's immature response to breathing. Bradycardia, slowness of the heart rate, and poor blood oxygenation may be associated with apnea. Caffeine can be given daily to prevent apnea of prematurity. Caffeine stimulates the infant to breathe by increasing the brain's sensitivity to carbon dioxide, stimulating the central respiratory drive, and improving skeletal muscle contraction of the diaphragm. Apnea also can be caused by a lack of oxygen, cold or hot environmental temperatures, medications, or illness. The cause of apnea must be determined to provide the correct treatment to the premature infant.

Oral sucrose is given to infants for pain management during procedures such as blood draws by heel stick or venipuncture. The taste of sucrose may release endorphins, but how sucrose aids in pain management is not clear.

TRANSITION FROM PARENTERAL TO ENTERAL FEEDING

It is beneficial to begin enteral feedings for preterm infants as early as possible because the feedings stimulate gastrointestinal enzymatic development and activity, promote bile flow, increase villous growth in the small intestine, and promote mature gastrointestinal motility. These initial enteral feedings also can decrease the incidence of cholestatic jaundice and the duration of physiologic jaundice and can improve subsequent feeding tolerance in preterm infants. At times small, initial feedings are used only to prime the gut and are not intended to optimize enteral nutrient intake until the infant demonstrates feeding tolerance or is clinically stable.

When making the transition from parenteral to enteral feeding, clinicians should maintain parenteral feeding until enteral feeding is well established to maintain adequate net intake of fluid and nutrients. In VLBW infants it may take 7 to 14 days to provide full enteral feeding, and it may take longer for infants with feeding intolerances or illness. The smallest, sickest infants usually receive increments of only 10 to 20 mL/kg/day. Larger, more stable preterm infants may tolerate increments of 20 to 30 mL/kg/day (see Chapter 12 for a more detailed discussion of transitional feeding).

NUTRITION REQUIREMENTS: ENTERAL FEEDING

Enteral alimentation is preferred for preterm infants because it is more physiologic than parenteral alimentation and is nutritionally superior. Initiating a tiny amount of an appropriate breastmilk feeding whenever possible is beneficial (Maffei and Schanler, 2017). However, determining when and how to provide enteral feedings is often difficult and involves consideration of the degree of prematurity, history of

TABLE 41.11 Factors to Consider Before Initiating or Increasing the Volume of Enteral Feedings

Category	Factors
Perinatal	Cardiorespiratory depression
Respiratory	Stability of ventilation, blood gases, apnea, bradycardia, cyanosis
Medical	Vital signs (heart rate, respiratory rate, blood pressure, temperature), lethargy
Gastrointestinal	Anomalies (gastroschisis, omphalocele), patency, gastrointestinal tract function (bowel sounds present, passage of stool), abdominal distension, risk of necrotizing enterocolitis
Infection	Sepsis or suspect sepsis

Data from Adamkin DH, et al: Nutrition and selected disorders of the gastrointestinal tract. In Fanaroff AA, Fanaroff JM, editors: *Klaus and Fanaroff's Care of the high-risk newborn*, Philadelphia, 2013, Elsevier Saunders.

perinatal insults, current medical condition, function of the gastrointestinal tract, respiratory status, and several other individual concerns (Table 41.11).

Preterm infants should be fed enough to promote growth similar to that of a fetus at the same gestational age, but not so much that nutrient toxicity develops. Although the exact nutrient requirements are unknown for preterm infants, several useful guidelines exist. In general the requirements of premature infants are higher than those of term infants because the preterm infant has smaller nutrient stores, decreased digestion and absorption capabilities, and a rapid growth rate. Stress, illness, and certain therapies for illness may further influence nutrient requirements. It is also important to remember that, in general, enteral nutrient requirements are different from parenteral requirements.

Energy

The energy requirements of premature infants vary with individual biologic and environmental factors. It is estimated that an intake of 50 kcal/kg/day is required to meet maintenance energy needs, compared with 110 to 130 kcal/kg/day for growth (Table 41.12). However, energy needs may be increased by stress, illness, and rapid growth. Likewise, energy needs may be decreased if the infant is placed in a **neutral thermal environment** (the environmental temperature at which an infant expends the least amount of energy to maintain body temperature). It is important to consider the infant's rate of growth in relation to average energy intakes. Some premature infants may need greater than 130 kcal/kg/day to sustain an appropriate rate of growth. Infants with BPD often require such increased amounts. To provide such a large number of calories to infants with a limited ability to tolerate large fluid volumes, it may be necessary to concentrate the feedings to a level of more than 24 kcal/oz (Box 41.2).

Protein

The amount and quality of protein must be considered when establishing protein requirements for the preterm infant. Amino acids should be provided at a level that meets demands without inducing amino acid or protein toxicity.

A reference fetus model has been used to determine the amount of protein that has to be ingested to match the quantity of protein deposited into newly formed fetal tissue (Ziegler, 2014). To achieve these

TABLE 41.12 Estimation of Energy Requirements of the Low Birthweight Infant

Kcal/oz RTF* Formula	Ratio 24/30 kcal oz RTF Formula	Volume (mL) RTF* Premature 24	Volume RTF* (mL) Premature 30
24	1/0	90	0
26	2/1	60	30
27	1/1	45	45
28	1/2	30	60
30	0/1	0	90

RTF, Ready-to-feed formula.

*RTF (at 24 and 30 kcal/oz).

Example: Recipe for making a 26 kcal/oz formula:

Goal = 90 mL (3 oz) of formula

2 parts of 24 kcal/oz formula + 1 part of 30 kcal/oz formula =
3 parts of formula

90 mL ÷ 3 parts = 30 mL per part

30 mL × 2 parts = 60 mL of RTF Premature 24 kcal/oz formula +

30 mL × 1 part = 30 mL of Premature 30 kcal/oz = 90 mL (3 parts)
of 26 kcal/oz formula

fetal accretion rates, additional protein must be supplied to compensate for intestinal losses and obligatory losses in the urine and skin. Based on this method for determining protein needs, the advisable protein intake is 3.5 to 4.5 g/kg/day. This amount of protein is well tolerated. For the ELBW infant, up to 4.5 g/kg/day of protein has been recommended for milk feedings (Agostoni et al, 2010; Koletzko et al, 2014).

The quality or type of protein is an important consideration because premature infants have different amino acid needs than term infants because of immature hepatic enzyme pathways. The amino acid composition of whey protein, which differs from that of casein, is more appropriate for premature infants. The essential amino acid cysteine is more highly concentrated in whey protein, and premature

infants do not synthesize cysteine well. In addition, the amino acids phenylalanine and tyrosine are lower, and the preterm infant has difficulty oxidizing them. Furthermore, metabolic acidosis decreases with consumption of whey-predominant formulas. Because of the advantages of whey protein for premature infants, breastmilk or formulas containing predominately whey proteins should be chosen whenever possible.

Taurine is a sulfonic amino acid that may be important for preterm infants. Human milk is a rich source of taurine, and taurine is added to most infant formulas. Term and preterm infants develop low plasma and urine concentrations of taurine without a dietary supply. The premature infant may have difficulty with synthesizing taurine from cysteine. Although no overt disease has been reported in infants fed low taurine formulas, low taurine may affect the development of vision and hearing (Klein, 2002).

Energy must be provided at sufficient levels to allow protein to be used for growth and not merely for energy expenditure. A range of 2.5 to 3.6 g of protein per 100 kcal is recommended. Inadequate protein intake is growth limiting, whereas excessive intake causes elevated plasma amino acid levels, azotemia, and acidosis.

Lipids

The growing preterm infant needs an adequate intake of well-absorbed dietary fat to help meet the high energy needs of growth, provide EFAs, and facilitate absorption of other important nutrients such as the fat-soluble vitamins and calcium. However, neonates in general, and premature and SGA infants in particular, digest and absorb lipids inefficiently.

Fat should constitute 40% to 50% of total calories. Furthermore, a diet that is high in fat and low in protein may yield more fat deposition than is desirable for the growing preterm infant. To meet EFA needs, linoleic acid should compose 3% of the total calories, and alpha-linolenic acid should be added in small amounts (AAP, 2019). Additional longer-chain fatty acids—ARA and DHA—are present in human milk and are added to infant formulas for term and premature infants to meet federal guidelines.

The premature infant has a greater need than the term infant for ARA and DHA supplementation. These fatty acids accumulate in fatty tissue and the brain during the last 3 months of gestation; thus the premature infant has decreased stores. Premature infants fed formulas supplemented with ARA and DHA frequently demonstrate greater gain in weight and length and higher psychomotor development scores than premature infants not receiving the fatty acid supplementation (Lapillonne and Moltu, 2016). The DHA and ARA content of human milk is variable, and the premature infant may require supplements of ARA and DHA. However, research is needed to document supplementation use for the premature infants provided human milk (AAP, 2019).

Preterm infants have low levels of pancreatic lipase and bile salts, and this decreases their ability to digest and absorb fat. Lipases are needed for triglyceride breakdown, and bile salts solubilize fat for ease of digestion and absorption. Because medium-chain triglycerides (MCTs) do not require pancreatic lipase and bile acids for digestion and absorption, they have been added to the fat mixture in premature infant formulas. Human milk and vegetable oils contain the EFA linoleic acid, but MCT oil does not. Premature infant formulas must contain vegetable oil and MCT oil to provide the essential long-chain fatty acids.

The composition of dietary fat also plays a role in the digestion and absorption of lipid. In general, infants absorb vegetable oils more efficiently than saturated animal fats, although one exception is the saturated fat in human milk. Infants digest and absorb human milk fat

better than the saturated fat in cow's milk or the vegetable oil in standard infant formulas. Human milk contains two lipases that facilitate fat digestion and has a special fatty acid composition that aids absorption.

Carbohydrates

Carbohydrates are an important source of energy, and the enzymes for endogenous production of glucose from carbohydrate and protein are present in preterm infants. Approximately 40% of the total calories in human milk and standard infant formulas are derived from carbohydrates. Too little carbohydrate may lead to hypoglycemia, whereas too much may provoke osmotic diuresis or loose stools. The recommended range for carbohydrate intake is 40% to 50% of total calories.

Lactose, a disaccharide composed of glucose and galactose, is the predominant carbohydrate in almost all mammalian milks and may be important to the neonate for glucose homeostasis, perhaps because galactose can be used for either glucose production or glycogen storage. Generally galactose is used for glycogen formation first, and then it becomes available for glucose production as blood glucose levels decrease. Because infants born before 28 to 34 weeks of gestation have low lactase activity, the premature infant's ability to digest lactose may be marginal. In practice, malabsorption is not a clinical problem because lactose is hydrolyzed in the intestine or fermented in the colon and absorbed. Sucrose is another disaccharide that is found in commercial infant formula products. Because sucrase activity early in the third trimester is at 70% of newborn levels, sucrose is well tolerated by most premature infants. Sucrase and lactase are sensitive to changes in the intestinal milieu. Infants who have diarrhea, are undergoing antibiotic therapy, or are undernourished may develop temporary intolerances to lactose and sucrose.

Glucose polymers are common carbohydrates in the preterm infant's diet. These polymers, consisting mainly of chains of five to nine glucose units linked together, are used to achieve the isoosmolality of certain specialized formulas. Glucosidase enzymes for digesting glucose polymers are active in small preterm infants.

Minerals and Vitamins

Premature infants require greater amounts of vitamins and minerals than term infants because they have poor body stores, are physiologically immature, are frequently ill, and will grow rapidly. Formulas and **human milk fortifiers** that are developed especially for preterm infants contain higher vitamin and mineral concentrations to meet the needs of the infant, obviating the need for additional supplementation in most cases (Table 41.13). One major exception is infants receiving human milk with a fortifier that does not contain iron. An iron supplement of 2 mg/kg/day should be sufficient to meet their needs (AAP, 2019). The other exception is the use of donor human milk fortifier, which requires the addition of a multiple vitamin and an iron supplement.

Calcium and Phosphorus

Calcium and phosphorus are just two of many nutrients that growing premature infants require for optimal bone mineralization. Intake guidelines have been established at levels that promote the bone mineralization rate that occurs in the fetus. An intake of 150 to 220 mg/kg/day of calcium and 75 to 140 mg/kg/day of phosphorus is recommended (Abrams, AAP, 2013). Two thirds of the calcium and phosphorus body content of the term neonate is accumulated through active transport mechanisms during the last trimester of pregnancy. Infants who are born prematurely are deprived of this important intrauterine mineral deposition. With poor mineral stores and low dietary intake, preterm infants can develop **osteopenia of prematurity**, a disease characterized

TABLE 41.13 Recommendations for Enteral Administration of Vitamins for the Premature Infant

Vitamin	Amount (kg/day)
Vitamin A	1332-3663 IU
Vitamin D	200-400 IU*
Vitamin E	2.2-11 IU
Vitamin K	4.4-28 mcg
Ascorbic acid	20-55 mg
Thiamin	140-300 mcg
Riboflavin	200-400 mcg
Pyridoxine	50-300 mcg
Niacin	1-5.5 mg
Pantothenate	0.5-2.1 mg
Biotin	1.7-16.5 mcg
Folate	35-100 mcg
Vitamin B ₁₂	0.1-0.8 mcg

Data from Koletzko B, et al: Recommended nutrient intake levels for stable, fully enterally fed very low birth weight infants. In Koletzko B et al, editors: *Nutritional care of preterm infants: scientific basis and practical guidelines*. World Rev Nutr Diet, 110:297, Germany, 2014, S. Karger AG.

*Maximum of 400 IU/day. American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, Greer FR, editors: *Pediatric nutrition*, ed 8, Itasca, IL, 2019, 2014, American Academy of Pediatrics.

by demineralization of growing bones and documented by radiologic evidence of "washed-out" or thin bones. Very immature babies are particularly susceptible to osteopenia and may develop bone fractures or florid rickets with a prolonged dietary deficiency. Osteopenia of prematurity is most likely to develop in preterm infants who are (1) fed infant formula that is not specifically formulated for preterm infants, (2) fed human milk that is not supplemented with calcium and phosphorus, or (3) receiving long-term PN without enteral feedings.

Vitamin D

Human milk with human milk fortifier or infant formula for preterm infants provides adequate vitamin D when infants consume the entire calorie intake suggested. The current recommendations for intake range from 200 to 400 IU/day for preterm infants (Abrams, AAP, 2013).

Vitamin E

Preterm infants require more vitamin E than term infants because of their limited tissue stores, decreased absorption of fat-soluble vitamins, and rapid growth. Vitamin E protects biologic membranes against oxidative lipid breakdown. Because iron is a biologic oxidant, a diet high in either iron or polyunsaturated fatty acids (PUFAs) increases the risk of vitamin E deficiency. The PUFAs are incorporated into the red blood cell membranes and are more susceptible to oxidative damage than when saturated fatty acids compose the membranes.

A premature infant with vitamin E deficiency may experience **hemolytic anemia** (oxidative destruction of red blood cells). However, this anemia is uncommon today because of improvements in human milk fortifiers and infant formula composition. The human milk fortifiers and premature infant formulas now contain appropriate vitamin E/PUFA ratios for preventing hemolytic anemia.

Because the dietary requirement for vitamin E depends on the PUFA content of the diet, the recommended intake of vitamin E is expressed commonly as a ratio of vitamin E to PUFA. The recommendation for vitamin E is 0.7 IU (0.5 mg of d-alpha-tocopherol) per 100 kcal, and at least 1 IU of vitamin E per gram of linoleic acid.

Pharmacologic dosing of vitamin E (50–100 mg/kg/day) has not proven to be helpful in preventing BPD or retinopathy of prematurity by reducing the toxic effects of oxygen. Furthermore, high doses of vitamin E have been associated with intraventricular hemorrhage, sepsis, NEC, liver and renal failure, and death.

Iron

Preterm infants are at risk for iron deficiency anemia because of the reduced iron stores associated with early birth. At birth most of the available iron is in the circulating hemoglobin. Thus frequent blood sampling further depletes the amount of iron available for erythropoiesis. Transfusions of red blood cells often are needed to treat the early physiologic anemia of prematurity. Recombinant erythropoietin (EPO) therapy has been used to prevent anemia. Iron supplementation is indicated to facilitate red blood cell production, and a dosage of 6 mg/kg/day of enteral iron has been used (AAP, 2014). This therapy has not consistently prevented anemia and the need for blood transfusions and EPO therapy is not recommended (AAP, 2019).

In general the recommendation for iron intake is 2 to 3 mg/kg/day (AAP, 2019). Infants fed human milk should be given ferrous sulfate drops beginning at 2 weeks of age (AAP, 2019). Formulas fortified with iron usually contain sufficient iron to provide 2 mg iron/kg/day (AAP, 2019).

Folic Acid

Premature infants seem to have higher folic acid needs than infants born at term. Although serum folate levels are high at birth, they decrease dramatically, probably as a result of high folic acid use by the premature infant for deoxyribonucleic acid (DNA) and tissue synthesis needed for rapid growth.

A mild form of folic acid deficiency causing low serum folate concentrations and hypersegmentation of neutrophils is not unusual in premature infants. Megaloblastic anemia is much less common. A daily folic acid intake of 25 to 50 mcg/kg effectively maintains normal serum folate concentrations. Fortified human milk and formulas for premature infants meet these guidelines when full enteral feedings are established.

Sodium

Preterm infants, especially those with VLBW, are susceptible to hyponatremia during the neonatal period. These infants may have excessive urinary sodium losses because of renal immaturity and an inability to conserve adequate sodium. Furthermore, their sodium needs are high because of their rapid growth rate.

Daily sodium intakes of 2 to 3 mEq/kg meet the needs of most premature infants, but 4 to 5 mEq/kg or more may be required by some infants to prevent hyponatremia (Dell, 2015). Routine sodium supplementation of fortified human milk and infant formulas is not necessary. However, it is important to consider the possibility of hyponatremia and monitor infants by assessing serum sodium until the blood level is normal. Milk can be supplemented with sodium if repletion is necessary.

FEEDING METHODS

Decisions about breastfeeding, bottle feeding, or tube feeding depend on the gestational age and the clinical condition of the preterm infant. The goal is to feed the infant via the most physiologic method possible and supply nutrients for growth without creating clinical complications.

Oral Care with Colostrum

The mother's colostrum can be used as oral care for her infant as soon as it is available. Drops of colostrum are placed inside the infant's mouth to aid in the prevention of infection. Colostrum is a rich source of proteins, minerals, and immunologic factors which may protect the infant from illness (Gephart and Weller, 2014; AAP, 2019; American College of Obstetricians and Gynecologists [ACOG], 2014). **Oral care with colostrum** can be initiated before feedings are started.

Gastric Gavage

Gastric gavage by the oral route often is chosen for infants who are unable to suck because of immaturity or problems with the central nervous system. Infants less than 32 to 34 weeks of gestational age, regardless of birthweight, have poorly coordinated sucking, swallowing, and breathing abilities because of their developmental immaturity. Consequently they have difficulty with nipple feeding.

With the oral **gastric gavage** method, a soft feeding tube is inserted through the infant's mouth and into the stomach. The major risks of this technique include aspiration and gastric distention. Because of weak or absent cough reflexes and poorly developed respiratory muscles, the tiny infant may not be able to dislodge milk from the upper airway, which can cause reflex bradycardia or airway obstruction. However, electronic monitoring of vital functions and proper positioning of the infant during feeding minimize the risk of aspiration from regurgitation of stomach contents. Tiny, immature infants whose small gastric capacity and slow intestinal motility can impede the tolerance of large-volume bolus feeds may need bolus feedings provided with a pump for a 30- to 60-minute infusion to aid in feeding tolerance.

Occasionally, elimination of the distention and vagal bradycardia requires the use of an indwelling tube for continuous gastric gavage feedings rather than intermittent administration of boluses. Continuous feedings may lead to loss of milk fat, calcium, and phosphorus, which deposit in the feeding tubing so that the infant does not receive the total amount of nutrition provided. Bolus feedings provided with the use of the pump infusion can decrease nutrient loss and promote better weight gain (Rogers et al, 2010; Senterre, 2014).

Nasal gastric gavage is sometimes better tolerated than oral tube feeding. However, because neonates must breathe through the nose, this technique may compromise the nasal airway in preterm infants and cause an associated deterioration in respiratory function. This method is helpful for infants who are learning to nipple feed. An infant with a nasal gastric tube can still form a tight seal on the bottle nipple, but it can be difficult if an oral feeding tube is in place during feedings (see Chapter 12).

Transpyloric Feeding

Transpyloric tube feeding is indicated for infants who are at risk for aspirating milk into the lungs or who have slow gastric emptying. The goal of this method is to circumvent the often slow gastric emptying of the immature infant by passing the feeding tube through the stomach and pylorus and placing its tip within the duodenum or jejunum. Infants with severe gastrointestinal reflux do well with this method, which prevents aspiration of feedings into the lungs. This method also is used for infants whose respiratory function is compromised and who are at risk for milk aspiration. The possible disadvantages of transpyloric feedings include decreased fat absorption, diarrhea, dumping syndrome, alterations of the intestinal microflora, intestinal perforation, and bilious fluid in the stomach. In addition, the placement of transpyloric tubes also requires considerable expertise and radiographic confirmation of the catheter tip location. Although associated with many possible complications, transpyloric feedings are used when gastric feeding is not successful.

Nipple Feeding

Nipple feeding may be attempted with infants whose gestational age is greater than 32 weeks and whose ability to feed from a nipple is indicated by evidence of an established sucking reflex and sucking motion. Before this time they are unable to coordinate sucking, swallowing, and breathing. Because sucking requires effort by the infant, any stress from other causes such as hypothermia or hypoxemia diminishes the sucking ability. Therefore nipple feeding should be initiated only when the infant is under minimum stress and is sufficiently mature and strong to sustain the sucking effort. Initial oral feedings may be limited to one to three times per day to prevent undue fatigue or too much energy expenditure, either of which can slow the infant's rate of weight gain. Before oral feedings begin, a standardized oral stimulation program can help infants successfully nipple feed more quickly (Fucile et al, 2011).

Breastfeeding

When the mother of a premature infant chooses to breastfeed, nursing at the breast should begin as soon as the infant is ready. Before this time the mother must express her milk so that it can be tube-fed to her infant. These mothers need emotional and educational support for successful lactation. Studies report that premature breastfed infants have better sucking, swallowing, and breathing coordination and fewer breathing disruptions than bottle-fed infants (Abrams and Hurst, 2018). **Kangaroo care**—allowing the mother to maintain skin-to-skin contact while holding her infant—facilitates her lactation. In addition, this type of contact promotes continuation of breastfeeding and enhances the mother's confidence in caring for her high-risk infant. The latter benefit also may apply to fathers who engage in kangaroo care with their infants (Kassity-Krich and Jones, 2014).

Feeding infants with cups instead of bottles to supplement breastfeeding has been suggested for preterm infants based on the rationale that it may prevent infant "nipple confusion" (i.e., confusion between nursing at the breast and from a bottle). Complications such as milk aspiration and low volume intakes have to be monitored. Cup feeding has been associated with successful breastfeeding at discharge, but increased length of stay in the hospital for the premature infant (AAP, ACOG, 2014).

Tolerance of Feedings

All preterm babies receiving EN should be monitored for signs of feeding intolerance. Vomiting of feedings usually signals the infant's inability to retain the provided amount of milk. When not associated with other signs of a systemic illness, vomiting may indicate that feeding volumes were increased too quickly or are excessive for the infant's size and maturity. Simply reducing the feeding volume may resolve the problem. If not, or if the infant has signs of a systemic illness, feedings may have to be interrupted until the infant's condition has stabilized.

Abdominal distention may be caused by excessive feeding, organic obstruction, excessive swallowing of air, resuscitation, sepsis (i.e., systemic infection), or NEC. Observing infants for abdominal distention should be a routine practice for nurses. Abdominal distention often indicates the need to interrupt feeding until its cause is determined and resolved.

Gastric residuals, measured by aspiration of the stomach contents, may be determined routinely before each bolus gavage feeding and intermittently in all continuous drip feedings. Whether a residual amount is significant depends partly on its volume in relation to the total volume of the feeding. For example, a residual volume of more than 50% of a bolus feeding or equal to the continuous infusion rate may be a sign of feeding intolerance. However, when interpreting the significance of a gastric residual measurement, clinicians must consider other concurrent signs of feeding intolerance and the previous pattern of residual volumes established for a particular infant.

Residuals are frequently present before feedings are initiated and as small volume feedings are started. As long as no signs of illness are present, feedings should not be withheld.

Bile-stained emesis or residuals frequently may be due to overdistention of the stomach with reflux of bile from the intestine, or to a feeding tube that has slipped into the intestine, or it may indicate that the infant has an intestinal blockage and needs additional evaluation (Hair, 2018). Bloody or bilious gastric residuals are more alarming than those that seem to be undigested milk.

The frequency and consistency of bowel movements should be monitored constantly when feeding preterm infants. Simple inspections can detect the presence of gross blood. All feeding methods for preterm infants have associated complications. Unless close attention is paid to symptoms that indicate poor feeding tolerance, serious complications may ensue. Certain diseases can be recognized by recognizing signs of feeding intolerance. For example, **necrotizing enterocolitis (NEC)** is a serious and potentially fatal inflammatory disease of the intestines associated with symptoms such as abdominal distention and tenderness, abnormal gastric residuals, and grossly bloody stools.

SELECTION OF ENTERAL FEEDING

During the initial feeding period, premature infants often require additional time to adjust to EN and may experience concurrent stress, weight loss, and diuresis. The primary goal of enteral feeding during this initial period is to establish tolerance to the milk. Infants seem to need a period of adjustment to be able to assimilate a large volume and concentration of nutrients. Thus parenteral fluids may be necessary until infants can tolerate adequate amounts of feedings by mouth.

After the initial period of adjustment, the goal of enteral feeding changes from establishing milk tolerance to providing complete nutrition support for growth and rapid organ development. All essential nutrients should be provided in quantities that support sustained growth. The following feeding choices are appropriate: (1) human milk supplemented with human milk fortifier and iron and vitamins as indicated by fortifier used, (2) iron-fortified premature infant formula for infants who weigh less than 2 kg, or (3) iron-fortified standard infant formula for infants who weigh more than 2 kg.

Premature infants who are discharged from the hospital can be given a transitional formula. Additional vitamin D may be indicated to provide 400 IU per day (Abrams, AAP, 2013). Breast-fed infants may be provided with two to three bottles of transitional formula daily to meet needs. The breastfed premature infant also should receive 2 to 3 mg/kg/day of iron for the first 6 to 12 months and a multiple vitamin for the first year of life (AAP, 2019). Premature infants discharged home on standard formula should receive a multivitamin until the infant reaches 3 kg in weight and then only vitamin D may be needed to provide 400 IU per day (AAP, 2019). Blood ferritin levels can be measured to access the infant's iron status and the need for iron supplements (AAP, 2019).

Human Milk

Human milk is the ideal food for healthy term infants and premature infants. Although human milk requires nutrient supplementation to meet the needs of premature infants, its benefits for the infant are numerous. During the first month of lactation, the composition of milk from mothers of premature infants differs from that of mothers who have given birth to term infants; the protein and sodium concentrations of breastmilk are higher in mothers with preterm infants (Klein, 2002). When premature infants are fed their own mother's milk, they grow more rapidly than infants fed banked, mature breastmilk (Brownell et al, 2018).

In addition to its nutrient concentration, human milk offers nutritional benefits because of its unique mix of amino acids and

long-chain fatty acids. The zinc and iron in human milk are more readily absorbed, and fat is more easily digested because of the presence of lipases. Moreover, human milk contains factors that are not present in formulas. These components include (1) macrophages and T and B lymphocytes; (2) antimicrobial factors such as secretory immunoglobulin A, lactoferrin, and others; (3) hormones; (4) enzymes; and (5) growth factors. It has been reported that human milk compared with premature infant formula fed to preterm infants reduces the incidence of NEC and sepsis, improves neurodevelopment, facilitates a more rapid advancement of enteral feedings, and leads to an earlier discharge (AAP, ACOG, 2014). The use of the mother's own milk for her infant supplemented with liquid donor human milk fortifier and donor human milk is linked to decreased incidence of NEC (Sullivan et al, 2010). The use of donor milk and liquid donor human milk fortifier compared with premature infant formula decreases the incidence of NEC treated by surgery and decreases the days of PN (Cristofalo et al, 2013).

However, one well-documented problem is associated with feeding human milk to preterm infants. Whether it is preterm, term, or mature, human milk does not meet the calcium and phosphorus needs for normal bone mineralization in premature infants. Therefore calcium and phosphorus supplements are recommended for rapidly growing preterm infants who are fed predominantly human milk. Currently three human milk fortifiers are available: powder bovine milk base, liquid bovine milk base, and liquid donor human milk base. The bovine products contain calcium and phosphorus, as well as protein, carbohydrates, fat, vitamins, and minerals, and are designed to be added to expressed breastmilk fed to premature infants (Table 41.14). Vitamin supplements are not needed. One bovine fortifier is iron fortified and the other requires the addition of iron. The human-milk base product is made from donor human milk that has been pasteurized, concentrated, and supplemented with calcium, phosphorous, zinc, and electrolytes. A multivitamin and an iron supplement are needed with the use of the human-milk base fortifier. The human-milk base fortifier comes as additives to make the milk 24, 26, 28, or 30 kcal/oz milk. The higher concentrations are used for infants who are volume restricted or not growing on lower caloric-dense milk (Hair et al, 2013). The calories and protein are higher with the increased concentrations, but the concentrations of calcium, phosphorous, and zinc remain the same with the donor human milk fortifier. Often the infant needs more energy and protein, but not increased mineral intake. A donor human milk cream supplement is available that is pasteurized human milk fat and can be added to human milk.

Providing human milk to a premature infant can be a very positive experience for the mother, one that promotes involvement and interaction. Because many preterm infants are neither strong enough nor mature enough to nurse at their mother's breast in the early neonatal period, their mothers usually express their milk for several days (and occasionally for several weeks) before nursing can be established. The proper technique of expression, storage, and transport of milk should be reviewed with the mother (see Table 14.18 in Chapter 14). Many summaries of the special considerations for nursing a preterm infant have been published (AAP, ACOG, 2014).

Donor Human Milk

Pasteurized donor human milk (DM) is recommended for the premature infant when the mother's own milk (MOM) is not available or is contraindicated (AAP, 2017; see *Focus On: What Is a Human Milk Bank?*). Neonatal intensive care units (NICUs) that use donor milk

may have guidelines to ensure that the infants most at risk for NEC receive donor milk. For example, an infant with a birthweight less than 1500 g and a gestational age less than 34 weeks would qualify to receive donor milk. The risk for NEC is highest at 32 weeks' gestation (Yee et al, 2012). At 34 weeks, the infant can transfer to a discharge diet of mom's milk and supplementation with transitional formula if needed. Donor milk would not be used after discharge to home.

FOCUS ON

What Is a Human Milk Bank?

Human milk banks are nonprofit and for-profit establishments around the globe that work to pasteurize milk safely from healthy donor mothers and make it available to infants who need it most (Haiden and Ziegler, 2016). Donors are screened carefully for infection and infection risk, medication and supplement use, nonsmoker status, and limited alcohol use. The donating mother's physician and her baby's physician must approve her donation status.

For high-risk infants who are premature, immune compromised, or unable to breastfeed because of human immunodeficiency virus (HIV)-positive mothers, donor breastmilk is a life-saving resource when the mother's own milk, the best choice, is not available (Arslanoglu et al, 2013). In developing countries mothers who are HIV-positive are encouraged to breastfeed and provide their infants the medication therapy for HIV (AAP, ACOG, 2014). The risk of death by infection is very high for the infant when proper water supplies and sanitation are not available. Because of its optimal nutrition profile and unique immunologic properties, no other source of nourishment compares when providing these vulnerable infants with the nutrition needed to get a healthy start in life. This precious commodity has saved lives and improved infant morbidity so greatly that the World Health Organization (WHO) has asked that all nations advocate for breastfeeding and the safe use of donor milk through human milk banking for low birthweight infants (WHO, 2011).

Hospitals with milk-banking systems are usually nonprofit, and each has its own guidelines around distributing the milk so that it remains as a safe and altruistic option for all who need it. Recent research also has shown that unpasteurized sources of human milk can be purchased over the Internet and have a high probability for microbial contamination and the contamination with cow milk products (Keim et al, 2013; Keim et al, 2015). Occasionally, mothers of healthy babies may seek out peer-to-peer sharing to avoid the cost, inconvenience, and depletion of resources for vulnerable babies who need pasteurized donor milk the most. If a mother expresses interest in these options, she should receive education on the risks for her infant of possible exposure to infection, medications, and illegal drugs with unscreened and unpasteurized human milk to discourage direct milk sharing (AAP, 2017).

Effective human milk banks protect, promote, and support breastfeeding at every level and are cradled by governmental support (PATH, 2017). The Human Milk Banking Association of North America (HMBANA) is the premier resource for information on the startup and management of this precious commodity in every community as a means to improve global health (HMBANA, 2018). For more information, see <https://www.hmbana.org/>. The European Milk Bank Association (EMBA) is a nonprofit organization that provides guidelines for milk banking and encourages international cooperation between milk banks of the countries of Europe (EMBA, 2018). Globally, more than 40 countries have systems developed to provide donor milk (PATH, 2017).

TABLE 41.14 Comparison of the Nutritional Content of Human Milk and Formulas

	Human Milk	Human Milk + Powder Bovine-Based Fortifier*	Human Milk + Liquid Bovine-Based Fortifier†	Human Milk + Liquid Donor Human Milk-Based Fortifier‡	Standard Formula§	Transitional Formula¶	Premature Formula**

Data from American Academy of Pediatrics, Committee on Nutrition: Appendix A. Composition of human milk. In Kleinman RE, Greer FR, editors: *Pediatric nutrition*, ed 8, Itasca, IL, 2019, American Academy of Pediatrics.

The use of donor milk has been linked with earlier initiation of feedings, less formula use, and no change in the percentage of MOM use. DM frequently is used with the initiation of feedings before the mother's milk can be expressed. Neonatologists were concerned that the use of DM would lead to mothers not providing milk for their infant, but there was no change in mothers providing milk for their own infants (Marinelli et al, 2014).

Premature Infant Formulas

Formula preparations have been developed to meet the unique nutritional and physiologic needs of growing preterm infants. The quantity and quality of nutrients in these products promote growth at intrauterine rates. These formulas, which have caloric densities of 20, 24, and 30 kcal/oz, are available only in a ready-to-feed form. These premature formulas differ in many respects from standard cow's

milk-based formulas (see Table 41.14). The types of carbohydrate, protein, and fat differ to facilitate digestion and absorption of nutrients. These formulas also have higher concentrations of protein, minerals, and vitamins.

Transitional Infant Formulas

Formulas containing 22 kcal/oz have been designed as transition formulas for the premature infant. Their nutrient content is less than that of the nutrient-dense premature infant formulas and more than that of the standard infant formula (see Table 41.14). These formulas can be introduced when the infant reaches a weight of 2000 g, and they can be used throughout the first year of life. Not all premature infants need these formulas to grow appropriately. It is not clear which premature infants need this specialized formula because studies have not always demonstrated improved growth with the use of transitional formula (Young et al, 2016). Gain of weight, length, and head circumference for age and weight for length should be monitored on the World Health Organization growth curves (Lapillonne, 2014). Transitional formulas are available in powder form and in ready-to-feed form.

Formula Adjustments

Occasionally it may be necessary to increase the energy content of the formulas fed to small infants. This may be appropriate when the infant is not growing quickly enough and already is consuming as much as possible during feedings.

Concentration

One approach to providing hypercaloric formula is to prepare the formula with less water, thus concentrating all its nutrients, including energy. Concentrated infant formulas with energy contents of 24 kcal/oz are available to hospitals as ready-to-feed nursettes. However, when using these concentrated formulas, clinicians must consider the infant's fluid intake and losses in relation to the renal solute load of the concentrated feeding to ensure that a positive water balance is maintained. This method of increasing formula density often is preferred because the nutrient balance remains the same; infants who need more energy also need additional nutrients. As mentioned, the transitional formulas are available in ready-to-feed and powder form and can be concentrated from 24 to 30 kcal/oz. However, this formula is still inadequate for infants who need additional calcium (e.g., infants with osteopenia).

A ready-to-feed 30 kcal/oz premature infant formula is available. It meets the nutritional needs for premature infants who must be fluid restricted because of illness. This 30 kcal/oz formula can be diluted with premature infant formula (24 kcal/oz) to make 26, 27, or 28 kcal/oz milks (see Box 41.2). These milks are sterile and are the preferred source of providing concentrated milks to premature infants in the NICU. Infant formula powder is not sterile and is not to be used with high-risk infants when a nutritionally adequate liquid, sterile product is available (Steele and Collins, *Pediatric Nutrition Dietetic Practice Group*, 2019).

Caloric Supplements

Another approach to increasing the energy content of a formula involves the use of caloric supplements such as vegetable oil, MCT oil, or glucose polymers. These supplements increase the caloric density of the formula without markedly altering solute load or osmolality. However, they do alter the relative distribution of total calories derived from protein, carbohydrate, and fat. Because even small amounts of oil or carbohydrate dilute the percentage of calories derived from protein, adding these supplements to human milk or standard (20 kcal/oz) formulas is not advised. Caloric supplements should be used only

when a formula already meets all nutrient requirements other than energy or when the renal solute load is a concern.

When a high-energy formula is needed, glucose polymers can be added to a base that has a concentration of 24 kcal/oz or greater (either full-strength premature formula or a concentrated standard formula), with a maximum of 50% of total calories from fat and a minimum of 10% of total calories from protein. Vegetable oil should be added to a feeding at the time or given as an oral medication. Vegetable oil added to a day's supply of formula that is chilled will separate out from the milk and cling to the milk storage container and will not be in the feeding to the infant.

NUTRITION ASSESSMENT AND GROWTH

Dietary Intake

Dietary intake must be evaluated to ensure that the nutrition provided meets the infant's needs. Parenteral fluids and milk feedings are advanced as tolerated, and the nutrient intakes must be reviewed to ensure that they are within the guidelines for premature infants and that the infant is thriving on the nutrition provided. Appropriate growth and growth charts are reviewed in the following paragraphs.

Laboratory Indices

Laboratory assessments usually involve measuring the following parameters: (1) fluid and electrolyte balance, (2) PN or EN tolerance, (3) bone mineralization status, and (4) hematologic status (Table 41.15). Hemoglobin and hematocrit are monitored as

TABLE 41.15 Monitoring of the Feeding of the Premature Infant

Monitor	Parenteral Nutrition	Enteral Nutrition
Fluid and electrolyte balance	Fluid intake	Fluid intake
	Urine output	Urine output
	Daily weights	Daily weights
Glucose homeostasis	Serum sodium, potassium, and chloride	
	Serum creatinine	
Fat tolerance	BUN	
	Serum glucose	Not routine
Protein nutriture: BUN	Serum triglycerides	Not indicated
	Not helpful	Low levels with human milk-fed infants may indicate need for more protein
Osteopenia	Serum calcium	
	Serum phosphorous	Serum phosphorous
	Serum alkaline phosphatase activity	Serum alkaline phosphatase activity
Parenteral nutrition toxicity	Cholestasis: conjugated bilirubin	Not indicated
	Liver function: ALT	

ALT, Alanine aminotransferase; BUN, blood urea nitrogen.

medically indicated. The early decrease in hematocrit reflects the physiologic drop in hemoglobin after birth and blood drawings for laboratory assessments. Early low hemoglobin levels are treated with blood transfusions if needed. Dietary supplementation does not change this early physiologic drop in hemoglobin.

Growth Rates and Growth Charts

All neonates typically lose some weight after birth. Preterm infants are born with more extracellular water than term infants and thus tend to lose more weight than term infants. However, the postnatal weight loss should not be excessive. Preterm infants who lose more than 15% of their birth weight may become dehydrated from the inadequate fluid intake or experience tissue wasting from poor energy intake. An infant's birth weight should be regained by the second or third week of life. The smallest and sickest infants take the longest time to regain their birth weights.

Intrauterine growth curves have been developed using birth weight, birth length, and birth head circumference data of infants born at several successive weeks of gestation. The intrauterine growth curves are the standard of growth recommended for premature infants. During the first week of life premature infants fall away from their birth weight percentile, which reflects the normal postnatal weight loss of newborn infants. After an infant's condition stabilizes and the infant begins consuming all needed nutrients, the infant may be able to grow at a rate that parallels these curves. An intrauterine weight gain of 15 to 20 g/kg/day can be achieved (Fenton et al, 2018).

Although weight is an important anthropometric parameter, measurements of length and head circumference also can be helpful. Premature infants should grow between 0.7 to 1 cm per week in body length and head circumference. A growth curve based on gender can be used to evaluate the adequacy of growth in all three areas (Figs. 41.3 and 41.4). This chart has a built-in correction factor for prematurity; the infant's growth can be followed from 22 to 50 weeks of gestation and it represents cross-sectional data from Canada, Australia, Germany, Italy, Scotland, and the United States (Fenton and Kim, 2013). The intrauterine curves are smooth into the World Health Organization Charts.

Additional intrauterine growth charts based on the birthweight, birth length, and head circumferences of infants born in the United States have been developed (Olsen et al, 2010). Separate charts for male and female infants are available and infants can be plotted from 23 to 41 weeks' gestation.

The 2006 World Health Organization Growth Charts designed for children from birth to 2 years of age also should be used for preterm infants once they reach 40 weeks' gestation, as long as the age is adjusted (see *Focus On: Long-Term Outcome for Premature Infants*). For example, an infant born at 28 weeks of gestation is 12 weeks premature (40 weeks of term gestation minus 28 weeks of birth gestational age). Four months after birth, the growth parameters of a premature infant born at 28 weeks of gestation can be compared with those of a 1-month-old infant born at term (Box 41.3). When using growth grids, age should be adjusted for prematurity until at least 2½ to 3 years of corrected age. In Fig. 41.5 A.R.'s pattern of growth is shown through 18 years of age. These charts are based on term, healthy infants who were breastfed the first year of life (Grummer-Strawn et al, 2010). By using this chart, the infant's growth can be compared with the term infant to assess catch-up growth.

Commonly used problem, etiology, and signs and symptoms (PES) statements for infants are provided in Box 41.4. Assessment of nutrient intakes and infant growth are reviewed.

FOCUS ON

Long-Term Outcome for Premature Infants

As the survival of premature infants continues to improve, their physical growth, cognitive development, health, and quality of life are being evaluated and investigated. Previously it was believed that, if premature infants experienced catch-up growth, it would occur only during the first few years of life. However, catch-up growth for weight and length can continue throughout childhood. Head circumference catch-up growth is limited to 6 to 12 months corrected age (Hack, 2013). Brain development occurs during the first year of life. As adults, extremely low birthweight (ELBW) infants tend to be shorter and weigh the same as infants born at term (Roberts et al, 2013a). The parents of the premature infants are often shorter than the parents of term infants, and this could contribute to the infant's adult height.

Growth in the neonatal intensive care unit (NICU) for ELBW infants is linked to growth and development at 18 to 22 months corrected age (Ehrenkranz, 2014). Infants with weight gains greater than 18 g/kg/day or head circumference growth of 0.9 cm/week had better neurodevelopment and physical growth than infants with slower growth.

Premature infants and very low birthweight infants often develop adult-onset type 2 diabetes. Premature infants have decreased glucose regulation compared with infants born at term. Higher fasting insulin levels, impaired glucose tolerance, and increased insulin resistance may occur (Kajantie and Hovi, 2014). Premature infants or very low birthweight infants have been reported to have higher blood pressures than infants born at term and normal weight (Lapillonne and Griffin, 2013).

More research is needed. What is the optimal rate of growth for premature infants in the NICU and postdischarge to maximize cognitive/developmental outcomes and decrease risk of adult cardiovascular and metabolic diseases (Lapillonne and Griffin, 2013)? How fast should the premature infant grow? What should the body composition be? When should catch-up growth occur?

Tools have been developed and validated that assess how adults report their health status and quality of life. The evaluations may be conducted by interviews or completion of written questionnaires (Saigal, 2014). As adults, premature and very low birthweight infants rate their quality of life to be similar to adults who were born at term. Roberts and colleagues (2013b) reported on 194 ELBW infants and 148 term infants who completed written evaluations at 18 years. Both groups were the same in their reported quality of life, health status, and self-esteem. Quality of life did not differ for the adults with the smallest birth weight or youngest gestational age. Premature infants not completing the evaluation at 18 years were more likely to have a neurosensory disability at 8 years of age, such as cystic periventricular leukomalacia, blindness, cerebral palsy, and a lower intelligence quotient.

Therefore not only are more premature infants surviving, but they also are growing into adults who are enjoying and living productive lives (Hack, 2013; Saigal, 2013). The medical and nutrition care in the hospital nursery continues to progress, which improves outcome in the nursery and sets the stage for later development.

DISCHARGE CARE

Establishment of successful feeding is a pivotal factor determining whether a preterm infant can be discharged from the hospital nursery. Preterm infants must be able to (1) tolerate their feedings and usually obtain all of their feedings from the breast or bottle, (2) grow adequately on a modified-demand feeding schedule (usually every 3–4 hours during the day for bottle-fed infants or every 2–3 hours for breastfed infants), and (3) maintain their body temperature without the help of an incubator. Medically stable premature infants who have delayed feeding development can go home on gavage feedings for a

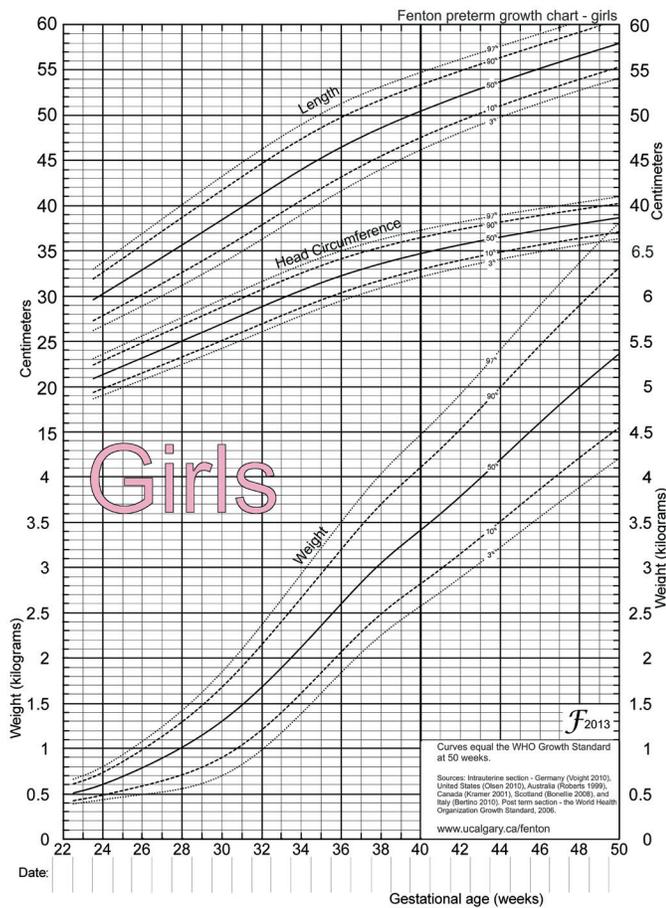

Fig. 41.3 Example of a growth record of weight, length, and head circumference for female infants from 22 to 50 weeks of gestation. This chart has a built-in correction factor for prematurity. <https://www.ucalgary.ca/fenton>. (From Fenton TR and Kim JH: A systematic review and meta-analysis to revise the Fenton growth chart for preterm infants, *BMC Pediatr* 13:59, 2013.)

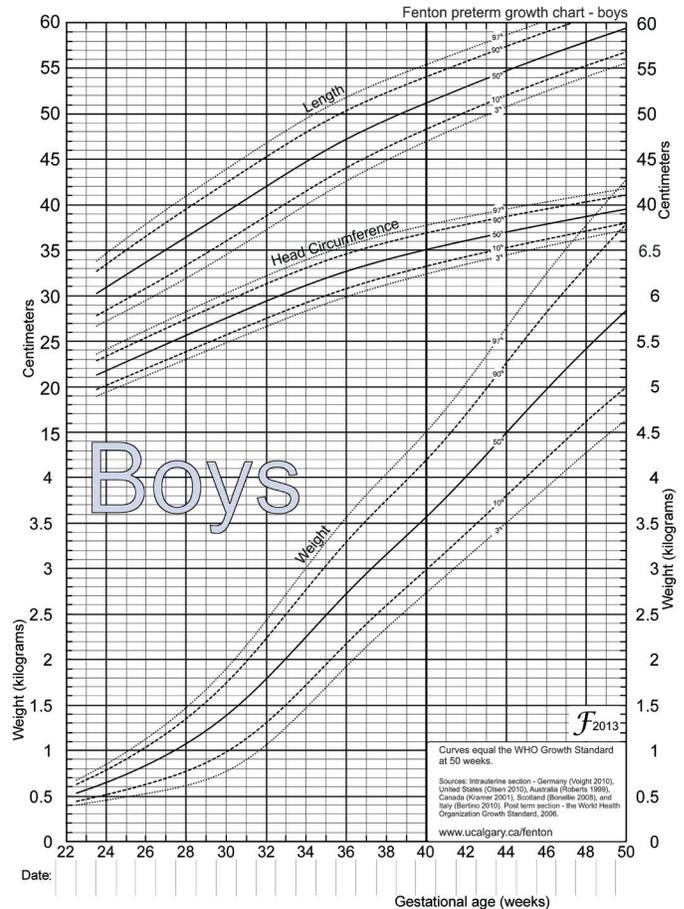

Fig. 41.4 Example of a growth record of weight, length, and head circumference for male infants from 22 to 50 weeks of gestation. This chart has a built-in correction factor for prematurity. <https://www.ucalgary.ca/fenton>. (From Fenton TR, Kim JH: A systematic review and meta-analysis to revise the Fenton growth chart for preterm infants, *BMC Pediatr* 13:59, 2013.)

short period. In addition, it is important that any ongoing chronic illnesses, including nutrition problems, be manageable at home.

Most important, the parents must be ready to care for their infant. In hospitals that allow parents to visit their infants in the nursery 24 hours a day, staff can help parents develop their caregiving skills and learn to care for their infant at home. Often, parents are permitted to “room in” with their infant (i.e., stay with the infant all day and night) before discharge, which helps build confidence in their ability to care for a high-risk infant (Fig. 41.6).

Many preterm infants who are discharged from the hospital weigh less than 5½ lb. Although these infants must meet certain discharge criteria before they can go home, the stress of a new environment may lead to setbacks. Small preterm infants should be followed very closely during the first month after discharge, and parents should be given as much information and support as possible. Within the first week of discharge, a home visit by a nurse, dietitian, or both and a visit to the pediatrician can be extremely educational, and they can provide opportunity for early intervention for developing problems.

Factors that affect the feeding skills and behavior of preterm infants are particularly important after the infants have been discharged. Physical

BOX 41.3 Steps for Adjusting Age for Prematurity on Growth Charts

Calculate the number of weeks the infant was premature:

- 40 weeks (term) – Weeks of birth gestational age = Number of weeks premature
- The resulting number of weeks is the correction factor.

Calculate the adjusted age for prematurity:

- Chronologic age – Correction factor = Adjusted age for prematurity

For example:

- 40 weeks – 28 weeks of gestation = 12 weeks premature
- Therefore 12 weeks (3 months) is the correction factor.
- 4 months (chronologic age) – 3 months (correction factor) = 1 month adjusted age

factors such as a variable heart rate, a rapid respiratory rate, and tremulousness are examples of physiologic events that interfere with feeding. In addition, infants weighing less than 5½ lb have poor muscle tone. Although muscle tone gradually improves as an infant becomes larger and more mature, it can deteriorate quickly in infants who are

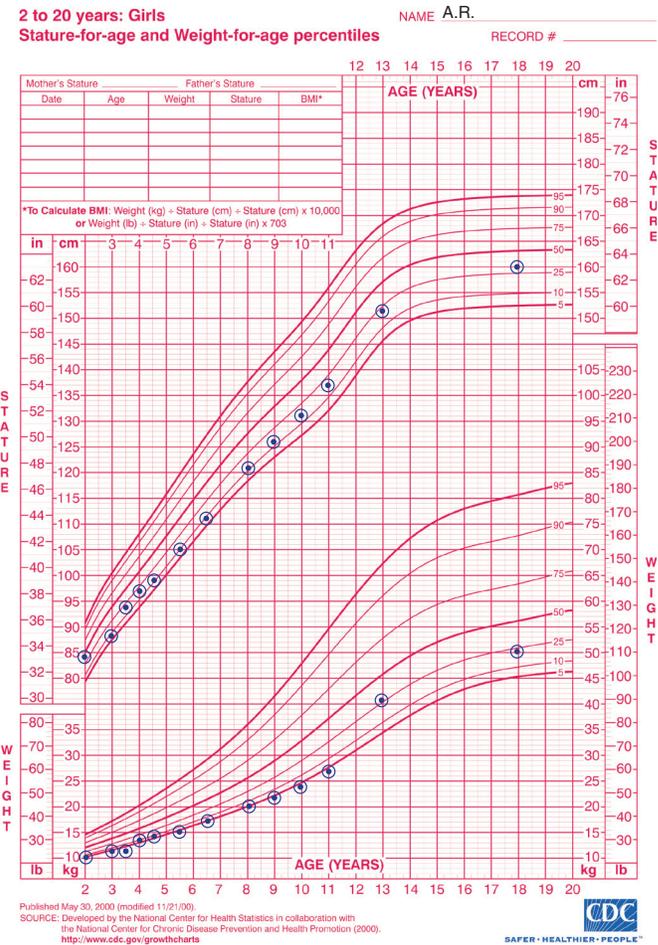

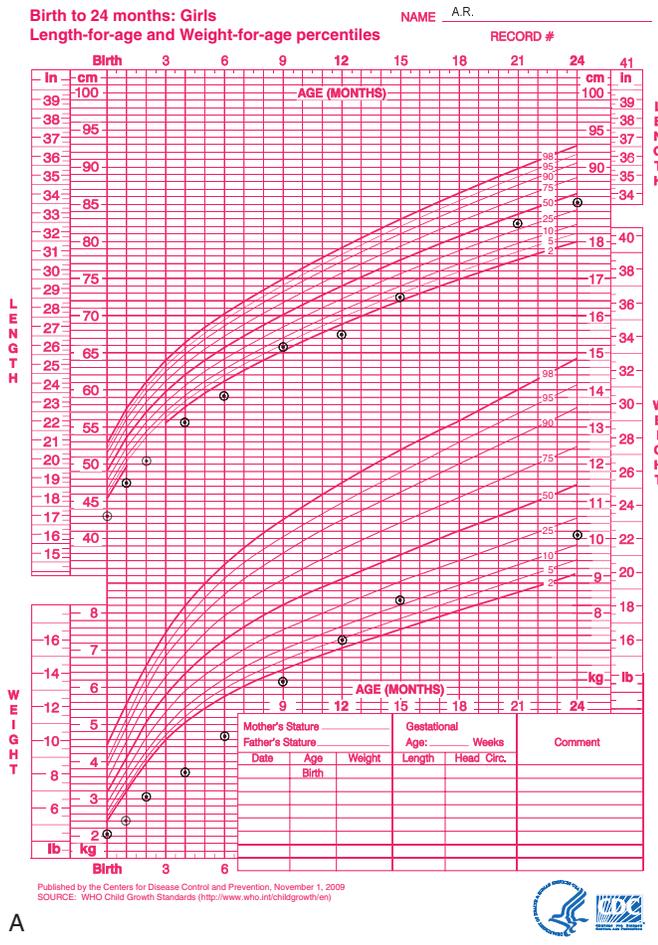

Fig. 41.5 A, Graphs showing how A.R. (from Fig. 41.2), who was born at 27 weeks of gestation, grew after leaving the neonatal unit 1 day before her due date at a weight of 4 ½ lb. Heights and weights until age of 24 months are plotted on the grid at “corrected age” points. A.R. experienced catch-up growth during the first 12 months. **B**, A.R.’s growth pattern from the age of 2 to 18 years. During the first 10 years she grew at the 5th percentile for weight and the 10th percentile for height. She followed her channel of growth but did not experience catch-up growth. However, between the ages of 10 and 13 she began to change growth channels and moved to the 25th percentile for weight and the 25th percentile for height (catch-up growth). At 18 years she crossed the 25th percentile for height and fell slightly below the 25th percentile for weight.

BOX 41.4 Problem, Etiology, and Signs and Symptoms (PES) Statements Commonly Used for Infants

- Increased nutrient (multinutrient) needs (NI-5.1) related to increased metabolic demand from prematurity as evidenced by weight gain less than 15 g/kg/day despite intake meeting estimated needs
- Growth rate below expected (NC-3.5) related to nutrient provision not meeting estimated needs as evidenced by weight gain less than 20 g/day
- No nutrition diagnosis at this time (NO-1.1) related to meeting estimated nutrition needs as evidenced by weight gain/growth appropriate overall

Data taken from commonly used PES statements used by Neonatal Dietitians at Texas Children’s Hospital, Houston, Texas, December, 2018.

tired or weak. Feeding is often difficult for infants who have limited muscle flexion and strength and poor head and neck control, which are needed to maintain a good feeding posture. Positioning these infants in a manner that supports normal body flexion and ensures proper alignment of the head and neck during feedings is helpful. Premature infants may also need their chin and cheeks supported while bottle feeding.

Small infants tend to sleep more than larger and term infants. It is much easier for preterm infants to feed effectively if they are fully awake. To awaken a preterm infant, the caregiver should provide one type of gentle stimulation for a few minutes and then change to a different type, repeating this pattern until the infant is fully awake. Lightly swaddling of the infant and then placing him or her in a semi-upright position also may help.

The feeding environment should be as quiet as possible. Preterm infants are easily distracted and have difficulty focusing on feeding when noises or movements interrupt their attention. They also tire quickly and are easily overstimulated. When they are overstimulated, they may show only subtle signs of distress. It is important to teach parents of premature infants to recognize the subtle cues that indicate the need for rest or comfort and to respond to them appropriately.

The premature infant may be able to breastfeed all feedings to meet nutritional needs. Infants with a birthweight less than 1500 g may need formula supplementation of human milk to meet their nutritional needs for adequate growth. Two to three feedings of the transitional formula can be provided, and the mother can

Fig. 41.6 Family in the nursery with their premature infant.

breastfeed the other feedings or provide expressed human milk in bottles. Transitional formula is available as a liquid ready-to-feed formula. The use of powder formula as a supplement can be avoided. Infant formula powders are not sterile and have been linked with *Cronobacter sakazakii* infections. The use of two or three bottles of ready-to-feed formula provides more protein and minerals than provided when human milk is fortified with infant formula powder (AAP, 2014). A multivitamin and iron supplementation should be provided to meet the infant's vitamin D and increased iron demands.

After discharge, most preterm infants need approximately 180 mL/kg/day (2¾ oz/lb/day) of breastmilk or standard infant formula containing 20 kcal/oz. This amount of milk provides 120 kcal/kg/day (55 kcal/lb/day). Alternatively, transitional formula with a concentration of 22 kcal/oz can be provided at a rate of 160 mL/kg/day (or 2.5 oz/lb/day). The best way to determine whether these amounts are adequate for individual infants is to compare their intake with their growth progress over time. Some infants may need a formula that provides 24 kcal/oz. As mentioned previously, powdered transitional formula can be readily altered to a concentration of 24 kcal/oz.

It is important to evaluate needs based on the three growth parameters: weight, length, and head circumference. Patterns of growth should be assessed to determine whether (1) individual growth rate curves at least parallel reference curves, (2) growth curves are shifting inappropriately across growth percentiles, (3) weight is appropriate for length, and (4) growth is proportionate in all three areas.

NEURODEVELOPMENTAL OUTCOME

It is possible to meet the metabolic and nutritional needs of premature infants sufficiently to sustain life and promote growth and development. In fact, more tiny premature infants are surviving than

ever before because of adequate nutrition support and the recent advances in neonatal intensive care technology. There is concern that the ELBW infant is often smaller at discharge than the infant of the same postmenstrual age who was not born prematurely. One report suggests that providing appropriate protein intake during week 1 of life to ELBW infants leads to improved growth of weight, length, and head circumference at 36 weeks' gestation, and improved head circumference in male infants at 18 months' corrected age (Poindexter, 2014). Improved neurodevelopment and growth at 18 months has been reported with ELBW infants who gained more weight and had greater head circumference growth during their stay in the nursery (Ehrenkranz, 2014). The developmental outcome scores for ELBW infants have been higher as the intakes of MOM increase (Lechner and Vohr, 2017). Supplements of donor milk and premature infant formula result in similar developmental outcomes (O'Connor et al, 2016). Research on the neurodevelopment of premature infants who receive fortified donor human milk is needed (Arslanoglu et al, 2013).

Family-centered care where the parents can stay and care for their infants increases the parents' knowledge and skills to care for their infant and the potential for their infant's growth and development (Klaus et al, 2013; Ballard, 2015). A multidisciplinary support is needed to meet the needs for the infant and parents. Complementary therapies have been suggested for improved growth and development of the premature infant. Individual studies have suggested benefits for infant massage and for music therapy (Klaus et al, 2013; Anderson and Patel, 2018). More research is needed to document long-term effect of these therapies.

The increased survival rate of ELBW infants has increased concerns about their short- and long-term neurodevelopmental outcomes. Many questions have been raised about the quality of life awaiting infants who receive neonatal intensive care. As a rule, VLBW infants should be referred to a follow-up clinic to evaluate their development and growth and begin early interventions (Wilson-Costello and Payne, 2015). The survival of ELBW infants has increased, with an increase in the number of children who are developmentally normal who attend school and live independent lives as adults (Wilson-Costello and Payne, 2015). Many of these premature infants reach adulthood with no evidence of any disability (Fig. 41.7).

Complementary and Integrative Approaches

Integrative approaches are frequently used with premature infants to facilitate optimal neurodevelopment. The premature infant develops in a NICU environment that differs from the in utero environment of the fetus during critical brain development. Exposure to sound, light, touch, movement, smell, and taste are different, and it is unclear what exposures are best for premature infants and for infants who are ill (Pineda et al, 2017). Examples of therapies include infant massage, music therapy, kangaroo care, and language exposure (Galicja-Connolly et al, 2012; Pineda et al, 2017). In addition nutrient stores are lower in infants born prematurely, so infant formulas have been supplemented with nutrients that are part of brain development. The addition of long-chain fatty acids and DHA have been helpful (Lapillonne, 2014). Together, parents and caretakers need to identify therapies that work for each infant (Pineda et al, 2017).

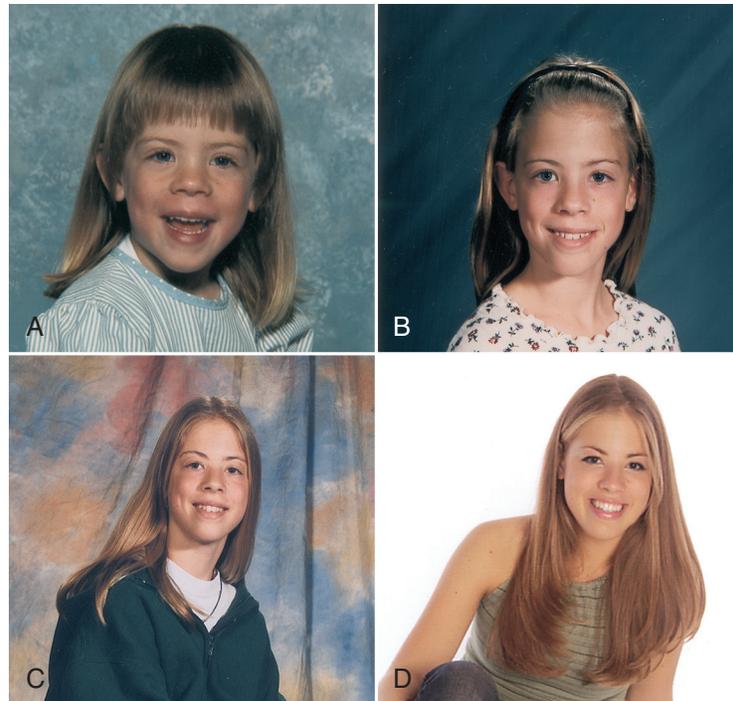

Fig. 41.7 The premature infant A.R. (see Figs. 41.2 and 41.6) as she grows up. **A**, 3½ years. **B**, 10 years. **C**, 14 years. **D**, 18 years. (D, Courtesy Yuen Lui Studio, Seattle, Wash.)

CLINICAL CASE STUDY 1

Heather, a white infant born at 26 weeks of gestation, was admitted to the neonatal intensive care unit. Her birth weight was 850 g (appropriate for gestational age). Heather had respiratory distress syndrome and had to receive a tube for mechanical ventilation. During the first few hours of her life, she was given surfactant, and her ventilator settings were lowered. She was also placed in a humidified incubator and given 100 mL/kg/day of starter parenteral nutrition (dextrose 10% in water with amino acids) intravenously.

On the second day after her birth, she had gained 20 g, and her serum sodium concentration and urine volume output were low. She was diagnosed with excessive fluid intake. Her blood pressure was low and the drug dopamine was provided to increase her urine output.

On the fourth day after birth, her body weight had decreased 50 g—6% of her birth weight—and her serum electrolyte levels were normal. The protein concentration of her parenteral fluids was increased, as was the volume of intravenous fat being provided.

By the fifth day, Heather was clinically stable. She began receiving feedings of milk from her mother—1.0 mL every 3 hours (10 mL/kg of her birth weight)—via bolus oral gastric tube. The feedings were tolerated well. She then began receiving a larger volume of her mother's breastmilk daily and less parenteral fluids.

On day eleven, full enteral feedings were established, and after extubation Heather was successfully breathing on her own.

Nutrition Diagnostic Statement, Day 2

- Excessive fluid intake (NI-3.2) related to intravenous fluids administered as evidenced by gain of 20 g and low serum sodium level.

Nutrition Diagnostic Statement, Day 11

- Inadequate intake (NI-5.11.1) of protein and minerals related to increased needs due to prematurity as evidenced by unfortified human milk not meeting established nutritional needs of premature infants.

Nutrition Care Questions

1. On the second day after birth, should Heather's intravenous fluid volume have been (1) increased because she needed more calories, (2) decreased because she was overhydrated, or (3) changed to enteral feedings because she was clinically stable?
2. How should the intravenous fat that was given to Heather have been administered?
3. The breastmilk from Heather's mother may have inadequate amounts of which nutrients? What do you recommend to resolve this?

CLINICAL CASE STUDY 2

Baby Le was born at 29 weeks of gestation, and his birthweight was 1400 g. He is now 1 week old or 30 weeks' postmenstrual age and weighs 1375 g. He is receiving parenteral nutrition at 130 mL/kg/day that contains 12.5% dextrose and 3.5% amino acids and a 20% intravenous fat emulsion at 15 mL/kg per day. The registered dietitian nutritionist (RDN) assesses the nutrient intake, and calculations are given in the following table. The patient's intakes are compared with the parenteral guidelines of the American Academy of Pediatrics (AAP, 2019) for premature infants.

Nutrient	Nutrient (kg/day)	Guidelines (kg/day)
Kilocalories kcal/kg/day	103	90-100
Glucose mg/kg/min	11.3	11-12
Protein g/kg	4.6	3-4
Fat g/kg	3	1-3

Nutrition Diagnostic Statement

- Excessive protein intake (NI-5.6.2) related to excessive provision in parenteral nutrition as evidenced by protein intake greater than recommendation of 4.0 g of protein per kilogram established by the AAP in 2019.

Nutrition Care Questions

- The RDN chooses the nutrition diagnosis and writes the problem, etiology, and signs and symptoms statement. Interventions include decreasing the amino acid concentration to 3%, which will provide 4.0 g of protein per kilogram per day.
- In how many days would you monitor and evaluate baby Le's nutrition status?
- What guidance is needed for the staff to evaluate him for signs of dehydration?

Medical Nutrition Therapy for Genetic Metabolic Disorders

*Beth N. Ogata, MS, RDN, CD, CSP
Cristine M. Trahms, MS, RDN, FADA*

KEY TERMS

argininosuccinic aciduria (ASA)	genetic metabolic disorders	medium-chain acyl-CoA dehydrogenase (MCAD) deficiency
autosomal-recessive	gluconeogenesis	methylmalonic acidemia
branched-chain ketoaciduria	glycogen storage diseases (GSDs)	ornithine transcarbamylase (OTC) deficiency
carbaryl-phosphate synthetase (CPS) deficiency	glycogenolysis	phenylketonuria (PKU)
citrullinemia	hereditary fructose intolerance (HFI)	propionic acidemia
fatty acid oxidation disorders	ketone utilization disorder	urea cycle disorders (UCDs)
galactokinase deficiency	L-carnitine	
galactosemia	long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency	
galactose-1-phosphate uridylyltransferase (GALT) deficiency	maple syrup urine disease (MSUD)	

Genetic metabolic disorders are inherited traits that result in the absence or reduced activity of a specific enzyme or cofactor necessary for optimal metabolism. Most genetic metabolic disorders are inherited as **autosomal-recessive** traits; autosomal means that the gene is located on a chromosome other than the X or Y chromosomes (see Chapter 6). The treatment for many metabolic disorders is medical nutrition therapy (MNT), with intervention specific to the disorder. The goals of MNT are to maintain biochemical equilibrium for the affected pathway, provide adequate nutrients to support typical growth and development, and support social and emotional development. Nutrition interventions are designed to circumvent the missing or inactive enzyme by (1) restricting the amount of substrate available, (2) supplementing the amount of product, (3) supplementing the enzymatic cofactor, or (4) combining any or all of these approaches. The primary conditions commonly found in the United States are discussed here, and [Table 42.1](#) outlines other disorders by the enzymatic defects, distinctive clinical and biochemical features, and current approaches to dietary therapy.

In some instances, when treatment is initiated early in the newborn period and meticulously continued for a lifetime, the affected individual can be cognitively and physically normal. For other conditions, cognitive and physical damage can occur despite early and meticulous treatment. Biochemical disorders range from variations in enzyme activity that are benign, to severe manifestations that are incompatible with life. For many, significant questions related to diagnosis and treatment remain.

NEWBORN SCREENING

Most inherited metabolic disorders are associated with severe clinical illness that often appears soon after birth. Intellectual disability and

severe neurologic involvement may be immediately apparent. Diagnosis of a specific disorder may be difficult, and appropriate treatment measures may be uncertain. Prenatal diagnosis is available for many metabolic disorders, but it usually requires the identification of a family at risk, which can be done only after the birth of an affected child. Effective newborn screening programs, as well as advanced diagnostic techniques and treatment modalities, have improved the outcome for many of these infants.

Infants suspected of having a metabolic disorder should be afforded access to care offered by centers with expertise in treating these disorders. Infants who are febrile for no apparent reason, lethargic, vomiting, in respiratory distress, or having seizures should be evaluated for an undiagnosed metabolic disorder. The initial assessment should include blood gas measurements, electrolyte values, glucose and ammonia tests, and a urine test for ketones.

Advances in newborn screening technology offer opportunities for earlier diagnosis, prevention of neurologic crisis, and improved intellectual and physical outcomes. When tandem mass spectrometry techniques are used in newborn screening laboratories, infants with a broader range of metabolic disorders can be detected, and the disorder can be identified earlier (see *Focus On: Newborn Screening* (NBS) and [Fig. 42.1](#)).

DISORDERS OF AMINO ACID METABOLISM

Nutrition therapy for amino acid disorders most commonly consists of substrate restriction, which involves limiting one or more essential amino acids to the minimum requirement while providing adequate energy and nutrients to promote typical growth and development (e.g., restricting phenylalanine [Phe] in phenylketonuria [PKU]). An inadequate intake of an essential amino acid is often as detrimental as

TABLE 42.1 Selected Genetic Metabolic Disorders That Respond to Dietary Treatment

Disorder	Affected Enzyme	Prevalence	Clinical and Biochemical Features	Medical Nutrition Therapy	Adjunct Treatment
Urea Cycle Disorders					
Carbamyl-phosphate synthetase deficiency	Carbamyl-phosphate synthetase	1:1,300,000 (1:35,000 for all UCDs)	Vomiting, seizures, sometimes coma → death Survivors usually have ID ↑ plasma ammonia and glutamine	Food: low protein Formula: without non-essential amino acids	L-carnitine, phenylbutyrate,* L-citrulline, L-arginine Hemodialysis or peritoneal dialysis during acute episodes
Ornithine transcarbamylase deficiency	Ornithine transcarbamylase (X-linked)	1:56,500 (1:35,000 for all UCDs)	Vomiting, seizures, coma → death as a newborn ↑ plasma ammonia, glutamine, glutamic acid, and alanine	Food: low protein Formula: without non-essential amino acids	L-carnitine, phenylbutyrate,* L-citrulline, L-arginine
Citrullinemia	Argininosuccinate synthetase	1:250,000 (1:35,000 for all UCDs)	<i>Neonatal:</i> vomiting, seizures, coma → death <i>Infantile:</i> vomiting, seizures, progressive developmental delay ↑ plasma citrulline and ammonia, alanine	Food: low protein Formula: without non-essential amino acids	L-carnitine, phenylbutyrate,* L-arginine
Argininosuccinic aciduria	Argininosuccinate lyase	1:218,750 (1:35,000 for all UCDs)	<i>Neonatal:</i> hypotonia, seizures Subacute: vomiting, FTT, progressive developmental delay ↑ plasma argininosuccinic acid, citrulline, and ammonia	Food: low protein Formula: lower protein SF (without non-essential amino acids)	L-carnitine, phenylbutyrate*
Argininemia	Arginase	1:950,000 (1:35,000 for all UCDs)	Periodic vomiting, seizures, coma Progressive spastic diplegia, developmental delay ↑ arginine and ammonia related to protein intake	Food: low protein Formula: lower protein SF (without non-essential amino acids)	L-carnitine, phenylbutyrate*
Organic Acidemias					
Methylmalonic acidemia	Methylmalonyl-CoA mutase or similar	1:80,000	Metabolic acidosis, vomiting, seizures, coma, often death ↑ organic urine acid and plasma ammonia levels	Food: low protein Formula: lower protein SF (without isoleucine, methionine, threonine, valine)	L-carnitine, vitamin B ₁₂ IV fluids, bicarbonate during acute episodes
Propionic acidemia	Propionyl-CoA carboxylase or similar	1:105,000 – 1:130,000	Metabolic acidosis, ↑ plasma ammonia and propionic acid, ↑ urine methylcitric acid	Food: low protein Formula: lower protein SF (without isoleucine, methionine, threonine, valine)	L-carnitine, biotin IV fluids, bicarbonate during acute episodes
Isovaleric acidemia	Isovaleryl-CoA dehydrogenase	1:80,000	Poor feeding, lethargy, seizures, metabolic ketoacidosis, hyperammonemia	Food: low protein Formula: SF (without leucine)	L-carnitine, L-glycine
Ketone utilization disorder	2-methylacetoacetyl-CoA-thiolase or similar	Unknown	Vomiting, dehydration, metabolic ketoacidosis	Food: low protein Formula: SF (without isoleucine) Avoid fasting, high complex carbohydrates	L-carnitine, Bicitra

TABLE 42.1 Selected Genetic Metabolic Disorders That Respond to Dietary Treatment—cont'd

Disorder	Affected Enzyme	Prevalence	Clinical and Biochemical Features	Medical Nutrition Therapy	Adjunct Treatment
Biotinidase deficiency	Biotinidase or similar	1:61,067 (both profound and partial)	In <i>infants</i> , seizures, hypotonia, rash, stridor, apnea; in <i>older children</i> , also see alopecia, ataxia, developmental delay, hearing loss		Supplemental oral biotin
Carbohydrate Disorders					
Galactosemia	Galactose-1-phosphate uridylyltransferase	1:48,000	Vomiting, hepatomegaly, FTT, cataracts, ID, often early sepsis ↑ urine and blood galactose	Eliminate lactose, low galactose, use soy protein isolate formula	
Hereditary fructose intolerance	Fructose-1-phosphate aldolase	1:20,000	Vomiting; hepatomegaly; hypoglycemia, FTT, renal tubular defects after fructose introduction ↑ blood and urine fructose after fructose feeding	No sucrose, fructose	
Fructose 1,6-diphosphatase deficiency	Fructose 1,6-diphosphatase	Unknown	Hypoglycemia, hepatomegaly, hypotonia, metabolic acidosis upon fructose introduction No ↑ blood/urine fructose	No sucrose, fructose	
Glycogen storage disease, type Ia	Glucose-6-phosphatase	1:100,000	Profound hypoglycemia, hepatomegaly	Low lactose, fructose, sucrose; low fat; high complex carbohydrate; avoid fasting	Raw cornstarch, iron supplements
Amino Acid Disorders					
Hyperphenylalaninemias					
Phenylketonuria	Phenylalanine hydroxylase	1:15,000		Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	
Mild phenylketonuria	Phenylalanine hydroxylase	1:24,000	↑ blood Phe	Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	
Dihydropteridine reductase deficiency	Dihydropteridine reductase	Rare	↑ blood Phe, irritability, developmental delay, seizures	Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	Biopterin, 5-hydroxytryptophan, L-dopa, folic acid
Biopterin synthase defect	Biopterin synthase	Rare	Mild ↑ blood Phe, irritability, developmental delay, seizures	None	L-dopa, tetrahydrobiopterin, 5-hydroxytryptophan
Tyrosinemia, type I	Fumarylacetoacetate hydrolase	<1:100,000 to 1:120,000	Vomiting, acidosis, diarrhea, FTT, hepatomegaly, rickets ↑ blood and urine tyrosine, methionine; ↑ urine para-hydroxy derivatives of tyrosine; liver cancer	Food: low protein Formula: SF (without tyrosine, Phe, methionine)	Nitisinone [†]
Maple Syrup Urine Disease (MSUD)					
MSUD	Branched-chain ketoacid decarboxylase complex (<2% activity)	1:185,000	Seizures, acidosis Plasma leucine, isoleucine, valine 10× normal	Food: low protein Formula: SF (without leucine, isoleucine, valine)	Thiamin [†]

Continued

TABLE 42.1 Selected Genetic Metabolic Disorders That Respond to Dietary Treatment—cont'd

Disorder	Affected Enzyme	Prevalence	Clinical and Biochemical Features	Medical Nutrition Therapy	Adjunct Treatment
Intermittent MSUD	Branched-chain ketoacid decarboxylase complex (<20% activity between episodes)	Rare	Intermittent symptoms Plasma leucine, isoleucine, valine 10× normal during illness	Food: low protein Formula: SF (without leucine, isoleucine, valine)	
Homocystinuria	Cystathionine synthase or similar	1:200,000	Detached retinas; thromboembolic and cardiac disease; mild to moderate ID; bony abnormalities; fair hair and skin; ↑ methionine, homocysteine	Food: low protein Formula: SF (without methionine, supplemented with L-cystine)	Betaine, folate, vitamin B ₁₂ , vitamin B ₆ [†] if folate levels are normal
Fatty Acid Oxidation Disorders					
Long chain acyl-CoA dehydrogenase deficiency	Long-chain acyl-CoA dehydrogenase	Rare	Vomiting, lethargy, hypoglycemia	Low fat, low long-chain fatty acids; avoid fasting	MCT oil, L-carnitine [§]
Long-chain 3-hydroxy-acyl-CoA dehydrogenase deficiency	Long-chain 3-hydroxy-acyl-CoA dehydrogenase	Rare	Vomiting, lethargy, hypoglycemia	Low fat, low long-chain fatty acids; avoid fasting	MCT oil, L-carnitine [§]
Medium-chain acyl-CoA dehydrogenase deficiency	Medium-chain acyl-CoA dehydrogenase	1:13,000 to 1:19,000	Vomiting, lethargy, hypoglycemia	Low fat, low medium-chain fatty acids, avoid fasting	L-carnitine [§]
Short-chain acyl-CoA dehydrogenase deficiency	Short-chain acyl-CoA dehydrogenase	1:35,000	Vomiting, lethargy, hypoglycemia	Low fat, low short-chain fatty acids, avoid fasting	L-carnitine [§]
Very-long-chain acyl-CoA dehydrogenase deficiency	Very-long-chain acyl-CoA dehydrogenase	1:30,000 to 1:100,000	Vomiting, lethargy, hypoglycemia	Low fat, low long-chain fatty acids, avoid fasting	L-carnitine, [§] MCT oil

*Phenylbutyrate is a chemical administered to enhance waste ammonia excretion; other compounds producing the same effect are also used.

[†]Nitisonone, formerly *NTBC*, 2-(2-nitro-4-trifluoromethyl-benzoyl-1,3-cyclohexanedione), commercially available as Orfadin and Nityr.

[‡]Patient may or may not respond to the compound.

[§]Use depends on clinic.

CoA, Coenzyme A; *FTT*, failure to thrive; *ID*, intellectual disability; *IV*, intravenous; *MCT*, medium-chain triglyceride; *MSUD*, maple syrup urine disease; *Phe*, phenylalanine; *SF*, specialized formulas are available for medical nutrition therapy for this disorder; *UCD*, urea cycle disorder.

FOCUS ON

Newborn Screening (NBS)

Since the 1960s, states across the United States have adopted mandatory newborn screening (NBS) as law (Waisbren, 2006). These programs were developed as a result of the efficacy of the Guthrie bacterial inhibition assay, in which dried blood spots were used to identify phenylketonuria (PKU). This simple, sensitive, and inexpensive screening test became the basis for population-based screening systems for newborns. Hemoglobinopathies, endocrine disorders, metabolic disorders, and some infectious diseases can be identified effectively with the use of dried blood spots.

Tandem mass spectrometry was first used in the 1990s and is now used across the United States. This technology makes it possible to identify multiple disorders from a single dried blood spot. The number of disorders screened for varies by state, and expanded screening also is offered by private, for-profit companies. Follow-up programs also vary; some states have single, organized programs, whereas follow-up in other states is less centralized. Conditions successfully screened for by early NBS programs include congenital hypothyroidism, PKU, congenital adrenal hyperplasia, galactosemia, sickle cell disease, and maple syrup urine disease (Brosco et al, 2006).

The Maternal and Child Health Bureau (MCHB) of the U.S. Health Resources and Services Administration commissioned a report from the American College of Medical Genetics (ACMG). This expert panel identified 29 conditions for which

newborn screening should be mandated and 25 secondary conditions that may be detected incidentally (Watson, 2006). The ACMG developed a series of ACTion (ACT) sheets and confirmatory algorithms for disorders that are identified by NBS screening. The ACT sheets describe the steps health professionals should follow in communicating with the family and determining follow-up (ACMG, 2001).

Other groups, including the World Health Organization, March of Dimes, and Massachusetts Newborn Screening Advisory Committee, also have issued recommendations.

Providers who may be involved in the care and follow-up of families identified by NBS should have a good understanding of their state's system, as well as the confounding factors that may affect results. Communication among families, primary health care providers, and tertiary clinics is critical to timely identification and treatment. Follow-up, including referral to the appropriate specialists, is important for any family who receives positive NBS results. NBS fact sheets from the Committee on Genetics of the American Academy of Pediatrics describe (1) newborn screening; (2) follow-up of abnormal screening results to facilitate timely diagnostic testing and management; (3) diagnostic testing; (4) disease management, which requires coordination with the medical home and genetic counseling; and (5) continuous evaluation and improvement of the NBS system (Kaye et al, 2006).

Fig. 42.1 Blood spots are collected from a newborn for newborn screening. (Courtesy Kelly McKean.)

excess. Supplementation of the product of the specific enzymatic reaction usually is required in nutrition therapy for amino acid disorders; for example, tyrosine (Tyr) is supplemented in formulas for treatment of PKU.

Requirements for individual amino acids are difficult to determine because typical growth and development can be achieved over a wide range of intake. The data of Holt and Snyderman (1967) often are used as the basis for prescribing amino acid intakes (Table 42.2). Careful and frequent monitoring is required to ensure the adequacy of the nutritional prescription. Although

nitrogen studies are the most precise, weight gain in infants is a sensitive and easily monitored index of well-being and nutritional adequacy.

PHENYLKETONURIA

Etiology

Phenylketonuria (PKU) is the most common of the hyperphenylalaninemias. In this disorder Phe is not metabolized to Tyr because of a deficiency or inactivity of phenylalanine hydroxylase (PAH) as shown in Fig. 42.2. Of the amino acid disorders, PKU provides a reasonable model for detailed discussion because it (1) occurs relatively frequently and most neonates are screened for it; (2) has a successful MNT treatment; and (3) has a predictable course, with available documentation of “natural” and “intervention” history (see *Focus On: Timeline of Events in the Diagnosis and Treatment of Phenylketonuria*).

Nutritional treatment involves restricting the substrate (Phe) and supplementing the product (Tyr) (see *Pathophysiology and Care Management Algorithm: Phenylketonuria*). Most affected infants exhibit PAH deficiency; the remainder (less than 3%) have defects in associated pathways. Low-Phe nutrition therapy does not prevent the neurologic deterioration present in the disorders of these other associated pathways.

Medical Treatment

All states have newborn screening programs for PKU and other metabolic disorders. Diagnostic criteria for PKU include an elevated blood concentration of Phe and an elevated (i.e., greater than 3) Phe:Tyr ratio. The diagnostic process also should include evaluation for hyperphenylalaninemia that results from the deficiency of

TABLE 42.2 Approximate Daily Requirements for Selected Dietary Components and Amino Acids in Infancy and Childhood

Dietary Component or Amino Acid	AGE AND REQUIREMENT		Dietary Component or Amino Acid	AGE AND REQUIREMENT	
	Birth to 12 mo (mg/kg)	1-10 yr (mg/day)		Birth to 12 mo (mg/kg)	1-10 yr (mg/day)
Phenylalanine	1-5 mo: 47-90 6-12 mo: 25-47	200-500 [*]	Cyst(e)ine [§]	15-50	400-800
Histidine	16-34		Lysine	90-120	1200-1600
Tyrosine [†]	1-5 mo: 60-80 6-12 mo: 40-60	25-85 (mg/kg)	Threonine	45-87	800-1000
Leucine	76-150	1000	Tryptophan	13-22	60-120
Isoleucine	1-5 mo: 79-110 6-12 mo: 50-75	1000	Energy	1-5 mo: 108 kcal/kg 6-12 mo: 98 kcal/kg	70-102 kcal/kg
Valine	1-5 mo: 65-105 6-12 mo: 50-80	400-600	Water	100 mL/kg	1000 mL
Methionine [‡]	20-45	400-800	Carbohydrate	kcal × 0.5 ÷ 4 = g/day	
			Total protein	1-5 mo: 2.2 g/kg 6-12 mo: 1.6 g/kg	16-18
			Fat	kcal × 0.35 ÷ 9 = g/day	

Compiled from amino acid data of Holt and Snyderman. Information on amino acid requirements of infants and children at different ages is limited; the figures given here are in excess of minimum requirements. Consequently, this table should be used only as a guide and should not be regarded as an authoritative statement to which individual patients must conform.

^{*}More phenylalanine (>800 mg) is required in the absence of tyrosine.

[†]Total phenylalanine plus tyrosine should be considered in the prescription because most phenylalanine is converted to tyrosine.

[‡]More methionine is required in the absence of cyst(e)ine.

[§]More cyst(e)ine is required in presence of a blocked *trans*-sulfuration outflow pathway for methionine metabolism.

Modified from American Academy of Pediatrics, Committee on Nutrition: Special diets for infants with inborn errors of metabolism, *Pediatrics* 57:783, 1976.

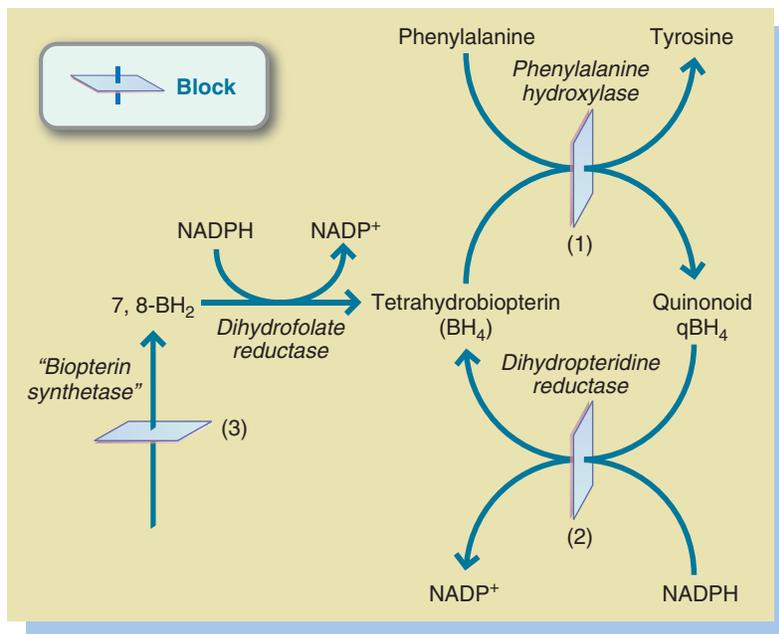

Fig. 42.2 Hyperphenylalaninemias. **1**, Phenylalanine hydroxylase deficiency; **2**, Dihydropteridine reductase deficiency; **3**, Biotin synthetase deficiency. *NADPH*, Nicotinamide-adenine dinucleotide phosphate (reduced form); *NADP*⁺, nicotinamide-adenine dinucleotide phosphate (oxidized form).

FOCUS ON

Timeline of Events in the Diagnosis and Treatment of Phenylketonuria

1934: A. Folling identifies phenylpyruvic acid in the urine of mentally retarded siblings.

1950s: G. Jervis demonstrates a deficiency of phenylalanine oxidation in the liver tissue of an affected patient. H. Bickel demonstrates that dietary phenylalanine restrictions lower the blood concentration of phenylalanine.

1960s: R. Guthrie develops a bacterial inhibition assay for measuring blood phenylalanine levels.

Mid-1960s: Semisynthetic formulas restricted in phenylalanine content become commercially available.

1965-1970: States adopt newborn screening programs to detect phenylketonuria (PKU).

1967-1980: Collaborative Study of Children Treated for Phenylketonuria is conducted. Data from this study form the basis for treatment protocols for PKU clinics in the United States.

Late-1970s: Detrimental effects of maternal PKU are recognized as a significant public health problem.

1980s: Lifelong restriction of phenylalanine intake becomes the standard of care in PKU clinics in the United States.

1983: The Maternal PKU Collaborative Study begins to study the effects of treatment on the pregnancy outcome of women with phenylketonuria.

1987: Techniques for carrier detection and prenatal diagnosis of PKU are developed.

Late-1980s: The gene for phenylalanine hydroxylase deficiency (MIM No. 261600) is located on chromosome 12q22-q24.1. DNA mutation analysis is accomplished with peripheral leukocytes.

1990s: Phenylalanine level of 2-6 mg/dL (120-360 $\mu\text{mol/L}$), lower than the previous level of less than 10 mg/dL (600 $\mu\text{mol/L}$), becomes the new standard of care for treatment of PKU.

2000s: Tetrahydrobiopterin-responsive forms of PKU are recognized, especially those with mild mutations.

2007: Sapropterin dihydrochloride (Kuvan), the commercial form of tetrahydrobiopterin receives FDA approval.

2010: Research into alternative and adjunct therapies such as the use of large neutral amino acids, enzyme substitution, and somatic gene therapy continues.

2014: Clinical trials for enzyme replacement therapy using pegylated phenylalanine ammonia lyase (PEG-PAL) injections are underway.

2018: Enzyme replacement therapy (pegvaliase-pqqz injection) receives FDA approval to lower blood Phe levels in adults who have uncontrolled Phe levels on current treatment.

Data from Maternal Child Health Bureau: Newborn screening: toward a uniform screening panel and system, *Genet Med* 8(Suppl 1):1S, 2006; Saugstad LF: From genetics to epigenetics, *Nutr Health* 18:285, 2006; Mitchell JJ, Scriver CR: Phenylalanine hydroxylase deficiency. In Pagon RA et al, editors: GeneReviews [Internet]. Seattle, 1993-2000, University of Washington, Seattle [updated January 5, 2017].

enzymes other than PAH, including defects in tetrahydrobiopterin (BH_4) synthesis or regeneration (Vockley et al, 2014). An effective newborn screening program and access to an organized follow-up program are critical to early identification and treatment of infants with PKU.

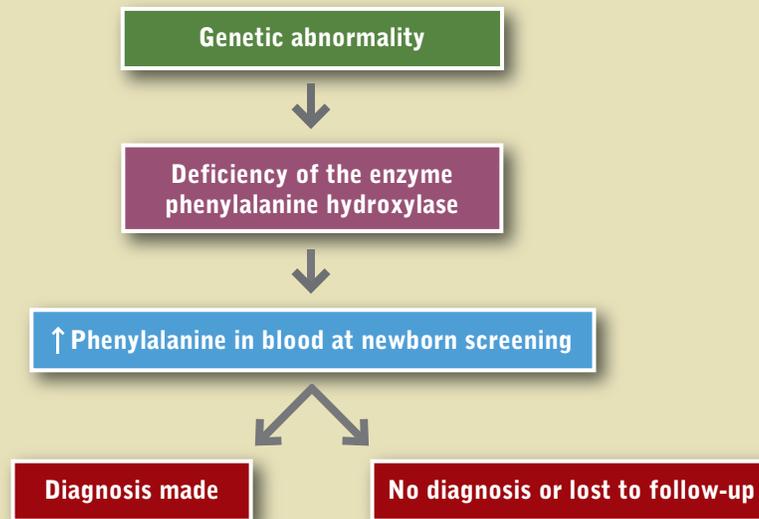

The advantage of rigorous nutrition therapy has been demonstrated by measurements of intellectual function. Individuals who do not receive diet therapy have severe intellectual disability, whereas individuals who are on therapy from the early neonatal period have normal intellectual function (McPheeters et al, 2012). Outcome,

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Phenylketonuria

ETIOLOGY

PATHOPHYSIOLOGY

Increased phenylalanine and abnormal phenylalanine/tyrosine ratio in blood

If left untreated or inadequate treatment – intellectual disability

Clinical Findings

- Blood phenylalanine >6-10 mg/dL (360-600 $\mu\text{mol/L}$)
- Blood tyrosine <3 mg/dL (165 $\mu\text{mol/L}$)

MANAGEMENT

Medical Management

Regular monitoring of blood phenylalanine to maintain at 1-6 mg/dL (60-360 $\mu\text{mol/L}$)

Nutrition Care

- Phenylalanine-free formula/medical food
- Low phenylalanine foods
- Supplement with tyrosine
- Education of family and child about formula/medical food preparation
- Adequate nutritional intake
- Regular monitoring of growth
- Education on label reading and food choices

measured as intellectual function, depends on the age of the infant at diagnosis and start of nutrition therapy, as well as the individual's biochemical control over time.

BH_4 has been studied to evaluate its effectiveness as an alternative treatment to severe dietary Phe restriction, since BH_4 is a

cofactor needed for proper activity of the enzyme. Treatment with sapropterin (a synthetic form of BH_4) is used as an adjunct therapy for some, especially with milder mutations (Longo et al, 2015). Those individuals who respond have what is called BH_4 -responsive PKU. However, even for BH_4 -responsive individuals, ongoing

intervention and nutrition monitoring is needed (Singh et al, 2010).

Enzyme replacement with phenylalanine ammonia lyase (PAL) was approved for use in adults with high blood Phe levels in 2018. This medication (pegvaliase-pqpz or Palynziq) is administered through daily injections. Gene therapy to restore PAH activity is also being studied.

Blood phenylalanine control. Blood Phe concentration must be checked regularly, depending on the age and health status of the child, to be sure it remains within the range of 2 to 6 mg/dL or 120 to 360 $\mu\text{mol/L}$ (McPheeters et al, 2012). Phe-containing foods are offered as tolerated as long as the blood concentration of Phe remains in the range of good biochemical control. The child's rate of growth and mental development must be monitored carefully.

Effective management requires a team approach in which the child, parents, registered dietitian nutritionist, pediatrician, psychologist, social worker, and nurse work together to achieve and maintain biochemical control in an atmosphere promoting normal mental and emotional development. An essential management tool for parents, children, and clinicians is the food diary used to monitor Phe intake. Daily record keeping supports compliance with treatment and builds self-management skills. An accurate record of food and formula intake for at least the 3 days before a laboratory specimen is obtained is critical for accurate interpretation of the results and subsequent adjustment of the Phe prescription.

Elevations in blood Phe concentration generally are caused by either excessive Phe intake or tissue catabolism. Intake of Phe in excess of the amount required for growth accumulates in the blood. Deficient energy intake or the stress of illness or infection can result in protein breakdown and the release of amino acids, including Phe, into the blood. In general, the anorexia of illness limits energy intake. Preventing tissue catabolism by maintaining intake of the formula/medical food as much as possible is essential. Although it occasionally may be necessary to offer only clear liquids during an illness, the Phe-free formula/medical food should be reintroduced as soon as it is feasible. Tube-feeding is an option if oral intake is not possible.

Continuing the restricted-Phe dietary therapy throughout childhood, adolescence, and beyond is recommended (McPheeters et al, 2012; Vockley et al, 2014). Progressively decreasing IQs, learning difficulties, poor attention span, and behavioral difficulties have been reported in children who have discontinued the dietary regimen. Children who maintain well-controlled blood Phe levels demonstrate comparatively higher intellectual achievement than those who do not. Good dietary control of blood Phe concentrations is the best predictor of IQ, whereas "off-diet" blood Phe concentrations of greater than 20 mg/dL (1200 $\mu\text{mol/L}$) are the best predictors of IQ loss. Subtle deficits in higher-level cognitive function may persist even at blood Phe levels of 6 to 10 mg/dL (360 to 600 $\mu\text{mol/L}$). Thus most clinics recommend treatment blood levels of 2 to 6 mg/dL (120 to 360 $\mu\text{mol/L}$). Restricted-Phe therapy should be continued for life to maintain normal cognitive function.

Medical Nutrition Therapy

Nutrition management guidelines for PKU have been published (Singh et al, 2014).

Formula. For PKU, dietary therapy is planned around the use of a formula/medical food with Phe removed from the protein. Formulas or medical foods provide a major portion of the daily protein and energy needs for affected infants, children, and adults. In general, the protein source in the formula/medical food is L-amino acids, with the critical amino acid (i.e., Phe) omitted. Glycomacropeptide (GMP), a whey protein with very little Phe, is used in a few medical foods as an

alternative to L-amino acids (van Calcar and Ney, 2012). Carbohydrate sources are corn syrup solids, modified tapioca starch, sucrose, and hydrolyzed cornstarch. Fat is provided by a variety of oils.

Some formula/medical foods contain no fat or carbohydrate, so these components must be provided from other sources. If using formulas without fat, clinicians must provide sources of essential fatty acids. Essential fatty acid deficiencies have been noted among individuals consuming fat-free formulas (Camp et al, 2014; Singh et al, 2014). Most formulas and medical foods contain calcium, iron, and all other necessary vitamins and minerals and are a reliable source of these nutrients. When others are devoid of these nutrients, supplementation is needed to ensure nutritional adequacy.

Phe-free formula is supplemented with regular infant formula or breastmilk during infancy and cow's milk in early childhood to provide high-biologic value protein, nonessential amino acids, and sufficient Phe to meet the individualized requirements of the growing child. The optimal amount of protein substitute depends on the individual's age (and thus requirements for growth) and enzyme activity; thus it must be prescribed individually. Because the protein in specialized formulas is synthetic, it is provided in amounts greater than the dietary reference intake (DRI) (Singh et al, 2014).

The Phe-free formula and milk mixture often provides approximately 90% of the protein and 80% of the energy needed by infants and toddlers. A method for calculating the appropriate quantities of a low-Phe food pattern is shown in Table 42.3. Calculations should provide adequate but not excessive energy for the infant, as well as appropriate fluid to maintain hydration. To support metabolic control effectively, formula/medical foods must be consumed in three or four nearly equal portions throughout the day.

Low-phenylalanine foods. Foods of moderate- or low-Phe content are used as a supplement to the formula or medical food mixture. These foods are offered at the appropriate ages to support developmental readiness and to meet energy needs. Pureed foods from a spoon may be introduced at 5 to 6 months of age, finger foods at 7 to 8 months, and the cup at 8 to 9 months, using the same timing and progression of texture recommended for typical children (see Chapters 15 and 16). Table 42.4 lists typical low-Phe food patterns for young children.

Low-protein pastas, breads, and baked goods made from wheat starch add variety to the food pattern and allow children to eat some foods "to appetite." A variety of low-protein pastas, rice, baked goods, egg replacers, and other foods are available. Wheat starch and a variety of low-protein baking mixes for breads, cakes, and cookies are also available. Table 42.5 compares low-protein and regular food items.

In many cases parents create recipes or adapt family favorites to meet the needs of their children. These recipes offer the children a variety of textures and food choices, allowing them to participate in family meals. Families are also able to meet the energy and Phe needs of their children without resorting to excessive intakes of sugars and concentrated sweets.

A formula or medical food that is free of Phe and has a more appropriate amino acid, vitamin, and mineral composition for an older child is generally introduced in the toddler or preschool period. The criteria for introduction of these "next-step" formulas are that the child accept the food pattern and formula well and reliably consume a wide variety of foods from the low-Phe food list. Successful management with consistently low blood Phe levels is based on habit (i.e., the formula/medical food is offered and consumed without negotiation or threat). Children respond favorably to the regularity of the time of ingestion of the formula/medical food and the familiarity of its taste and presentation. Table 42.6 compares a restricted Phe food pattern with a typical food pattern for a child of the same age.

TABLE 42.3 Guidelines for Low-Phenylalanine Food Pattern Calculations

Step 1: Calculate the child's needs for phenylalanine, protein, and energy (kcal).
 Phenylalanine
 $7.7 \text{ kg} \times 40^* \text{ mg phenylalanine} = 308 \text{ mg Phe/kg/day}$
 Protein
 $7.7 \text{ kg} \times 2.5\text{-}3^{\dagger} \text{ g pro} = 19\text{-}25 \text{ g pro/kg/day}$
 Energy
 $7.7 \text{ kg} \times 100^{\ddagger} \text{ kcal} = 770 \text{ kcal/kg/day}$
 Step 2: Estimate the amount of phenylalanine, protein, and energy to be obtained from foods other than the formula mixture.

APPROXIMATE NEEDS			
	Phenylalanine (mg/day)	Protein (g/day)	Energy (kcal/day)
Foods	30	1-2	100
Formula	~288	18-24	670
<i>Total</i>	<i>318</i>	<i>19-25</i>	<i>770</i>

Step 3: Confirm that a reasonable food pattern is provided with the estimated phenylalanine from food guideline. A sample food pattern:

	Phenylalanine (mg)	Protein (g)	Energy (kcal)
Green beans, strained, 2 Tbsp	15	0.4	8
Banana, mashed, 2 Tbsp	10	0.3	28
Carrots, strained, 2 Tbsp	6	0.2	7
<i>Total</i>	<i>31</i>	<i>0.9</i>	<i>43</i>

Step 4: Determine the amount of standard infant formula to be included in the formula. This information is determined from the infant's estimated phenylalanine needs.
 Step 5: Determine the amount of phenylalanine-free formula required per day. This information is determined from the infant's estimated protein and energy needs.
 Step 6: Determine the amount of water to mix with the formula. The consistency of the formula will vary according to the infant's age and fluid requirements. For example, for the infant described in the case study, add water to make a total volume of 32 oz.
 Step 7: Determine the amounts of phenylalanine, protein, and energy provided by formulas and foods.

	Phenylalanine (mg/day)	Protein (g/day)	Energy (kcal/day)
Phenex-1 powder (70 g)	0	10.5	325
Enfamil powder (70 g)	294	7.4	350
Food	30	1-2	100
<i>Total</i>	<i>324</i>	<i>18.9-19.9</i>	<i>775</i>

Step 8: Determine the actual amounts of phenylalanine, protein, and energy per kilogram body weight.
 Phenylalanine
 $324 \div 7.7 \text{ kg} = 42 \text{ mg Phe/kg/day}$
 Protein
 $19.4 \div 7.7 \text{ kg} = 2.5 \text{ g pro/kg/day}$
 Energy
 $774 \div 7.7 \text{ kg} = 101 \text{ kcal/kg/day}$

*A phenylalanine intake of 40 mg/kg/day is chosen as a moderate intake level. The prescription for phenylalanine must be adapted to individual needs as judged by growth and blood levels.

†Although these intakes are higher than the recommended dietary allowance, they are the intakes found by the Collaborative Study to promote normal growth with consumption of protein hydrolysate-based formula.

‡Total energy intake must be adjusted to meet individual needs, and an excess must be avoided.

Acosta PB: Recommendations for protein and energy intakes by patients with phenylketonuria, *Eur J Pediatr* 155(Suppl 1):S121, 1996; Singh RH, et al: Recommendations for the nutrition management of phenylalanine hydroxylase deficiency, *Genet Med* 16:121, 2014.

TABLE 42.4 Typical Menus for a 3-Year-Old with Phenylketonuria

Tolerance: 300 mg phenylalanine/day		Tolerance: 400 mg phenylalanine/day	
Formula/medical food for 24 hours: 120 g Phe-free-2, 100 g 2% milk, water to 24 oz		Formula/medical food for 24 hours: 120 g Phe-free-2, 100 g 2% milk, water to 24 oz	
This formula mixture provides 30 g protein, 460 kcal, 170 mg phenylalanine.		This formula mixture provides 30 g protein, 460 kcal, 170 mg phenylalanine.

Education about therapy management. The energy needs and amino acid requirements of children with PKU do not differ appreciably from those of children in general. With proper management, typical growth can be expected (Fig. 42.3). However, parents may tend to offer excessive energy as sweets because they feel their child is being

TABLE 42.5 Comparison of Protein and Energy Content of Foods Used in Low-Protein Diets

Food Item	Energy (kcal)	Protein (g)
Pasta, ½ cup, cooked

deprived of food experiences. Health care providers should support families in recognizing that children with PKU are healthy children who must make careful food choices for themselves, not chronically ill children who require food indulgences.

Appropriate clinical interaction with family members provides them with the information and skills to differentiate between food behaviors that are typical for the age and developmental level of the child and those related specifically to PKU. To avoid power struggles and conflicts over food, it is advisable to involve the child in choosing appropriate foods at an early age. Children who are 2 to 3 years old can master the concept of appropriate choices when foods are categorized as “yes foods” and “no foods.” The concept of an appropriate quantity of a food can be introduced to a 3- or 4-year-old child in terms of “how

Fig. 42.3 Two young children, both with phenylketonuria, who were identified by a newborn screening program and started on treatment by 7 days of age, demonstrate typical growth and development. (Courtesy Beth Ogata, Seattle.)

PKU, Phenylketonuria.

TABLE 42.7 Tasks Expected of Children with Phenylketonuria by Age Level

Age (yr)	School Level	Task
2-3	Preschool	Distinguishing between “yes” and “no” foods
3-4	Preschool	Counting: how many?
4-5	Preschool	Measuring: how much?
5-6	Kindergarten	Preparing own formula; using scale
6-7	Grade 1-2	Writing basic notes in food diary
7-8	Grade 2	Making some decisions on after-school snack
8-9	Grade 3	Preparing breakfast
9-10	Grade 4	Packing lunches
10-14	Middle school	Managing food choices with increasing independence
14-18	High school	Independently managing phenylketonuria

many” by counting crackers or raisins and then in terms of “how much” by weighing or measuring foods such as cereal or fruit. The child then moves to more complex tasks (e.g., formula and food preparation) and planning of meals (e.g., breakfast or a packed lunch). Responsibility for planning a full day’s menu by calculating the quantity of Phe in portions of food and compiling the daily total is the ultimate goal. These age-related tasks are shown in [Table 42.7](#).

Psychosocial development. The necessity of carefully controlling food intake may prompt parents to overprotect their children and perhaps to restrict their social activities. The children, in turn, may react negatively to their parents and to their nutrition therapy. The ability of the family to respond to the stresses of PKU, as reflected by adaptability and cohesion scores, is demonstrated by improved blood Phe concentrations and the positive coping behaviors of older children with PKU. Thus continuing nutrition therapy beyond early childhood requires that children become knowledgeable about and responsible for managing their own food choices. The health care team becomes responsible for working with families and children to provide strategies that enable children and adolescents to participate in social and school activities, interact with peers, and progress through the typical developmental stages with self-confidence and self-esteem.

Children require parental and professional support as they assume responsibility for their food management. Self-management of food choices is a strategy to prevent the child using dietary noncompliance as a wedge against parental restrictions. Normal intellectual development is a laudable goal of management of PKU, but to be entirely successful children with PKU concomitantly need to develop self-assurance and a strong self-image. This can be achieved in part by fostering self-management, problem-solving skills, independence, and a typical lifestyle.

Maternal PKU

A pregnant woman with elevated blood Phe concentrations endangers her fetus because of the active transport of amino acids across the placenta. The fetus is exposed to approximately twice the Phe level contained in normal maternal blood. Babies whose mothers have elevated blood Phe concentrations have an increased occurrence of cardiac defects, restricted growth, microcephaly, and intellectual disability, as presented in [Table 42.8](#). The fetus appears to be at risk of damage even with minor elevations in maternal blood Phe levels, and the higher the level, the more severe the effect. Strict control of maternal Phe levels before

TABLE 42.8 Frequency of Abnormalities in Children Born to Mothers with Phenylketonuria

Complication (% of Offspring)	MATERNAL PHENYLALANINE LEVELS (mg/dL)				Non-PKU Mother
	20	16-19	11-15	3-10	
Mental retardation	92	73	22	21	5.0
Microcephaly	73	68	35	24	4.8
Congenital heart disease	12	15	6	0	0.8

Modified from Lenke RR, Levy HL: Maternal phenylketonuria and hyperphenylalaninemia: an international survey of the outcome of untreated and treated pregnancies, *N Engl J Med* 303:1202, 1980. PKU, Phenylketonuria.

conception and throughout pregnancy offers the best opportunity for normal fetal development ([Koch et al, 2010](#); [Martino et al, 2013](#)).

Nutrition management for pregnant women with hyperphenylalaninemia is complex. The changing physiology of pregnancy and fluctuating nutritional needs are difficult to monitor with the precision required to maintain appropriately low blood-Phe concentrations. Even with meticulous attention to Phe intake, blood concentrations, and the nutrient requirements of pregnancy, a woman cannot be ensured a normal infant ([Lee et al, 2005](#)). The risks of abnormal development of the fetus, even with therapeutic dietary management and maintenance of blood Phe concentrations at 1 to 5 mg/dL (60-300 μ mol/L), are an important consideration for young women with PKU considering pregnancy ([Waisbren and Azen, 2003](#)).

Nutritional management during pregnancy is challenging, even for women who have consistently followed a low-Phe dietary regimen since infancy. Women who have discontinued Phe dietary treatment find that reinstating medical food consumption and limiting food choices can be difficult and overwhelming. Inadequate maternal nourishment (i.e., inadequate intakes of total protein, fat, and energy) may contribute to poor fetal development and should be prevented. Adherence to nutrition therapy during pregnancy for even the well-motivated woman requires family and professional support, as well as frequent monitoring of biochemical and nutritional aspects of pregnancy and PKU.

Adults Living with Phenylketonuria

Many adults with PKU have had the benefits of early diagnosis and treatment and are less likely to be affected by neurologic damage. However, among those who have had some degree of intellectual disability, hyperactivity and self-abuse are often major concerns. Not all patients respond to late initiation of treatment with improved behavioral or intellectual function. For the difficult-to-manage older patient, a trial of a low-Phe food pattern is recommended. If successful, continued Phe restriction therapy may facilitate behavioral management.

Reinstating a Phe-restricted food pattern is difficult after the eating pattern has been liberalized. However, the current recommendation of most clinics is effective management of blood Phe concentration throughout a lifetime. This recommendation is based on reports of declining intellectual capabilities and changes in the brain after prolonged, significant elevation of Phe concentrations ([Camp et al, 2014](#)). The efficacy of continued treatment throughout

adulthood has been documented by reports of improved intellectual performance and problem-solving abilities when blood Phe levels are kept low. Dietary management of PKU throughout the life span is similar to that of other chronic disorders, and prudent MNT results in a normal quality of life.

Maple Syrup Urine Disease

Maple syrup urine disease (MSUD), or **branched-chain ketoaciduria**, results from a defect in enzymatic activity, specifically the branched-chain alpha-ketoacid dehydrogenase complex. It is an autosomal-recessive disorder. Infants appear normal at birth, but by 4 or 5 days of age they demonstrate poor feeding, vomiting, lethargy, and periodic hypertonia. A characteristic sweet, malty odor from the urine and perspiration can be noted toward the end of the first week of life.

Pathophysiology

The decarboxylation defect of MSUD prevents metabolism of the branched-chain amino acids (BCAAs) leucine, isoleucine, and valine (Fig. 42.4). Leucine tends to be more problematic than the others. The precise mechanism for the complete decarboxylase reaction and the resultant neurologic damage is not known. Neither is the reason why leucine metabolism is significantly more abnormal than that of the other two BCAAs (Strauss et al, 2013).

Medical Treatment

Failure to treat this condition leads to acidosis, neurologic deterioration, seizures, and coma, proceeding eventually to death. Management

of acute disease often requires peritoneal dialysis and hydration (see Chapter 34).

Depending on the severity of the enzyme defect, early intervention and meticulous biochemical control can provide a more hopeful prognosis for infants and children with MSUD. Reasonable growth and intellectual development in the normal-to-low-normal range have been described. Diagnosis before 7 days of age and long-term metabolic control are critical factors in long-term normalization of intellectual development. Maintenance of plasma leucine concentrations in infants and preschool children should be as close to physiologically normal as possible. Concentrations greater than 10 mg/dL (760 $\mu\text{mol/L}$) often are associated with alpha-ketoacidemia and neurologic symptoms.

Because the liver is the central site of metabolic control for amino acids and other compounds that cause acute degeneration of the brain during illness, therapeutic liver transplantation is sometimes an option in MSUD. Liver transplantation can prevent decompensation and crises associated with elevated leucine levels, but it does not reverse existing neurologic damage (Díaz et al, 2014; Oishi et al, 2016).

Medical Nutrition Therapy

Nutrition therapy requires very careful monitoring of blood concentrations of leucine, isoleucine, and valine as well as growth and general nutritional adequacy. Several formulas specifically designed for the treatment of this disorder are available to provide a reasonable amino acid and vitamin mixture. These generally are supplemented with a small quantity of standard infant formula or cow's

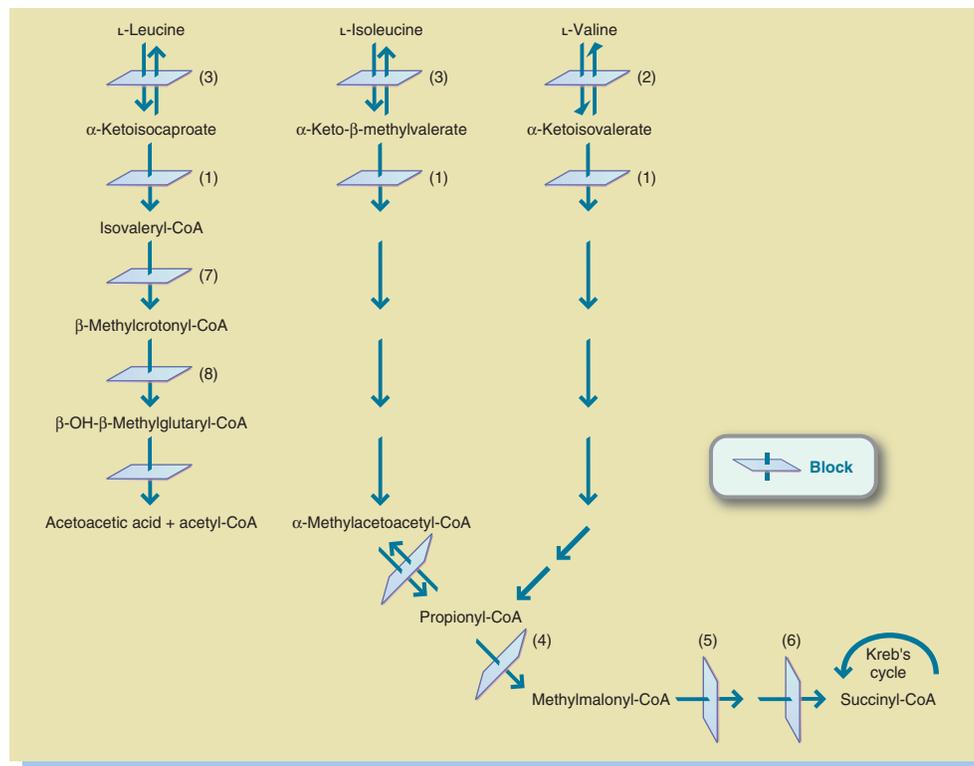

Fig. 42.4 Organic acidemias and maple syrup urine disease (MSUD). **1**, Branched-chain ketoacid decarboxylase (MSUD); **2**, Valine aminotransferase; **3**, Leucine-isoleucine aminotransferase; **4**, Propionyl-CoA carboxylase (propionic acidemia); **5**, Methylmalonyl-CoA racemase (methylmalonic aciduria); **6**, Methylmalonyl-CoA mutase (methylmalonic aciduria); **7**, Isovaleryl-CoA dehydrogenase (isovaleric acidemia); **8**, Beta-methylcrotonyl-CoA carboxylase (biotin-responsive multiple carboxylase deficiency). CoA, Coenzyme A.

milk to provide the BCAAs needed to support growth and development. Some infants and children may require additional supplementation with L-valine or L-isoleucine to maintain biochemical balance.

BCAAs may be introduced gradually into the diet when plasma leucine concentrations are decreased sufficiently (Frazier et al, 2014). Clinical relapse is related most often to the degree of elevation of leucine concentrations, and these relapses often are related to infection. Acute infections represent life-threatening medical emergencies in this group of children. If the plasma leucine concentration increases rapidly during illness, BCAAs should be removed from the diet immediately and intravenous therapy can be started.

DISORDERS OF ORGANIC ACID METABOLISM

The organic acid disorders are a group of disorders characterized by the accumulation in the blood of nonamino acid organic acids. Usually most of the organic acids are excreted efficiently in the urine. Diagnosis is based on excretion of compounds not normally present or the presence of abnormally high amounts of other compounds in the urine. The clinical course can vary but is generally marked by vomiting, lethargy, hypotonia, dehydration, seizures, and coma. Survivors often have permanent neurologic damage.

Pathophysiology

Propionic acidemia is a defect of propionyl-coenzyme A (CoA) carboxylase in the pathway of propionyl-CoA to methylmalonyl-CoA, as illustrated in Fig. 42.4. Metabolic acidosis with a marked anion gap and hyperammonemia is characteristic, and long-chain ketonuria also may be present.

At least five separate enzyme deficiencies have been identified that result in **methylmalonic acidemia** or aciduria. The defect of methylmalonyl-CoA mutase apoenzyme is the most frequently identified. In methylmalonic acidemia, the clinical features are similar to those of propionic acidemia. Acidosis is common, and diagnosis is confirmed by the presence of large amounts of methylmalonic acid in blood and urine. Other findings include hypoglycemia, ketonuria, and elevation of plasma ammonia and lactate levels.

Ketone utilization disorders (mitochondrial 2-methylacetoacetyl-CoA thiolase deficiency or similar enzyme defect) are disorders of isoleucine and ketone body metabolism. Affected individuals are usually older infants or toddlers who present with ketoacidosis, vomiting, and lethargy with secondary dehydration and sometimes coma. This event often is preceded by febrile illness or fasting.

Medical Treatment

Some patients with propionic acidemia may respond to pharmacologic doses of biotin. Long-term outcome in propionic acidemia is variable; hypotonia and cognitive delay may result even in children who are diagnosed early and who receive rigorous treatment. Liver damage and cardiomyopathy are possible sequelae. Liver transplantation may limit intellectual disability and cardiac changes (Sutton et al, 2012).

Individuals with methylmalonic acidemia may respond to pharmacologic doses of vitamin B₁₂. Responsiveness should be determined as part of the diagnostic process (Manoli et al, 2016). Progressive renal insufficiency is often a long-term outcome. Developmental delay is often caused by early and/or prolonged hyperammonemia.

For ketone utilization disorders, the treatment is dietary protein restriction (usually 1.5 g/kg of body weight per day); supplementation with **L-carnitine**, a carrier of fatty acids across the mitochondrial membranes; avoidance of fasting by providing small, frequent meals

that consist primarily of complex carbohydrates; and the use of Bicitra (sodium citrate-citric acid) to treat ketoacidosis.

Medical Nutrition Therapy

The goals of managing acute episodes of propionic acidemia and methylmalonic acidemia are to achieve and maintain normal nutrient intake and biochemical balance. Maintenance of energy and fluid intake is important to prevent tissue catabolism and dehydration. Intravenous fluids correct electrolyte imbalances, and abnormal metabolites are removed through urinary excretion, promoted by a high fluid intake. Relapses of metabolic acidosis may result from excessive protein intake, infection, constipation, or unidentified factors. Treatment for these episodes must be rapid because coma and death can occur quickly. Parents become skilled at identifying early signs of illness (Southeast Regional Genetics Network [SRGN], 2017).

Restricted protein intake is an essential component of the treatment of organic acid disorders. A daily protein intake of 1 to 1.5 g/kg of body weight is often an effective treatment modality for infants who have a mild form of the disorder. This can be supplied by diluting standard infant formula to decrease the protein content and adding a protein-free formula to meet other nutrient needs. Specialized formulas that limit threonine and isoleucine and omit methionine and valine are used, as clinically indicated, to support an adequate protein intake and growth.

Requirements for the limited amino acids may vary widely. Growth rate, state of health, residual enzyme activity, and overall protein and energy intakes must be monitored carefully and correlated with plasma amino acid levels. Adequate hydration is critical to maintain metabolic equilibrium. Food refusal and lack of appetite may complicate nutrition therapy, which compromises medical management.

DISORDERS OF UREA CYCLE METABOLISM

All **urea cycle disorders (UCDs)** result in an accumulation of ammonia in the blood. The clinical signs of elevated ammonia are vomiting and lethargy, which may progress to seizures, coma, and ultimately death. In infants the adverse effects of elevated ammonia levels are rapid and devastating. In older children symptoms of elevated ammonia may be preceded by hyperactivity and irritability. Neurologic damage may result from frequent and severe episodes of hyperammonemia. The severity and variation of the clinical courses of some urea cycle defects may be related to the degree of residual enzyme activity. The common urea cycle defects are discussed in a progression that proceeds around the urea cycle, as shown in Fig. 42.5.

Pathophysiology

Ornithine transcarbamylase (OTC) deficiency is an X-linked disorder marked by blockage in the conversion of ornithine and carbamyl phosphate to citrulline. OTC deficiency is identified by hyperammonemia and increased urinary orotic acid, with normal levels of citrulline, argininosuccinic acid, and arginine. Severe OTC deficiency is usually lethal in males. Heterozygous females with various degrees of enzyme activity may not demonstrate symptoms until they are induced by stress, as from an infection, or a significant increase in protein intake.

Citrullinemia is the result of a deficiency of argininosuccinic acid synthetase in the metabolism of citrulline to argininosuccinic acid. Citrullinemia is identified by markedly elevated citrulline levels in the urine and blood. Symptoms may be present in the neonatal period, or they may develop gradually in early infancy. Poor feeding and recurrent vomiting occur which, without immediate treatment, progress to seizures, neurologic abnormalities, and coma.

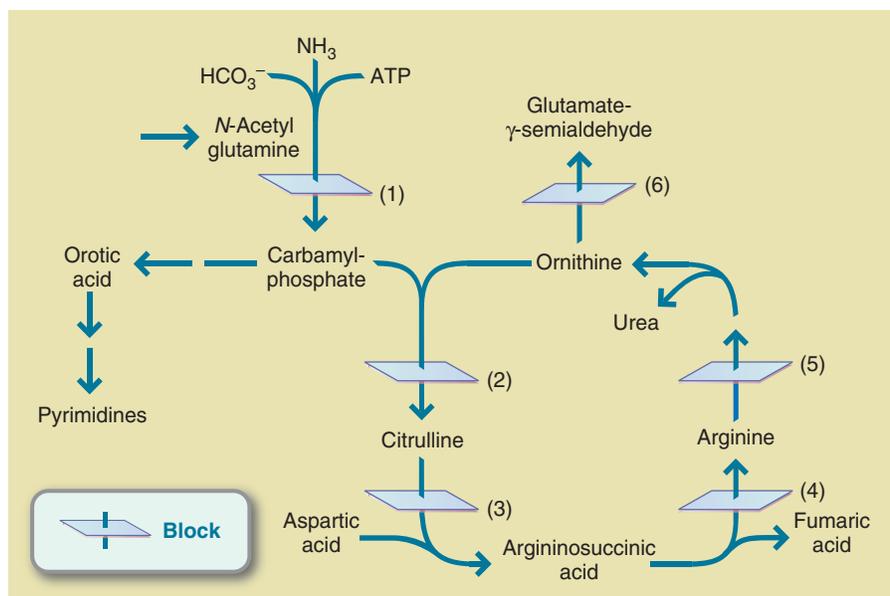

Fig. 42.5 Urea cycle disorders. **1**, Carbamyl-phosphate synthetase deficiency; **2**, Ornithine carbamyl transferase deficiency; **3**, Argininosuccinic acid synthetase (citrullinemia); **4**, Argininosuccinic acid lyase (argininosuccinic aciduria); **5**, Arginase deficiency (argininemia); **6**, Adenosine triphosphatase.

Argininosuccinic aciduria (ASA) results from deficiency of argininosuccinate lyase, which is involved in the metabolism of argininosuccinic acid to arginine. ASA is identified by the presence of argininosuccinic acid in urine and blood. L-arginine must be supplemented to provide an alternative pathway for waste nitrogen excretion.

Carbamyl-phosphate synthetase (CPS) deficiency is the result of deficient activity of CPS. The onset is usually in the early neonatal period, with vomiting, irritability, marked hyperammonemia, respiratory distress, altered muscle tone, lethargy, and often coma. Specific laboratory findings usually include low plasma levels of citrulline and arginine and normal orotic acid levels in urine.

Medical Treatment

Acute episodes of illness are managed by discontinuing protein intake and administering intravenous fluids and glucose to correct dehydration and provide energy. If hyperammonemia is severe, peritoneal dialysis, hemodialysis, or exchange transfusion may be required. Intravenous sodium benzoate or other alternative pathway compounds have been beneficial in reducing the hyperammonemia.

Neurologic outcome and intellectual development in individuals with UCDs vary, with a range from normal IQ and motor function to severe intellectual disability and cerebral palsy. Although information on long-term follow-up is limited, the use of alternative pathways for waste nitrogen excretion and a protein-restricted food pattern may improve the outcome.

Medical Nutrition Therapy

Nutritional management of patients who have UCDs is a challenging task. The aim of therapy for the UCDs is to prevent or decrease hyperammonemia and the detrimental neurologic consequences associated with it. Treatment is similar for all of the disorders. For mildly affected infants a standard infant formula can be diluted to provide protein at 1 to 1.5 g/kg body weight per day. The energy, vitamin, and mineral concentrations can be brought up to recommended intake levels with the addition of a protein-free formula that contains these nutrients. However, for most individuals, specialized formulas are needed to adjust protein composition in an effort to limit ammonia production.

The amount of protein tolerated is affected by variables such as the specific enzyme defect, age-related growth rate, health status, level of physical activity, amount of free amino acids administered, energy needs, residual enzyme function, and the use of nitrogen-scavenging medications. Recommendations must take family lifestyle and the individual's eating behaviors into consideration. Long-term therapy consists of restricting dietary protein to 1 to 2 g/kg/day, depending on individual tolerance. For most infants and children with these disorders, L-arginine supplements are required to prevent arginine deficiency and assist in waste nitrogen excretion. L-arginine is supplemented based on individual needs, except in the case of arginase deficiency (Brusilow and Horwich, 2010). Phenylbutyrate or other compounds that enhance alternative metabolic pathways usually are required to normalize ammonia levels.

Protein-Restricted Diets

Infants and children with urea cycle defects or organic acidemias generally require restricted-protein intakes and specialized formulas. The amount of protein prescribed is based on the individual's tolerance or residual enzyme activity, age, and projected growth rate. The highest protein level tolerated should be given to ensure adequate growth and a margin of nutritional safety. The steps for effective planning of a low-protein food pattern are shown in Box 42.1.

In general, low-protein or restricted-protein food patterns can be formulated from readily available, lower-protein infant, toddler, and table foods. Special low-protein foods (see Table 42.5) can be used to provide energy, texture, and variety in the food pattern without appreciably increasing the protein load. The prescribed protein level can be met by adding a protein-free or specialized formula product to standard infant formula. Supplementing carbohydrate and fat makes up the resultant energy deficit.

Specialty formulas are available when needed. The appropriate choice depends on the level of protein restriction, age, and condition of the child. The usual recommendations for energy density and vitamin and mineral composition are generally appropriate to support growth for the infant or child. Osmolarity of the formula and the individual's ability to tolerate hyperosmolar solutions must be considered.

BOX 42.1 Steps in Designing a Low-Protein Eating Plan

1. Determine the protein tolerance of the individual based on (1) diagnosis, (2) age, and (3) growth. Consider the metabolic stability and total protein intake required for the infant's or child's weight.
2. Calculate the protein and energy needs of the individual based on age, activity, and weight.
3. Provide at least 70% of total protein as high-biologic value protein from formula for infants, and from milk or dairy foods for older children. Use a specialized formula if the infant or child cannot tolerate the entire protein intake from intact protein.
4. Provide energy and nutrient sources to meet basic needs.
5. Add water to meet fluid requirements and maintain appropriate concentration of formula mixture.
6. For the older infant and child, provide foods to meet food variety, texture, and energy needs.
7. Provide adequate intake of calcium, iron, zinc, and all other vitamins and minerals for age.

DISORDERS OF CARBOHYDRATE METABOLISM

Disorders of carbohydrate metabolism vary in presentation, clinical course, and outcome. Galactosemia may present in the early newborn period as life-threatening seizures and sepsis. Hereditary fructose intolerance may present during midinfancy when solids that contain offending ingredients are introduced. Glycogen storage diseases (GSDs) may present at the time when feedings are spaced and subsequent hypoglycemia appears. All of these disorders require early and aggressive nutritional therapy.

Hereditary Fructose Intolerance

Hereditary fructose intolerance (HFI) results from a deficiency of the liver enzyme aldolase B. The disorder typically presents in infancy and toddlerhood, when dietary sources of sucrose and fructose are introduced. Initial symptoms include nausea, bloating, and vomiting. Untreated, liver and kidney damage can occur, along with growth restriction.

Medical Nutrition Therapy

Current management for HFI is restriction of dietary sources of fructose (including disaccharides composed of fructose) and some sugar alcohols, such as sorbitol. HFI (incidence of about 1 in 20,000 to 30,000 in Europe) is different than the more common fructose malabsorption, in which individuals experience gastrointestinal symptoms after ingesting large amounts of fructose (Baker et al, 2015) (see Chapter 27).

Galactosemia

Galactosemia, an elevated level of plasma galactose-1-phosphate combined with galactosuria, is found in two autosomal-recessive metabolic disorders: **galactokinase deficiency** and **galactose-1-phosphate uridylyl-transferase (GALT) deficiency**, which is also called “classic galactosemia.” Illness generally occurs within the first 2 weeks of life. Symptoms are vomiting, diarrhea, lethargy, failure to thrive, jaundice, hepatomegaly, and cataracts. Infants with galactosemia may be hypoglycemic and susceptible to infection from gram-negative organisms. If the condition is not treated, death frequently ensues secondarily to septicemia.

Pathophysiology

Galactosemia results from a disturbance in the conversion of galactose to glucose because of the absence or inactivity of one of the enzymes shown in Fig. 42.6. The enzyme deficiency causes an accumulation of galactose, or galactose and galactose-1-phosphate, in body tissues. In

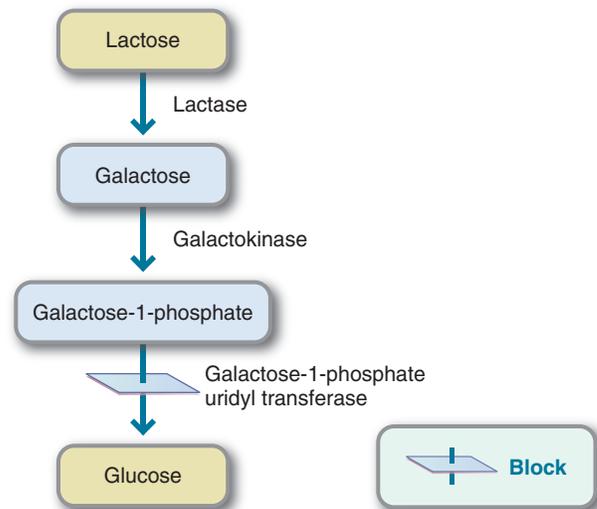

Fig. 42.6 Schematic diagram of the metabolism of galactose in galactosemia.

addition, expanded newborn screening programs have identified many newborns with Duarte galactosemia. These infants have one allele for galactosemia and one for Duarte galactosemia and are often said to have “D/G galactosemia.” The Duarte allele produces approximately 5% to 20% of the GALT enzyme. Little is known about the natural history of D/G galactosemia; apparently infants and children develop normally without medical complications.

Medical Treatment

When diagnosis and therapy are delayed, intellectual disability can result (Berry, 2017). With early diagnosis and treatment, physical and motor development should proceed normally. However, intellectual achievement may be depressed. Patients often have IQs of 85 to 100, visual-perceptual and speech difficulties, and problems with executive function (Doyle et al, 2010; Kaufman et al, 1995). Ovarian failure affects approximately 75% to 95% of women with galactosemia (Forges et al, 2006).

Medical Nutrition Therapy

Galactosemia is treated with lifelong galactose restriction (van Calcar et al, 2014). Although galactose is required for the production of galactolipids and cerebroside, it can be produced by an alternative pathway if galactose is omitted from the diet. Galactose restriction mandates strict avoidance of all milk and milk products and lactose-containing foods because lactose is hydrolyzed into galactose and glucose. Effective galactose restriction requires careful reading of food product labels. Milk is added to many products, and lactose often appears in the coating of the tablet form of medications. Infants with galactosemia are fed soy-based formula (see Chapter 25). Some fruits and vegetables contain significant amounts of galactose. Table 42.9 presents a low-galactose food pattern.

Medical opinions differ about the intensity and duration of treatment for Duarte galactosemia (Berry, 2017). Many centers eliminate galactose from the diets of these children for the first year of life; other centers do not.

Glycogen Storage Diseases

Glycogen storage diseases (GSDs) reflect an inability to metabolize glycogen to glucose. There are a number of possible enzyme defects along the pathway. The most common of the GSDs are types I and III. Their symptoms are poor physical growth, hypoglycemia, hepatomegaly, and abnormal biochemical parameters, especially for cholesterol

TABLE 42.9 Food Lists for Low-Galactose Food Pattern

Allowable Foods	Galactose-Containing Foods to Be Avoided*
Milk and Milk Substitutes	
Similac Soy Isomil	All forms of animal milk
Enfamil Prosobee	Imitation or filled milk
Gerber Good Start Soy	Cream, butter, some margarines
	Cottage cheese, cream cheese
	Hard cheeses
	Yogurt
	Ice cream, ice milk, sherbet
	Breastmilk
Fruits	
All fresh, frozen, canned, or dried fruits except those processed with unsafe ingredients†	
Vegetables	
All fresh, frozen, canned, or dried vegetables except those processed with unsafe ingredients,† seasoned with butter or margarine, breaded, or creamed	
Meat, Poultry, Fish, Eggs, Nuts	
Plain beef, lamb, veal, pork, ham, fish, turkey, chicken, game, fowl, Kosher frankfurters, eggs, nut butters, nuts	
Breads and Cereals	
Cooked and dry cereals, bread or crackers without milk or unsafe ingredients,† macaroni, spaghetti, noodles, rice, tortillas	
Fats	
All vegetable oils; all shortening, lard, margarines, and salad dressings except those made with unsafe ingredients‡; mayonnaise; olives	

*Lactose is often used as a pharmaceutical bulking agent, filler, or excipient; thus tablets, tinctures, and vitamin and mineral mixtures should be evaluated carefully for galactose content. The *Physician's Desk Reference* now lists active and inactive ingredients in medications, as well as manufacturers' telephone numbers.

†Unsafe ingredients include milk, buttermilk, cream, lactose, galactose, casein, caseinate, whey, dry milk solids, or curds. Labels should be checked regularly and carefully because formulations of products change often (see Chapter 25).

and triglycerides. Advances in the treatment of GSDs may improve the quality of life for affected children (Weinstein et al, 2018).

Pathophysiology

GSD type Ia is a defect in the enzyme glucose-1-6-phosphatase, which impairs the formation of new glucose (gluconeogenesis) and the breakdown of glycogen from storage (glycogenolysis). The affected

person is unable to metabolize glycogen stored in the liver. Severe hypoglycemia can result and cause irreparable neurologic damage.

Amylo-1, 6-glucosidase deficiency (GSD III or debrancher enzyme deficiency) prevents glycogen breakdown beyond branch points. This disorder is similar to GSD Ia in that glycogenolysis is inefficient but gluconeogenesis is amplified to help maintain glucose production. The symptoms of GSD III are usually less severe and range from hepatomegaly to severe hypoglycemia.

Medical Treatment

The outcome of treatment has been good. The hazard of severe hypoglycemic episodes is diminished, physical growth is improved, and liver size is decreased. The risk of progressive renal dysfunction is not entirely eliminated by current treatment, but liver transplantation for some types of GSD (e.g., type Ib) is sometimes an option. Treatment guidelines include various kinds of carbohydrates at various doses during the day and night (Kishnani et al, 2014). Individual tolerance, body weight, state of health, ambient temperature, and physical activity are important considerations when designing the specific pattern of carbohydrate administration. The goal for all of the protocols remains the same: normalization of blood glucose levels.

Medical Nutrition Therapy

The rationale for intervention is to maintain plasma glucose in a normal range and prevent hypoglycemia by providing a constant supply of exogenous glucose. Administration of raw cornstarch (e.g., a slurry of cornstarch mixed with cold water) at regular intervals and a high-complex carbohydrate, low-fat dietary pattern are advocated to prevent hypoglycemia. Some infants and children do very well with oral cornstarch administration, whereas others require glucose polymers administered via continuous-drip gastric feedings to prevent hypoglycemic episodes during the night. The dose of cornstarch should be individualized; doses of 1.6 to 2.5 g/kg at 4- to 6-hour intervals are generally effective for young children with GSD I (Kishnani et al, 2014). A modified (extended-release) cornstarch product (Glycosade) is also used to manage GSD, typically used at night with older children and adults (Weinstein et al, 2018). Iron supplementation is required to maintain adequate hematologic status because cornstarch interferes with iron absorption.

DISORDERS OF FATTY ACID OXIDATION

Laboratory advancements have enabled identification of **fatty acid oxidation disorders** such as **medium-chain acyl-CoA dehydrogenase (MCAD) deficiency** and **long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency** (Fig. 42.7). Children who are not identified by newborn screening usually present during periods of fasting or illness with symptoms of variable severity, including failure to thrive, episodic vomiting, and hypotonia.

Pathophysiology

Children with MCAD deficiency who present clinically typically have hypoglycemia without urine ketones, lethargy, seizures, and coma. Children with LCHAD deficiency become hypoglycemic and demonstrate abnormal liver function, reduced or absent ketones in the urine, and often secondary carnitine deficiency. They also may have hepatomegaly and acute liver disease. Hypoglycemia can progress quickly and be fatal (Matern and Rinaldo, 2015). Both disorders are included in the newborn screening panels in all U.S. states.

Medical Nutrition Therapy

The concept underlying effective treatment for fatty acid oxidation disorders is straightforward: avoidance of fasting. This is accomplished

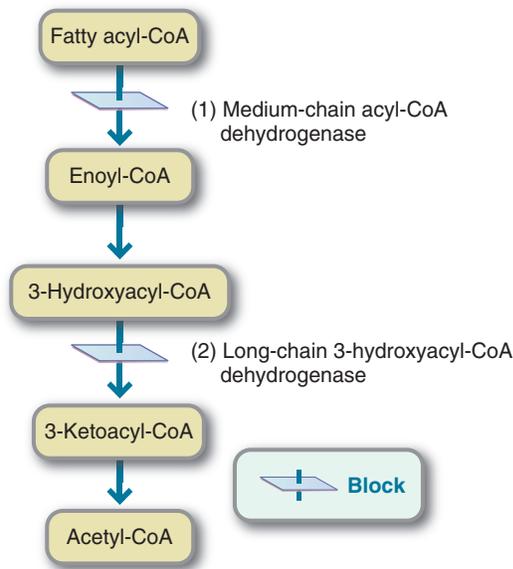

Fig. 42.7 Mitochondrial fatty acid oxidation disorders: **1**, Medium-chain acyl-Coenzyme A dehydrogenase deficiency, the most common fatty acid oxidation disorder. **2**, Long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency.

by the regularly spaced intake of foods that provide an adequate energy intake and are high in carbohydrates. A low-fat diet is advocated because fats are not effectively metabolized. Consumption of not more than 30% of energy as fat has been recommended; some individuals require more restriction. Supplementation with L-carnitine, a substance that functions as a carrier of fatty acids across the mitochondrial membranes, is recommended by some clinics.

Children often do very well with three meals and three snacks offered at regular intervals. Most children may require additional carbohydrate before bed, based on individual ability to maintain blood glucose levels throughout the night (Matern and Rinaldo, 2015). Depending on the disorder, supplementation with specific fatty acids (e.g., medium-chain fats for disorders that involve blocks of long-chain metabolism) may be indicated.

ROLE OF THE NUTRITIONIST IN GENETIC METABOLIC DISORDERS

The role of the pediatric nutrition specialist in the treatment of metabolic disorders is a complex one that requires expertise in MNT for the specific disorder. Preparation and competency requires access to detailed information about the disorders and treatment modalities. A family-centered approach, knowledge of feeding-skill development, and understanding of behavior modification techniques, as well as the support and counsel of a team of health care providers involved in the care of the patient, are also required. Nutrition intervention is often a lifelong consideration. Specific objectives of nutrition care are shown in Box 42.2.

BOX 42.2 Intervention Objectives for the Nutritionist Involved in the Treatment of Genetic Metabolic Disorders

In the clinic the registered dietitian nutritionist (RDN) has a major role in ongoing therapy and planning for each child. These responsibilities include gathering of objective food intake data from the family, assessing the adequacy of the child's intake, and working with the family to incorporate appropriate ways to monitor the restricted food intake pattern. The child with a metabolic disorder often presents with a wide range of concerns, which may include unstable biochemical markers, failure to gain weight, excessive weight gain, difficulty adhering to the diet, and behaviors that cause an adverse feeding situation. Thus managing a child with a metabolic disorder requires input from the entire health care team. The nutritionist uses skills and knowledge of foods as sources of nutrients, parent-child relationships, growth, development, and interviewing to obtain the necessary information for assessing and planning for the child with a genetic metabolic disorder.

- I. The RDN functions as an effective interdisciplinary team member by doing the following:
 - A. Becoming familiar with the background and current status of the child by reviewing the medical record
 - B. Recognizing and accepting the responsibility as the nutritionist by doing the following:
 1. Identifying appropriate intake of nutrients for growth, activity, and biochemical balance
 2. Identifying developmental stages of feeding behavior
 3. Understanding the concept of food as a support of developmental progress
 4. Identifying behavior as it affects nutrient intake
 - C. Understanding, respecting, and using the expertise of the team disciplines in providing care for the child
- II. The RDN provides adequate and supportive patient services by doing the following:
 - A. Establishing a positive, cooperative working relationship with the parent, child, and other family members

- B. Interviewing the family about dietary intake and the feeding situation in a nonjudgmental manner
- C. Assessing the parent-child relationship as it relates to dietary management and control of the disorder
- D. Developing a plan for appropriate dietary management based on growth, biochemical levels, nutrient needs, developmental progress, and nutrition diagnosis, such as:
 - Excessive protein intake
 - Altered nutrition-related laboratory values
 - Intake of inappropriate amino acids
 - Inadequate vitamin intake
 - Inadequate mineral intake
 - Food medication interaction
 - Food- and nutrition-related knowledge deficit
 - Limited adherence to nutrition-related recommendations
- E. Developing a plan that includes appropriate foods and recognizes the family's skills in food preparation, as well as family routines
- F. Working with the family to establish a method to deal effectively with negative feeding behaviors, if necessary
- G. Contacting the family after receiving laboratory results and calculating food records to make necessary and appropriate changes in diet prescription
- III. Supporting families in their efforts at effective dietary and behavior management
- IV. The RDN develops a professional knowledge base by doing the following:
 - A. Being familiar with the current literature on the treatment of metabolic disorders
 - B. Understanding the genetic basis of metabolic disorders
- V. The RDN works with team members to understand the long-term patient care and create a written care plan for the patient.

CLINICAL CASE STUDY

Adelaide was born weighing 6 lb, 7 oz and her 1-day newborn screening test result for phenylalanine (Phe) was 3.7 mg/dL (222 $\mu\text{mol/L}$). She was breastfed with no supplemental formula. A repeat sample was requested to further document the Phe concentration in her blood. The result from this sample, collected on day 4 of life, was 6.2 mg/dL (372 $\mu\text{mol/L}$). To confirm the diagnosis for this child, which was considered to be “presumptive positive,” a quantitative sample was obtained, and Phe and tyrosine levels were both measured. On day of life 9 the serum Phe concentration was 16.6 mg/dL (1328 $\mu\text{mol/L}$), and the tyrosine level was 1.1 mg/dL (60.5 $\mu\text{mol/L}$); the Phe to tyrosine ratio was 22.0:1. Blood and urine were collected for bipterin screening; results were later found to be normal.

To provide adequate protein and energy intake and at the same time decrease the serum Phe concentration, a Phe-free formula was introduced at standard dilution without a Phe supplement. Within 24 hours Adelaide’s serum Phe concentration had decreased to 8.3 mg/dL (498 $\mu\text{mol/L}$) while she was being provided an intake of 12 to 14 oz of the Phe-free formula. Breastfeedings were reintroduced; she was offered 3 breastfeedings and Phe-free formula ad lib. Within 48 hours the level was 6.6 mg/dL (396 $\mu\text{mol/L}$), with an intake of 4 oz of the formula.

Adelaide’s Phe concentrations were measured every 4 days, and the levels were 3.6 mg/dL (216 $\mu\text{mol/L}$) and 2.2 mg/dL (132 $\mu\text{mol/L}$). In subsequent weeks growth and serum Phe concentrations continued to be monitored carefully, and energy and Phe intakes were adjusted as necessary to maintain blood Phe

concentrations between 2 and 6 mg/dL (120 to 360 $\mu\text{mol/L}$) and to maintain growth in appropriate channels.

By age 2 months, Adelaide’s intake had increased to approximately 12 oz formula along with 3 breastfeedings daily (alternating breastmilk and formula feedings), and her feeding pattern was fairly consistent. Blood Phe was measured at 8.7 mg/dL (522 $\mu\text{mol/L}$), which is outside the desired range. Her Phe-free formula was increased to 14 oz/day to effectively decrease the amount of Phe provided by breastmilk.

Nutrition Diagnostic Statement

- Altered nutrition-related laboratory values (phenylalanine) (NC-2.2) related to phenylketonuria and dietary Phe intake, as evidenced by blood Phe outside desired range.

Nutrition Care Questions

- What is the expected energy requirement for Adelaide?
- What are the baseline expectations for intake for a 6-lb, 7-oz neonate? If breastmilk is expected to provide about half of this amount, how much Phe-free formula would you use to provide protein and energy intakes at recommended levels?
- What are the growth expectations for Adelaide?
- What steps would you take if Adelaide’s plasma Phe concentration exceeded 6 mg/dL (360 $\mu\text{mol/L}$) on subsequent measurements?

translocation

Individuals with developmental disabilities were generally housed in institutions for the first half of the 20th century. Little attention was paid to their education, or medical or nutritional care. In 1963 the Developmental Disabilities Assistance and Bill of Rights Act was passed. Through this Act federal funds supported the development and operation of state councils, protection and advocacy systems, university centers, and projects of national significance. This Act provided the structure to assist people with developmental disabilities to pursue meaningful and productive lives. The institutions that housed these individuals gradually were closed or reduced in size. By 1975 these individuals were cared for at home, in schools, or in small residential facilities. In 1975 Public Law (P.L.) 94-142 was passed, opening public schools to children with developmental disabilities. In 1985 P.L. 99-487 (102-119 in 1992), the Early Intervention Act, was passed, bringing services to children from birth to school age. In 2004 the Individuals with Disabilities Education Act (IDEA) reauthorized this legislation.

A **developmental disability** is defined as a severe chronic disability that is attributable to an intellectual or physical impairment or combination of intellectual and physical impairments. It is manifested before the person reaches age 22; is likely to continue indefinitely; results in substantial functional limitations in three or more areas of major life activity (self-care, receptive and expressive language, learning, mobility, self-direction, capacity for independent living, and economic self-sufficiency); and reflects the person's need for a combination of generic or specialized interdisciplinary care, treatments, or other services that are lifelong or of extended duration and individually planned and coordinated. Developmental disabilities affect individuals of all ages and are not a disease state. Intellectual disability replaced the term *mental retardation* in the 11th edition of the *Definition Manual of the American Association on Intellectual and Developmental Disabilities (AAIDD, 2013)*.

Intellectual disability is the most common developmental disability, characterized by significantly below-average intellectual functioning along with related limitations in areas such as communication, self-care, functional academics, home living, self-direction, health and safety, leisure, or work and social skills. An estimated 1% to 3% of the population have this diagnosis.

Developmental disabilities have been traced to many causes: chromosomal aberrations, congenital anomalies, specific syndromes, neuromuscular dysfunction, neurologic disorders, prematurity, cerebral palsy (CP), untreated inborn errors of metabolism, toxins in the environment, and nutrient deficiencies. The Centers for Disease Control and Prevention (CDC) reported in 2018 that one in seven or 15% of American children have a developmental disability.

MEDICAL NUTRITION THERAPY

Medical nutrition therapy (MNT) services vary depending on the individual and much has been learned about the role of nutrition in the prevention of disabilities and interventions. The role of the registered dietitian nutritionist (RDN) is essential. Because there is an abundance of information that parents and caretakers use from support groups and websites that are untested scientifically, RDNs often are providing evidence-based counseling to provide support and counteract misinformation.

Numerous nutrition problems have been identified in the individual with developmental disabilities. Growth restriction, obesity, failure to thrive, feeding problems, metabolic disorders, gastrointestinal disorders, drug-nutrient interactions, constipation, and cardiac and renal problems may be present. Other health problems exist, depending on the disorder. [Table 43.1](#) lists the most common developmental disabilities and their associated nutrition problems.

TABLE 43.1 Common Nutrition-Related Issues in Individuals with Intellectual and Developmental Disabilities and Children and Youth with Special Health Care Needs with Suggested Nutrition Diagnosis Terms

Syndrome or Developmental Disability	Nutrition Diagnosis	Etiology and/or Signs and Symptoms
Autism Spectrum Disorders (ASD) ASD is a group of developmental disabilities that are characterized by delayed speech and language development, ritualistic or repetitive behaviors, and impairments in social interactions. Individuals may also have delays in feeding skills and the ability to self-feed.	Inadequate energy intake	Limited food choices Medication side effects affecting appetite
	Limited food acceptance	Sensory processing issues Avoidance of foods/food groups
	Inadequate intake of calcium/vitamin D/iron/other nutrient(s)	Limited food choices; avoidance of foods/food groups Following a special diet, such as a gluten free, casein free diet may place child at risk for nutrient deficiencies, including calcium and fiber if food acceptance is already low.
	Underweight	Inadequate energy intake BMI <5th percentile for children aged 2-20 yr Medication side effects affecting appetite Limited food choices secondary to behaviors
	Overweight/obesity	BMI >85th percentile for children aged 2-20 yr Use of food for behavioral interventions Estimated excessive energy intake Medication side effects affecting appetite Low physical activity level Limited food choices that are excessive in calories
Cerebral Palsy (CP) A nonprogressive disorder of muscle control or coordination that affects different parts of the body. This results from an injury to the brain during fetal, perinatal, or early childhood development. The severity is variable. Intellectual disability is often present.	Increased energy expenditure	Unintended weight loss
	Excessive energy intake	Increased body adiposity Reduced energy expenditure secondary to treatment with medication to reduce muscle tone Hypotonia Weight gain greater than expected Changes in mobility status Enteral nutrition provides more calories than measured/estimated energy expenditure
	Inadequate oral intake	Unintended weight loss Inability to self-feed due to lack of coordination Poor dentition, presence of cavities, and/or abscesses Gastroesophageal reflux disease Oral-motor dysfunction/dysphagia Medications affecting appetite Malnutrition and failure to thrive
	Inadequate fluid and fiber intake	Constipation Inability to independently consume fluid and food Dysphagia Altered thirst sensation, inability to communicate thirst
	Swallowing difficulty	Abnormal swallow study showing aspiration and/or oral/pharyngeal dysphagia Coughing, choking, prolonged chewing, pocketing of food, regurgitating, and facial expression changes during eating Reduced food intake Unintended weight loss Prolonged feeding times, lack of interest in food, food avoidance, mealtime resistance
	Altered GI function	Constipation Gastroesophageal reflux disorder, delayed gastric emptying Medication side effects
	Food–medication interactions	Constipation related to antispasticity medications Increased risk of osteopenia/osteoporosis related to antiseizure and antigastroesophageal reflux disease medications Risk of B ₁₂ deficiency related to antigastroesophageal reflux disease medications

Continued

TABLE 43.1 Common Nutrition-Related Issues in Individuals with Intellectual and Developmental Disabilities and Children and Youth with Special Health Care Needs with Suggested Nutrition Diagnosis Terms—cont'd

Syndrome or Developmental Disability	Nutrition Diagnosis	Etiology and/or Signs and Symptoms
	Underweight	BMI <5th percentile/age in children aged 2-20 yr Reduced muscle mass, muscle wasting Inadequate energy intake to promote weight gain compared with estimated or measured needs Hypertonia, dystonia
	Overweight	BMI >85th percentile/age for children aged 2-20 yr Excessive energy intake Low physical activity level Hypotonia
Drug exposed and fetal alcohol spectrum disorders Physical, behavioral, mental, or learning disabilities that occur when a fetus is exposed to drugs and/or alcohol during development. Growth may also be affected.	Food–medication interaction	Side effects of medications affecting appetite
	Overweight/obesity	BMI >85th percentile for children aged 2-20 yr Estimated excessive energy intake Sedentary activity level
	Self-monitoring deficit	Altered self-regulation Overweight/obesity Underweight
Down syndrome A genetic disorder that results from an extra chromosome 21, resulting in developmental problems such as congenital heart disease, cognitive delay, short stature, gastrointestinal problems, and decreased muscle tone.	Inadequate oral intake	Dementia Swallowing difficulty Unintended weight loss
	Breastfeeding difficulty	Feeding difficulty with weak suck Poor weight gain
	Altered GI function	Constipation (related to hypotonia, low activity, and/or low fiber intake) Celiac disease
	Overweight/obesity	Increased body adiposity Estimated excessive energy intake Reduced energy needs related to hypotonia BMI >85th percentile for children aged 2-20 yr
Genetic or inherited metabolic disorders Genetic conditions that result in a deficiency or defective enzyme in a metabolic pathway. Some of these, such as phenylketonuria, can result in significant lifetime intellectual and developmental disabilities. Others can cause death if not properly treated.	Imbalance of nutrients Impaired nutrient utilization Altered nutrition-related laboratory values	Food and nutrition knowledge deficit of dietary changes related to new diagnosis Nutrient restriction due to metabolic disorder
	Unintended weight loss	Poor appetite due to metabolic disorder Inadequate energy intake Lack of adequate insurance coverage for low protein foods/special metabolic formulas, limited access to formula Food and nutrition knowledge deficit of dietary changes related to new diagnosis
	Unintended weight gain	Excessive energy intake
Orofacial cleft A birth defect that occurs when the lip and/or the roof of the mouth does not form or close properly, resulting in a cleft lip and/or cleft palate.	Swallowing difficulty	Abnormal swallow study showing aspiration and/or oral/pharyngeal dysphagia Inadequate oral intake Frequent respiratory infections/pneumonias Coughing/choking with foods/liquids Cleft lip/cleft palate
	Breastfeeding difficulty	Inability to form proper latch Inadequate oral intake
	Underweight	Inadequate energy intake Increased energy expenditure

TABLE 43.1 Common Nutrition-Related Issues in Individuals with Intellectual and Developmental Disabilities and Children and Youth with Special Health Care Needs with Suggested Nutrition Diagnosis Terms—cont'd

Syndrome or Developmental Disability	Nutrition Diagnosis	Etiology and/or Signs and Symptoms
Prader-Willi syndrome A genetic disorder resulting from a deletion in chromosome 15. Hypotonia in infancy can result in failure to thrive before onset of hyperphagia. Common medical issues include obesity as a result of hyperphagia, short stature, and varying levels of intellectual abilities.	Breastfeeding difficulty	Feeding difficulty with weak suck
	Inadequate oral intake	Poor weight gain
	Excessive energy intake	Increased body adiposity
	Overweight/obesity	BMI >85th percentile for children aged 2-20 yr Reduced energy needs Self-monitoring deficit
	Limited adherence to nutrition-related recommendations	Inability to limit or refuse foods offered Lack of social support for implementing changes
Spina bifida (myelomeningocele) A neural tube defect resulting from incomplete closure of the spine during early pregnancy. This results in nerve damage, including neurogenic bowel/bladder and paralysis. Other common medical issues include Arnold Chiari II malformation, hydrocephalus, growth hormone deficiency, and learning differences.	Undesirable food choices	Intake inconsistent with diet quality guidelines Unable to independently select foods consistent with food quality and energy controlled guidelines
	Intake of unsafe food	Food obsession Hyperphagia Eating serves a purpose other than nourishment Pica
	Increased protein needs	Chronic, nonhealing wounds
	Swallowing difficulty	Abnormal swallow study showing aspiration and/or oral/pharyngeal dysphagia Frequent respiratory infections/pneumonias Coughing/choking with foods/liquids Presence of Arnold Chiari II malformation of the brain
	Altered GI function	Low fluid and fiber intake Neurogenic bowel Constipation
	Overweight/obesity Unintended weight gain	Increased body adiposity BMI >85th percentile for children aged 2-20 yr Estimated excessive energy intake Self-monitoring deficit Limited mobility Reduced energy needs related to altered body composition, short stature

ASD, Autism spectrum disorder; BMI, body mass index; GI, gastrointestinal.

Adapted from Figure 1 of 2010 Academy position on developmental disabilities and special health care needs and references 24 and 26.

The Academy of Nutrition and Dietetics confirms that nutrition services provided by RDNs are essential components of comprehensive care for infants and children with special health care needs and adults with intellectual and developmental disabilities. Nutrition services should be provided throughout the life cycle in a manner that is interdisciplinary, family centered, community based, and culturally competent. Poor nutrition-related health habits, limited access to services, and long-term use of multiple medications are considered health risk factors in this population. Timely and cost-effective nutrition interventions promote health maintenance, reduce risk, and reduce the cost of comorbidities and complications (Ptomey and Wittenbrook, 2015).

Nutrition Assessment

Anthropometric Measures

Anthropometric measures are altered when an individual is unable to stand, suffers from contractures or scoliosis, or has other gross motor problems. Measuring body weight may require special equipment such as chair, sling, or bucket scales. Wheelchair scales are used in some clinics but require that the wheelchair weight be known and checked

at each clinic visit. Height or length measurements are very challenging to obtain accurately and may be estimated using a recumbent board. Other measures of height include arm span, knee-to-ankle height, or sitting height (Fig. 43.1 and see Appendix 6).

Although growth charts for children with various syndromes do exist, most clinicians recommend using the general CDC charts (see Appendix 3) because the information in the specialized charts is often based on small numbers, mixed populations, and old data (CDC, 2014). For the infant with a developmental disability, the World Health Organization (WHO) growth charts are recommended from birth to 24 months.

Other measures that can be used to explore weight issues include arm circumference, triceps skinfold measures, and body mass index (BMI). BMI is a part of the CDC growth charts and can also be found in Appendix 3. Using the BMI for age can be controversial. For example, BMI is limited for identifying overweight in children with developmental disabilities who are overly fat because of decreased muscle mass and short stature. Also, BMI may not be accurate if height measurement is not accurate. Height age may also be used to assess BMI if an individual plots far below expected height for age.

Fig. 43.1 **A**, Knee height measure. **B**, Sitting height measure. **C**, Arm span measure. (Courtesy Cristine M. Trahms, 2002.)

Biochemical Measures

Laboratory assessment for the child and adult with developmental disabilities is generally the same as that discussed in Chapter 5 and Appendix 13. Additional tests may be indicated for the individual with epilepsy or seizures who is receiving an anticonvulsant medication such as phenytoin, divalproex sodium, topiramate, or carbamazepine. Use of these medications can lead to low blood levels of folate, carnitine, ascorbic acid, vitamin D, alkaline phosphatase, phosphorus, and pyridoxine.

Assessment of thyroid status is part of the protocol for children with Down syndrome (DS), and a glucose tolerance test is recommended for evaluation of the child with Prader-Willi syndrome (PWS). As appropriate, genetic testing may be encouraged for affected individuals and their biological family members to identify any potential risks to the individual and to future pregnancies.

Dietary Intake and Feeding Problems

Dietary information should be obtained for the child with a developmental disability through a diet history or a food frequency questionnaire (see Chapter 4). However, obtaining an accurate recall is difficult as written diaries are difficult to obtain when the child has multiple caretakers or when they are in day care or school. When working with an adult with developmental disabilities, it is often difficult to obtain accurate information unless the individual has supervision, such as in

special residential housing. Use of pictures and food models are helpful in obtaining an estimate of the individual's intake (see Box 4.5 Apps for Tracking Intake and Physical Activity in Chapter 4).

Many children and adults with developmental disabilities display feeding problems that seriously impair their ability to eat an adequate diet. Feeding problems are defined as the inability or refusal to eat and/or drink certain foods and liquids because of neuromotor dysfunction, obstructive lesions such as strictures, and behavioral or psychosocial factors. Other causes of feeding problems in this population include oral-motor difficulties, dysphagia, positioning problems, conflict in parent-child relationships, sensory issues, and tactile resistance from previous intubation (Heiss et al, 2010). The nutritional consequences of feeding problems include inadequate or excessive weight gain, poor growth in length, lowered immunity, anemia, vitamin and mineral deficiencies, dental caries, and psychosocial problems. Feeding problems should be assessed with an understanding of the anatomy, physiology, and normal development of feeding (see Chapters 15 through 17 and Chapter 39).

Estimates are that feeding problems are found in 40% to 70% of children with special health care needs and 80% of children with developmental delays. Feeding problems are often classified as oral-motor, gross motor, behavioral, or sensory yet feeding problems are usually multifactorial in origin and treatment. **Oral-motor problems**

BOX 43.1 Oral-Motor Problems

Problem	Description
Tonic bite reflex	Strong jaw closure when teeth and gums are stimulated
Tongue thrust	Forceful and often repetitive protrusion of an often bunched or thick tongue in response to oral stimulation
Jaw thrust	Forceful opening of the jaw to the maximum extent during eating, drinking, attempting to speak, or general excitement
Tongue retraction	Pulling back the tongue within the oral cavity at the presentation of food, spoon, or cup
Lip retraction	Pulling back the lips in a very tight smile-like pattern at the approach of the spoon or cup toward the face
Sensory defensiveness	A strong adverse reaction to sensory input (touch, sound, light)

include difficulty with suckling, sucking, swallowing, and chewing. They also include sensory motor integration and problems with self-feeding and are described as exaggerations of normal neuromotor mechanisms that disrupt the rhythm and organization of oral-motor function and interfere with the feeding process (Box 43.1).

Children with developmental disabilities such as DS, CP, or cleft lip and/or cleft palate (CL/CP) often have oral-motor feeding problems that may be related to the cleft, muscle tone, and inability to accept complex texture. The oral-motor problem also can be related to developmental level, which may be delayed.

Positioning a child for feeding relates to their motor development, head control, trunk stability, and ability to have hips and legs at a right angle (Figs. 43.2 and 43.3). This is frequently a problem for individuals with CP, spina bifida, and DS. Without proper positioning, oral-motor problems are difficult to correct.

The ability to self-feed may be delayed or absent in the child with developmental disabilities and requires intervention and training by a feeding specialist. A feeding evaluation is best completed with actual observation by a team composed of a speech therapist, a dentist, a physical therapist, an occupational therapist, and an RDN. Frequently, adaptive feeding equipment is needed such as special bottles, nipples, cups, utensils, and so on.

Behavioral issues may result from oral-motor or sensory problems, medical problems, certain medications, and the amount of emphasis placed on feeding. Issues such as control of the feeding process along with lack of autonomy in the child may create negative behavior. Environmental factors also influence the eating behavior of the child (see Chapter 16). Examples include where the child is fed, distractibility, serving sizes, delayed weaning, and frequency of feeding. The feeding relationship concept is important and is further discussed in Chapter 16.

Nutrition Diagnosis

Once the nutrition assessment has been completed, problems should be identified related to growth. Excessive or inadequate weight gain velocity; inadequate or excessive dietary intake; excessive or inadequate fluid intake; altered gastrointestinal problems such as constipation, gastroesophageal reflux, vomiting, and diarrhea; intake of foods that are unsafe because of contamination or food allergies; food-medication interactions; chewing and swallowing difficulties; and problems with self-feeding may be issues. The nutrition diagnoses should be listed and priorities established, using a family-centered or client-centered approach.

Fig. 43.3 Good feeding position for a child ages 6 to 24 months, showing hip flexion, trunk in midline, and head in midline. Good foot support with a stool should continue throughout childhood. (From Cloud H: *Team approach to pediatric feeding problems*, Chicago, 1987, American Dietetic Association. © American Dietetic Association. Reprinted with permission.)

Interventions

Once the nutrition diagnoses are identified and prioritized, short- and long-term goals should be created. Consideration must be given to the motivational level and readiness of the parent or client, their cultural background, and how the therapy can be community based and family centered. This means that consideration must be given to where the client will be served so that it becomes a part of the **individualized education plan (IEP)** or the **individualized family plan**.

Intervention plans should include all aspects of an individual's treatment program to avoid issuing an isolated set of instructions relevant to only one treatment goal. In some cases MNT may not be the family's first priority in the care of the child or adult, making it important for the RDN to recognize the family's needs and goals (see Chapter 13). Even when the family is ready for an intervention, such as weight management for a child with spina bifida, many factors require consideration. The parent or caregiver's educational level and income, language barriers, access to safe and appropriate food, and family coping strategies always should be identified (see Chapter 13).

Monitoring and Evaluation

Once MNT has been initiated, the need for follow-up evaluation and monitoring by either the RDN or another health care professional is important. Giving information in writing, ideally followed by a phone call, gives the chance to repeat some of the discussion and to answer any questions not asked during the initial session. Clarification of suggestions often is needed when monitoring nutrition changes that affect growth and development; a follow-up visit also may be needed.

A case manager may be involved who communicates with the adult with the disability, and a family resource coordinator may be available to assist families of children with disabilities. The RDN may need to assist in finding appropriate resources to pay for supplemental nutrition products, tube feedings, and special food products as a part of the follow-up process. Community and agency resources are identified and discussed, such as the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) and other government and non-government assistance programs.

CHROMOSOMAL ABNORMALITIES

Down Syndrome

Down syndrome (DS) is a chromosomal aberration of chromosome 21 (trisomy 21). It has an incidence of 1 in 600 to 800 live births and results from the presence of an extra chromosome in each cell of the body. This anomaly causes the physical and developmental features of short stature; congenital heart disease; intellectual disability; decreased muscle tone; hyperflexibility of joints; speckling of the iris (Brushfield spots); upward slant of the eyes; epicanthal folds; small oral cavity; short, broad hands with the single palmar crease; and a wide gap between the first and second toes (Bull and Committee on Genetics, 2011; Fig. 43.4).

Pathophysiology

Normally every cell of the human body except for the gametes (sperm or ova) contains 46 chromosomes, which are arranged in pairs (see Chapter 6). With DS there is one extra chromosome for a total of 47. This anomaly can occur by one of these three processes: nondysjunction, translocation, and mosaicism. In **nondysjunction**, chromosome 21 fails to separate before conception and the abnormal gamete joins with a normal gamete at conception to form a fertilized egg with three of chromosome 21. This also may occur during the first cell division after conception. This type of DS is usually sporadic and has a recurrence rate of 0.5% to 1%. In **translocation**, the extra chromosome is attached to another chromosome (usually 14, 15, or 22). Approximately half the time, this type of DS is inherited from a parent who is a carrier; it has a much higher risk of recurrence in a subsequent pregnancy. In **mosaicism** the abnormal separation of chromosome 21 occurs sometime after conception. All future divisions of the affected cell result in cells with an extra chromosome. Therefore the child has some cells with the normal number of chromosomes and other cells with an extra chromosome. Frequently the child with this type of DS lacks some of the more distinctive features of the syndrome (Bull and

From Bull MJ, Committee on Genetics: Health supervision for children with Down syndrome, *Pediatrics* 128:393-406, 2011.

Committee on Genetics, 2011) (see *Pathophysiology and Care Management Algorithm: Down Syndrome*).

Medical Treatment

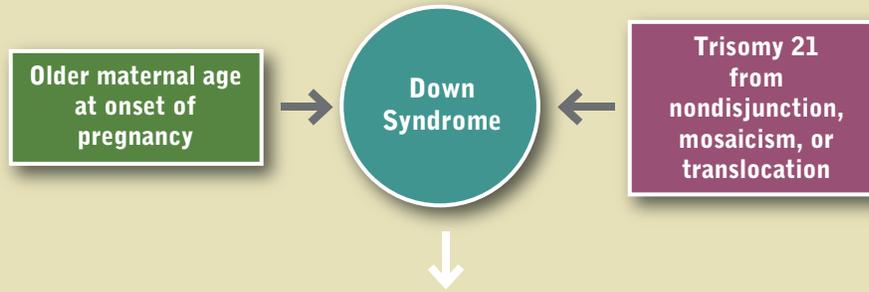

The National Down Syndrome Congress has published a listing of the health concerns for individuals with DS; many have nutrition implications (Table 43.2). The American Academy of Pediatrics (AAP) has published health supervision guidelines for children and young adults up to age 21 (Bull and Committee on Genetics, 2011).

PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

Down Syndrome

ETIOLOGY

PATHOPHYSIOLOGY

Clinical Findings

- Hypotonia
- Hyperflexibility/mobility of the joints
- Hip subluxation or dislocation
- Scoliosis
- Foot deformity
- Microbrachycephaly
- Short neck
- Depressed nasal bridge and small nose
- Upward-slanting eyes
- Abnormally shaped ears
- Enlarged, protruding tongue
- Single simian crease in center of the palm
- Excessive space between large and second toe
- Mental retardation
- Speech and motor delay
- Cardiac anomalies
- GI atresia or stenosis
- Hearing loss
- Hypothyroidism
- Dental problems
- Cataracts

MANAGEMENT

Nutrition Assessment

- Feeding problems
- Nutritional intake
- Fluid intake
- BMI compared with Down syndrome standards
- Weight changes
- Dysphagia
- Hemoglobin concentration

Medical Management

- Monitor for leukemia
- Management of infections
- Management of respiratory problems
- Signs of Alzheimer’s disease later
- Annual monitoring of hypothyroidism

Nutrition Care

- Assess for feeding challenges
- Provide supportive feeding environment
- Use of adaptive feeding utensils
- Monitor weight changes
- Monitor for signs of nutrient deficiencies

Medical Nutrition Therapy

Anthropometric measures. Height, weight, head circumference, triceps skinfold, and arm circumference are obtained for the child with DS with the usual measurements (see Chapter 5). BMI can be taken but may be higher than normal because of short stature. Muscle tone is low and gross motor ability is often delayed, leading to the possibility of the individual becoming overweight. Monitoring should be frequent, and growth is plotted on the CDC charts or the WHO charts for the younger child (see Appendix 3).

Biochemical measures. Numerous studies have shown biochemical and metabolic abnormalities in individuals with DS; however, many have involved small samples and were difficult to interpret (Bull and Committee on Genetics, 2011). Although serum concentrations of albumin have been found to be low, the guidelines from the Down Syndrome Medical Congress do not list serum albumin assessment as routine. Increased glucose levels have been reported, with an increased incidence of diabetes mellitus.

Current guidelines for the treatment of infants and children with DS include evaluation of thyroid function at birth and thereafter annually. A number of studies have looked at zinc, copper, and selenium as possible deficiencies but concluded that they do not usually exist in children with DS as long as food access and appetite are good (Lima et al, 2010).

Dietary intake. During infancy the food intake of the infant with DS may differ from that of the typically developing infant. Although human breastmilk is recommended, many infants with DS are formula fed. Infant illnesses, admission to the neonatal unit, frustration, depression, perceived milk insufficiency, and difficulty in suckling by the infant are some of the reasons why formula feeding is used.

Progression to solid food has been found to be delayed in children with DS, mostly as a result of delays of oral-motor development. Introduction of solid food may not be offered at 6 months if the infant has poor head control or is not yet sitting. Low tone and sucking problems also delay weaning from the breast or bottle to the cup. IEPs include feeding and feeding progression instruction and practice.

An important part of evaluating dietary intake is determining energy and fluid needs, because children with DS have a high prevalence of obesity. Studies have indicated that the resting energy expenditure (REE) of the child with DS is lower than for children without DS—and may be as much as 10% to 15% lower than the dietary reference intake (DRI) for energy (Medlen, 2006). For the child older than age 5, calculations for energy requirements may have to be based on height rather than weight (Table 43.3 and see Chapter 2).

Feeding skills. Feeding skills are delayed in the infant and child with DS. Some parents find it difficult to initiate oral-motor skills such as suckling and sucking. The infant with DS often has difficulty in coordinating sucking, swallowing, and breathing, which are the foundations for early feeding. When the infant has a congenital heart defect, which occurs in 40% to 60% of DS infants, sucking is weakened, and fatigue interferes with the feeding process. Gastrointestinal anomalies are found in 8% to 12% of infants with DS, and these infants often require nasogastric or gastrostomy feedings.

Other physical factors that make feeding difficult in the first years of life include a **midfacial hypoplasia** (a craniofacial deformity common in cleft palate), a small oral cavity, a small mandible, delayed or abnormal dentition, misaligned teeth, nasal congestion, facial hypotonia, and small hands and short fingers. Weaning and self-feeding are usually late compared with the typically developing infant and frequently do not emerge until 15 to 18 months of age. The DS infant strives for independence and autonomy approximately 6 months later than the child without DS.

TABLE 43.3 Estimated Caloric Needs for Special Conditions

Condition	kcal/centimeter of height	Comments
Developmentally normal child	Average 16	
Prader-Willi syndrome	Maintain growth: 10-11 Promote weight loss: 8.5	For all children and adolescents
Cerebral palsy		
Mild	14	For children ages 5-11 yr
Severe, limited mobility	11	For children ages 5-11 yr
Down syndrome	Girls: 14.3 Boys: 16.1	For children ages 5-11 yr
Motor dysfunction		
Nonambulatory	7-11	For children ages 5-12 yr
Ambulatory	14	For children ages 5-12 yr
Spina bifida	Maintain weight: 9-11 Promote weight loss: 7	For all children older than 8 years of age and minimally active

Modified from Weston S, Murray P: Alternative methods of estimating daily energy requirements based on health condition. In Devore J, Shotton A, editors: *Pocket guide to children with special health care and nutritional needs*, Chicago, 2012, Academy of Nutrition and Dietetics.

Intervention Strategies

Overweight. Children with DS (and all children who have low muscle tone) are at increased risk for becoming overweight because of lower than typical energy expenditure. Weight management includes assessing the feeding developmental level of the child, their physical capability related to gross motor skills and physical activity levels, and environmental challenges. Environmental recommendations are the same as those for all children and include following a regular eating schedule that includes three meals and two to three snacks at regular times with the child sitting either in a high chair or at the table. Planned snacks should be nutrient dense, avoiding foods with excessive amounts of fat and sugar. Soft drinks should be discouraged and physical activity encouraged. It may be helpful to design a calorie-controlled eating plan based on kilocalories per centimeter of height as shown in Table 43.3 (Murray and Ryan-Krause, 2010).

Counseling in which the parent or caregiver helps determine a realistic plan that emphasizes appetite awareness and self-regulation may focus on serving sizes, healthy food choices, and food preparation and decreasing the number of times meals are purchased in fast-food restaurants. If the child or adolescent is school age, a prescription for a special meal at school can be obtained by using the school food service prescription (to be discussed later in the chapter). Prevention of overweight and promotion of an active lifestyle are the goals. Recent studies involving adolescents and young adults have addressed the success of exercise and healthy lifestyles for obese participants with DS. Successful programs include parent training in behavioral intervention and nutrition and activity education over multiple sessions (Curtin et al, 2013).

Eating skills. Parents may wrongly expect more typical eating development for the child with DS. An example of this is the unnecessary delay of weaning to a cup or progression of food textures because of inadequate effort or education. Behavioral problems related to feeding may develop based on what happens between the parent and child at mealtime. An intervention program with a feeding team can guide the

parent in working with the child toward attainable feeding skills related to the developmental level.

Constipation. This is a frequent problem for the child with DS because of overall low tone that is exacerbated by a lack of fiber and fluid in the diet. Treatment should involve providing adequate fiber and fluid, with water consumption emphasized. Fiber content of the diet for children after age 3 is 5 to 6 g per year of age per day. For adults the recommendation is for 25 to 30 g of dietary fiber daily (see Chapter 27).

Prader-Willi Syndrome

Prader-Willi syndrome (PWS) was first described in 1956 by Prader, Willi, and Lambert. It is a genetic condition caused by the absence of chromosomal material. PWS occurs with a frequency of 1 in 10,000 to 1 in 25,000 live births. Characteristics of the syndrome include developmental delays, poor muscle tone, short stature, small hands and feet, incomplete sexual development, and unique facial features. Insatiable appetite leading to obesity is the classic feature of PWS; however, in infancy the problem of **hypotonia** (low muscle tone) interferes with feeding and leads to failure to thrive (Miller et al, 2011; Fig. 43.5). Developmental delays (affecting 50% of the population), learning disabilities, and intellectual disabilities (affecting 10%) are associated with PWS.

The genetic basis of PWS is complex. Individuals with PWS have a portion of genetic material deleted from chromosome 15 received from the father. Of the cases of PWS, 70% are caused from the paternal deletion, occurring in a specific region on the q arm of the chromosome. PWS also can develop if a child receives both chromosome 15s from the mother. This is seen in approximately 25% of the cases of PWS and is called maternal uniparental disomy. Early detection of PWS is now possible because of the use of DNA methylation analysis, which correctly diagnoses 99% of the cases (Miller et al, 2011). This is an important development in the early identification and subsequent treatment of these children to prevent obesity and growth restriction, and it is used to identify the infant born with features and characteristics described previously.

Pathophysiology

Metabolic abnormalities. Short stature in the individual with PWS has been attributed to growth hormone deficiency. In addition to decreased growth hormone release, children have low serum insulin-like

growth factor (IGF)-1, low IGF-binding protein-1, and low insulin compared with developmentally typical obese children. Growth hormone (GH) therapy was approved by the Food and Drug Administration (FDA) in 2000, and in one 5-year study in Japan 37 patients from age 3 to 21 years experienced significant increase in height gain velocity when given GH (Obata et al, 2003). A more recent study found that GH therapy of infants and toddlers for 12 months significantly improved body composition and mobility skill acquisition (Carrel et al, 2010).

In addition to the GH deficiency, individuals have a deficiency in the hypothalamic-pituitary-gonadal axis, causing delayed and incomplete sexual development. Finally there is a decreased insulin response to a glucose load in children with PWS compared with age-matched non-PWS obese children (Haqq et al, 2011).

Appetite and obesity. Appetite control and obesity are common problems for individuals with PWS. After the initial period of failure to thrive, children begin to gain excessively between the ages of 1 and 4, and appetite slowly becomes excessive. Based on longitudinal study, Miller et al describe this gradual and complex progression in terms of seven nutritional phases based on levels of appetite, metabolic changes, and growth. In fact, some adults with PWS may progress to the last phase, with no insatiable appetite, and the person is able to feel full (Miller et al, 2011).

This uncontrollable appetite, a classic feature of PWS, when combined with overeating, a low basal metabolic rate, and decreased activity, leads to the characteristic obesity. The cause of the uncontrollable appetite is suspected to involve the hypothalamus and altered levels of satiety hormones and peptides such as ghrelin (Scerif et al, 2011).

Body composition is an important consideration in the evaluation of individuals with PWS. They have decreased lean body mass and increased body fat, even in infancy (Reus et al, 2011). Body fat generally is deposited in the thighs, buttocks, and abdominal area. The lowered energy expenditure is found in young children, adolescents, and adults with PWS, with one study showing adolescents with PWS having a total energy expenditure (TEE) 53% of that of typically developing adolescents who have a larger body size (McCune and Driscoll, 2005). The low muscle tone contributes greatly to the lack of interest in physical activity.

Nutrition Assessment

Anthropometric measures. Height measurements tend to be lower in PWS infants and young children, with the rate of height gain tapering off between the ages of 1 and 4. The usual measurements of length or height, weight, and head circumference should be taken and plotted on the CDC growth curves. Other clinically relevant measurements include arm circumference and triceps skinfold. BMI may be distorted for the individual with PWS because of the short stature; however, plotting the BMI over time is useful in determining unusual changes (see Appendix 3). It is important that anthropometric measures be taken frequently and reported to the parents or caregiver.

Biochemical measures. Biochemical studies are generally the same for the PWS individual, with the exception of either fasting blood glucose tests or glucose tolerance tests. These are added because of the risk for diabetes mellitus, possibly related to the decreased insulin response and obesity that usually accompany PWS.

Dietary intake. Dietary information varies for individuals with PWS depending on their age. In infancy the dietary information should be obtained with a careful dietary history and analyzed for energy and nutrient intake. Infants are commonly difficult to feed because of their hypotonia, poor suck, and delayed motor skills. Generally their feeding development is slower than in the typically developing infant, and transitioning to food at 4 to 6 months of age may be

Fig. 43.5 Child with Prader-Willi syndrome.

difficult. Many infants with PWS have gastroesophageal reflux, requiring medication or thickening of their formula. Some infants may require nasogastric or G-tube feeds initially. A video fluoroscopic swallow study (VFSS) may be recommended to rule out dysphagia and aspiration. VFSS is an x-ray done using barium and the speech, or the occupational therapist determines whether there is any aspiration on various liquids. Feeding therapy is also beneficial. Our clinic has been requesting VFSS on infants and we have been finding silent aspiration. We have been proactive in including speech and occupational therapy as part of the assessment (Salehi et al, 2017).

During the toddler years, weight gain may increase rapidly as dietary intake increases. This requires careful assessment of portion sizes, frequency of feeding, and types of foods served. Although some parents may report that the child with PWS does not eat more than other children in the family, they have to be educated that the energy needs of the child are lower because of the reduced lean muscle mass and slow development of motor skills and activity. As the child gets older, interest in food increases; and, starting around ages 5 through 12, the child may be hungry all the time and display difficult behaviors such as tantrums, stubbornness, and food stealing. Information gathered during the dietary interview should include asking about feeding routine and management. The phrase “No doubt, no hope (no chance), no disappointment” has been used. With routines there is no doubt the child is fed, and no chance of getting extra foods leading to no disappointment. Determination of energy needs for the infant with PWS is the same as for a developmentally typical infant. However, when entering the toddler years, children with PWS will need fewer calories to maintain weight gain along the growth curve. This will apply in adulthood when fewer calories are needed to maintain weight. Energy needs have been calculated according to centimeters of height from 2 years and older (Miller et al, 2013). It has been recommended that the macronutrient intake of the diet be 25% protein, 45% carbohydrate, and 30% fat and at least 20 grams of fiber. A reduced energy intake and well-balanced diet improves weight control in children with PWS (Miller et al, 2013) (see Table 43.3).

Feeding skills. The infant with PWS often presents with weak oral skills and poor sucking skills in the first year of life. As the child matures, feeding skills are not a problem, but they may be delayed. Chewing and swallowing problems usually are not seen, although they may be associated with the low muscle tone. Behavioral feeding issues are associated with an insatiable appetite and not being provided with food. This can bring about tantrums.

Intervention Strategies

Intervention for PWS should occur at each developmental stage: infancy, toddler, preschool age, school age, and adult.

Infancy. Providing adequate nutrition as established by the AAP related to breastfeeding or formula feeding is recommended. Because feeding may be difficult related to sucking, concentrating the formula or breastmilk may be necessary to promote adequate weight gain. Feeding intervention will assist in improving the sucking problems caused by hypotonia. As the infant matures, a concentrated formula is not necessary, and solid foods can be added when head control and trunk stability are achieved, usually at approximately ages 4 to 6 months.

Toddler and preschool age. Most children begin to gain excessive weight between 1 and 4 years of age. Beginning a structured dietary plan for the child and the family is important so that the toddler learns that meals are provided at specified times and a pattern of grazing doesn't develop. Encourage parents and caregivers to provide balanced meals including protein, vegetables, whole grains, and fruits and limited amounts of sweets. Early intervention during the preschool years

is very important in working with feeding issues and intake regulation as children grow older. Monitoring weight, height, and nutrient intake monthly will help identify early signs of weight acceleration so that dietary patterns and meal composition can be assessed and modified as needed. Regular physical activity is an important part of the IEP, and physical therapy services can be made available if necessary.

School age. For the school-age child, collaboration with the school food service program becomes important. Energy needs should be calculated per centimeter of height (see Table 43.3) and are generally 50% to 75% of the energy needs of typically developing children. This may require using a prescription for special meals through the school food service program.

At home environmental controls may be required, with cupboards and even kitchens being locked, because the child and adolescent have limited satiety and will search for food away from mealtime. Some parents report that GH therapy for their child helps, but it doesn't seem to change the child's lack of satiety. Appetite-suppressing medications have been used but are largely unsuccessful.

Adulthood. Prevention of obesity is truly the key for successful treatment of PWS; however, many adults who are not identified early become very obese. Weight management programs providing a very low 6 to 8 kcal per centimeter of height may be required. If a lower calorie diet is being recommended, patients will likely benefit from vitamin-mineral and essential fatty acid (EFA) supplements if micronutrient needs cannot be met through the diet. Many dietary treatments have been tried such as the ketogenic diet (see Appendix 19) and the protein-sparing modified-fast diets. However, with any approach strict supervision is usually required, and great emphasis must be placed on physical activity. A behavior management approach also has been recommended to implement the dietary management and physical activity plans. In many states there are group homes for adults with PWS, in which supervised independent living is possible and meals can be very structured and exercise programs implemented.

MNT of children and adults with PWS requires follow-up with many health care providers and schools. Fortunately parents of the individual with PWS now have access to a number of support groups and organizations dedicated to education, research, and establishing treatment programs.

NEUROLOGIC DISORDERS

Spina Bifida

Spina bifida is a neural tube defect that presents in a number of ways: meningocele, **myelomeningocele (MM)**, and spina bifida occulta. MM is the most common derangement in the formation of the spinal cord and generally occurs between 26 to 30 days of gestation, with the date of occurrence affecting the location of the lesion. The lesion may occur in the thoracic, lumbar, or sacral area and influences the amount of paralysis. The higher the lesion, the greater is the paralysis. Manifestations range from weakness in the lower extremities to complete paralysis and loss of sensation. Other manifestations include incontinence and hydrocephalus (fluid accumulation in the brain). The incidence of spina bifida is about 2.7 to 3.8 per 10,000 live births in the United States per year, with Hispanics having the highest incidence (Canfield et al, 2014).

Prevention of spina bifida is now possible. In the 1980s, studies reported a positive effect from supplementation of mothers with folic acid plus multivitamins (Smithells et al, 1983). This reduced the risk of a second pregnancy with spina bifida as an outcome. As a result of numerous studies showing folic acid supplementation before conception to be effective, the national recommendation is 400 mcg/day for

all women of childbearing age, and 4 mg for women who have had previous affected pregnancies (Committee on Genetics AAP, 1999). Through its Public Health Program, the WHO advocates globally for folic acid supplementation. Folic acid has been added to many flours and other cereal and grain products in the food supply since 1996. The CDC has reported that mandatory folic acid fortification of cereal and grain products has helped about 1300 babies to be born without neural tube defects (NTD) every year (CDC, 2015b). These public health measures have resulted in increased folate blood levels in U.S. women of childbearing age and a decrease of 20% in the national rate of spina bifida (Das et al, 2013; see Chapter 14).

Pathophysiology

The spinal lesion may be open and is typically repaired surgically shortly after birth, usually within 24 hours, to prevent infection. Although the spinal opening can be repaired surgically, the nerve damage is permanent, resulting in the varying degrees of paralysis of the lower limbs. In addition to physical and mobility issues, most individuals have some form of learning disability.

The spinal lesion affects many systems of the body and can result in weakness in the lower extremities, paralysis, and nonambulation; poor skin condition resulting in pressure injuries (see Chapter 19); loss of sensation with bowel and bladder incontinence; hydrocephalus; urinary tract infections; constipation; and obesity. Seizures also occur in approximately 20% of children with MM and may require medication. If medication fails, a ketogenic diet can be tried in some cases (see Appendix 19). Chronic medication is frequently required for prevention and treatment of urinary tract infections and for bladder control. The resultant nutrition problems include obesity, feeding problems, constipation, and drug-nutrient interactions. According to the Spina Bifida Association, children with spina bifida have an increased risk of developing an allergy to latex because of repeated exposures to latex products. The risk is decreasing with the use of latex-free products. Children who are allergic to latex may also develop an allergy to certain foods that cross react with latex such as banana, avocado, chestnut, kiwi, apple, carrot, celery, papaya, tomato, and melon. The Spina Bifida Association recommends that these foods should not be avoided unless there is an established reaction.

Nutrition Assessment

Anthropometric measures. Infants and children with spina bifida are usually shorter than typically developing children because of reduced length and atrophy of the lower extremities, although other problems such as hydrocephalus, scoliosis, renal disease, and malnutrition may contribute. The level of the lesions also can affect the length and height of the individual.

Obtaining accurate length and height measures can be difficult, especially as the child grows older. An alternate measure for determining height, the arm span/height ratio, is used and modified, depending on leg muscle mass. Arm span can be used directly as a height measure ($\text{arm span} \times 1$) if there is no leg muscle mass loss, as in a sacral lesion. $\text{arm span} \times 0.95$ can be used to determine height if there is partial leg muscle loss, and $\text{arm span} \times 0.90$ is used for a height measurement when there is complete leg muscle loss, such as with a thoracic spinal lesion (Kreutzer and Wittenbrook, 2013; see Fig. 43.1 and Appendix 6).

Weight measures can be obtained for the child unable to stand by using chair, sling, bucket, or wheelchair scales. To monitor weight accurately, it should be obtained in a consistent manner, with the person in light clothing or, if under age 2 years, undressed and wheelchairs weighed at each visit. Triceps skinfold measures can also be used, along with subscapular measures and abdominal and thorax measures, to determine the amount of body fat. They may be used as adjuncts to stature and weight measurements.

Head circumference should be measured in infants and toddlers up to age 3. A high percentage of children with spina bifida have head shunts as a result of their hydrocephalus. Unusual changes in the size of the head may indicate a problem with the shunt.

Biochemical measures. Useful biochemical tests in the health monitoring of individuals with spina bifida include iron status tests, measurements of vitamin D, and other tests related to the nutritional consequences of medications needed for seizures and urinary tract infection control (see Chapter 5 and Appendix 13).

Dietary intake. Many children with spina bifida eat a limited variety of foods, and they are frequently described as “picky eaters” by the parents. When doing a dietary history, it is important to ask about the variety of foods, particularly of high-fiber foods. The school-age child may be prone to skipping breakfast because early morning preparations for school require more time than for the nonaffected child.

Energy needs are lower for the child with spina bifida (see Table 43.3), and calorie requirements must be determined carefully to prevent the obesity to which many are prone. Ekvall and Cerniglia (2005) found that for MM children 8 years or older, the caloric need is 7 cal/cm of height for weight loss and 9 to 11 cal/cm of height to maintain weight. They also found that it is important to evaluate how the mother or caretaker perceives food for the child because it represents sympathy and love for many parents.

It is important to evaluate fluid intake because so many children are prone to having urinary tract infections as a result of daily catheterization. They may be drinking inadequate amounts of water and excessive amounts of soft drinks or tea that contain caffeine, which is a mild diuretic. Cranberry juice can be offered as it may help to prevent urinary tract infections, but calorie intake must be taken into consideration. Physical activity needs to be evaluated and may be found to be very limited, particularly when the child is nonambulatory. Ambulatory individuals with a shunt may be restricted from contact sports but can be involved in walking and running.

Feeding skills need to be evaluated, along with oral-motor function in particular. Many children with spina bifida are born with **Arnold Chiari malformation of the brain**, which affects the brainstem and swallowing (see Chapter 39 and Appendix 20 for dietary recommendations for dysphagia). Difficulty in swallowing may contribute to the child avoiding certain foods. Because of this there may be delays in weaning from the breast or bottle to the cup, but there should be no delays in gaining self-feeding skills.

Clinical evaluation. Evaluation should include looking for pressure injuries and signs of dehydration, along with asking about the amount and type of foods and fluids consumed. Constipation may be caused by the neurogenic bowel (fecal incontinence due to lack of normal bowel function) combined with a diet low in fiber and fluids.

Intervention Strategies

Many children with spina bifida are overweight. The Spina Bifida Association reports that after age 6, 50% of children are overweight and in adolescence and adulthood over 50% are obese (Spina Bifida Association, 2017). This may occur when ambulation is a problem leading to decreased energy needs. Refusal to accept a wide variety of foods is also common. Frequent feeding may be due to an oral-motor or a behavioral problem. Counseling includes introducing foods around age 6 months, limiting the intake of high-sucrose infant jar foods, and supporting the child to accept a wide variety of flavors and textures.

In addition to the generally known health consequences of obesity, specific concerns for individuals who have Spina Bifida include further limits of mobility and increased pressure on skin, increasing the already high risk of skin breakdown. Increased social isolation and decreased self-worth are also consequences (Spina Bifida Association, 2017).

Obesity prevention includes addressing the problems of limited physical activity, increasing fluids and fiber, and estimating the appropriate amount of calories. For school aged children it may be useful to provide a prescription for a low-calorie breakfast and lunch, with weight management listed as a part of the IEP. Enrollment in a group weight management program has been used successfully along with encouraging physical activity. The ideal program uses a team approach with involvement of the individual, the family, RDN, nurse, occupational therapist, physical therapist, educator, and psychologist (see Chapter 20).

In many clinics the child or adult with spina bifida is seen on a semiannual or annual basis. This frequent follow-up is necessary and should include monitoring of growth, particularly weight; food and fluid intake; and medication use. School programs and IEPs are excellent follow-up tools; however, the school often lacks appropriate scales for weighing a nonambulatory student. In this situation the parent should be encouraged to bring the child to the clinic for weight checks or, if distance is a problem, find a long-term care facility that will permit use of its scales. Follow-up by phone contact or email can be done for evaluating dietary intake and fluid management.

Cerebral Palsy

Cerebral palsy (CP) is a group of disorders of motor control or coordination resulting from injury to the brain during its early development. Among the causative agents of CP are prematurity; blood-type incompatibility; placental insufficiency; maternal infection that includes German measles; other viral diseases; neonatal jaundice; anoxia at birth; and other bacterial infections of the mother, fetus, or infant that affect the central nervous system.

The problem in CP lies in the inability of the brain to control the muscles, even though the muscles themselves and the nerves connecting them to the spinal cord are normal. The extent and location of the brain injury determine the type and distribution of CP. The incidence of CP varies with different studies, but the most commonly used rate is 1.5 to 4 in 1000 live births. The prevalence of premature births has contributed to maintenance of this figure despite electronic fetal monitoring (Fig. 43.6).

Pathophysiology

There are various types of CP, which are classified according to the neurologic signs involving muscle tone and abnormal motor patterns and postures. The diagnosis of CP is generally made between 9 to 12

months of age and as late as 2 years with some types (Box 43.2). The severity of CP is classified by levels of self-sufficiency in activities of daily living (ADLs). There are five categories of gross motor function, with category one being the least affected and five the most affected (Box 43.3).

BOX 43.2 Different Types of Cerebral Palsy

Spastic cerebral palsy (CP): Spasticity implies increased muscle tone. This type accounts for 70% to 80% of cases. Muscles continually contract, making limbs stiff, rigid, and resistant to flexing or relaxing. Reflexes can be exaggerated, while movements tend to be jerky and awkward. Often, the arms and legs are affected. The tongue, mouth, and pharynx can be affected as well, impairing speech, eating, breathing, and swallowing.

Non-spastic CP: Ataxic CP affects coordinated movements. Balance and posture are involved. Walking gait is often very wide and sometimes irregular. Control of eye movements and depth perception can be impaired. Often, fine motor skills requiring coordination of the eyes and hands, such as writing, are difficult. Does not produce involuntary movements, but instead indicates impaired balance and coordination.

Dyskinetic: Dyskinetic CP is separated further into two different groups; athetoid and dystonic.

Athetoid CP includes cases with involuntary movement, especially in the arms, legs, and hands.

Dystonia/Dystonic CP encompasses cases that affect the trunk muscles more than the limbs and results in fixed, twisted posture.

Because non-spastic CP is predominantly associated with involuntary movements, some may classify CP by the specific movement dysfunction, such as: Athetosis—slow, writhing movements that are often repetitive, sinuous, and rhythmic

Chorea—irregular movements that are not repetitive or rhythmic, and tend to be more jerky and shaky

Choreoathetoid—a combination of chorea and athetosis; movements are irregular, but twisting and curving

Dystonia—involuntary movements accompanied by an abnormal, sustained posture

Mixed CP: A child's impairments can fall into both categories, spastic and non-spastic, referred to as mixed CP. The most common form of mixed CP involves some limbs affected by spasticity and others by athetosis.

BOX 43.3 Gross Motor Function Classification System (GMFCS)

The 5-level GMFCS is used in clinical and research settings.

1. Walks without limitations
2. Walks with limitations
3. Walks using a hand-held mobility device
4. Self-mobility with limitations, may use powered mobility
5. Transported in a manual wheelchair
 - fed orally without a feeding tube
 - fed with a feeding tube

Reference: Palisano R, Rosenbaum P, Walter S, et al. Development and reliability of a system to classify gross motor function in children with cerebral palsy. *Cev Med Child Neural* 1997; 39(4):214-223.

Poor nutrition status and growth failure, often related to feeding problems, are common in children with CP. Meeting energy and nutrient needs is particularly difficult in children and adults with more severe forms of CP such as spastic quadriplegia and athetoid CP, which is typically classified as Gross Motor Function Classification System (GMFCS) 4-5.

For example, bone mineral density of children and adolescents with moderate to severe CP is reduced in those with gross motor function and feeding difficulties (Andrew and Sullivan, 2010).

Other health problems include constipation exacerbated by inactivity, abnormal muscle coordination, and lack of fiber and fluids. Dental problems occur and often are related to malocclusion, dental irregularities, and fractured teeth. Lengthy and prolonged bottle-feedings of milk and juice promote the decay of the primary upper front teeth and molars (see Chapter 24). Hearing problems and especially visual impairments, intellectual disability, respiratory problems, and seizures affect nutrition status. Seizures are controlled with anticonvulsants, and a number of drug-nutrient interaction problems occur (see Appendix 13).

Nutrition Assessment

Anthropometric measures. This is an important area of assessment because of growth failure in the more severely involved child or adult with CP. Children with CP are often shorter, and, depending on the level of severity, some children with CP may have to be measured for length using alternative measuring techniques such as recumbent length boards or standing boards as they grow older (see Appendix 5). However, some of the measuring devices are inappropriate for the child with contractures and inability to be stretched out full length. Arm span can be used when the individual's arms are stretchable, as well as upper arm and lower leg length. Stevenson (1995) has recommended lower leg length or knee height as a possible measure for determining height for children and adults with lower-leg CP (see Fig. 43.1). The CDC recommends using the CDC/WHO curves designed for nonaffected children, plotting sequentially for indications of malnutrition rather than using the disease-specific curves.

Weight measures should be collected over time. Scales may require modifications, with positioning devices for the individual with CP who has developed scoliosis, contractures, and spasticity. Working with a physical therapist to find a positioning device that can be placed in a chair scale or using a bucket scale often works well. Mid-upper arm circumference and triceps skinfold measures are recommended reliable ways to screen for fat stores in children with CP. Head circumference should be measured regularly from birth to 36 months and plotted on the CDC growth charts (see Appendix 3).

Biochemical measures. Although no specific laboratory tests are indicated for the child with CP, a complete blood count, including hemoglobin, hematocrit, and ferritin, should be done when food intake is limited and malnutrition is a possibility. Because bone fractures are a significant problem for many children and adults with spastic quadriplegia, bone mineral density may require evaluating. Medications for seizures may be given; many have nutrition interaction problems (see Appendix 13). Evaluation of vitamin D, carnitine, and vitamin K levels may be useful.

Dietary intake. Oral-motor difficulties can result in limiting the intake of food and fluid, making it difficult for caretakers to meet nutritional needs. The energy needs of the individual with CP vary according to the type of CP. Studies show that the REE and TEE are lower in those with spastic quadriplegic CP than in developmentally typical controls (see Table 43.3).

Intervention Strategies

A high percentage of children with CP have feeding problems that are largely the result of oral-motor, positioning, and behavioral factors. As infants they may have difficulty swallowing and after infancy,

coordinating chewing and swallowing, so the normal progression to solid foods is later than usual. Oral-motor problems may be permanent requiring lifelong modifications such as modified textures of foods and fluids to assure swallowing safety and the need for tube feeding for part or all of nutrition and hydration needs. All this may lead to inadequate intake and growth limitations. For those infants and children with IEPs, the team of RDN, speech therapist, occupational therapist, and physical therapist should evaluate the problem and work together in planning therapy to maximize skill development.

Gastroesophageal reflux frequently is seen in these infants and toddlers. Tube feeding may be required if swallowing studies reveal aspiration. Alternative techniques in feeding should be considered, which could include modifying food textures, thickening all beverages, or placing a gastrostomy tube (Mahant et al, 2011). RDNs should evaluate gastrostomy feedings for caloric and nutritional value and volume required for hydration as well as including oral solids and liquids into the tube feeding formula if possible.

Typical problems identified in the evaluation are altered growth, inadequate energy or fluid intakes, drug-nutrient interactions, constipation, and feeding problems. Working out an intervention plan is most successful when it involves the parent as part of the team, addresses cultural issues, and recognizes the importance of the feeding problem. Children with CP have complex problems that require routine follow-up with the family and appropriate agencies, schools, and institutions in the community. State agencies often provide tube-feeding formulas and special wheelchairs and equipment to assist with feeding problems. These agencies vary from state to state.

Autism

Autism spectrum disorders (ASD) were originally described in the 1940s as a behavioral disorder. It is now understood to be a pervasive and systemic syndrome with neurologic, immunologic, gastrointestinal, and endocrine involvement. There is no test to diagnose ASD at this time, rather ASD is diagnosed by the presence of impaired reciprocal social interaction; impaired communication skills with restricted, repetitive, stereotypical interests and behaviors as specified by the *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition (DSM-5) (American Psychiatric Association, 2013).

Before 2013, **pervasive developmental delay (PDD)** and **Asperger's syndrome** were considered to be related but separate disorders (American Psychiatric Association, 2013). Now these disorders are included as part of the diagnosis of ASD as defined by the DSM-5. Rett's syndrome is also a related developmental disorder but is not part of the ASD diagnosis as it is significantly different in causation, is progressive, and is almost exclusively found in girls (Leonard et al, 2013). The CDC estimates 1 in 59 children were identified with ASD in 2014, an increase of 15% from 2012. ASD is four times more common in boys than girls. Most children are diagnosed at 4 years of age, yet it can be reliably diagnosed earlier. Since early diagnosis is essential for best outcomes, the AAP recommends screening all children for autism at the 18- and 24-month well child visits.

Pathophysiology

The etiology of ASD is as complex as the individuals with the disorder. Many theories have been proposed in both the scientific literature and popular press, with some unsubstantiated claims causing harm, such as the discredited link between vaccines and ASD leading to a worldwide resurgence of measles. It is estimated that specific genes or gene mutations account for 10% to 25% of ASD cases, with interaction between genetics and environment assumed to be the primary cause (Ornoy et al, 2016). Various causal theories are listed in Table 43.4.

TABLE 43.4 ASD: Proposed Causes, Contributors, and Associated Disorders

Causes of ASD	Disorders Associated with ASD
Genetics Presence of specific gene Gene mutation Gene deletion	Prematurity, small for gestational age (SGA)
Prenatal Environmental Exposure Pesticides Air pollution, particularly particulates Phthalates, BPA, solvent, flame retardant Medication: valproic acid, Misoprostol, Thalidomide Virus: Rubella, CMV	Birth defects: present in 11% of children with ASD compared with 6.4% of typically developing children
Parental characteristics Older age of mother or father Maternal autoimmune disorder Parental mental health diagnosis Obesity	Genetic syndromes: 10% of all children with ASD have a genetic syndrome such as Down Syndrome, fragile X, tuberous sclerosis, neurofibrosis, Angelman's syndrome
Prenatal vitamin deficiency; folate	Psychiatric diagnosis: ADHD, anxiety disorders, depression
Birth spacing: conceived less than 18 months or more than 60 months	IDD: 30% with IDD, additional 23% borderline IQ Sleep disorders: present in 2/3 of individuals with ASD, 80% with presence of IDD and ASD Gastrointestinal disorders prevalence studies vary from 7% up to 90%, constipation and diarrhea primary disorders Allergies; primarily food allergies Seizure disorders with prevalence increasing with age Autoimmune disorders

ADHD, Attention-deficit/hyperactivity disorder; ASD, autism spectrum disorder; BPA, bisphenol-A; CMV, cytomegalovirus; IDD, intellectual and developmental disabilities.

Ornoy et al, 2016; Chaidez et al, 2014; Garcia et al, 2017; Campbell et al, 2014; Marshall et al, 2014.

ASD frequently occurs with other developmental or medical diagnoses; these are described in Table 43.4. Children with ASD are more likely to have gastrointestinal (GI) disorders than typically developing children, with up to 90% of children with ASD having some type of GI issue. Compared with children with developmental disabilities, constipation, bloating, or diarrhea are three times more common (Chaidez et al, 2014). GI problems are often expressed atypically as poor sleep, anxiety, aggression, or social withdrawal, resulting in lower quality of life (Garcia et al, 2017). Reasons for GI problems include alterations in the gut microbiome (lack of diversity and characteristic microbiota), carbohydrate intolerance, and limited diets (Chaidez et al, 2014). Children with ASD frequently have restricted diets due to higher rates of food allergies, parent-imposed restricted diet, feeding problems, or selective “picky” eating (Marshall et al, 2014).

Overall, children with ASD who consume adequate nutrition grow well although there is a subgroup of children who demonstrate a general overgrowth pattern with macrocephaly (Campbell et al, 2014).

Nutrition Assessment

Anthropometric measures. Height and weight are determined using standard equipment and growth charts. Head circumference should be monitored up to 36 months, or longer if abnormal growth has been noted (Campbell et al, 2014). Weight gain and growth may be decreased with use of stimulant medicine, and excessive weight gain can occur with psychoactive medications such as risperidone (Ptomey and Wittenbrook, 2015; Richardson et al, 2017).

Biochemical measures. There is no standard pattern of tests other than regular newborn screening and blood work for health monitoring. If pica is noted or restrictive diets followed, pertinent nutrition blood work should be ordered. Since autoimmune disorders and allergies are more common, appropriate testing should be done when suspected (Ly et al, 2017). When psychotropic medicines are used blood lipids, hemoglobin A1C, and liver enzymes should be followed due to risk of metabolic syndrome.

Dietary intake. Dietary assessment is important due to limited diets and frequent constipation (see Chapter 4). Up to 89% of children with ASD exhibit some form of eating issue compared with 25% of typically developing children (Marshall et al, 2014). Limited dietary intake coupled with rigid, monotonous eating patterns place children with ASD at risk for both nutrient deficiencies and excesses (Marshall et al, 2014; Stewart et al, 2015). Idiosyncratic dietary patterns such as avoiding a certain color of food, eating specific foods in specific locations, or avoiding certain food textures are common. One multicenter study found that up to 40% of children with ASD had probable nutrient deficiencies (Stewart et al, 2015). Fruits and vegetables are commonly low in the diet while processed carbohydrates are high (Garcia et al, 2017). When variety is low and only a few foods are regularly consumed, the diet can be unbalanced with high levels of sodium, poor quality fat choices, and low fiber, especially if fortified foods or highly processed foods are consumed in large amounts. Pica or mouthing/chewing nonfood items can be a concern in ASD and cause significant health problems including hepatitis, parasitic disease, lead toxicity, and anemia. Including a feeding assessment along with a diet assessment (see Chapter 4) is helpful in determining whether feeding skills are age appropriate or if sensory processing is interfering with eating—both issues associated with ASD (Ptomey and Wittenbrook, 2015). Since social interaction is impaired, children often do not understand or display typical feeding cues and the feeding relationship may be challenged. Rigid eating habits, poor sense of hunger/satiety, textural aversions, and limited access to physical activity has resulted in a higher rate of obesity in ASD, especially among adolescents (Marshall et al, 2014).

Medical Nutrition Therapy

No one therapy or treatment modality works for all individuals with ASD (Marshall et al, 2014). Most children with ASD participate in a variety of interventions to address rigid or stereotypic behavior, sensory processing, and communication. These can include behavior intervention, structured educational approaches, medication, speech therapy, and occupational therapy. Interdisciplinary feeding therapy is warranted to address selective eating secondary to rigidity, motor planning, or sensory processing. Food rewards are commonly used in behavioral treatment, and alternatives should be explored as food rewards promote eating when not hungry, associate eating with reward, and are linked to emotional eating and obesity.

MNT is an effective complement to other treatments. Addressing selective eating habits can be challenging, and expanding the child's food repertoire takes time due to the rigidity inherent in the disorder. Treatment strategies need to respect the child's and parents' anxiety

around mealtime as it can be great due to the child's rigidity, motor skills and sensory preferences, and parents' stress (Marshall et al, 2014). Common techniques include operant behavioral, systematic sensory desensitization, and food chaining (Marshall et al, 2014; Ptomey and Wittenbrook, 2015). Obesity, allergies, intolerances, and GI complaints are all common in children with ASD yet often go untreated (Chaidez et al, 2014; Garcia et al, 2017; Ly et al, 2017). Obesity treatment can be especially challenging due to dietary rigidity, hypersensitivity to sensory characteristics of food, and limited access to physical activity. Specialized diets are often trialed in children with ASD both due to medical concerns (GI complaints, seizures, allergies) as well as media reports (Garcia et al, 2017).

The most popular diet has been the gluten free (GF)–casein free (CF) diet. The majority of studies have not found measurable benefit, but parents often cite subtle improvements (Sathe et al, 2017). It has been theorized that the GF/CF diet or somewhat related Specific Carbohydrate Diet may be helpful in a small group of children as the diet is not treating the ASD per se but addressing undiagnosed immune or GI disorders, which are common in ASD (Garcia et al, 2017). Studies have documented the potential for nutritional deficits with the use of restrictive diets, specifically poor bone status with casein restriction, yet the risk can be minimized with dietitian supervision (Ly et al, 2017; Stewart et al, 2015). Tables 43.5 and 43.6 describe nutritional treatments commonly used in ASD. Care should be taken when beginning a diet trial as once a food is removed from a child's diet, it may be difficult to reintroduce that food if the child is a selective eater. Conversely if special products need to be used, such as GF alternatives, acceptance must be assured before starting the diet trial to assure dietary adequacy. Length of the trial and outcome

measures should be clearly identified and the trial continued or ended based on measured effectiveness. When instituting a diet plan, the overarching consideration is to assure a health-promoting, developmentally appropriate diet that allows for social inclusion at home and in the community.

When MNT is used, care providers and the child, when possible, are key contributors to the process, identifying priorities, preferences, and potential challenges (Garcia et al, 2017). Collaborating with occupational therapists, speech and language pathologists, and others on that child's team is critical for success especially if a child is a highly selective eater. As a result of years of rigid and monotonous diets, use of food rewards, psychotropic drug use, and limited physical activity, rates of diet-related disorders such as hypertension, obesity, and diabetes are 40% to 50% higher in adults with ASD compared with the general population (Garcia et al, 2017; Marshall et al, 2014). Nutritional guidance throughout the life course is essential, directed not only toward the caregiver but also toward the adolescent with ASD especially as they achieve independence (Garcia et al, 2017).

Attention-Deficit/Hyperactivity Disorder

Attention-deficit/hyperactivity disorder (ADHD) is a neurobehavioral problem beginning in childhood and often extending into adulthood. Between 9.5% and 11% of children in the United States have been diagnosed with ADHD (CDC, 2018). Nearly two thirds of children with ADHD have another behavioral diagnosis. Diagnosis is based on the presence of specific behaviors noted in different settings: home, school, and community (Wolraich, 2019). According to the DSM-5 criteria for diagnosis, the child must consistently show signs of inattention, hyperactivity, and impulsivity inappropriate for age that

TABLE 43.5 Proposed Dietary Interventions in Neurobehavioral Disorders

Dietary Interventions	Associated Disorders	Guidance for Use
Additive/food dye free diet Removal of synthetic food dyes: Blue 1&2, Citrus Red 2, Green 3, Red 40, Yellow 5&6, sodium benzoate	May reduce hyperactive and attentional issues in ADHD, ASD, and typically developing children with sensitivities (Garcia et al, 2017; Lange et al, 2017; Ly et al, 2017)	Requires instruction in label reading, may increase cost of some food products
Elimination diets Elimination of common allergens, usually milk, egg, wheat, soy, peanuts, tree nuts, fish/shellfish May also exclude other foods limiting diet to a handful of hypoallergenic foods	Food allergies Eosinophilic esophagitis ADHD ASD	Used temporarily for identification of problematic foods Requires detailed logs of intake and behavior to detect patterns Foods introduced systematically Removal of food for prolonged time can lead to rebound allergy response in sensitive children and can lead to food refusal in ASD. When foods are reintroduced, identify foods that the whole family can eat to encourage social inclusion. Requires instruction in label reading, may increase constipation especially if highly processed grains are used
FODMAPs diet SCD Elimination of classes of carbohydrate to address low levels of digestive enzymes or alterations in microbiome	Gastrointestinal concerns such as Crohn's disease, ulcerative colitis, carbohydrate intolerance, ASD with gastrointestinal symptoms	Requires detailed education for both consumer and RDN, both diets include staggered restriction/introduction which is helpful for identifying target foods and minimizes risk, specifically with SCD. SCD can lead to nutrient deficits for young children with limited diets. SCD may limit variety of textures which may influence progression of textures in feeding therapy
Gluten free (GF) and Casein free (CF) diets Eliminate casein-containing foods (milk from cow, goat, sheep, etc.) and/or gluten containing foods (wheat, rye, barley)	Celiac disease (GF), commonly used with DS, ASD, and ADHD Cerebral folate deficiency (CF) Food allergies	Identify foods that whole family can eat to encourage social inclusion, requires instruction in label reading, may increase constipation especially if highly processed GF grains are used. Ensure calcium adequacy with CF diet.

ADHD, Attention-deficit/hyperactivity disorder; ASD, autism spectrum disorder; CF, casein free; DS, Down syndrome; FODMAPs, fermentable oligosaccharides, disaccharides, monosaccharides, and polyols); GF, gluten free; SCD, Specific Carbohydrate Diet. References: Sathe et al, 2017; Ly et al, 2017; Ptomey and Wittenbrook, 2015; Mastrangelo, 2018; Garcia et al, 2017.

TABLE 43.6 Examples of Effects of Nutrient Supplementation in Neurobehavioral Disabilities

Omega-3 fatty acid supplementation	ASD: Little evidence supports the effectiveness of omega-3 supplementation to improve core or associated ASD symptoms (Sathe et al, 2017) ADHD: Modest support for decreased lability, increased attention, and decreased oppositional behavior with GLA and EPA supplementation (Lange et al, 2017) FAS: Possible benefit pre- and postnatally (Murawski et al, 2015)
Digestive enzymes	ASD: Evidence is inadequate to assess the effects of short-term digestive enzyme supplements (Sathe et al, 2017)
Vitamin B ₆	ALDH7A1 deficiency, Pyridox(am)ine 5'-phosphate oxidase deficiency Hyperprolinemia type II: reduced seizure activity (Mastrangelo, 2018) ASD: Evidence inadequate to support improvements in function, used individually, in various forms or with magnesium (Garcia et al, 2017)
Folic acid, Folicin	Cerebral folate deficiency: Possible reduced seizure activity, improved motor function (Mastrangelo, 2018) Mitochondrial disorders: often included
B ₁₂ sublingual or injection	ASD: Few significant group communication or behavioral benefits (Sathe et al, 2017)
Multivitamin supplement: riboflavin, ALA, coenzyme Q ₁₀ ; often with folic acid and L-carnitine added when warranted	Mitochondrial disorders: Standard treatment to improve muscle function (Parikh et al, 2015) ASD: May warrant trial for children with ASD if mitochondrial disorder is suspected
Magnesium	ASD: No evidence to support use (Garcia et al, 2017) ADHD: Evidence inadequate to support use (Lange et al, 2017)
Probiotics	ASD: No evidence to support use for ASD, but moderate evidence to support use in treating gastrointestinal issues such as constipation (Garcia et al, 2017) Other disorders: May help to relieve constipation

ADHD, Attention-deficit/hyperactivity disorder; ASD, autism spectrum disorders; EPA, eicosapentaenoic acid; FAS, fetal alcohol syndrome; GLA, gamma-linolenic acid.

interfere with daily functioning and are not attributed to other diagnoses. Based on symptoms noted, three types are differentiated: (1) predominately inattentive type, (2) predominately hyperactive-impulse type, and (3) combined presentation. Presentation may change over time as the demands on the child increase. The causes of ADHD are not well understood, but genetic factors play a role. Additionally, other potential causes or risk factors include (Lange et al, 2017):

- Alcohol, drug, or tobacco use during pregnancy
- Premature delivery or low birth weight
- Environment, exposure at a young age; lead, pesticides, institutional care
- Brain injury

Television, parenting styles, sugar, and/or family dysfunction do not cause ADHD although they can exacerbate symptoms.

Nutrition Assessment

Anthropometric measures. Measurements of height and weight should be taken and recorded on a regular basis. Medications used in treatment may cause anorexia resulting in inadequate energy intake and slowing of growth, especially with long-term use (Richardson et al, 2017).

Biochemical measures. Follow recommendations for well child care with increased frequency if child is not gaining weight or has limited intake.

Dietary intake. A detailed dietary history should be obtained (see Chapter 4) especially in children who are exhibiting limited dietary intake. Evaluate the mealtime environment to identify ways to reduce distractions through changing seating or limiting electronics.

Medical Nutrition Therapy

Standard treatment includes behavioral therapy (47% of children) and/or stimulant medication (62% of children). Stimulants tend to reduce appetite and weight gain, especially in the first year of use (Richardson et al,

2017). This contributes to a small but statistically significant lower adult height with long-term treatment with potential negative effects on bone mineralization (Richardson et al, 2017). Since the ability to feel hunger has been reduced, the child cannot be expected to appropriately modulate their own intake. Treatment should consider how to maximize interest in eating, first by adjusting medication timing or dosing when possible (i.e., eating breakfast before medication) (Richardson et al, 2017). When weight gain is a concern, care providers often resort to forcing, bribing, or offering higher fat/sugar foods to encourage intake. These practices rarely are successful and may contribute to the higher rates of obesity seen in adolescents and adults with ADHD. Encourage weight gain by offering calorically dense foods before medication dosing or when effect is waning; small and short frequent meals; and limiting visual/auditory distractions at meals (TV, tablets). In severe cases, a child may need extra support in school meal settings due to the amount of stimulation.

Restricted diets for ADHD have been promoted since the early 1970s starting with the Feingold diet. Despite mixed evidence of success, many families chose to follow this diet, which eliminates naturally occurring salicylates and artificial food dyes (FD&C numbered dyes) and additives (Ly et al, 2017). Recent research suggests that dietary manipulation may be beneficial in a subset of children, specifically the use of Restricted Elimination Diets (RED) and elimination of artificial food dyes (Lange et al, 2017).

Studies on RED and food dyes suggest that there are children with ADHD who have greater sensitivity to food additives and may also have atypical allergic responses (Ly et al, 2017). While there are higher rates of food allergies seen in ADHD, positive response to elimination of a food did not correlate with results of allergy testing, suggesting a non-immunoglobulin E (IgE) response (Ly et al, 2017). Table 43.5 details dietary interventions commonly used.

Supplemental omega-3 fatty acids have also shown mixed results in children with both normal and low blood levels. Meta-analysis has suggested that there is a modest benefit for some children, dependent

on age or “critical period,” presence of comorbidities, and length of time of use (Lange et al, 2017). Gamma-linolenic acid (GLA) and eicosapentaenoic acid (EPA) appear to be the most effective of the EFAs trialed (Lange et al, 2017). Studies with strict inclusion criteria indicate that there is a subgroup of children who do respond positively to supplementation with slightly improved emotional ability, increased attention, and decreased oppositional behavior (Lange et al, 2017). Typical “Western” diets are low in omega-3 fats and have been linked to ADHD, raising the question if supplementation alone is beneficial or if changing the diet to improve variety of fat intake, and reduce food additive intake, would have the same benefit as supplementation (Ly et al, 2017). Table 43.6 details use of nutritional supplements.

While research on diet and ADHD remains inconclusive and there is significant individual variation in response, reducing intake of processed foods, increasing intake of omega-3 fatty acids, and assuring appropriate weight gain and growth should be part of MNT for ADHD.

Cleft Lip and Palate

Cleft lip and/or cleft palate (CL/CP), also known as orofacial clefts, are some of the most commonly occurring birth defects, with an incidence of 1 in 500 to 700 births worldwide (Shkoukani et al, 2013). There is a wide variation of incidence by ethnic origin and geographic location, with the highest and lowest incidence respectively in Japan and in South Africa. Cleft lip is a condition that creates an opening of the upper lip. It can range from a slight notch to complete separation in one or both sides of the lips and extending upward. If it occurs on one side of the lip, it is called a unilateral cleft lip; if it occurs on both sides, it is called a bilateral cleft lip. The cleft palate occurs when the roof of the mouth has not joined completely; it can be either unilateral or bilateral. Cleft palate can range from just an opening at the back of the soft palate or separation of the roof of the mouth with both soft and hard palate involved. CL/CP result from incomplete merging and fusion of embryonic processes during formation of the face. There is also a condition called submucous cleft palate in which there is incomplete fusion of the muscular layers of the soft palate with fusion of the overlying mucosa (Figs. 43.7 and 43.8).

Lip and palate development occur between 5 and 12 weeks of gestation. Lip development begins first, usually at 5 weeks of gestation, followed by the development of the maxilla prominences and the primary palate. Fusion of the hard palate is completed by 10 weeks of gestation and the soft palate by 12 weeks. Cleft lip, but not cleft palate, can sometimes be identified in-utero with fetal ultrasound. CL/CP have multiple causes: genetic, environmental, and idiopathic. It is estimated that 20% of orofacial clefts are associated with underlying syndromes (syndromic clefts) such as 22q11.2-related disorders, Treacher Collins syndrome, and Stickler syndrome. Syndromic clefts are more likely to be genetic.

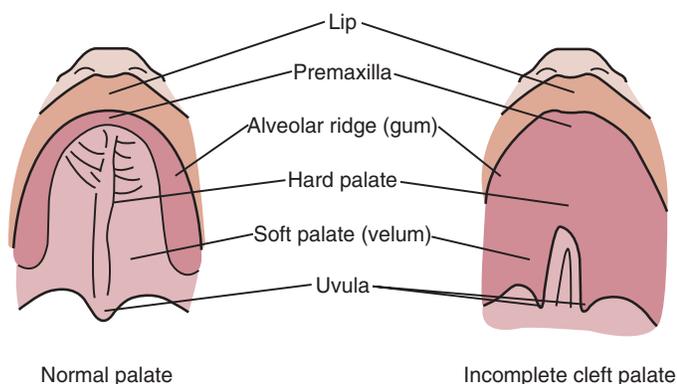

Fig. 43.7 Cleft palate. (From American Cleft Palate-Craniofacial Association, ACPA Family Services. <http://acpa-cpf.org/families>).

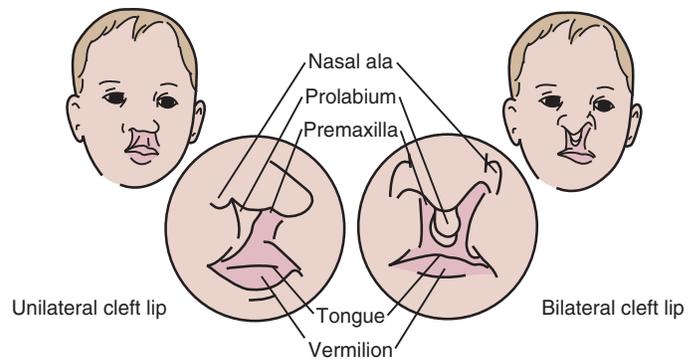

Fig. 43.8 Cleft lip. (From American Cleft Palate-Craniofacial Association, ACPA Family Services. <http://acpa-cpf.org/families>).

Pierre Robin sequence (RS) is often referred to as a syndrome but it is actually a set of abnormalities affecting the head and face consisting of a small lower jaw (micrognathia), a tongue that is placed further back than normal (glossoptosis), and breathing problems. A horseshoe-shaped cleft palate may or may not be present. Genetic counseling can now identify high-risk families for syndromic and nonsyndromic clefts (Leslie et al, 2013). Environmental causes include teratogens such as maternal smoking, alcohol use, and use of antiepileptic medications.

Nutrition Assessment

Nutrition assessment for CL/CP includes the usual anthropometric measures for all infants and children. Biochemical measures are also those used with nonaffected children, and dietary intake information depends on the feeding problems that exist. Other problems include dental abnormalities and missing teeth, speech difficulties, and increased incidence of middle ear infections. Some infants (i.e., those with RS) may have increased difficulty breathing. The feeding evaluation is a major part of the assessment and is best accomplished with a team approach, including the parents. Because the major nutrition problem in CL/CP is feeding and providing adequate intake, growth can be jeopardized and must be assessed regularly.

Medical Nutrition Therapy

Treatment for CL/CP includes surgical treatment and nonsurgical treatment. The goal of surgical treatment is to repair the defect for good cosmetic and functional results. Nonsurgical treatment addresses how to feed the infant until the cleft is repaired and how to optimize growth and nutrition and promote successful surgical treatment (Lanier and Wolf, 2017) (Table 43.7).

TABLE 43.7 Feeding and Nutrition Goals for Children with Orofacial Clefts

- Effective feeding method with expected number of feedings and length of feeding in normal range of time
- Expected weight gain and growth for age, taking into account any related syndrome
- Feeding development typical for age (introduction of complementary foods at 6 months, introduction of cup drinking at 6 months)
- Maximized healing and minimized weight loss postsurgeries
- Healthy nutrition and oral health habits appropriate for age, including principles of Ellyn Satter’s Division of Responsibility of Eating
- For tube-fed infants and children, feeding plan that promotes oral intake, if appropriate

Adapted from: Lanier, C and Wolf, L. Children with cleft lip and/or palate: Feeding and nutrition. *Nutrition Focus for Children with Special Health Care Needs*. Nov/Dec 2017;32:6.

TABLE 43.8 Surgical, Feeding, and Nutrition Management of Cleft Lip and Palate

Age	Surgical Management	Feeding Modality	Nutrition Management
3-6 months	Lip repair	Cleft lip only: breastfeeding or bottle feeding with wide-based nipple. Cleft palate: Specialty bottle. Upright position helps keep milk out of nasopharynx. Side lying position if tongue-based obstruction (Pierre Robin). Burp often secondary to increased air swallowing. After lip repair: Resume typical feeding modality soon after lip repair.	Breastmilk or standard infant formula. 400 IU vitamin D for babies receiving breastmilk. Introduction of complimentary foods at 6 months or when baby is showing readiness. Progression of textures typical for age. After lip repair: Resume breastmilk or formula
9-15 months	Palate repair (syndromic clefts at late end) Ear tubes for otitis media	See above. Introduction of cup typical for age. Cup must not contain valve. Wean from bottle to cup typical for age (~age 1) or after palate repair After palate repair: For 2-4 weeks, bottle feeding with specialty bottle and/or may use open cup or unvalved cup without hard or long spouts; nothing hard (no utensils or straws or fingers/hands) in mouth.	Wean to whole milk typical for age (age 1) but may wait until after palate is repaired. Toddler diet typical for age. Ensure meeting calcium and vitamin D requirement. After palate repair: For 2-4 weeks, soft, no chew diet.
2-5 years	Velopharyngeal insufficiency (VPI) surgery ("speech surgery") Nose and lip revision considered	After VPI surgery: Nothing hard (no utensils or straws) in mouth for 4-6 weeks.	Preschool diet typical for age. After VPI surgery: Soft, no chew diet for 4-6 weeks.
6-11 years	Bone graft of alveolar cleft after primary dentition complete and closure of oro-nasal fistulae Orthodontic interventions and teeth extractions as needed	After bone grafting: Nothing hard (no utensils or straws) in mouth for 4-6 weeks.	Diet typical for age. After bone grafting: Soft, no chew diet for 4-6 weeks.
12-21 years	Nose revision (rhinoplasty) if needed Jaw surgery in some cases (Orthognathics) Orthodontic bridges and implants	After jaw surgery: Straws are ok.	Diet typical for age. After jaw surgery: Soft, no chew diet for 6-8 weeks; may need blenderized liquid diet.

*Timing of surgeries, feeding modalities, and nutrition interventions may vary between craniofacial centers.

Adapted from Bernstein M and McMahon-Jones K. *Nutrition Across Life Stages*. 2017: Jones & Bartlett Learning, Burlington, MA. www.jblearning.com.

Surgical repair of the cleft lip generally is performed at 3 to 6 months of age, and cleft palate repair at 9 to 15 months. Other operations performed before the child starts school may include ear tubes for otitis media (usually performed at the same time as the palate repair), velopharyngeal insufficiency (VPI) surgery, and minor improvements to the lip or nose. Surgical interventions in later years include alveolar bone graft and, if needed, orthognathic (jaw) surgery (Table 43.8).

Breastfeeding is difficult for these infants because of problems with sucking, although those infants with just the cleft lip may be successful. It is generally recommended that the mother who wishes to breastfeed express her milk and give it to her baby from a specialized bottle and nipple. The use of an appropriate hospital-grade breast pump is recommended for milk expression. Parents and caregivers must be educated in the positioning of the child for feeding, nipple selection, bottle selection, feeding technique, and monitoring of intake (American Cleft Palate-Craniofacial Association, 2018).

Energy needs are generally the same as for a nonaffected infant. The exceptions to this are if the feeding process is too difficult (either adequate volumes are not achieved and/or energy needs are increased with the work of feeding) and if the infant has increased difficulty breathing (which results in increased energy demand). Strategies for solving these problems vary and include adjustment of the feeding modality (appropriate bottles and nipples) and feeding technique/infant

positioning, and/or using more concentrated formula or breastmilk (Table 43.9 and see Chapter 41). Enteral support (tube feeding) is rarely needed, and this may be only for a short while.

Effective feeding requires that the infant be able to form a vacuum inside the mouth and form a seal around the nipple with the lips. This is achieved through the proper bottle, nipple, and position for feeding. Acceptable nipples and bottles include the Mead Johnson Cleft Palate Nurser, the Medela Special Needs Feeder, the Pigeon Bottle and Nipple, and the Dr. Brown's Specialty Feeding System (Dr. Brown's bottle with one-way feeding valve) (Table 43.10). Babies with CL/CP have unique feeding challenges; thus, it is extremely important that an infant-feeding therapist or nurse experienced in feeding infants with clefts evaluate various types of equipment and carefully educate the parent in their use. Positioning in an upright position, choosing the appropriate bottle and nipple, and directing the liquid flow to the side or back of the mouth are strategies for optimal feeding. Babies with clefts swallow more air when feeding and should be given ample opportunities for frequent burping in an upright position.

Introduction of solid foods for the CL/CP infant can follow the usual protocol at 6 months of age or when the baby is showing readiness to feed (i.e., good head control and trunk stability and showing interest in food). Care that the food is presented slowly is important, allowing the infant to control each bite while gradually learning how to direct the

TABLE 43.9 Increasing Calories Through Concentration of Formulas and Addition of Oils and Carbohydrates

Using 20 cal/oz Formula Caloric Density Required		
Density Required Per Ounce	Measures of Powder	Water Added
20 calories	1 scoop	2 fl oz
22 calories	2 scoops	3.5 fl oz
24 calories	3 scoops	5 fl oz
27 calories	3 scoops	4.25 fl oz
Using 22 cal/oz Formula		
22 cal	1 scoop	2 fl oz
24 cal	3 scoops	5.5 fl oz
27 cal	5 scoops	8 fl oz
Adding Oil or Carbohydrates		
Product	kcal	Source
Corn oil or safflower oil	9/g or 8.3/mL	Corn or safflower oil
Microlipid	4.5/mL	Safflower oil
MCT oil	8.3/g or 7.6/mL	Fractionated coconut oil
Karo syrup	1 Tbsp = 58 kcal	Polysaccharides
Polycose liquid	2/mL or 60/fl oz	Glucose polymers
Polycose powder	3.8/g; 8/tsp; 23/Tbsp	Glucose polymers
Moducal powder	30/Tbsp	Glucose polymers

food around the cleft. After the repair and healing of the cleft palate, feeding along the developmental pathway should progress slowly but normally (see Chapter 15 and Table 43.9).

FETAL ALCOHOL SYNDROME

Fetal alcohol spectrum disorder (FASD) is a lifelong consequence of maternal alcohol consumption leading to growth retardation, facial malformations, and central nervous system impairment. Since identified in 1973 by Drs. Kenneth Jones and David Smith at the University of Washington School of Medicine, FASD has been documented throughout the world with prevalence ranging from 2.4% to 20.8%; in high-risk populations such as Russian orphanages, rates have been estimated as high as 40% to 68% (Hoyme et al, 2016).

Alcohol consumption during pregnancy interferes with normal fetal growth and development of all body systems and organs. Maternal nutritional status, use of multiple drugs, genetic susceptibility, and alcohol use pattern can influence the severity of the disorder (Murawski et al, 2015). Diagnosis of fetal alcohol syndrome (FAS) requires that the following criteria are fully met: (1) pre- or postnatal growth deficiency, (2) FAS facial features, (3) abnormal brain structures and/or microcephaly, and (4) neurobehavioral impairment, with developmental or cognitive impairment depending on age. The three facial features include smooth filtrum (the groove between the upper lip and the nose), thin upper lip, and small palpebral (between the upper and lower eyelid) fissures. Partial fetal alcohol syndrome (PFAS) is diagnosed when two of the criteria are met with known alcohol exposure, or three of the four criteria when exposure is not documented. **Alcohol-related neurodevelopmental disorders (ARND)** and **alcohol-related birth defects (ARBD)** are additional diagnoses used to identify children without facial manifestations or

TABLE 43.10 Specialty Bottles

Specialty Bottle	How It Works	How to Pay and Where to Find
Mead Johnson Cleft Palate Nurser (Squeeze Bottle)	Milk is squeezed into the infant's mouth; flow is controlled by the person feeding.	Some insurance will cover Available through home care companies May be available at no cost from craniofacial centers Available to purchase on the Internet
Medela Special Needs Feeder (Haberman Bottle)	The nipple has a large chamber with a one-way valve. Milk flows into the nipple chamber but cannot flow back into the bottle. Milk is extracted either by squeezing the nipple (by person feeding) or clamping down on the nipple (the baby controls the flow). The nipple has different sized cuts allowing for fast or slow flow.	Some insurance will cover Available through home care companies May be available at no cost from craniofacial centers Available to purchase on the Internet
Pigeon Cleft Palate Nurser	The nipple has a one-way valve and the rubber on one side of the nipple is very thin. Milk flows into the nipple and the baby can extract by clamping down on nipple: the flow is controlled by the baby.	Some insurance will cover Available through home care companies May be available at no cost from craniofacial centers Available to purchase on the Internet
*Dr. Brown's Specialty Feeding System (Dr. Brown's bottle with one-way feeding valve) Nipple options include ultra preemie, preemie, and #1-4.	Same feeding mechanism as Pigeon Nurser.	Not covered by insurance Bottles and/or valves may be available at no cost from craniofacial centers Available to purchase on the Internet

*The valve fits in the nipple of any Dr. Brown bottle.

Adapted from: Lanier, C and Wolf, L. Children with cleft lip and/or palate: Feeding and nutrition. *Nutrition Focus for Children with Special Health Care Needs*. Nov/Dec 2017;32:6.

poor growth but with alcohol-associated psychological or medical problems (Hoyme et al, 2016). Children with ARND may have intellectual disabilities and problems with behavior and learning, particularly with math, memory, attention, judgment, and poor impulse control. Children with ARBD may have problems with the heart, kidney, bones, or hearing. Due to the clinical complexity, a multidisciplinary team should make the diagnosis (Hoyme et al, 2016).

Nutrition Assessment

Anthropometric measures are very important in the assessment of the FASD child due to characteristic growth deficiency. Prenatal growth restriction of the infant often persists postnatally despite a high caloric intake. Growth should be evaluated frequently and plotted on the CDC and WHO growth curves (Hoyme et al, 2016). Feeding problems are associated with FAS, including oral-motor problems expressing as poor suck in infancy and delayed feeding progression in toddlers. Poor growth and feeding issues often result in the diagnosis of failure to thrive (Amos-Kroohs et al, 2016). Impulse control, food hoarding, and hyperphagia are common in older children (Amos-Kroohs et al, 2016; Ptomey and Wittenbrook, 2015).

Medical Nutrition Therapy

Use of MNT with FASD emphasizes prevention of secondary disability beginning with prenatal vitamin-mineral supplementation when alcohol consumption is suspected as this may reduce disability both by addressing maternal nutritional deficits and mitigating teratogenic effects of alcohol (Murawski et al, 2015; Popova et al, 2016). While breastfeeding generally is encouraged, excessive alcohol use is a contraindication. Considering the array of potential nutritional concerns, MNT for the child with FASD is focused on the specific nutrition problem that exists for that child. Motor impairment, ADHD, developmental delay, seizure disorders, communication challenges, hyperphagia, and sensory impairments (visual/hearing) are common comorbidities that can put nutrition at risk (Amos-Kroohs et al, 2016; Popova et al, 2016). Short stature, sensory processing issues, and impulsivity increase the risk of overweight or obesity in the older child and adolescent. In addition, parental substance abuse, past or present, may impact the parent-child feeding relationship, requiring supportive intervention with referral to social services as needed (Amos-Kroohs et al, 2016).

Overall, caloric and nutrient needs do not differ from an unaffected child, although poor fetal nutrition or feeding problems may increase the risk of deficiencies (Popova et al, 2016). Vitamin, mineral, omega fatty acid, and choline supplementation may be warranted to maximize brain development and address prenatal deficits (Murawski et al, 2015). It can be difficult to determine caloric need in the young child when growth restriction is present. Increasing calories potentially can support improved growth but may also lead to excessive weight gain without increasing the rate of growth. Comparing serial measurements of weight to linear gains is necessary to individualize calorie recommendations. Strategies for increasing calorically dense foods may be required for those who have difficulty gaining weight. Food texture may need adaptation if oral-motor impairments are present.

FASD is the leading preventable developmental disability in the world today. Education regarding FASD should occur in all women of child-bearing age as there is no safe time or amount of alcohol during pregnancy (Murawski et al, 2015).

Complementary and Integrative Medicine (CIM) in Intellectual and Developmental Disabilities (IDD)/ASD

Current standard treatments for IDD/ASD include therapies (occupational, physical, speech/language), medication, and MNT. Often, standard interventions are time consuming, are expensive, or have negative side effects (Lindly et al, 2018). These treatments may reduce disease progression and improve function, but they may not provide significant

reduction of the child's overall disability. In hoping for greater improvements, caregivers and health professionals seek out CIM to maximize development and quality of life. Over the past 50 years, a variety of studies have been initiated to assess if dietary manipulation or nutritional supplementation can treat or even cure developmental diagnoses. With the exception of the ketogenic diet for seizures and dietary management of metabolic disorders/inborn errors of metabolism, research on supplementation or dietary manipulation has found minimal or transitory improvements in developmental, behavioral, or functional measures (Lewanda et al, 2018; Mastrangelo, 2018; Sathe et al, 2017). As indicated in Chapter 11, research in CIM can be difficult to interpret in pediatrics and even more so in children with IDD/ASD, a very heterogeneous group likely to take multiple medications, participate in multiple therapies, and require frequent medical intervention—all of which will confound research results (Sathe et al, 2017). Studies may have bias, small sample size, multiple agents trialed in one study, lack of long-term follow-up, and flawed assessment of both nutritional adequacy and behavioral/functional change (Garcia et al, 2017; Lewanda et al, 2018; Brizee, 2019; Sathe et al, 2017). Harm is often underassessed, and the long-term effects of supplementation and dietary restriction are unknown (Garcia et al, 2017; Stewart et al, 2015). Despite the lack of clear recommendations, media, consumer groups, and supplement-industry sponsored conferences promote nutritional supplements and special diets in this population. This has resulted in greater use of CIM in this population compared with typically developing children (Lindly et al, 2018; Stewart et al, 2015).

Dietitians and caregivers are challenged with determining whether the potential for benefit from a diet or supplement outweighs the potential risk. Negative side effects include direct effects such as a nutrient deficit or excess and also indirect effects such as the financial and time costs. This can be considerable with use of multiple supplements, need for special dietary products, and payment for practitioners, many of whom are not covered by insurance (Lewanda et al, 2018; Lindly et al, 2018; Stewart et al, 2015). There is also the risk that, considering time and finances, unproven interventions will replace established, evidenced-based treatments (Lindly et al, 2018).

While various CIM methods, including herbs, yoga, and massage, are accessed in this population, the primary CIM modalities used are nutritional supplementation and dietary manipulation; see Chapter 11 for discussion of a wider range of CIM (Lindly et al, 2018).

Nutritional Supplements

Nutritional supplementation has shown benefits in rare metabolic disorders and mitochondrial disorders, but evidence that supplementation improves function in most developmental disorders is lacking (Lewanda et al, 2018; Mastrangelo, 2018; Parikh et al, 2015; Sathe et al, 2017). Other than in those examples, supplementation has been studied without clear or replicated success (supplements studied include B vitamins—B₆, B₁₂, folic acid, biotin, and riboflavin—vitamin E, l-carnitine, magnesium, zinc, and iron) (Garcia et al, 2017; Lewanda et al, 2018). While there often are changes in biochemical indices, significant parallel changes in behavior or function have not been found or replicated (Sathe et al, 2017). Meta-analyses and review articles caution on making supplement conclusions or recommendations due to flawed research methodology. Although research methods are improving, evidence remains insufficient to recommend use of nutritional supplementation (Garcia et al, 2017; Lewanda et al, 2018; Ly et al, 2017; Sathe et al, 2017).

Omega fatty acids and probiotics both have moderate evidence for improvements in mood and attention yet are not necessarily specific to IDD/ASD. It is unclear if this is a direct result of the supplement or of rectifying unbalanced dietary fats (Lange et al, 2017; Ly et al, 2017). Probiotics are thought to improve GI dysbiosis, immune function, and inflammation in ASD and potentially may have more global benefit for ASD and other disabilities (Chaidez et al, 2014; Garcia et al, 2017). This

is an emerging area of research; use of probiotics has limited harm but may be contraindicated in children with immune suppression, and it may initially cause bloating and gas (Garcia et al, 2017).

Although data is tenuous, individuals with IDD use supplements twice as frequently as the general population, with use highest when children are young (Lindly et al, 2018). A study of children enrolled in the Autism Treatment Network revealed that more than 50% of children with ASD used nutritional supplements compared with 32% of typically developing children (Stewart et al, 2015). This same study found that supplementation did not address actual areas of deficit and led to excessive nutrient intake. This emphasizes the importance of RDN-supervised supplement use; initiating discussion when clients request use, addressing deficits indicated by poor diet or blood testing, and minimizing harm through attention to dosage, especially when fortified foods are consumed or contraindications exist such as calcium supplementation in William's Syndrome (Ptomey and Wittenbrook, 2015; Stewart et al, 2015). Table 43.6 summarizes use of supplementation. See Chapter 11 for more information about the safe recommendation of dietary supplements.

Special Diets

In 1954 the discovery that restriction of dietary phenylalanine in the diet of a child with phenylketonuria (PKU) prevented intellectual disability created hope that diet could treat or even cure development disabilities. Dietary treatments have been proven effective for some inborn errors of metabolism and for minimizing seizures, but have not yet shown similar success in treating other disabilities (Mastrangelo, 2018; Ptomey and Wittenbrook, 2015). Although there is a lack of empirical evidence, parents report that they chose CIM because they were unhappy with traditional interventions and felt more comfortable and in control using food rather than medication as treatment (Lindly et al, 2018; Ly et al, 2017). Studies of the most popular diets—ketogenic diet, GF diet, CF diet, and Specific Carbohydrate Diet (SCD)—have not found significant behavioral or functional change (other than the noted seizure control), yet caregivers chose to continue the diet after the study ended. It is suggested that parental perceptions of change may be influenced by desire for change, emotional investment in the treatment, and misinterpretation or attribution of any improvement to dietary change (Garcia et al, 2017; Lindly et al, 2018). Conversely, the subtle improvements noted may not be variables being measured, and therefore parents see benefit when researchers do not. For example, parents may see improved bowel movements or sleep, which are not assessed. Use of a special diet may be addressing underlying anemia, GI discomfort, or allergy, reducing discomfort and irritability (Garcia et al, 2017; Ly et al, 2017).

A nutrition assessment may reveal reasons to trial a diet such as a history of or current allergy, reflux, or constipation. The use of special diets is not without nutritional risk, but this can be minimized with RDN supervision. In addition to the risk of nutrient deficits, especially when entire food groups are eliminated or severely restricted, prescribed diets with very limited variety can exacerbate existing conditions like constipation through dependence on highly processed foods. Children with special needs are often socially isolated and restricted diets can further isolate the child by making eating with others challenging. Table 43.5 describes diets frequently used in this population.

Choosing CIM Treatments

Children with neurodevelopmental disorders are at greater risk of harm from both conventional and CIM intervention. Drug-nutrient interactions, GI problems, or altered immune status may make negative response more likely while concurrently making use of CIM attractive for resolving outstanding issues. The RDN can facilitate effective use of CIM by helping parents and other health care providers better understand the applicability and veracity of research (Brizee, 2019; Garcia et al, 2017; Ptomey and Wittenbrook, 2015).

Products that are promoted or advertised as follows should be avoided:

- Personal anecdotes, celebrity endorsement, or industry backed research are the only evidence for effectiveness.
- Claims of effectiveness are grandiose, universal, and apply to many different disorders; the magnitude of improvement is great, and the product is claimed as a cure.
- Reported benefits are general, vague, and unmeasurable.
- Exclusive to this company with a “special” formulation that is a propriety blend; company will not provide ingredients when asked (often necessary for safety concerns).
- Advertised as “opposed by the medical establishment.”
- Expensive or costly for what is offered, requires extensive testing that is only available through a partner site, or special promotions that require prepayment; unable to use insurance.
- Clay baths, enemas, and chelation therapy are promoted to remove toxic chemicals to cure or treat various conditions. These procedures can be harmful and have resulted in death. The FDA has issued a warning against use of chelation therapies and highlights the risk of lead exposure in clay baths.

While there is risk for harm, this can be minimized with nutritional monitoring. In some cases the exploration of integrative therapies has led to successful treatment and a better understanding of brain, immune, and GI function in children with neurodevelopmental concerns. Each child should be assessed individually to determine whether any dietary or CIM therapy is appropriate.

COMMUNITY RESOURCES

For many types of nutrition problems and MNT, the school system is an excellent resource through the school lunch and school breakfast programs. Children and adolescents may receive modified meals at school. Child and adult care food programs must provide meals at no extra cost for children and adolescents with special needs and developmental disabilities. School food service is required to offer special meals at no additional cost to children whose disabilities restrict their diets as defined in the U.S. Department of Agriculture's nondiscrimination regulations.

The term “child with a disability” under Part B of IDEA refers to a child evaluated in accordance with IDEA as having one of the 13 recognized disability categories: (1) autism; (2) deaf-blindness; (3) deafness; (4) mental retardation; (5) orthopedic impairments; (6) other health impairments caused by chronic or acute health problems such as asthma, nephritis, diabetes, sickle cell anemia, a heart condition, epilepsy, rheumatic fever, hemophilia, leukemia, lead poisoning, or tuberculosis; (7) emotional disturbances; (8) specific learning disabilities; (9) speech or language impairment; (10) traumatic brain injury; (11) visual impairment; (12) multiple disabilities; and (13) developmental delays. Attention deficit disorder may fall under one of the 13 categories.

When a referral is made to the school system for a special meal related to a developmental disability, it must be accompanied by a medical statement for a child with special dietary needs. The request requires an identification of the medical or other special dietary condition, the food or foods to be omitted, and the food or choice of foods to be substituted. The statement requires the signature of the physician or recognized medical authority. The school food service may make food substitutions for individual children who do not have a disability but who are medically certified as having a special medical or dietary need. An example is the child with severe allergies or an inborn error of metabolism. The availability of school food service for children with developmental disabilities is an important resource in the long-term implementation of MNT.

CLINICAL CASE STUDY

Child with Down Syndrome

Nutrition Assessment

Client History

Colin is a 21-month-old boy with Down syndrome. He was born prematurely (30 weeks of gestation) and was started on nasogastric tube feeding at 10 days of age because of his poor weight gain and severe gastroesophageal reflux. The poor weight gain was caused by a weak suck, although swallowing was not a problem. After hospital discharge he was first seen by a nutritionist in an early intervention program at 4 months of age when it was noted that he had a gastrostomy tube placed at age 2 months.

Food/Nutrition-Related History

Colin received tube feeding instructions while hospitalized for his g-tube placement. He participated in early intervention oral-motor therapy. He was seen every 3 to 6 months for nutrition assessment and adjustment of g-tube formula to meet nutritional needs.

At 16 months Colin was tube fed PediaSure and just started eating table foods. His usual intake was 1 jar of baby food per day along with the tube-feeding formula.

Anthropometric Measurements

At 4 months of age Colin was 22.5 in long (< 5th percentile) and weighed 10 lb 7 oz (< 5th percentile). Weight/length was 10th to 25th percentile.

At 21 months, height was 28 in (< 5th percentile) weight was 18.5 lb (< 5th percentile)

Weight/length was 25th to 50th percentile.

Physical Findings

Colin is crawling but not yet walking, and he has very limited self-feeding skills. Now at age 21 months, his mother's highest priority is to stop the tube feeding and have Colin continue to grow well. She is concerned about his rate of weight gain. She also is concerned that constipation has become a problem requiring use of the medication lactulose. He also has respiratory problems and extreme hypotonia.

Feeding problems identified:

- History of weak suck and swallow
- Hyperactive gag reflex
- Refusal or inability to drink formula from a bottle or cup
- Poor appetite for oral foods
- Not self-feeding

Nutrition Diagnostic Statements

- Self-feeding difficulty (NB-2.6) related to developmental delays and feeding difficulty as evidenced by poor weight gain and below 5% wt/age.
- Inadequate oral intake (NI-2.1) of food and fluids related to feeding difficulty as evidenced by need of supplement to meet nutritional needs by g-tube.

Nutrition Intervention

1. Tube-fed toddler with daily caloric requirement estimated at 670 (estimated energy requirement [EER] = ~80 cal/kg).
2. Work with occupational therapist (OT) to determine chewing and swallowing challenges and to support development of safe eating and drinking.
3. Introduction of oral foods and fluids as recommended by OT before gastrostomy feedings.
4. Reduction of tube feedings to support transition to oral eating and to meet estimated needs.

Nutrition Care Questions

1. What would be your approach in working with this mother and the other team members?
2. What do you think would be Colin's nutritional needs, starting with energy?
3. How many ounces of a 30 cal/oz tube-feeding formula would you recommend for Colin to promote weight gain?
4. What steps should be taken to increase Colin's oral intake and decrease the tube feeding?
5. What would you recommend for management of his constipation?

CLINICAL CASE STUDY

Adolescent with ASD and Obesity

Nutrition Assessment

History

Alex, a 16-year-old boy with ASD, was admitted to a residential facility after being removed from his special education class. Alex has age-appropriate receptive language but expresses himself usually using phrases from superhero TV shows and movies. Three months before referral, he began a trial of risperidone to address increasing irritability and aggression both at home and at school. Medical evaluation identified sleep apnea, elevated liver enzymes, hypertriglyceridemia, and impaired fasting blood glucose. The contributing factor to the medical problems is his severe obesity.

Food/Nutrition-Related History

Alex's birth weight was 7 lb 8 oz, his birth length was 19 in, and he was full term. He had typical feeding development until 2 years of age when he gradually started refusing previously accepted foods. Gradually, his intake was reduced to primarily crunchy foods including chicken nuggets, fish sticks, French fries, green apples, celery, most crackers, any type of Cheerios, chips, bacon, and beef jerky. Portions are large. His parents have tried to introduce more fruits and have had some success with other crunchy green vegetables such as green peppers or raw broccoli and freeze-dried fruits. Alex drinks milk, usually 24 to 30 ounces a day, and soda is provided as a reward. If he is denied food, he tends to throw a tantrum and family members often relent.

Alex has been overweight since 2 years of age, when his weight for age was between the 85th and 90th percentiles. When he began middle school, his rate of weight gain increased, with his body mass index (BMI) at the 95th percentile. Since starting high school, his rate of weight gain has continued to increase, which his

mother attributes to the role of food in the classroom as part of living skills training and for rewards. Since starting the risperidone, he has gained an additional 15 lbs in 3 months.

Alex enjoys physical activity when it can be related to superheroes. He enjoys watching and playing soccer but has limited opportunity.

Anthropometric Measurements:

Weight 210 lb (95.4 kg) > 97th percentile

Height: 66 in (167.6 cm) - 25th to 50th percentile

BMI index: 34 kg/m², 120% to 130% of the 95th percentile, classified as severe obesity

Biochemical Data

Total cholesterol: 210 mg/dL (high)

High-density lipoprotein (HDL) cholesterol: 29 mg/dL (low)

Triglycerides: 580 mg/dL (very high)

Glucose: 120 mg/dL (high)

Hemoglobin A1C: 6.1% (high)

Liver enzymes: AST 74 U/L, ALT 124 U/L (high)

Nutrition-Focused Physical Findings

Excessive appetite

Poor hygiene

Sedentary with excessive screen time

Constipation (2 to 3 bowel movements [BMs] per week)

CLINICAL CASE STUDY—cont'd

Adolescent with ASD and Obesity

Nutrition Diagnostic Statements

- Obesity, pediatric (NC-3.3.2) related to excessive food and beverage intake, large portion sizes, and high calorie food choices, as evidenced by BMI of 34.
- Altered nutrition related laboratory value (NC-2.2) related to obesity and risperidone use as evidenced by elevated cholesterol and triglycerides and hemoglobin A1C of 6.1%.
- Altered nutrition-related laboratory value (NC-2.2) related to obesity and excessive soda intake as evidenced by elevated liver enzymes ALT and AST.
- Altered gastrointestinal (GI) function (NC-1.4) related to low activity level and insufficient fiber and fluid intake as evidenced by report of only 2 to 3 BMs per week.

Intervention Goals

1. Work with family and school to decrease portion sizes, especially of highly processed foods

2. Increase fiber and fluid intake
3. Reduce sugary beverages due to elevated triglycerides, A1C, and liver enzymes
4. Increase access to physical activity

Nutrition Care Questions

1. When asked to limit food at school, teachers report that reward tokens to purchase snacks at the student store are part of the living skills curriculum. What would be your response?
2. What tools can you offer Alex and his family to help manage portion size and increase fruit/vegetable intake?
3. What resources are available to help Alex increase his physical activity?
4. What suggestions can you make to help Alex's parents respond to his demands for food?

Milliequivalents and Milligrams of Electrolytes

To Convert Milligrams to Milliequivalents: Divide milligrams by atomic weight and then multiply by the valence.

$$\text{Example: } \frac{\text{Milligrams}}{\text{Atomic weight}} \times \text{Valence} = \text{Milliequivalents}$$

Mineral Element	Chemical Symbol	Atomic Weight (mg)	Valence
Calcium	Ca	40	2
Chlorine	Cl	35	1
Magnesium	Mg	24	2
Phosphorus	P	31	2
Potassium	K	39	1
Sodium	Na	23	1
Sulfate	SO ₄	96	2
Sulfur	S	32	

To Convert Specific Weight of Sodium to Sodium Chloride: Multiply by 2.54.

$$\text{Example: } 1000 \text{ mg Sodium} \\ 1000 \times 2.54 = 2540 \text{ mg Sodium chloride (2.5 g)}$$

To Convert Specific Weight of Sodium Chloride to Sodium: Multiply by 0.393.

$$\text{Example: } 2.5 \text{ g Sodium chloride} \\ 2.5 \times 0.393 = 1000 \text{ mg sodium}$$

Milligrams	Sodium in Milliequivalents (mEq)	Grams of Sodium Chloride
500	21.8	1.3
1000	43.5	2.5
1500	75.3	3.8
2000	87.0	5.0

Modified from Merck Manual: *Ready Reference Guide*. <http://www.merckmanuals.com/professional/print/appendixes/ap1/ap1a.html>. Accessed March 22, 2011; Nelson JK, Moxness KE, Jensen MD, et al: *Mayo Clinic diet manual*, ed 7, St. Louis, 1994, Mosby.

Equivalents, Conversions,* and Portion (Scoop) Sizes

LIQUID MEASURE—VOLUME EQUIVALENTS

- 1 tsp = $\frac{1}{3}$ Tbsp = 5 mL or cc
- 1 Tbsp = 3 tsp = 15 mL or cc
- 2 Tbsp = 1 fluid oz = $\frac{1}{8}$ cup = 30 mL or cc
- 2 Tbsp + 2 tsp = $\frac{1}{6}$ cup = 40 mL or cc
- 4 Tbsp = $\frac{1}{4}$ cup = 2 fluid oz = 60 mL or cc
- 5 Tbsp + 1 tsp = $\frac{1}{3}$ cup = 80 mL or cc
- 6 Tbsp = 3 fluid oz = $\frac{3}{8}$ cup = 90 mL or cc
- 8 Tbsp = $\frac{1}{2}$ cup = 120 mL or cc
- 10 Tbsp + 2 tsp = $\frac{2}{3}$ cup = 160 mL or cc
- 12 Tbsp = $\frac{3}{4}$ cup = 180 mL or cc
- 48 tsp = 16 Tbsp = 1 cup (8 fluid ounces) = $\frac{1}{2}$ pint = 240 mL or cc
- 2 cups = 1 pint (16 fluid oz) = 0.4732 L
- 4 cups = 2 pints = 1 quart (32 fluid oz) = 0.9462 L
- 1.06 quarts = 34 fluid oz = 1000 mL or cc
- 4 quarts = 1 gallon = 3785 mL or cc

DRY MEASURE

- 1 quart = 2 pints = 1.101 L
- Dry-measure pints and quarts are approximately $\frac{1}{6}$ larger than liquid-measure pints and quarts.

WEIGHTS	
English (Avoirdupois Weight**)	Metric
1 oz	Approx 30 g
1 lb (16 oz)	454 g
2.2 lb	1 kg

**A system of weights based on a pound of 16 ounces commonly used in English-speaking countries.

SCOOP SIZES

It is important to use the proper scoop size when portioning out foods to serve to patients.

Number	Approximate Liquid Volume
6	$\frac{2}{3}$ cup (5 fluid oz)
8	$\frac{1}{2}$ cup (4 fluid oz)
10	$\frac{3}{8}$ cup (3 $\frac{1}{4}$ fluid oz)
12	$\frac{1}{3}$ cup (2 $\frac{2}{3}$ fluid oz)
16	$\frac{1}{4}$ cup (2 fluid oz)
20	3 $\frac{1}{5}$ Tbsp (1 $\frac{3}{5}$ fluid oz)
24	2 $\frac{3}{3}$ Tbsp (1 $\frac{1}{3}$ fluid oz)
30	2 $\frac{1}{5}$ Tbsp (1 fluid oz)
40	1 $\frac{3}{5}$ Tbsp (0.8 fluid oz)
60	1 Tbsp (0.5 fluid oz)

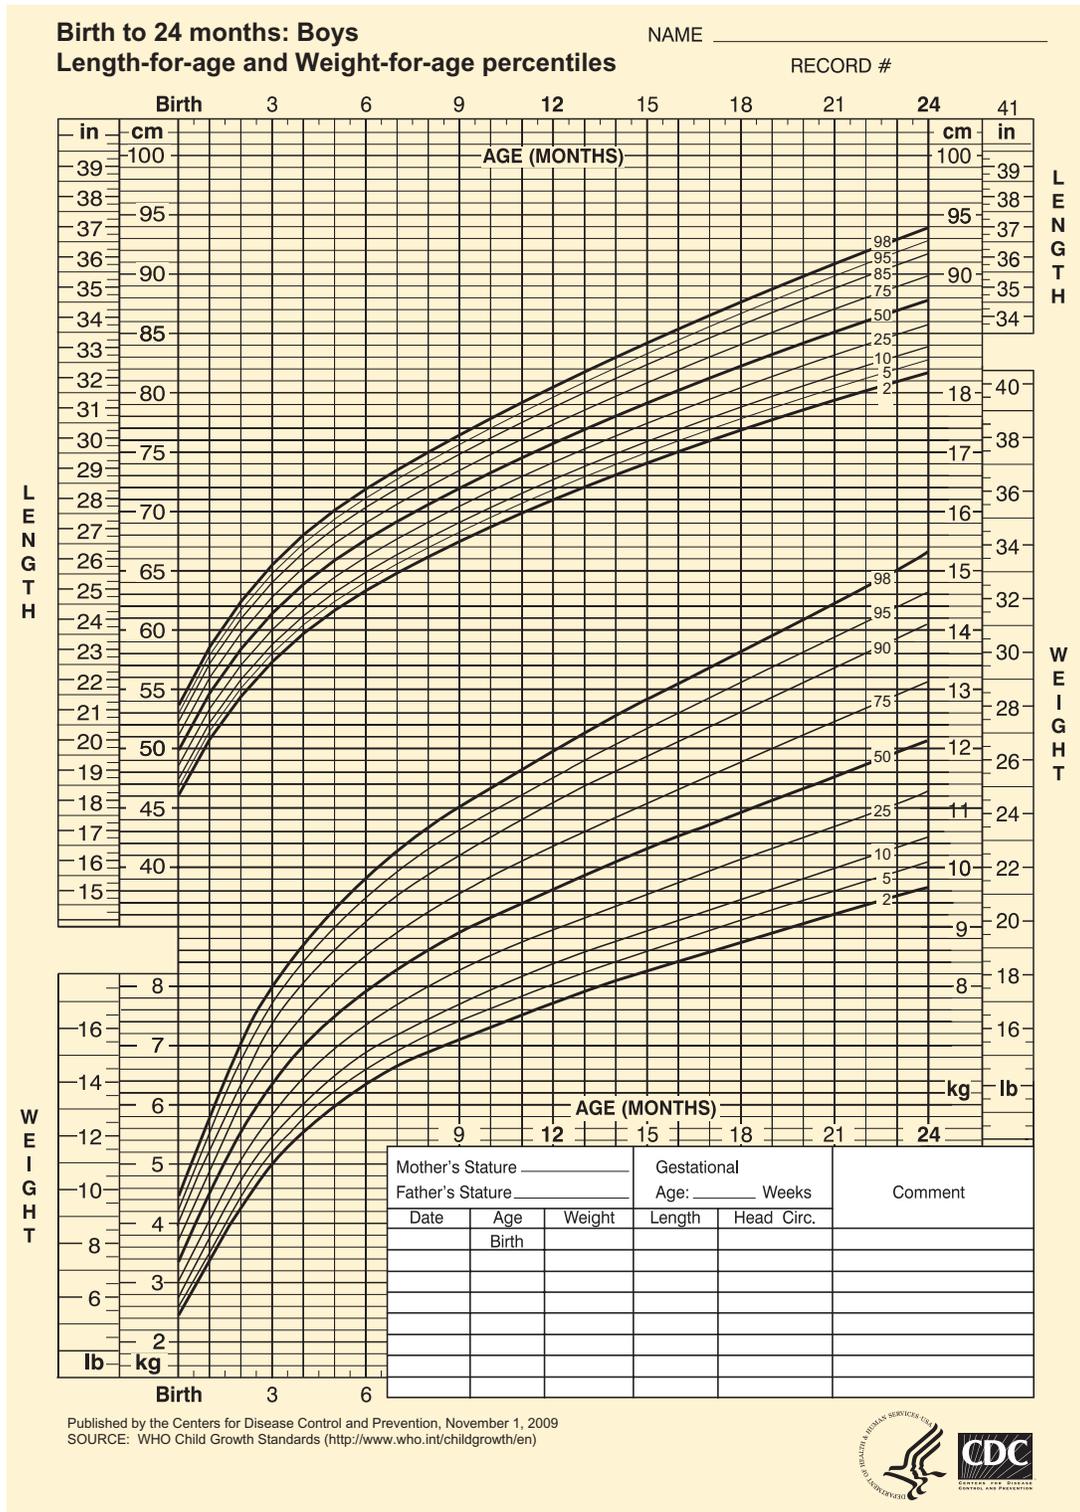

Metric Conversion Factors

Multiply	By	To Get
Fluid ounces	29.57	Grams
Ounces (dry)	28.35	Grams
Grams	0.0353	Ounces
Grams	0.0022	Pounds
Kilograms	2.21	Pounds
Pounds	453.6	Grams
Pounds	0.4536	Kilograms
Quarts	0.946	Liters
Quarts (dry)	67.2	Cubic inches
Quarts (liquid)	57.7	Cubic inches
Liters	1.0567	Quarts
Gallons	3.785	Cubic centimeters
Gallons	3.785	Liters

From North Carolina Dietetic Association: *Nutrition care manual*, Raleigh, NC, 2011, The Association.

*Note: In the U.S. measuring systems, the same word may have two meanings. For example, an ounce may mean $\frac{1}{16}$ of a pound and $\frac{1}{16}$ of a pint, but the former is strictly a weight measure and the latter is a volume measure. Except in the case of water, milk, or other liquids of the same density, a fluid ounce and an ounce of weight are two completely different quantities. These measures are not to be used interchangeably.

Tanner Stages of Adolescent Development for Girls and Boys

TANNER STAGES OF ADOLESCENT DEVELOPMENT FOR GIRLS

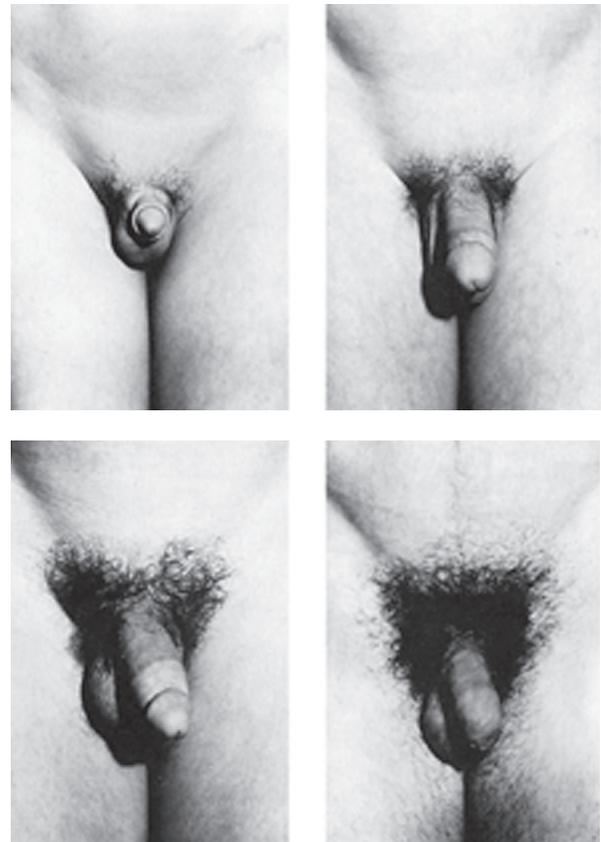

Chronologic age is not always the best way to assess adolescent growth because of individual variations in beginning and completing the growth sequence. A more useful way of describing pubertal development, and thus the varying needs for nutrients throughout adolescence, is to divide growth into stages of breast and pubic hair development in girls. These are termed the *Tanner Stages of Adolescent Development*. Nutritional requirements vary, depending on the stage of development.

From Mahan LK, Rees JM: *Nutrition in adolescence*, St. Louis, 1984, Mosby.

TANNER STAGES OF ADOLESCENT DEVELOPMENT FOR BOYS

Chronologic age is not always the best way to assess adolescent growth because of individual variations in beginning and completing the growth sequence. A more useful way of describing pubertal development, and thus the varying needs for nutrients throughout adolescence, is to divide growth into stages pubic hair and penis and testicle development in boys. These are termed the *Tanner Stages of Adolescent Development*. Nutritional requirements vary, depending on the stage of development.

From Mahan LK, Rees JM: *Nutrition in adolescence*, St. Louis, 1984, Mosby.

Direct Methods for Measuring Height and Weight and Indirect Methods for Measuring Height

DIRECT METHODS FOR MEASURING HEIGHT AND WEIGHT

Height

1. Height should be measured without shoes.
2. The individual's feet should be together, with the heels against the wall or measuring board.
3. The individual should stand erect, neither slumped nor stretching, looking straight ahead, without tipping the head up or down. The top of the ear and outer corner of the eye should be in a line parallel to the floor (the "Frankfort plane").
4. A horizontal bar, a rectangular block of wood, or the top of the stadiometer should be lowered to rest flat on the top of the head.
5. Height should be read to the nearest $\frac{1}{4}$ inch or 0.5 cm.

Weight

1. Scale accuracy must be determined. Frequent calibration is required.
2. Use a beam balance scale, not a spring scale, whenever possible.
3. Weigh the subject in light clothing without shoes.
4. Record weight to the nearest $\frac{1}{2}$ lb or 0.2 kg for adults and $\frac{1}{4}$ lb or 0.1 kg for infants. Measurements above the 90th percentile or below the 10th percentile warrant further evaluation.

INDIRECT METHODS FOR MEASURING HEIGHT

Measuring Arm Span

Steps:

1. The arms are extended straight out to the sides at a 90-degree angle from the body.
2. The distance from the longest fingertip of one hand to the longest finger of the other hand is measured.

Adult Recumbent

Steps:

1. Stand on right side of the body.
2. Align body so that the lower extremities, trunk, shoulders, and head are straight.

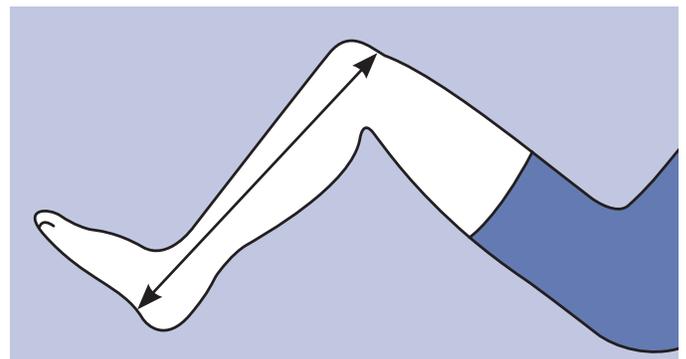

3. Place a mark at the top of the sheet in line with the crown of the head and one at the bottom of the sheet in line with the base of the heels.
4. Measure length between marks with measuring tape.

Knee Height

Knee height measurement is highly correlated with upright height. It is useful in those who cannot stand and in those who may have curvatures of the spine.

Steps:

1. Use the left leg for measurements.
2. Bend the left knee and the left ankle to 90-degree angles. A triangle may be used if available.
3. Using knee height calipers, open the caliper and place the fixed part under the heel. Place the sliding blade down against the thigh (approximately 2 inches behind the patella).
4. Measure from the heel to the anterior surface of the thigh, using a cloth measuring tape.

1. Obtain the measurement and convert it to centimeters by multiplying by 2.54.
2. Formulas to use to calculate estimated height from knee height:

$$\text{Men (height in centimeters)} = 64.19 (0.04 \text{ Age}) + (2.02 \times \text{Knee height in centimeters})$$

$$\text{Women (height in centimeters)} = 84.8 (0.24 \text{ Age}) + (1.83 \times \text{Knee height in centimeters})$$

Using Population-Specific Formula, Calculate Height From Standard Formula:

Population and Gender Group	Equation: Stature (cm) =
Non-Hispanic white men (U.S.) [SEE = 3.74 cm]	$78.31 + (1.94 \times \text{knee height}) - (0.14 \times \text{age})$
Non-Hispanic black men (U.S.) [SEE = 3.80 cm]	$79.69 + (1.85 \times \text{knee height}) - (0.14 \times \text{age})$
Mexican American men (U.S.) [SEE = 3.68 cm]	$82.77 + (1.83 \times \text{knee height}) - (0.16 \times \text{age})$
Non-Hispanic white women (U.S.) [SEE = 3.98 cm]	$82.21 + (1.85 \times \text{knee height}) - (0.21 \times \text{age})$
Non-Hispanic black women (U.S.) [SEE = 3.82 cm]	$89.58 + (1.61 \times \text{knee height}) - (0.17 \times \text{age})$
Mexican American women (U.S.) [SEE = 3.77 cm]	$84.25 + (1.82 \times \text{knee height}) - (0.26 \times \text{age})$
Taiwanese men [SEE = 3.86 cm]	$85.10 + (1.73 \times \text{knee height}) - (0.11 \times \text{age})$
Taiwanese women [SEE = 3.79 cm]	$91.45 + (1.53 \times \text{knee height}) - (0.16 \times \text{age})$
Elderly Italian men [SEE = 4.3 cm]	$94.87 + (1.58 \times \text{knee height}) - (0.23 \times \text{age}) + 4.8$
Elderly Italian women [SEE = 4.3 cm]	$94.87 + (1.58 \times \text{knee height}) - (0.23 \times \text{age})$
French men [SEE = 3.8 cm]	$74.7 + (2.07 \times \text{knee height}) - (-0.21 \times \text{age})$
French women [SEE = 3.5 cm]	$67.00 + (2.2 \times \text{knee height}) - (0.25 \times \text{age})$
Mexican men [SEE = 3.31 cm]	$52.6 + (2.17 \times \text{knee height})$
Mexican women [SEE = 2.99 cm]	$73.70 + (1.99 \times \text{knee height}) - (0.23 \times \text{age})$
Filipino men	$96.50 + (1.38 \times \text{knee height}) - (0.08 \times \text{age})$
Filipino women	$89.63 + (1.53 \times \text{knee height}) - (0.17 \times \text{age})$
Malaysian men [SEE = 3.51 cm]	$(1.924 \times \text{knee height}) + 69.38$
Malaysian women [SEE = 3.40]	$(2.225 \times \text{knee height}) + 50.25$

SEE = Standard error of estimate

Determination of Frame Size

Method 1: Height is recorded without shoes. Wrist circumference is measured just distal to the styloid process at the wrist crease on the right arm, using a tape measure. The following formula is used (From Grant JP: *Handbook of total parenteral nutrition*, Philadelphia, PA, 1980, Saunders):

$$r = \frac{\text{Height (cm)}}{\text{Wrist circumference (cm)}}$$

Frame size can be determined as follows:

Males	Females
r > 10.4 small	r > 11.0 small
r = 9.6–10.4 medium	r = 10.1–11.0 medium
r < 9.6 large	r < 10.1 large

Method 2: The patient's right arm is extended forward perpendicular to the body, with the arm bent so the angle at the elbow forms 90 degrees with the fingers pointing up and the palm turned away from

the body. The greatest breadth across the elbow joint is measured with a sliding caliper along the axis of the upper arm on the two prominent bones on either side of the elbow. This is recorded as the elbow breadth. The following tables give the elbow breadth measurements for medium-framed men and women of various heights (from Metropolitan Life Insurance Co., 1983). Measurements lower than those listed indicate a small frame size; higher measurements indicate a large frame size.

MEN		WOMEN	
Height in 1" Heels	Elbow Breadth (inches)	Height in 1" Heels	Elbow Breadth (inches)
5'2"–5'3"	2½–2 ⁷ / ₈	4'10"–4'11"	2¼–2½
5'4"–5'7"	2 ⁵ / ₈ –2 ⁷ / ₈	5'0"–5'3"	2¼–2½
5'8"–5'11"	2¾–3	5'4"–5'7"	2 ³ / ₈ –2 ⁵ / ₈
6'0"–6'3"	2¾–3 ¹ / ₈	5'8"–5'11"	2 ³ / ₈ –2 ⁵ / ₈
6'4"	2 ⁷ / ₈ –3¼	6'0"	

Adjustment of Desirable Body Weight for Amputees

The percentages listed here are estimates because body proportions vary in individuals. Use of these percentages provides an approximation of desirable body weight, which is more accurate than a comparison with the standards for adults without amputations. Ideal body weight (IBW) must be adjusted downward to compensate for missing limbs or paralysis. It is estimated that 5% to 10% should be subtracted from IBW for a paraplegic and from 10% to 15% subtracted for a tetraplegic (quadriplegic).

Adjustment of Ideal Body Weight for Amputees

Body Segment	Average % of Total Weight
Lower arm and hand	2.3
Trunk without extremities	50.0
Entire arm	5.0
Hand	0.7
Entire lower leg	16.0
Below knee including foot	5.9
Lower leg without foot	4.4
Foot	1.5

Lefton J, Malone A: Anthropometric assessment. In Charney P, Malone A, editors: *ADA pocket guide to nutrition assessment*, ed 2, Chicago, IL, 2009, American Dietetic Association, p 160.

$$\text{Estimated IBW} = \frac{100 - \% \text{ amputation}}{100} \times \text{IBW for original height}$$

To use this information, determine the patient's approximate height before the amputation. Span measurement is a rough estimate of height at maturity and is calculated as follows: With the upper extremities, including the hands, fully extended and parallel to the ground, measure the distance between the tip of one middle finger and the tip of the other middle finger. Use this height or actual measurement to calculate the desirable body weight for the normal body size, then adjust the figures according to the type of amputation performed.

Example: To determine the desirable body weight for a 5'10" male with a below-the-knee amputation:

1. Calculate desirable body weight for a 5'10" male:	166 lb
2. Subtract weight of amputated limb (6%) = 166×0.06 :	- 9.96 (approx. 10 lb)
3. Desirable weight of a 5'10" male with a below-knee amputation:	156 lb

From North Carolina Dietetic Association: *Nutrition care manual*, Raleigh, NC, 2011, The Association.

From Durnin JV, Womersley J: Body fat assessed from total body density and its estimation from skinfold thickness: measurements on 481 men and women aged from 16 to 72 years, *Br J Nutr* 32:77-97, 1974.

*Measurements made on the right side of the body, using biceps, triceps, subscapular, and suprailiac skinfolds.

Physical Activity and Calories Expended per Hour

Activity	Type	BODY WEIGHT							
		(110 lb)	(130 lb)	(150 lb)	(170 lb)	(190 lb)	(210 lb)	(230 lb)	(250 lb)

NOTE: This chart is not intended to be a comprehensive list for all nutritional or metabolic deficiencies or nonnutrition examples.

From Hammond K: Physical Assessment: A Nutritional Perspective, *Nurs Clin North Am* 32(4):779–790, 1997.

Nutrition-Focused Physical Assessment

PART 1 Parameters Useful in the Assessment of General Nutritional Status and the Presence of Malnutrition

Examination Areas	Tips	Severe Malnutrition	Mild-Moderate Malnutrition	Well Nourished
Subcutaneous Fat Loss				
Orbital Region – Surrounding the Eye	View patient when standing directly in front of them, gently touch above cheekbone, below the lower eyelid, and the supraorbital area above the eye below the eyebrow	Hollow look, depressions, dark circles, loose skin, no evidence of fat pads below the lower eyelid or below the eyebrow	Slightly dark circles, somewhat hollow look	Slightly bulged fat pads. Fluid retention may mask loss
Upper Arm Region – Triceps/Biceps	Arm bent, roll skin between fingers, do not include muscle in pinch	Very little space between folds, fingers touch	Some depth pinch but not ample	Ample fat tissue obvious between folds of skin
Thoracic and Lumbar Region – Ribs, Lower Back, Midaxillary Line	Have patient press hands hard against a solid object	Depression between the ribs very apparent. Iliac crest very prominent	Ribs apparent, depressions between them less pronounced. Iliac crest somewhat prominent	Chest is full, ribs do not show. Slight to no protrusion of the iliac crest
Muscle Loss				
Temple Region – Temporalis Muscle	View patient when standing directly in front of them; ask patient to turn head side to side; gently palpate the temple region	Hollowing, scooping, depression	Slight depression	Can see/feel well-defined muscle
Jaw Region – Masseter Muscle	View patient when standing directly in front of him or her; ask patient to clench teeth and move jaw from side to side. Palpate the masseter muscle while the jaw is in motion	Patient is unable to clench teeth or move jaw from side to side. Note: this may be due to a medication condition unrelated to malnutrition	Patient demonstrates moderate ability to clench teeth	Patient demonstrates strong ability to clench teeth
Clavicle Bone Region – Pectoralis Major, Deltoid, Trapezius Muscles	Look for prominent bone. Make sure patient is not hunched forward	Protruding, prominent bone	Visible in male, some protrusion in female	Not visible in male, visible but not prominent in female
Clavicle and Acromion Bone Region – Deltoid Muscle	Patient arms at side; observe shape	Shoulder to arm joint looks square. Bones prominent. Acromion protrusion very prominent	Acromion process may slightly protrude	Rounded, curves at arm/shoulder/neck
Scapular Bone Region – Trapezius, Supraspinatus, Infraspinatus Muscles	Ask patient to extend hands straight out, push against solid object	Prominent, visible bones, depressions between ribs/scapula or shoulder/spine	Mild depression or bone may show slightly	Bones not prominent, no significant depressions
Dorsal Hand – Interosseous Muscle	Look at thumb side of hand; look at pads of thumb when tip of forefinger touching tip of thumb	Depressed area between thumb and forefinger	Slightly depressed	Muscle bulges, could be flat in some well-nourished people

PART 1 Parameters Useful in the Assessment of General Nutritional Status and the Presence of Malnutrition—cont'd

Examination Areas	Tips	Severe Malnutrition	Mild-Moderate Malnutrition	Well Nourished
Lower Body Less Sensitive to Change				
Patellar Region – Quadriceps Muscles	Ask patient to sit with leg propped up, bent at knee	Bones prominent, little sign of muscle around knee	Kneecap less prominent, more rounded	Muscles protrude, bones not prominent
Anterior Thigh Region – Quadriceps Muscles	Ask patient to sit, prop leg up on low furniture. Palpate quads to differentiate amount of muscle tissue from fat tissue	Depression/line on thigh, obviously thin	Mild depression on inner thigh	Well rounded, well developed
Posterior Calf Region- Gastrocnemius Muscle	Palpate the calf muscle to determine amount of tissue	Thin, minimal to no muscle definition; may feel stringy	Not well developed	Well-developed bulb of muscle
Edema				
Rule out other causes of edema, patient at dry weight	View and palpate ankles and hands for evidence of edema	Deep to very deep pitting, depression lasts a short to moderate time (31-60 sec) extremity looks swollen (3-4+)	Mild to moderate pitting, slight swelling of the extremity, indentation subsides quickly (0-30 sec)	No sign of fluid accumulation

Notes:

1. Introduce yourself to the patient/family
2. Provide rationale for examination request
3. Ask the patient for permission to examine him or her
4. Wash/dry hands thoroughly; wear gloves
5. Use standard precautions to prevent disease transmission

PART 2 Clinical Characteristics That the Clinician Can Obtain and Document to Support a Diagnosis of Malnutrition (Academy/ASPEN)

Clinical Characteristic	MALNUTRITION IN THE CONTEXT OF SOCIAL OR ENVIRONMENTAL CIRCUMSTANCES		MALNUTRITION IN THE CONTEXT OF CHRONIC ILLNESS		MALNUTRITION IN THE CONTEXT OF ACUTE ILLNESS OR INJURY	
	Nonsevere (Moderate) Malnutrition	Severe Malnutrition	Nonsevere (Moderate) Malnutrition	Severe Malnutrition	Nonsevere (Moderate) Malnutrition	Severe Malnutrition
Energy intake¹ Malnutrition is the result of inadequate food and nutrient intake or assimilation; thus recent intake compared with estimated requirements is a primary criterion defining malnutrition. The clinician may obtain or review the food and nutrition history, estimate optimum energy needs, compare them with estimates of energy consumed, and report inadequate intake as a percentage of estimated energy requirements over time.	<75% of estimated energy requirement for >7 days	≤50% of estimated energy requirement for ≥5 days	<75% of estimated energy requirement for ≥1 month	≤75% of estimated energy requirement for ≥1 month	<75% of estimated energy requirement for ≥3 months	≤50% of estimated energy requirement for ≥1 month

Continued

PART 2 Clinical Characteristics That the Clinician Can Obtain and Document to Support a Diagnosis of Malnutrition (Academy/ASPEN)—cont'd

Clinical Characteristic	MALNUTRITION IN THE CONTEXT OF SOCIAL OR ENVIRONMENTAL CIRCUMSTANCES				MALNUTRITION IN THE CONTEXT OF CHRONIC ILLNESS				MALNUTRITION IN THE CONTEXT OF ACUTE ILLNESS OR INJURY			
	Nonsevere (Moderate) Malnutrition		Severe Malnutrition		Nonsevere (Moderate) Malnutrition		Severe Malnutrition		Nonsevere (Moderate) Malnutrition		Severe Malnutrition	
	%	Time	%	Time	%	Time	%	Time	%	Time	%	Time
Interpretation of weight loss²⁻⁵	%	Time	%	Time	%	Time	%	Time	%	Time	%	Time
The clinician may evaluate weight in light of other clinical findings, including the presence of under- or overhydration. The clinician may assess weight change over time reported as a percentage of weight lost from baseline.	1–2	1 wk	>2	1 wk	5	1 mo	>5	1 mo	5	1 mo	>5	1 mo
	5	1 mo	>5	1 mo	7.5	3 mo	>7.5	3 mo	7.5	3 mo	>7.5	3 mo
	7.5	3 mo	>7.5	3 mo	10	6 mo	>10	6 mo	10	6 mo	>10	6 mo
					20	1 y	>20	1 y	20	1 y	>20	1 y
Physical Findings^{5,6}	Malnutrition typically results in changes to the physical examination. The clinician may perform a physical examination and document any one of the physical examination findings below as an indicator of malnutrition.											
Body fat	Mild		Moderate		Mild		Severe		Mild		Severe	
Loss of subcutaneous fat (e.g., orbital, triceps, fat overlying the ribs)												
Muscle mass	Mild		Moderate		Mild		Severe		Mild		Severe	
Muscle loss (e.g., wasting of the temples [temporalis muscle], clavicles [pectoralis and deltoids], shoulders [deltoids], interosseous muscles, scapula [latissimus dorsi, trapezius, deltoids], thigh [quadriceps], and calf [gastrocnemius])												
Fluid accumulation	Mild		Moderate to severe		Mild		Severe		Mild		Severe	
The clinician may evaluate generalized or localized fluid accumulation evident on examination (extremities or ascites). Weight loss is often masked by generalized fluid retention (edema), and weight gain may be observed.												
Reduced grip strength⁷	NA		Measurably reduced		NA		Measurably reduced		NA		Measurably reduced	
Consult normative standards supplied by the manufacturer of the measurement device												

A minimum of two of the six characteristics above is recommended for diagnosis of either severe or nonsevere malnutrition. NA, Not applicable.

Notes:

Height and weight should be measured rather than estimated to determine body mass index (BMI).

Usual weight should be obtained to determine the percentage and to interpret the significance of weight loss.

Basic indicators of nutrition status such as body weight, weight change, and appetite may substantively improve with refeeding in the absence of inflammation. Refeeding and/or nutrition support may stabilize but not significantly improve nutrition parameters in the presence of inflammation.

The National Center for Health Statistics defines *chronic* as a disease/condition lasting 3 months or longer.⁸

Serum proteins such as serum albumin and prealbumin are not included as defining characteristics of malnutrition because recent evidence analysis shows that serum levels of these proteins do not change in response to changes in nutrient intake.⁹⁻¹²

PART 3 Nutrition-Focused Physical Examination

System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
Body Habitus – See Part 1. General Survey	Weight for height appropriate, well-nourished, alert, and cooperative with good stamina	Loss of weight, muscle mass and fat stores, skeletal muscle wasting (hands, face, quadriceps, and deltoids), subcutaneous fat loss (face, triceps, thighs, waist) or overall weight loss, sarcopenia (loss of lean body mass in older adults). See Part 1 Growth retardation in children Inappropriate rates of height and weight gain in children and adolescents	Suboptimal energy and protein intakes Nonsevere malnutrition Severe malnutrition	Endocrine disorders, osteogenic disorders, menopausal disorders secondary to estrogen depletion Sarcopenia related to decreased physical activity, increased cytokine (interleukin-6) and decreased levels of growth hormone and insulin-like growth factor
Skin	Healthy color, soft, moist turgor with instant recoil, smooth appearance	Excess fat stores Poor or delayed wound healing, pressure ulcers Dry with fine lines and shedding, scaly (xerosis) Spine-like plaques around hair follicles on buttocks, thighs, or knees (follicular hyperkeratosis)	Excess energy intake Protein deficiency Vitamin C deficiency Zinc deficiency Essential fat deficiency Vitamin A deficiency Vitamin A deficiency Essential fat deficiency	Diabetes, steroids Poor vascular perfusion Environmental or hygiene factors

Continued

PART 3 Nutrition-Focused Physical Examination—cont'd				
System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
		Pellagrous dermatitis (hyperpigmentation of skin exposed to sunlight)	Niacin deficiency Tryptophan deficiency	Thermal, sun, or chemical burns; Addison's disease
		Pallor	Iron deficiency Folic acid deficiency Vitamin B ₁₂ deficiency	Skin pigmentation disorders, hemorrhage, low volume, low perfusion state
		Generalized dermatitis	Zinc deficiency Essential fatty acid deficiency	Atopic dermatitis, contact dermatitis, allergic or medication rash, psoriasis, connective tissue disease
		Yellow pigmentation	Carotene excess Vitamin B ₁₂ deficiency	Jaundice
		Poor skin turgor	Fluid loss	Aging process
		Petechiae, ecchymoses	Vitamin K deficiency Vitamin C deficiency	Aspirin overdose, liver disease, or trauma
Nails	Smooth, translucent, slightly curved nail surface and firmly attached to nail bed; nail beds with brisk capillary refill	Spoon-shaped (koilonychia)	Iron deficiency Nonsevere malnutrition Severe malnutrition	COPD, heart disease, aortic stenosis, diabetes, lupus, chemotherapy
		Dull, lackluster	Protein deficiency Iron deficiency	Chemical effects
		Pale, mottled, poor blanching	Vitamin A deficiency Vitamin C deficiency	Infection, chemical effects
		Ridging, transverse-more than one extremity	Protein deficiency	Beau's lines, grooves caused by trauma, coronary occlusion, skin disease, transient illness
Scalp	Pink, no lesions, tenderness; fontanels without softening, bulging	Softening or craniotabes	Vitamin D deficiency	
		Open anterior fontanel (usually closes by <18 months of age)	Vitamin D deficiency	Hydrocephalus
Hair	Natural shine, consistency in color and quantity, fine to coarse texture	Lack of shine and luster, thin, sparse	Protein deficiency Zinc deficiency Biotin deficiency Linoleic acid deficiency	Hypothyroidism, chemotherapy, psoriasis, color treatment
		Easily pluckable	Protein deficiency Biotin deficiency	Hypothyroidism, chemotherapy, psoriasis, color treatment
		Alternating bands of light and dark hair in young children (flag sign)	Protein deficiency	Chemically processed or bleached hair
		"Corkscrew" hair	Copper deficiency Vitamin C deficiency	Menkes disease Chemical alteration
		Premature whitening	Selenium deficiency Vitamin B ₁₂ deficiency	Graves' disease, medications
Face	Skin warm, smooth, dry, soft, moist with instant recoil	Diffuse depigmentation, swollen	Protein deficiency	Steroids and other medications
		Pallor	Iron deficiency Folic acid deficiency Vitamin B ₁₂ deficiency	Low-perfusion, low-volume states
		Moon face	Protein deficiency	Cushing's disease, steroids

PART 3 Nutrition-Focused Physical Examination—cont'd

System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
		Bilateral temporal wasting. See Part 1	Protein deficiency Energy deficit	Neuromuscular disorders
		Undifferentiated mucocutaneous border	Riboflavin deficiency	
Eyes	Evenly distributed brows, lids, lashes; conjunctiva pink without discharge; sclerae without spots; cornea clear; skin without cracks or lesions	Pale conjunctiva	Iron deficiency Folate deficiency Vitamin B ₁₂ deficiency	Low output states
		Night blindness	Vitamin A deficiency	
		Dry, grayish, yellow or white foamy spots on whites of eyes (Bitot's spots)	Vitamin A deficiency	Pterygium, Gaucher's disease
		Dull, milky, or opaque cornea (corneal xerosis)	Vitamin A deficiency	
		Dull, dry, rough appearance to whites of eyes and inner lids (conjunctival xerosis)	Vitamin A deficiency	Chemical, environmental
		Softening of cornea (keratomalacia)	Vitamin A deficiency	
		Cracked and reddened corners of eyes (angular palpebritis)	Riboflavin deficiency Niacin deficiency	Infection, foreign objects
Nose	Uniform shape, septum slightly to left of midline, nares patent bilaterally, mucosa pink and moist, able to identify aromas	Scaly, greasy, with gray or yellowish material around nares (nasolabial seborrhea)	Riboflavin deficiency Niacin deficiency Pyridoxine deficiency	
		Inflammation, redness of sinus tract, discharge, obstruction or polyps	Irritation of skin membranes	Need to reconsider if placing nasoenteric feeding tube; evaluate for nonfood allergies
Oral Cavity				
Lips, mouth	Pink, symmetric, smooth intact	Angular stomatitis (bilateral cracks, redness of lips)	Riboflavin deficiency Niacin deficiency Pyridoxine deficiency Dehydration	Poor-fitting dentures, herpes, syphilis, HIV, environmental exposure
		Cheilosis (vertical cracks of lips or fissuring)	Riboflavin deficiency Niacin deficiency Dehydration	HIV (Kaposi's sarcoma), environmental exposure
		Chapped or peeling	Dehydration	Environmental exposure
		General inflammation	Protein, energy, folic acid	Xerostomia
Tongue	Pink, moist, midline, symmetric with rough texture	Magenta (purplish-red color), inflammation of the tongue (glossitis)	Riboflavin deficiency, B ₆ deficiency Niacin deficiency Folate deficiency Vitamin B ₁₂ deficiency Riboflavin deficiency Iron deficiency	Crohn's Disease, uremia, Infectious disease state, antibiotics, malignancy, Irritants (excess tobacco, alcohol, spices), generalized skin disorder
		Smooth, slick, loss of papillae (atrophic filiform papillae)	Folate deficiency Niacin deficiency Riboflavin deficiency Iron deficiency Vitamin B ₁₂ deficiency Nonsevere malnutrition Severe malnutrition	

Continued

PART 3 Nutrition-Focused Physical Examination—cont'd

System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
		Distorted taste (dysgeusia)	Zinc deficiency	Cancer therapy, medications, advanced age, trauma, syphilis, xerostomia, poor-fitting dentures, poor hygiene
		Decreased taste (hypogeusia)	Zinc deficiency Vitamin A deficiency	Cancer therapy, advanced age, medications, xerostomia
Gums	Pink, moist without sponginess	Spongy, bleeding, receding	Vitamin C deficiency Riboflavin deficiency	Dilantin and other medication, poor hygiene, lymphoma, polycythemia, thrombocytopenia
		Red, swollen interdental gingival hypertrophy	Vitamin C deficiency Folic acid deficiency, vitamin B ₁₂ deficiency	Dilantin, poor oral hygiene, lymphoma, vitamin A toxicity
Teeth	Repaired, no loose teeth; color may be various shades of white	Missing, poor repair, caries, loose teeth	Excess sugar intake	Trauma, syphilis, aging, poor dental hygiene
		White or brownish patches (mottled)	Excess fluoride	Enamel hypoplasia, erosion
Cranial nerves	Intact	Abnormal	Feeding route	
Gag reflex	Intact	Absent	Route of feeding	
Jaw	Proper alignment, movement from side to side	Improper alignment and movement	Ability to chew properly	
Parotid gland	Located anterior to ear-lobe, no enlargement	Bilateral enlargement	Nonsevere malnutrition Severe malnutrition	Bulimia, cysts, tumors, hyperparathyroidism
Neck nodules	Trachea midline, freely movable without enlargement or nodules	Enlarged thyroid	Iodine deficiency	Cancer, allergy, cold infection
Cardiopulmonary				
Chest, lungs	Anterior and posterior thorax; adequate muscle and fat stores, respirations even and unlabored, symmetric rise and fall of chest during inspiration and expiration, lung sounds clear	Somatic muscle- and fat-wasting; labored respirations; breath sounds such as crackles, rhonchi, and wheezing; evaluate for fluid status vs. tenacious secretions that may labor breathing and increase energy expenditure; also consider increased rate and depth, decreased rate and depth	Nonsevere malnutrition Severe malnutrition Metabolic acidosis Metabolic alkalosis	Respiratory disease (e.g., COPD)
Heart	Rhythm regular and rate within normal range; S ₁ and S ₂ heart sounds	Irregular rhythm	Potassium deficiency or excess Calcium deficiency Magnesium deficiency or excess Phosphorus deficiency	Cardiopulmonary disease states, stress
		Enlarged heart	Thiamin deficiency associated with anemia and beriberi	
		Pitting edema	Retention of sodium chloride, which causes the body to retain water Edema-associated disease of heart, liver, kidneys Fluid leaking into the interstitial tissue spaces	
Vascular access devices intact	No swelling, redness, drainage	Purulent drainage, swelling, excessive redness	Nutrition effects if device has to be removed	

PART 3 Nutrition-Focused Physical Examination—cont'd

System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
Abdomen	Soft, nondistended, symmetric, bilateral without masses, umbilicus in midline, no ascites, bowel sounds present and normoactive; tympanic on percussion; feeding device intact without redness, swelling	Generalized symmetric distention	Obesity	Enlarged organs, fluid, or gas, ileus from other disease
		Protruding, everted umbilicus; tight glistening appearance (ascites)	Effects on protein, fluid, sodium concerns of feeding	
		Scaphoid appearance	Nonsevere malnutrition Severe malnutrition	
		Increased bowel sounds	Nutrition effects in gastroenteritis (normal if hunger pains)	
		High-pitched tinkling	Nutrition effects if intestinal fluid and air present, indicating early obstruction	
		Decreased bowel sounds	Nutrition effects if peritonitis or paralytic ileus present	
Kidney, ureter, bladder	Urine golden yellow (ranges from pale yellow to deep gold), clear without cloudiness, adequate output	Decreased output, extremely dark, concentrated	Dehydration	
Musculoskeletal	Full range of motion without joint swelling or pain, adequate muscle strength	Inability to flex, extend, and rotate neck adequately	Interference with ability to feed or make hand-to-mouth contact	
		Decreased range of motion, swelling, impaired joint mobility of upper extremities; muscle wasting on arms, legs; skin folding on buttocks	Nonsevere malnutrition Severe malnutrition	
		Swollen, painful joints	Vitamin C deficiency Vitamin D deficiency	Connective tissue disease
		Bone tenderness	Vitamin A deficiency	
		Enlargement of epiphyses at wrist, ankle, or knees	Vitamins D deficiency Vitamin C deficiency	Trauma, deformity, or congenital cause
		Bowed legs	Vitamin D deficiency Calcium deficiency	
		Beading of ribs	Vitamin D deficiency Calcium deficiency	Renal rickets, malabsorption
		Pain in calves, thighs	Thiamin deficiency	Deep vein thrombosis, other neuropathy, or other
Neurologic	Alert, oriented, hand-to-mouth coordination; no weakness or tremors	Decreased or absent mental alertness; inadequate or absent hand-to-mouth coordination	Interference with the ability to eat or make hand-to-mouth contact	
		Psychomotor changes, cognitive and sensory deficits, memory loss, confusion, peripheral neuropathy	Nonsevere malnutrition Severe malnutrition Thiamin deficiency Pyridoxine deficiency Vitamin B ₁₂ deficiency	Trauma, neurologic disease, brain injury, brain tumor, chemotherapy

Continued

PART 3 Nutrition-Focused Physical Examination—cont'd				
System	Normal Findings	Abnormal Findings	Possible Nutrition and Metabolic Etiologies	Nonnutritional Etiologies
		Dementia	Thiamin deficiency Niacin deficiency Vitamin B ₁₂ deficiency	Trauma, neurologic disease, vascular disease, brain injury, brain tumor, chemotherapy
		Tetany	Calcium deficiency Magnesium deficiency	
		Paresthesias or numbness in stocking-glove distribution	Vitamin B ₁₂ deficiency Thiamin deficiency	Diabetic neuropathy
	Cranial nerves intact: primary nutritionally focused ones include trigeminal, facial, glossopharyngeal, vagus, and hypoglossal			
	Reflexes (biceps, brachioradialis patella, and Achilles common in examination), functioning within normal range of 2 ⁺⁺	Hyperactive reflexes	Hypocalcemia	Tetany, upper motor neuron disease
	Hypoactive reflexes	Hypokalemia		Associated with metabolic diseases such as diabetes mellitus and hypothyroidism
		Hypoactive Achilles, patellar reflex	Thiamin deficiency Vitamin B ₁₂ deficiency	Neurologic disorder

COPD, Chronic obstructive pulmonary disease; HIV, human immunodeficiency virus.

PEDIATRIC MALNUTRITION

Abnormal anthropometric measurements are often the first sign of pediatric malnutrition. Using the Nutrition Care Process, the registered dietitian nutritionist (RDN) uses clinical reasoning skills to determine the etiology of the abnormal pattern of growth (e.g., related to acute or chronic illness and the degree of inflammation present). Illness-related conditions contributing to pediatric malnutrition include starvation, malabsorption, increased rate of metabolism, altered nutrient utilization, and increased nutrient losses. Data gathered in the assessment step will be compared with the diagnostic criteria. There are two categories of diagnostic criteria. The first set of criteria use only one data point. These criteria are anthropometric measurements compared with a growth standard. A growth standard reflects optimal growth or potential growth for children at different ages. Growth standards are defined in terms of percentiles or Z-scores. Percentiles are a percentage of observations that fall above or below the value of the variable. For example, if a child's height is at the 25th percentile, this

means that out of 100 normal children of the same gender and age, 75 will be taller than this child and 25 will be shorter.

The characteristics of pediatric malnutrition use Z-scores because these data points are calculated based on the distribution of the reference population including both the means and standard deviation. The advantage of using Z-scores is that the Z-scores are comparable across age and gender and these scores quantify growth status of children whose anthropometric measurements fall outside of the percentile ranges. The criteria include Z-scores for weight to height, BMI, length or height, and midupper arm circumference.

The second set of diagnostic criteria is used when two or more data points are available. The criteria include weight gain velocity, weight loss, deceleration of weight to length or weight to height, Z-score, and inadequate energy and protein intake. For more information, refer to the consensus statement of the Academy of Nutrition and Dietetics/American Society for Parenteral and Enteral Nutrition: Indicators recommended for the identification and documentation of pediatric malnutrition, *J Acad Nutr Diet* 114:1988–2000, 2014.

Laboratory Values for Nutritional Assessment and Monitoring

I. PRINCIPLES OF NUTRITIONAL LABORATORY TESTING

A. Purpose

Laboratory-based testing is used to estimate nutrient availability in biologic fluids and tissues. It is critical for assessment of both nutrient insufficiencies and frank deficiencies. Laboratory data are the only objective data used in nutrition assessment that are “controlled”—that is, the validity of the method of the measurement is checked each time a specimen is assayed by also assaying a sample with a known value. The known sample is called a *control*, and if the value obtained for the sample is outside the range of normal analytic variability, both the specimen and control are measured again.

The nutrition professional can use laboratory test results to support subjective data and clinical findings to determine a personalized nutritional assessment leading to more targeted interventions and successful outcomes. The laboratory values provide objective data useful in regular monitoring and can be used to assess progress and manage side effects such as inflammation, aberrant lipid and glucose metabolism, and immune status.

B. Specimen Types

Ideally the specimen to be tested reflects a high percentage of total body content of the nutrient to be assessed. However, often the best specimen is not readily available. The most common specimens for analysis are the following:

Whole blood—Must be collected with an anticoagulant if entire content of the blood is to be evaluated. The two common anticoagulants for whole blood analyses are ethylenediaminetetraacetic acid, a calcium chelator used in hematologic analyses, and heparin (maintains the blood in its most natural state).

Blood cells—Separated from uncoagulated whole blood for measurement of cellular analyte content: Red blood cells (indicate a 120-day window into intracellular and membrane composition), various blood components like white blood cells, protein-bound molecules, and others.

Plasma—The uncoagulated fluid that bathes the formed elements (blood cells).

Serum—The fluid that remains after whole blood or plasma has coagulated. Coagulation proteins and related substances are missing or significantly reduced.

Urine—Contains a concentrate of excreted metabolites and potential toxins.

Feces—Important in identifying various gastrointestinal functional parameters including inflammatory markers, microbiology, mycology, parasitology, digestive markers, and nutritional analyses when nutrients are not absorbed and therefore are present in fecal material.

Saliva—Laboratory analysis to identify endocrine, inflammatory, infectious, immunologic, some nutrients, and other parameters with buccal cell or whole saliva samples.

Genomic—Expanding beyond the historical metabolic macro- and micronutrient testing, genomic polymerase chain reaction (PCR) assays are emerging genomic clinical indicators for nutrigenetic and nutrigenomic influences on the metabolism of an individual (see Chapter 6).

Expired Air—Concentration of expired gases is a noninvasive and useful estimate of bacterial metabolism. Emerging measurements of expired nitric oxide and ketosis may be useful in estimating inflammatory or ketotic status in selected medical conditions.

Hair—An easy-to-collect tissue; most commonly measuring minerals; usually a poor indicator of actual body levels.

Other tissues—Fat biopsies have been used to estimate vitamin D stores in research studies.

C. Interpretation of Laboratory Data

As with all data, nutrition data may be quantitative (e.g., how much, how often, how fast), semiquantitative (e.g., many, most, few, a lot, usually, majority, several), or qualitative (e.g., color, shape, species). The advantage of quantitative data is that they are less ambiguous or more objective than other types of observations. Although objective laboratory data are extremely important resources in nutrition assessment, one should be extremely cautious about using a single isolated laboratory test value to make an assessment. An isolated value is often misleading, especially when used without the context of an individual’s lifestyle habits; clinical status; dietary, medical, and genomic histories; and test results if available. Besides the importance of identifying frank deficiencies or excesses of nutrients, the best data are obtained from analysis of changes in laboratory values and overt clinical physical signs (e.g., compromised skin conditions). It is especially important to monitor laboratory values when contemplating nutritional interventions that involve potentially unsafe levels beyond upper limits (UL), such as fat-soluble vitamins or a mineral like selenium.

When monitoring patients for changes in nutrition test values, one must consider how much change is necessary to give confidence that a difference is significant. The change required for statistical significance has been called the *critical difference*. It is calculated from

measurement of the variances calculated from repeated measurements of an analyte: (1) specimens that have been obtained, at several different times, from each of several healthy persons (intrasubject variation), and (2) separate samples from a large specimen pool (analytic variation).

In practice, assessments are not based on the measurement of a single analyte at one point in time except in the case of severe deficiencies or dangerous excesses. Changes in laboratory tests may have biologic significance (e.g., patient's condition is improving) long before statistical significance is achieved. The changes in laboratory data may precede changes in other nutritional indices, but generally, although not always, the data available should point to the same conclusion.

D. Reference Ranges

To determine whether a particular laboratory value is abnormal, particularly when serial data are not available, the value is generally compared with a diagnostic reference range. The reference range is constructed from a large number of test values (20 to >1000). The average value and the standard deviation for these data are determined, and the reference range is calculated from the mean \pm 2 standard deviations. If the sample group is representative of the reference population, the reference range will include values that reflect those found in approximately 95% of the reference population. Approximately 2.5% of this normal population will have values greater than the upper end of the reference range, and 2.5% will have values less than the lower end. This means that one normal individual in 20 would have a value below or above the reference range.

Reference ranges can be made for different populations. For example, reference ranges based on gender, age, ethnicity, and so forth can be developed. In practice, the differences between populations are often ignored because the importance of small differences in a nutrient analyte is not usually significant. However, in the event of borderline values, the possible influence of differences between the patient's population and the reference population may need to be considered.

Reference ranges are often determined by obtaining blood from personnel working in or near the clinical laboratory. This population is often skewed toward younger persons, has limited ethnic diversity, and is overrepresented by women.

As the science of nutrition continues to rapidly evolve due to technological and scientific advances including genomic tests results for individuals, changes in laboratory values can be interpreted as indicating metabolic trends and genotypic influences, even within the reference range of a test. The nutritionist's skill in perceiving nutrient insufficiencies or imbalances related to nutritional influences can provide a more targeted assessment resulting in improved outcomes from therapy.

E. Units

Many types of units are used in reporting nutrient-dependent laboratory values. Two basic systems of units are in common use: the conventional system and the *Système Internationale d'Unités* (SI) system. The conventional system sometimes lacks convention; thus different laboratories adopt different units to report the same analyte. For example, the conventional report of an ionized calcium value could be 2.3 mEq/L, 46 mg/L, or 4.6 mg/dL. However, in the SI system only 1.15 mmol/L is allowed.

F. Nature of Nutritional Testing and Types of Tests

Typically laboratory tests are static assays (i.e., the concentration of an analyte is measured in a biologic fluid [e.g., a fasting blood specimen] at a point in time). Assessment of nutrient status made by this approach is often inaccurate or distorted. Some nutrients can be assessed by tests that are based on measurements that reflect the endogenous availability of a nutrient to a measurable biologic function (e.g., biochemical, tissue, or organ). Most often, functional assessment of nutrient status may be done by measurement of a biochemical marker (i.e., a normal or abnormal metabolite) of function. The results of this type of testing can be reliably considered to reflect the adequacy of a nutrient pool or possible individual genomic nutrient requirements.

CLINICAL INSIGHT

Bioelectrical Impedance Analysis (BIA) and Bioimpedance Spectroscopy (BIS)—A Functional Test for Nutritional Status

Nutrition assessment is taking on a new level of specificity with the explosion of technology and discoveries of the pathophysiology of disease and functions of the human body. These breakthroughs assist in molecular-level identification of nutrition status. Bioelectrical impedance analysis (BIA) and bioimpedance spectroscopy (BIS) have a credible history of use in research, but recently have found an increasing use as a clinical tool in nutrition assessment.

BIA estimates body composition and cellular activity by measuring the bulk electrical impedance of the body. The testing procedure involves application of conductors (electrodes) to a person's hand and foot and sending a small alternating electric current through the body (see figure on next page). The different electrical conductive properties of various body tissues (adipose, muscular, and skeletal) and hydration affect the impedance measurement. An algorithm derived from statistical analysis of BIA measurements is used to calculate the various parameters that can be measured by this technique.

Normal hydration is critical for results to be valid, with these guidelines before testing:

1. Drink water (16-24 oz during the 4 hours before test)
2. No alcohol for 12 hours before test
3. No food or caffeine drinks for 4 hours before test
4. No moderate to intense exercise for 12 hours before test

Contraindications to BIA testing are pregnancy or the presence of implants like pacemakers or defibrillators. Follow-up monitoring of BIA testing should attempt to be near the same time of day.

There are commercially available BIA devices that measure only body fat % and weight. But professional BIA or BIS instruments are available that provide reliable, more comprehensive full body data, and automatically calculate total body water, intracellular and extracellular water, fat-free mass, percent body fat, phase angle, capacitance, and body cell mass. They are very useful in tracking changes in an individual's progress over time. Research in the past decade has shown promise for the BIA phase angle as a prognostic indicator of some cancers (Norman et al, 2010) and other chronic conditions (Maddocks et al, 2014).

The multiple parameters measured in a BIA or BIS test provide three categories of data:

1. **Anthropometry:** BMI (body mass index), BMR (basal metabolic rate), body fat percentage, and lean body mass percentage. These measurements are used with weight management, monitoring of wasting syndromes, and acute care formulation of dietary prescriptions. Weight, height, age, gender, and date must be entered to obtain these results.
2. **Cellular metabolism:** Phase angle, which measures cell membrane fluidity, is a prognostic marker of mortality, capacitance (electrical resistance of the cell

CLINICAL INSIGHT—cont'd**Bioelectrical Impedance Analysis (BIA) and Bioimpedance Spectroscopy (BIS)—A Functional Test for Nutritional Status**

membrane), and body cell mass (the number or amount of metabolically active cells). Using these three measurements provides an easy-to-use, noninvasive, and reproducible technique to evaluate changes in body composition and nutritional status. Phase angle (BIA) detects changes in tissue electrical properties, and it is hypothesized as a marker of malnutrition for investigating various diseases in the clinical setting. Lower phase angles suggest cell death or decreased cell integrity, while higher phase angles suggest large quantities of intact cell membranes (Selberg and Selberg, 2002).

3. **Hydration:** Total body water (in pounds and as a percentage), intracellular water (in pounds and as a percentage), and extracellular water (in pounds and as a percentage).

Every professional practicing nutrition therapy can now consider adding a reasonably priced BIA or BIS instrument to their nutritional assessment toolbox to assist in the management of a client or patient. The four companies from which professional BIA or BIS instruments can currently be obtained are:

<https://www.impedimed.com>

<https://www.inbody.com>

<https://www.biodynamics.com>

<https://www.rjlsystems.com>

These companies also provide informative education on the technology and operation of their bioimpedance or bioimpedance spectroscopy instruments.

II. Clinical Chemistry				
A. Protein Markers				
Test	Principles	Interpretation	Reference Range	Limitations and Implications
nPCR	nPCR is determined by measuring the intradialytic appearance of urea in body fluids plus any urea lost in the urine in patients with residual renal function. $\text{nPCR} = 0.22 + (0.036 \times \text{intradialytic rise in BUN} \times 24) / (\text{intradialytic interval}).$ (also called protein nitrogen appearance (PNA) rate (g/day) = 13 + 7.31 UNA (mmol/day) $[\text{UNA (mmol/day)} = \text{Vd (mL)} \times \text{Cd (mmol/L)} + \text{Vu (mL)} + \text{Cu (mmol/L)}]$	Useful in assessing DPI in patients who are in a steady state on hemodialysis, as a means toward determining adequate nutrition status.	0.81-1.02 g UN/kg per day	nPCR considered superior to sAlb for monitoring nutrition protein status due to sAlb influence by processes other than nutrition status. ² During hemodialysis, the PCR can also reflect inadequate dialysis.
(U : Cr)	U : Cr concentration in fasting, first-void urine used to compare amino acid catabolism (BUN) with muscle mass (creatinine).	Urine concentration (mg/dL) $\text{U : Cr} = \text{Urine area (mg/dL)} \div \text{Urine creatinine (mg/dL)}. \text{ The U : Cr is used in comparing other markers like microalbumin, albumin, GFR ratios.}$	Risk Low Medium High	Ratio >12.0 6.0-12.0 <6.0
UUN	The protein pool (visceral and somatic) N is catabolized to urea; urine urea represents ~80% of N catabolized; requires accurate estimate of protein intake; thus usually used only for PN or tube-feeding patients.	UUN is compared with the actual N intake. $\text{Nitrogen Balance} = \text{Nitrogen intake (Protein g/day} \div 6.25) - \text{Nitrogen Losses (UUN (g) + 4)}^a$	– = Catabolism 0 = Catabolism + = Anabolism (3-6 g/24 hr = optimal use range)	24-hour urine collection must be quantitative (complete); UUN not appropriate in renal insufficiency; does not account for wound leakage, cell losses, or diarrhea; inaccurate in metabolically stressed patients.
TUN	Some N is excreted as nonurea N (e.g., ammonia and creatinine); 24-hour TUN reflects total protein catabolism, accounting for all sources of urinary N; as for UUN, it requires accurate protein intake. Used primarily to accurately follow the protein catabolic response during disease and response to nutritional support.	TUN is compared with the actual N intake; $\text{Nitrogen balance} = \text{Nitrogen intake (Protein g/day} \div 6.25) - \text{Nitrogen losses (TUN (g) + 2)}^b$	– = Catabolism 0 = Catabolism + = Anabolism (3-6 g/24 hr = optimal use range)	Urine 24-hour collection must be quantitative (complete); TUN not appropriate in renal insufficiency; not done in many institutions; does not account for wound leakage, cell losses, or diarrhea.
UKM	Formulas used to estimate nPCR (normalized protein catabolic rate) from changes in BUN concentration in patients with impaired renal function.	Urinary urea (KrU) and BUN levels (urea generation rate—UG) are used to determine nPCR; 1- to 3-day diet intake compared with nPCR. Urea kinetic Modeling (Kt/V_{urea} and nPCR)	In protein balance, $\text{nPCR} = \text{protein intake (g/kg/day)}$	Urea lost in dialysis must be accounted for in calculating urea nitrogen appearance. Dietary protein intake is hard to estimate.
B. Inflammatory Markers				
ALB	Easily and quickly measured colorimetrically; large body pool (3-5 g/kg body weight), ~60% is outside the plasma in the extravascular pool; long half-life of 3 weeks.	Decreased levels can occur following acute and chronic inflammatory states; often associated with other deficiencies (i.e., zinc, iron, and vitamin A) reflecting that ALB transports many small molecules.	3.5-5 g/dL (35-50 g/L)	Stable half-life ~3 weeks. A negative phase reactant, impacted by inflammatory stress, (protein losing conditions and hemodilution). Hepatic proteins are indicators of morbidity and mortality.
GLOB	Large body pool (3-5 g/kg body weight), ~35% is outside the plasma in the extravascular pool; long half-life averages 23 days but varies with particular globulins.	GLOB proteins include enzymes and carriers that transport proteins including antibodies that primarily assist in immune function and fight infection.	2.3-3.4 g/dL (23-34 g/L)	Significance confounded by acute stress reaction, infection, inflammatory conditions.

A/G Ratio	Calculated from ALB and GLOB values by direct measurement of TP and ALB.	It represents the relative amounts of ALB and GLOB.	A/G ratio 1:1 - normal <1:1 - disease state	ALB levels fall and globulin levels rise with inflammatory stress.
Tf or TFN	The iron-bound GLOB protein that responds to the need for iron. Can be calculated from TIBC and serum iron; half-life ~9 days.	Tf increased with low iron stores and prevents build-up of highly toxic excess unbound iron in circulation. In iron overload states Tf levels decrease. Because B ₆ is required for iron to bind to Hgb, B ₆ deficiency promotes ↑ Tf from the ↑ circulating iron that binds to Tf; smaller extravascular pool than ALB.	Adult male: 215-365 mg/dL (2.15-3.65 g/L) Adult female: 250-380 mg/dL (2.50-3.80 g/L) Newborn: 130-275 mg/dL (1.3-2.75 g/L) Child: 203-360 mg/dL (2.03-3.6 g/L) Pregnancy and estrogen HRT associated with ↑ Tf.	Lead can biologically mimic and displace iron, thus releasing Fe into circulation and ↑ Tf. Tf is a negative acute phase reactant diminished in chronic illness and hypoproteinemia.
Tf-sat	Tf-sat (%) = Serum iron level ÷ TIBC × 100%	Tf-sat decreases to <15% in Fe deficiency; useful in diagnosis of iron toxicity or Fe overload (hemochromatosis). See Chapter 31.	M: 20%-50% F: 15%-50% Chronic illness: normal Tf-sat%. Late pregnancy: low Tf-sat%.	Increased Tf-sat when low vitamin B ₆ as in aplastic anemia.
PAB/(TTR)	Transports T ₄ and acts as a carrier for retinol-binding protein; PAB also called thyroxin-binding protein; half-life 2 days.	Measure of inflammatory status. Zinc deficiency reduces PAB levels.	15-36 mg/dL or 150-360 mg/L (15-36 mg/dL female, 21-43 mg/dL male) Malnutrition: <8 mg/dL (<0.8g/L or <80 mg/L)	Sensitive to acute zinc deficiency and acute stress reaction. PAB values do not reflect protein status but are a prognostic index for mortality and morbidity. ⁴
RBP	Transport retinol; because of low molecular weight, RBP is filtered by glomerulus and catabolized by the kidney tubule; half-life = 12 hours	Measure of inflammatory status.	2.6-7.6 mg/dL (1.43-2.86 mmol/L)	Sensitive to stress response; vitamin A and zinc deficiencies, and hemodilution; increased in chronic renal disease.
hs-CRP	A nonspecific acute phase reactant; short half-life 5-7 hr; CRP responds to inflammation in 6-10 hours. (also called CRP-ultra sensitivity and CRP-cardio)	A sensitive marker of bacterial disease and systemic inflammation; associated with periodontitis, trauma, cardiovascular disease, neoplastic proliferation, and bacterial infections.	Low Risk for CVD = Less than 1.0 mg/L Intermediate Risk for CVD = 2.9 mg/L High Risk for CVD = Greater than 3.0 mg/L Seek inflammatory cause if >10 mg/L	Useful metabolic indicator for adults. ⁹ Acute-phase reactant; relates mostly to bacterial infection, central adiposity, trauma, and neoplastic activity.
Fibrinogen	Acute-phase reactant protein essential to blood-clotting mechanism/coagulation system.	Decreased fibrinogen related to prolonged PT and PTT; produced in liver; rises sharply during tissue inflammation or necrosis; association with CHD, stroke, myocardial infarction, and peripheral arterial disease.	200-400 mg/dL If <100 mg/dL, increased risk of bleeding. Should be monitored in conjunction with blood platelet levels involved with coagulation status.	Good test and retest reliability, and covariance is stable over time; diets rich in omega-3/6 fatty acids reduce fibrinogen blood levels.
C. Metabolic Indicators				
IGF-1 or Somatomedin C	The peptide mediator of growth hormone activity produced by the liver; half-life of a few hours; much less sensitive to stress response than other proteins.	Low in chronic undernutrition; increases rapidly during nutrition repletion; TSAT, PAB, and RBP are not affected. Elevated levels associated with elevated GH in acromegaly and neoplastic activity.	Adult: 42-110 ng/mL Children age 0-19: can vary with age, gender and Tanner Stages (Appendices 17 & 18) used for references per age.	Reduced levels seen in hypopituitarism, hypothyroidism, liver disease, and with estrogen use. Growing evidence of elevated IGF-1 as a prognostic biomarker of neoplastic activity. ^{5,6}
Hgb A1C	Glycosylated hemoglobin; dependent on blood glucose level over life span of RBC (120 days); the more glucose the Hgb is exposed to, the greater the % Hgb A1C.	Assessment of the mean glycemic blood level and of chronic diabetic control detecting for the previous 2-3 months. ⁷	Nondiabetic adult/child: 4%-5.9% Controlled DM: 4%-7% Fair DM control: 7%-8% Poor DM control: >8%	Hgb A1C measurement is a simple, rapid, and objective procedure. Home testing available.

Continued

Insulin, fasting	Pancreatic hormone signaling cell membrane insulin receptors to initiate glucose transport into cell; test fasting 7 hours, or 1 or 2 hours postprandial; usually ordered with blood glucose test.	Elevated levels associated with hyperinsulinemia related to metabolic syndrome; diagnosis of insulin producing neoplasms; excess insulin associated with inflammatory conditions.	Adult values: Fasting 6-27 μ IU/mL 1 or 2 hours PP: see laboratory reference	Good to test and retest reliability, and covariance is stable over time. ⁸ Insulin antibodies may invalidate the test.
D. Immune Dysregulation Tests				
Allergies/Sensitivity				
Immunoglobulins (IgA, IgG, IgE, IgM,)	Serologic antibody screening tests; testing of Immunoglobulins; Total IgE ELISA; RAST (radioallergosorbent-blood IgE); Bloodspot: IgG Provocative specific antigen skin prick: (IgE related skin response) used to diagnose allergy and identify the allergen.	Used to determine immunodeficiency states; measurement of +IgE = allergic disorders; (see Table 27-3) +IgG = delayed immunologic sensitivity or intolerance response (see Table 27-3). IgA = largest % Ig primarily made in GI lymphoid tissue and marker of immune strength and response.	Total IgA: Adults = 85-463 mg/dL Children = 1-350 mg/dL Total IgG: <2.0 mcg/mL Total IgE = <10 IU/mL RAST IgE = <1 IU/mL low allergic risk Total IgM: Adults = 48-271 mg/dL Children = 17-200 mg/dL Total IgD = <15.3 mg/dL	NSAIDS, glucocorticoids, vitamin C, bioflavonoids can suppress the immunologic response and promote a false negative. IgA used as a biomarker reference of adequate immune response to enable measurement of IgG, IgE, IgM, IgD.
Innate Immune Factors				
TLC	Calculated from the percentage of lymphocytes reported in the hemogram and the WBC count. Units = cells/ μ l or cells/mm ³	Decreased in protein-energy malnutrition and immunocompromised state.	Normal: >2700 Moderate depletion: 900-1800 Severe depletion: <900	
Delayed Cutaneous Hypersensitivity	Anergy for antigens, such as mumps and <i>Candida</i> ; occurs in malnutrition; antigens intradermal injection; redness (erythema) and hardness (induration) read 1, 2, or 3 days later.	Response affected by protein-energy status and vitamin A, iron, zinc, and vitamin B ₆ deficiencies.	Induration 1+: <5 mm 2+: 6-10 mm 3+: 11-20 mm 4+: >20 mm Erythema present or absent	Usefulness in acute care limited by drugs, effect of aging and disease (metabolic, malignant, and infectious diseases); difficult to administer and interpret results; semiquantitative.
Cytokines	Serum or joint fluid proteins tested from venous blood. They include lymphocytes (T & B cells), monocytes, leukocytes (interleukins), eosinophils, interferon, and growth factors. (See Chapter 7.)	A group of immune reactant proteins that have many functions even from one cell to another. They respond to the environmental influences to communicate and orchestrate the immune response to protect from cancer, infection, and inflammation.	Cytokine examples: Interleukins: IL-1, IL-6, IL-8, IL-10, TNF- α , TH-1, TH-2 (per laboratory references)	
Adaptive Immune Factors				
Eosinophils (Eosinophil leukocyte)	Blood: BAL fluid CSF specimen to rule out eosinophilic meningitis.	Blood: Wide range of clinical conditions reflect nonspecific eosinophilia; elevated related to possible allergies, asthma, sensitivities, or cancers; particularly elevated eosinophils are found with intestinal parasites; noninfectious conditions.	Blood: 1% to 3% 50-500/mm ³ BAL negative for infection CSF <10 mm ³	Because of the nonspecific nature of blood eosinophilia, it can require further clinical investigation to determine the causal agent.

Food Intolerance/Sensitivity Panels				
ALCAT	Measurement of leukocyte cellular reactivity in whole blood, measures levels of mediators by blood cells presented with food or chemical antigens; measures relative changes in cell size.	Food and chemical non-IgE sensitivity (intolerance) testing for up to 350 foods plus gliadin/gluten, casein/whey, and <i>Candida albicans</i> ; food additives, molds, environmental chemicals, pharmacologic agents, and other suspected items upon request.	350 Foods: Acceptable Foods Normal = no response Mild intolerance Moderate intolerance Severe intolerance Candida/gluten-gliadin/casein-whey, chemicals/molds: No reaction mild, moderate, or severe reaction.	NSAIDS, glucocorticoids, vitamin C, bioflavonoids can suppress the immunologic response and promote a false negative. IgA used as a biomarker reference of adequate immune response.
MRT (immunologic food reaction test)	Untreated whole blood assay; sample is divided into 150 aliquots plus control samples and incubated with a precise dilution of pure extract of a specific food or food additive (see Chapter 25).	Non IgE-mediated reactions; measurement of blood components; blood specimen checked against the specific signs of cell-mediated reactivity to the antigen challenged (imminent or actual mediator release).	Normal = no response Mild, moderate, or severe reactions are delineated.	NSAIDS, glucocorticoids, vitamin C, bioflavonoids can suppress the immunologic response and promote a false negative. IgA used as a biomarker of adequate immune response.
Celiac Panel/ Gluten Sensitivity Panel	1. Immunologic and genomic for celiac or gluten sensitivity–related genes.	Measurements to identify a possible genetic or immunologic disease of the small bowel in response to exposure to gluten or gliadin molecules in diet. Continued long-term exposure to gluten or gliadin molecules leads to nutrient deficiencies and insufficiencies.	See celiac tests 2-10.	Any of the celiac tests 2-10 should be compared with baseline IgA serum levels and presence of immune suppressive medications to rule out IgA deficiency, which can skew test results to false negative because of compromised or suppressed immune response. Undiagnosed celiac is associated with increased incidence of all chronic diseases and shortened life span. ^{10,11,12}
	2. EMA	High specificity for celiac disease; may obviate need for small bowel biopsy for diagnosis; become negative on gluten-free diet.	EMA negative	Sensitivity/Specificity 90+%/95%
	3. tTG-IgA, tTG-IgG	Autoantigen of celiac disease, tTG is indicative of villous atrophy secondary to gluten exposure causing damage to GI small intestine villi. tTG negative test results indicate gluten-free diet compliance; marker of restoration of GI villi tight junctions and small bowel villi integrity.	tTG-IgA negative tTG-IgG negative	Sensitivity/specificity 98%/95% in adults; 96%/99% in children. Best age to begin measuring tTG is age 2-3 years. ¹³
	4. AGA IgA, AGA IgG	Positive results are evidence of immune response to the gliadin proteins in gluten-containing foods.	AGA IgA negative AGA IgG negative	Lowest sensitivity among celiac panel (70%-85%) and specificity (70%-90%) for celiac. Also useful for nonceliac gluten sensitivity.
	5. DGP	DGP antibodies improves ¹⁴ diagnostic accuracy for diagnosis of CD when tested with tTG; proteins present in the submucosa of affected person's bond to deamidated peptides to form molecular complexes that stimulate the immune system.	DGP negative	Specificity varied between 97.3% and 99.3%. Sensitivity of IgG anti-DGP significantly better than that of IgG anti-tTG (p < 0.05). Specificity was significantly better than IgA and IgG AGA. ¹⁵

Continued

6. Celiac genetic HLA haplotype HLA-DQ2 HLA-DQ8 Cellular assay/MLC to test HLA class II types	HLA-DQ2 and HLA-DQ8 positive indicates a low positive predictive value but a very high negative predictive value for celiac disease. Higher prevalence of CD in patients with type 1 DM or autoimmune thyroid disease (2%-4%) than in general population.	Genotype: HLA DQ2 negative HLA DQ8 negative	More than 97% of individuals with celiac disease share the two HLA markers DQ2 and DQ8, which have high sensitivity and poor specificity. One of the markers can increase possible nonceliac gluten sensitivity (e.g., type 1 DM DQA1*0501:DQB1*0201 haplotype). ^{14,15,16}	
7. Wheat/gluten proteome reactivity & autoimmunity	Functional medicine serum laboratory tests to broaden the view of celiac and gluten sensitivity by assessing antibody production against an array of protein, enzyme, and peptide antigens; includes <i>glutens</i> , <i>lectins</i> , <i>opioids</i> , and the enzyme <i>glutamic decarboxylase</i> (GAD65) IgG, IgA. Available from https://www.cyrexlabs.com .	ELISA Index Wheat IgG 0.30-1.30 mcg/mL IgA 0.40-2.40 mg/dL Agglutinin IgG 0.30-1.50 mcg/mL IgA 0.90-1.90 mg/dL Alpha Gliadin 17 MER IgG 0.30-1.50 mcg/mL IgA 0.60-2.00 mg/dL Alpha Gliadin 33 MER IgG 0.30-1.40 mcg/mL IgA 0.60-1.80 mg/dL Gamma Gliadin 15 MER Omega Gliadin IgG 0.50-1.60 mcg/mL IgA 0.60-1.80 mg/dL Glutenin IgG 0.20-1.50 mcg/mL IgA 0.50-1.70 mg/dL Gluteomorphin IgG 0.30-1.50 mcg/mL IgA 0.60-1.80 mg/dL Prodynorphin IgG 0.40-1.70 mcg/mL IgA 0.60-1.80 mg/dL GAD65 IgG 0.40-1.30 mcg/mL IgA 0.80-1.50 mg/dL	Enhances clinical sensitivity and specificity in detection of celiac and gluten sensitivity reactions.	
8. Gluten-associated cross-reactive foods and foods sensitivity IgG + IgA combined Cow's milk Alpha-casein & beta-casein Casomorphin Milk butyrophilin American cheese Chocolate (Others available)	Functional medicine serum laboratory tests to assess IgG and IgA immune antibody reactions to known cross-reactive food antigens, with the most common being casein. Other foods included are sesame, hemp, rye, barley, wheat, buckwheat, sorghum, millet, spelt, amaranth, quinoa, yeast, tapioca, oats, coffee, corn, rice, potato.	ELISA Index: IgG & IgA combined 0.20 mcg/mL /0.40 mg/dL -1.80 mcg/mL/ 2.00 mg/dL	Assists further dietary evaluation for celiac or gluten sensitive individuals that are nonresponsive to a gluten-free diet; can relate to gut dysbiosis and continued GI inflammation. Available from https://www.cyrex-labs.com .	
III. Tests of Carbohydrate Absorption Lactose Intolerance				
Hydrogen Breath Test for Lactose (HBT- lactose)	Lactose loading (2 g/kg) in lactase deficiency allows bacterial metabolism of lactose with production of H ₂ gas. Breath analyzed for H ₂ by gas chromatography.	Breath H ₂ measured fasting and 0.5 and 2 hours after dosing with lactose; a significant increase is associated with malabsorption.	Normal increase: <50 parts/million (i.e., <50 ppm) Lactose intolerance: 50 ppm or greater	Bacterial overgrowth can cause false-positive results; consumption of soluble fiber or legumes and smoking are associated with H ₂ production; false-negative results caused by antibiotics.

Lactose Tolerance Test	Lactose loading (50 g) followed by blood sampling at 5, 10, 30, 60, 90, and 120 min after dose; glucose produced from lactose is assayed.	Lactase deficiency associated with <20 mg/dL increase in serum glucose.	Normal serum glucose Lactose increase >20 mg/dL	Test is not specific (many false positives) or sensitive (many false negatives).
Fructose Intolerance				
Hydrogen Breath Test-Fructose (HBT-fructose)	An assessment for the change in the level of hydrogen and/or methane gas is diagnostic for fructose malabsorption.	HBT-fructose can be used to diagnose a mutation in the aldolase B gene. If hereditary fructose intolerance, may result in GI symptoms and hypoglycemia.	Normal increase <20 parts/million (<20 ppm) Positive HBT-fructose >20 parts per million (>20 ppm)	Positive test results indicate probable benefit of a fructose-restricted diet; research supports use in abdominal pain, IBS, gout.
Fructose Sensitivity	Blood lymphocyte specimen grown with a mitogen to measure growth by incorporating tritiated radioactive thymidine into the DNA of the cells. A functional test of fructose metabolism.	Functional intracellular metabolic test of possible genetic errors compromising fructose metabolism like fructose-6-phosphate.	>34% patient's growth response test media measured by DNA synthesis compared with optimal growth observed in 100% media (valid for male and female of 12 years or older)	Rule out fructose sensitivity in hypoglycemia of unknown etiology, overweight, obesity.
IV. Tests of Lipid Status				
Lipids				
CHOL, Total Serum or Plasma	CHOL is enzymatically released from cholesterol esters; fasting test.	Total CHOL correlated with risk for cardiovascular diseases.	AHA/ACC/NHLBI 2014 Guidelines do not have target levels for CHOL. Generally <200 mg/dL is desirable (see Chapter 32).	CHOL measurements have considerable within subject variability. May partly result from variability in specimen collection or handling.
HDL-c	LDL-c (and VLDL-c) are precipitated from the serum before measurement of residual HDL-c particle size; direct measurement of HDL-c is now done in some laboratories.	HDL-c is called "good cholesterol" to indicate that it is protective against atherosclerotic vascular development.	Generally levels should be above 40 mg/dL. The higher the better.	Some precipitation methods cause underestimation of HDL; HDL can be divided into classes: HDL ₁ , HDL ₂ , and HDL ₃ ; elevated HDL ₃ correlates with risk of CVD.
LDL-c	LDL-c is estimated by the Friedewald formula, LDL-c = total CHOL – HDL-c – TG/5, or by new direct assays. Available lipid particle size testing examples: https://www.privateMDLab.com (VAP Lipid Profile) https://www.BerkeleyHeartLab.com	LDL-c is called "bad cholesterol" to indicate that it is a positive risk factor for CVD. See NCEP guidelines in Chapter 32. LPP size: Pattern B (small, dense LDL-c) is associated with increased risk of CHD and is responsive to diet. Pattern A (larger, buoyant LDL) is not associated with risk. LPP are not recommended in new ATP4.	Generally, below 130 mg/dL is considered desirable.	Calculation only valid when TG concentration is <400 mg/dL, cannot be determined in nonfasting serum or plasma. Direct assay methods preferred.
TGs	Lipases release glycerol and fatty acids from TGs.	The association of TGs and CHD has been shown. Elevated TG increases blood viscosity.	<150 mg/dL normal >500 mg/dL high	Fasting specimen is essential; sugar concentrated foods and alcohol ingestion can increase TG level; some anticoagulants may affect TG level; carnitine-dependent fatty acids synthesis.
Fat Malabsorption				
Fecal Fat Screening	Microscopic inspection of fat-stained (Sudan stain) specimens for the presence of lipid droplets.	Trained observers are able to identify excessive fat in ~80% of persons with fat malabsorption.	Qualitative results	Patient must be consuming sufficient fat for analysis to reveal malabsorption. Semiquantitative.

Continued

PT	Fat malabsorption decreases absorption of fat-soluble vitamins A, E, D, K, beta-carotene; low vitamin K levels impair coagulation, causing a prolonged PT (also can be called international normalized ratio [INR]).	A prolonged PT is a relatively sensitive but nonspecific indicator of the fat-soluble vitamin K from fat malabsorption.	10-15 sec INR: 0.8-1.1 Possible critical value: >20 sec INR: >5.5	Tests affected by oral anticoagulants and other drugs, reduced platelet count, acquired and hereditary bleeding diseases, and liver disease PT.
Quantitative Fecal Fat Determination	Patient must consume 100 g fat/day (4-8 oz whole milk/day, and 2 Tbsp vegetable oil/meal/day) for 2 days before collection.	Quantitative 72-hour stool collection required for accurate assessment; average daily discharge used for interpretation.	Normal: <5 g fat/24 hr Malabsorption: >10 g/24 hr	Failure to adhere to the diet invalidates the results.
Vitamin A, D, E, K	See V. Tests of Micronutrient Status.			
Fatty Acid Analysis	Whole blood or RBC levels of ALA (C18:3n3) and LA (C18:2n6) reflect essential fatty acid status; also, complex relationships regarding fatty acid analysis are related to neurologic and inflammatory diseases, cell membrane dysfunction and genetic disorders. ^{17,18}	RBC fatty acid shown to be associated with fatty acid tissue composition. Plasma fatty acid levels are associated with dietary fat or supplement intake or fat digestion and absorption.	AA/EPA = 1.5-3.0 = Normal AA/EPA = High Risk >15 Omega-3 (EP+DHA) Index Risk: Index <2.2 High Index 2.2-3.2 Moderate Index >3.2 Low Omega-6/Omega-3 Ratio 5.7-21 EPA/AA Ratio </= 0.2 AA 520-1490 nmol/mL 5.2-12.9% EPA 14-100 nmol/mL 0.2-1.5% DHA 30-250 nmol/mL 0.2-3.9% GLA 16-150 nmol/mL Omega-6:omega-3 optimal between 1:1 and 4:1.	Is not specific for risk of atherosclerotic disease; inflammation influences this fatty acid test. Likely causes are minor injuries, trauma, and bacterial infections, periodontal/cavitations, orodental disease, ¹⁹ <i>Chlamydia pneumoniae</i> , ²⁰ dietary fats, and central adiposity. ²¹
V. Tests of Micronutrient Status				
A. Vitamins				
Thiamin (B ₁) ^c	Thiamin status is usually assessed by measuring the amount of TPP needed to fully activate the RBC enzyme transketolase.	The TPP needed to fully activate transketolase is inversely related to B ₁ status; percent stimulation by TTP.	Normal: 70-200 nmol/L (for individuals not taking (B ₁)) Stimulation >20% (index >1.2) indicates deficiency	Amount (and activity) of enzyme affected by drugs, iron, folate, or vitamin B ₁₂ status, malignant or GI diseases, and diabetes.
Riboflavin (B ₂)	Riboflavin status is assessed by measuring the amount of FAD needed to fully activate RBC enzyme GR.	The FAD needed to fully activate GR is inversely related to B ₂ status; percent stimulation.	% Stimulation >40% (index >1.4) indicates deficiency	Amount or activity of enzyme may change with age, iron status, liver disease, and glucose-6-phosphate dehydrogenase deficiency.
Niacin (B ₃)	Urinary excretion of N ¹ - NMN is decreased; <0.8 mg/day (<5.8 μmol/day) suggests a niacin deficiency.	Blood: Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). Niacin (nicotinic acid) is a water-soluble vitamin that is also referred to as vitamin B ₃ .	Nicotinic acid: 0.0-5.0 ng/mL Nicotinamide: 5.2-72.1 ng/mL	Niacin (nicotinic acid) is a water-soluble vitamin that is also referred to as vitamin B ₃ . Nicotinamide (nicotinic acid amide) is the derivative of niacin.

Pyridoxine (B ₆) ⁹ PLP (pyridoxal-5-phosphate) compounds	1. RBC enzymes, ALT (SGPT) or AST (SGOT), ⁹ are assayed for the presence of PLP as the enzyme's cofactor.	1. Difference between enzyme activities before and after addition of PLP is inversely related to B ₆ status.	1. % ALT stimulation of >25% or AST activity of >50% in deficiency.	1. Disease and drugs that affect the liver and heart, and pregnancy confound interpretation.
	2. Plasma PLP can be directly measured by HPLC with fluorescence detection.	2. PLP is major transport form of B ₆ ; therefore serum levels reflect body stores.	2. Normal: 0.50-3.0 mcg/dL (20-120 nmol/L) Male: 5.3-46.7 µg/L Female: 2.0-32.8 µg/L	2. Deficiency may be seen clinically before plasma PLP levels decrease.
	3. Trp load test, measures excretion of the PLP-dependent metabolite XA. 24-hour urine collection required.	3. Functional test indicating marginal vitamin B ₆ status when the levels of urinary XA decrease significantly following the ingestion of 3-5 g of L-Trp.	3. Marginal status: Level of urinary XA decreases <50 mg/24 hr	3. Steroid drugs and estrogen enzyme activity and some drugs cause analytic errors. Trp load test most sensitive and responsive to functional adequacy of B ₆ .
Folate ⁹	1. Because of ↓ DNA synthesis, large RBCs are produced. See Chapter 31.	1. Deficiency leads to increase in MCV and macrocytic RBCs.	1. Normal: MCV 80-100 fL	1. Not sensitive or specific for folate. Possible involvement with B ₆ , B ₁₂ , SAME, and other cofactors in the methionine pathway.
	2. Shape of neutrophil nucleus affected by folate deficiency.	2. Increased neutrophil lobe count seen in folate deficiency.	2. Normal: < or equal 4 lobes per neutrophil	2. Lobe count sensitive but not specific.
	3. Blood folate levels can be directly measured by radioimmunoassay.	3. Both RBC and serum folate are indicators of body stores.	3. 2-10 mcg/L serum; 140-960 ng/L RBC (3.2-22 nmol/L)	3. Plasma from nonfasting subjects may reflect recent intake; RBC folate is not measured accurately.
	4. Functional folate status assayed by FIGLU in 24-hour urine or after oral histidine loading.	4. After 2-15 g loading dose, 10-50 mg of FIGLU should be excreted in 8 hours.	4. Normal: <7.4 mg/24 hours (<42.6 mmol/24 hr) without loading	4. FIGLU affected by vitamin B ₁₂ , drugs, liver disease, cancer, tuberculosis, and pregnancy.
	5. SNPs MTHFR 677C, MTHFR 1298C	5. SNPs of compromised methylation (transfer of methyl groups in metabolism) potential in use and conversion of folate or folic acid intracellularly. See Chapter 6.	MTHF 677C/1298C Normal = Wild type -/-	Other SNPs are known that affect methylation metabolism: COMT, CYP1B1, and other cytochrome enzymes. See Chapter 6.
	6. Homocysteine (Hcy)	Hcy level is an independent risk factor for CVD, venous thrombotic disease, and other diseases; folic acid and vitamins B ₁₂ and B ₆ reduce plasma Hcy levels. Total Hcy (oxidized + reduced forms) is an intermediate amino acid in methionine metabolism.	Normal: 4-14 mmol/L Suggested optimal levels: 4-7 mmol/L	Cardiovascular event risk is increased even at slightly elevated levels. Hcy has a strong association with degenerative neurologic conditions like Parkinson's disease and dementias. Hcy suggests poor methylating capacity of client with need for increased intake of folic acid, B ₆ , B ₁₂ , and SAME.
Cobalamin (B ₁₂)	1. Because of low B ₁₂ resulting in decreased DNA synthesis, large RBCs are produced.	1. Deficiency leads to increase in MCV.	1. Normal: MCV 80-100 fL	1. Not sensitive or specific for B ₁₂ .
	2. Shape of neutrophil nucleus is affected by B ₁₂ deficiency.	2. Increased neutrophil lobe count in B ₁₂ deficiency.	2. Normal: < or equal 4 lobes per neutrophil	2. Lobe count sensitive but not specific.
	3. B ₁₂ can be directly measured by radioimmunoassay.	3. Levels <150 ng/L indicate deficiency (age affects level).	3. 160-950 pg/mL (118-701 pmol/L)	3. Marginal deficiency not correlated with level.
	4. MMA excretion reflects a functional test of B ₁₂ availability for BCAA metabolism.	4. MMA excretion >300 mg/24 hr in B ₁₂ deficiency. Sensitive test without being overly specific.	4. Normal excretion: 5 mg/24 hr (42 mmol/24 hr) Serum MMA - 0.08-0.56 mmol/L (Normal < 105 ng/mL)	4. Specific for B ₁₂ but requires normal BCAA levels; available at most laboratories.
	5. Schilling test for intrinsic factor and B ₁₂ absorption assesses radiolabeled B ₁₂ absorption as reflected by urinary excretion.	5. Abnormal B ₁₂ absorption indicated by excretion <3% of B ₁₂ radioactivity per 24 hours.	5. Normal excretion: ~8% of radioactivity per 24 hours	5. Test must be repeated with oral administration of IF to differentiate IF deficiency and malabsorption. Rarely used because of necessity of radioactive B ₁₂ .

Continued

Ascorbic Acid (vitamin C)	Plasma or leukocyte vitamin C measured by (1) chromatography; (2) by ascorbate oxidase; (3) spectrophotometrically by reaction with 2,4-dinitrophenylhydrazine.	Leukocyte C is less affected by recent intake, but plasma levels in fasting person parallel leukocyte levels; plasma preferred for acutely ill patients because leukocyte level is affected by infection, ²² some drugs, and hyperglycemia.	Normal: 0-11 months: Not established 1-12 years: 0.2-2.3 mg/dL 13+ years: 0.2-2.0 mg/dL (30-80 mmol/L) Adult: 0.2-1.5 mg/dL (12-90 mmol/L) Leukocyte vitamin C: 20-50 mcg/10 ⁸	Blood samples must be carefully prepared for assay to prevent vitamin C breakdown. Oxalate, glucose, and proteins interfere with some assays; recent intake can mask deficiency.
Retinols (vitamin A)	Serum retinol and retinol esters; functional tests (e.g., dark adaptation) only detect severe deficiency; age and sex are important determining factors for normal retinol levels.	Retinol levels <20 mcg/dL (<0.7 mmol/L) indicate severe deficiency; specific levels are being determined for placental/newborn deficiency serum levels.	Normal: 20-100 mcg/dL (0.7-3.5 mmol/L) Suboptimum (NHANES II/ Gibson): Age 3-11 y: < 0.35 mmol/L Age 12-17 y <0.70 mmol/L Age 18-74 y 0.70-1.05 mmol/L Pregnancy 0.79-1.91 mmol/L Upper Limit: 3.5 mmol/L	Exposure of serum to bright light or oxygen destroys vitamin A; low RBP level is associated with low vitamin A, zinc, and iron (see protein-energy section). Vitamin A's gene transcription is on the nuclear RXR; ²² the vitamin D receptor forms a heterodimer, requiring balance between vitamins A and D for optimum function.
Carotenoids (CARO)	CARO, fat-soluble pigments in plant foods, poorly absorbed in fat malabsorption; light sensitive; transport specimen in amber transport tube; quantitative spectrophotometry testing.	A CARO level of less than 50 mg/dL is seen in ~85% of patients with fat malabsorption.	50-200 mcg/dL (0.74-3.72 mmol/L)	Decreased CARO levels or low spectrophotometry score are also seen in those with low vegetable and fruit diets (e.g., in PN or tube feeding), liver failure, celiac disease, cystic fibrosis, human immunodeficiency virus, and some lipoprotein disorders.
Tocopherols (vitamin E)	Serum alpha- and beta-gamma tocopherols serve different antioxidant functions. Growing evidence that beta and gamma tocopherols may be more important than alpha-tocopherol for human vitamin E nutrition.	Lower values found in infants. Interpretation requires monitoring lipid levels; if hyperlipidemia calculate plasma alpha-tocopherol: cholesterol mmol/L ratio <2.2 or alpha-tocopherol <5 mg/L indicates risk of vitamin E deficiency. ²³	Normal: alpha-tocopherol 5.7-20 mg/L beta-gamma tocopherol 4.3 or less mg/L	Plasma level depends on recent intake and level of lipids, especially TGs, in blood. Smoking and BMI also negatively affect tocopherol levels.
Cholecalciferol (D ₃) and (D ₂) ergocalciferol	1. Alkaline phosphatase activity reflects level of bone activity and indirectly vitamin D status (see further discussion of ALP in Liver Enzymes section).		1. Adult: 25-100 U/L Child 1-12 yr: <350 U/L	1. Not specific, but a sensitive indicator; serum Ca and PO ₄ should also be evaluated. Zinc and B ₁₂ are rate-limiting cofactors for production of alkaline phosphatase, therefore low levels of < 40 U/L suggest possible zinc or B ₁₂ or intrinsic factor insufficiencies.
	2. Cholecalciferol (D ₃ 25-OH-D) and ergocalciferol (D ₂ 25-OH-D).	2. <20 ng/mL (<50 nmol/L) indicates deficiency; >200 ng/mL (500 nmol/L) indicates hypervitaminosis D.	2. 30-100 ng/mL (75-250 nmol/L)	2. Best indicator of status (liver stores), but marginal levels are hard to interpret. ²⁴ Increased BMI and body fat % may reduce serum D ₃ 25-OH-D.
	3. Calcitriol (1,25[OH] ₂ D ₃)	3. Used to show that vitamin D metabolism is occurring normally; active vitamin D to signal nuclear RXR receptor.	3. 2.5-4.5 ng/dL (60-108 pmol/L) (little seasonal change)	3. Poor indicator of status because of tight control of synthesis independent of body stores.

25-hydroxyvitamin D (25-OH-D)/ Calcifediol/ Calcidiol	Prohormone vitamin D malabsorption can lead to secondary malabsorption of calcium. Vitamin D supplementation can lead to increased absorption of calcium and phosphorus; supplementation contraindicated for individuals with kidney or gall stones, sarcoidosis, tuberculosis, lymphoma, or when hypercalcemic with vitamin D supplementation.	Vitamin D insufficiency is defined as the lowest threshold value for plasma 25-OH-D that prevents secondary hyperparathyroidism, bone turnover, bone mineral loss, or seasonal variations in plasma PTH.	25-OH-D: 30-100 ng/mL (85-160 nmol/L) Deficiency: <20 ng/mL (<50 nmol/L (laboratory references vary per individual laboratory)	Available at all laboratories. If elevated serum calcium, further evaluation recommended by testing vitamin 1,25 D-OH, PTH, ionized or free calcium, vitamin A retinol, and osteocalcin (as a vitamin K2 marker) before supplementation.
Phylloquinone (K ₁) and Menaquinone (K ₂) Mena-dione (K ₃)	Normal coagulation factor synthesis requires K ₁ ; PT assesses coagulation status. K ₂ primarily involved with calcium metabolism, including bone health.	In K ₁ deficiency, PT increases with increasing production of abnormal coagulation factors. ^h K ₁ vegetable plant source; drug-nutrient interaction with blood thinners. K ₂ animal and bacterial fermented sources. K ₃ synthetic form of Vitamin K; vitamin precursor to Vitamin K ₂ known as a provitamin.	K ₁ : 0.13-1.19 ng/mL (0.29-2.64 nmol/L) K ₂ : (not commercially available—see K ₂ marker, Osteocalcin, below)	The level of vitamin K available for vitamin K-dependent bone proteins may not be reflected by the PT; test references vary significantly with method.
OC/ucOC (K ₂ marker)	Serum noncollagenous protein specific for bone and dentin formation and turnover. Functional marker of vitamin K ₂ , a rate-limiting cofactor of formation of osteocalcin. One of the osteocalcin fragments, undercarboxylated osteocalcin, is most sensitive K ₂ marker and associated with risk of fracture.	Can be used as a marker of metabolic trend, suggesting low or high vitamin K ₂ ; useful in assessing need for a vitamin K ₂ -rich diet or K ₂ supplementation to optimize formation of intracellular bone osteocalcin. K ₂ inhibits soft tissue calcification. OC and ucOC are considered more sensitive markers of bone activity than alkaline phosphatase during corticosteroid therapy.	OC: 11-50 ng/mL ucOC: Normal <1.65 ng/mL High >1.65 ng/mL NOTE: Elevated levels associated with low 25-OH-D levels	Vitamin K ₂ is not as involved with coagulation as K ₁ . Vitamin K ₂ is important in calcium metabolism and therefore calcium and vitamin D status. There is a synthetic vitamin K ₃ , usually administered IV that has similar actions as K ₂ , and is being used as adjunctive to integrative cancer therapy.
B. Minerals				
Electrolytes				
Sodium (Na ⁺) Potassium (K ⁺) Chloride (Cl ⁻) Bicarbonate or total CO ₂	Serum electrolytes, including bicarbonate, are usually measured together by ion-specific electrodes in autoanalyzers; sometimes Na and K are measured by flame emission spectrophotometry. ⁱ	Elevated serum Na seen in water loss; decreased serum Na and K occurs in diarrhea and with poor dietary intake or cellular uptake. Decreased chloride levels are seen with cation and osmotic changes in the body. Bicarbonate levels reflect acid-base balance.	Na: 135-145 mEq/L (135-145 mmol/L) K: 3.5-5 mEq/L (3.5-5 mmol/L) Cl: 100-110 mEq/L (100-110 mmol/L) Bicarb or total CO ₂ : 21-30 mEq/L (21-30 mmol/L)	Electrolytes change rapidly in response to changes in physiology (e.g., hormonal stimulus, renal and other organ dysfunction, acid-base balance changes, and drug action). Serum electrolytes are minimally affected by diet.
Major Minerals				
Calcium (Ca ²⁺)	1. Total serum Ca ²⁺ (bound and unbound)	Usually slightly more than half of the serum Ca ²⁺ is bound to ALB or complexed with other molecules; the remaining Ca ²⁺ is called <i>ionized Ca (ICA)</i> ; ICA is available physiologically. Elevated IgE and mast cell release increases intracellular calcium ion levels and negatively distributes ICA.	1. 8.6-10 mg/dL (2.15-2.5 mmol/L)	Calcium status is related to many factors, including vitamin D, vitamin K ₂ , phosphate, parathyroid function, renal function; medications (thiazide diuretics, lithium), vitamin A toxicity, presence of malignancy.

Continued

	2. Ionized (free) Ca ²⁺	Interpretation of ionized calcium levels requires consideration of other related markers: osteocalcin, vitamin D25-OH-D and D1,25-OH-D, and serum retinol (vitamin A).	2. 4.64-5.28 mg/dL (1.16-1.32 mmol/L)	Ionized calcium depends on vitamin K ₂ to enter the bone matrix and to prevent calcification of soft tissue. If phosphate <3.0 mg/dL, check intake of phosphate-binding medications.
Phosphate (H ₂ PO ₄ , Phosphorus)	Phosphorus in body as phosphate form; test measures inorganic phosphate. Most phosphate is part of organic compounds; small part is inorganic.	Abnormal P level is most closely associated with disturbed intake, distribution, or renal function.	1. 7-4.5 mg/dL (0.87-1.45 mmol/L) (higher in children)	Reported as phosphorus (P), not phosphate; hemolyzed blood cannot be used because of high RBC phosphate levels.
Magnesium (Mg ²⁺)	1. Total serum Mg ²⁺ measured after reaction to form chromogenic or fluorescent complexes.	Neuromuscular function. Hyperirritability, tetany, convulsion, and electrocardiographic changes occur when levels of total serum Mg ²⁺ fall to <1 mEq/L.	1. 1.3-2.5 mEq/L (0.65-1.25 mmol/L)	Usually 45% of the serum Mg ²⁺ is complexed with other molecules; the remaining Mg ²⁺ is called ionized magnesium. Serum levels remain constant until body stores are nearly depleted.
	2. Ionized (free) Mg ²⁺		2. 0.7-1.2 mEq/L (0.35-0.60 mmol/L)	
Trace Minerals				
Iron CBC* and RBC indices	1. HCT = % RBC in whole blood 2. Hgb = blood hemoglobin concentration 3. MCV = mean RBC volume = mean corpuscular volume	A CBC with RBC indices is one of the first set of tests that a patient receives; although CBC data are not specific for nutrition status, their universal and repeated presence in the patient's record makes them very important.	1. Females: 35%-47% (0.35-0.47) Males: 42%-52% (0.42-0.52) 2. Females: 12-15 g/dL (7.45-9.31 mmol/L) Males: 14-17 g/dL (8.44-10.6 mmol/L) 3. 82-99 mm ³ (82-99 fL)	These tests are affected only when iron stores are essentially depleted. HCT and Hgb are sensitive to hydration status; low MCV also occurs in thalassemias and lead poisoning as well as with iron and copper deficiencies; high MCV suggests macrocytic RBCs and possible inadequate folate, vitamins B ₆ , or B ₁₂ .
Serum Iron (Fe)	Serum Fe ³⁺ reduced to Fe ²⁺ and then complexed with chromogen.	Slightly higher in males than in premenopausal females; reflects recent Fe intake.	F: 40-150 mcg/dL (7.2-26.9 mmol/L) M: 50-160 mg/dL (8.9-28.7 mmol/L)	Very insensitive index of total Fe stores; extremely variable (day-to-day and diurnal).
TIBC	TIBC determined by saturating serum transferrin with Fe and then remeasuring serum Fe.	Reflects transferrin concentration.	250-400 mcg/dL (45-71 mmol/L)	TIBC does not increase until Fe stores are essentially completely depleted. TIBC decreases with increased Fe stores; used to rule out excess iron intake or hemochromatosis. See Chapter 31.
Tf or TFN	The iron-bound globulin protein that responds to the need for iron; half-life ~9 days (see Chapter 5)	(see Section I:A. Protein Status: Tf)	Females: 250-380 mg/dL (2.15-3.80 g/L) Males: 215-365 mg/dL (2.15-3.65 g/L) Newborn: 130-275 mg/dL Child: 203-360 mg/dL	Transferrin is low when Fe stores essentially depleted. Transferrin is low with low vitamin B ₆ and low Tf-sat in aplastic anemia.
Tf-sat or TSAT	Tf-sat (%) = Serum iron level ÷ TIBC x 100%	(see Section I:A. Protein Status: Tf-sat)	Females: 15%-50% Males: 20%-50% Chronic illness - normal Tf-sat%. Late pregnancy low Tf-sat%.	
RDW	Measurement of variation in RBC diameter (anisocytosis); reported to be helpful in distinguishing Fe deficiency from anemia associated with chronic inflammation.	Very sensitive indicator of Fe status; normal RDW reportedly rules out anemia caused by chronic inflammatory diseases. ^m Thalassemia (low MCV, normal RDW) differentiated from iron-deficiency (low MCV, high RDW).	Normal value: 11.0-14.5% Microscopic electronic interpretation required.	Specificity of RDW for Fe deficiency is relatively low; interpretation confounded by RBC transfusion; measurement usually not reported.

Ferritin	The primary intracellular Fe storage protein; stored mostly in liver; serum levels parallel iron stores.	Best biochemical index of uncomplicated iron deficiency or overload (iron toxicity) and excess storage. Rule out hemochromatosis or pancreatitis if Ferritin >1000 ng/dL (>1000 mcg/L).	Iron overload: >400 ng/mL (mcg/L) With anemia of chronic disease: <100 ng/mL (<100 mcg/L) F: 10-150 ng/mL (10-150 mcg/L) M: 12-300 ng/mL (12-300 mcg/L) Females with anemia of chronic disease: <20 ng/mL (<20 mcg/L) 6 mo-15 yr: 7-142 ng/mL (7-142 mcg/L) <1 mo-5 mo: 50-200 ng/mL (50-200 mcg/L) Newborn: 25-200 ng/mL (25-200 mcg/L)	A positive acute phase reactant that increases during metabolic response to injury, even when Fe stores are adequate; not useful in anemia of chronic and inflammation diseases.
Zinc (Zn) ¹⁰	Serum levels measured by atomic absorption spectrophotometry.	Serum levels affected by diet and the inflammatory response. Zn deficiency associated with many diseases and trauma.	0.7-1.2 mg/L (11-18 mmol/L)	Serum levels detect frank—but not marginal—deficiency; blood must be collected in Zn-free tubes.
Copper (Cu)	1. Serum levels measured by flame emission atomic AS or ICP/MS. 2. Ceruloplasmin is the major Cu-bound containing plasma protein; measured by immunoassay (e.g., nephelometry).	1. Cu deficiency is associated with neutropenia, anemia, and scurvy-like bone disease and megadoses of Zn (excess Zn suppresses Cu blood and tissue levels). 2. Ceruloplasmin is required for conversion of Fe ³⁺ to Fe ²⁺ during cellular Fe uptake. Anemia and/or neutropenia can result from low ceruloplasmin. Ceruloplasmin is useful biomarker to follow TM copper chelation for Wilson's Disease (ATP7B gene mutation) and cancer antiangiogenesis copper chelation therapy. ²⁵	Adult: 85-150 mcg/dL (13.4-23.6 μmol/L) 27-50 mg/dL (1.5-2.8 mmol/L)	1. Serum levels detect frank but not marginal deficiency; use of oral contraceptives lowers serum Cu. 2. Ceruloplasmin not a useful marker of Cu status, but can be used to assess changes in status after supplementation; useful to calculate free Cu index with serum Cu and serum Zn as potential cancer biomarker.
Selenium (Se)	1. Serum Se test 2. Whole blood levels better reflect long-term status.	Margin between deficiency and toxicity is narrower for Se than any other trace component of the antioxidant enzyme element; important in glutathione peroxidase.	1. 80-320 mcg/L (1-4 mmol/L) 2. 60-340 mcg/L (0.75-4.3 mmol/L)	Cutoff points for deficiency or toxicity are not well established.
Iodine (I)	Urinary excretion is best indicator of I status, either mcg/24 hr or mcg/g creatinine; thyroid hormone level related to I status. Urine test can use 50 mg I/KI challenge.	Excretion should be 24-hour urine >70 mcg/g creatinine. It can be beneficial to test thyroid hormone and antibodies (TSH, T ₃ -free, T ₄ -free, thyroid peroxidase, and thyroglobulin antibodies) for improved interpretation. I important for other metabolic functions.	No urinary I reference range; T ₄ reference range: F: 5-12 mcg/dL (64-154 mmol/L) M: 4-12 mcg/dL (51-154 mmol/L)	Thyroid hormone levels are affected by many factors besides iodine status. Other halogen elements (Br ⁺ , F ⁺ , Cl ⁺) are known antagonists to iodine metabolism; when completing the iodine urine testing, some laboratories will also test for bromine, fluorine, and chlorine.

Continued

Creatinine (Cr)	Urinary excretion usually tested by atomic absorption spectrophotometry.	Excretion should be 0.63-2.50 g/24 hr; deficiency reported in patients on long-term PN; decreased levels in diabetes mellitus.	10-200 ng/dL (1.9-38 nmol/L)	Test not available in most clinical laboratories; special handling required to prevent specimen contamination during collection.
VI. Blood Gases and Hydration Status				
pH	$\text{pH} = -\log [\text{H}^+]$; H^+ depends mainly on the CO_2 from respiration: $\text{CO}_2 + \text{H}_2\text{O} \rightleftharpoons \text{H}_2\text{CO}_3 \rightleftharpoons \text{HCO}_3^- + \text{H}^+$ Measured by ion-selective electrodes (like those found in common pH meters).	Acidosis: $\text{pH} < 7.35$ Alkalosis: $\text{pH} > 7.45$ pH compatible with life: 6.80-7.80	Whole blood: Arterial pH: 7.35-7.45 Venous pH: 7.32-7.42	Blood must not be exposed to air before or during measurement.
PO_2 and O_2 saturation (SaO_2)	Whole blood O_2 measured by oxygen electrode. $\text{PO}_2 =$ "pressure" contributed by O_2 to the total "pressure" of all the gases dissolved in blood. O_2 Content (CaO_2) = $\text{O}_2/\text{g SaO}_2 \times \text{Hgb (g/dL)} \times 1.34 \text{ mL} + \text{PaO}_2 \times (.003 \text{ mL O}_2/\text{mm Hg/dL})$ $\text{PaO}_2 = \text{FiO}_2(\text{PB}-47) - 1.2(\text{PaCO}_2)$	Affected by alveolar gas exchange, ventilation-perfusion inequalities, and generalized alveolar hypoventilation.	Arterial blood: PaO_2 : 83-108 mm Hg <40 mm Hg = critical value (gravely dangerous) O_2 saturation: 0.95-0.98 (95%-98%) Elderly = 95% Newborn = 40%-90%	Blood must not be exposed to air before or during measurement.
PCO_2	Measured by ion-selective electrode; "pressure" contributed by CO_2 to the total "pressure" of all the gases dissolved in blood.	Increased in respiratory acidosis (increased CO_2 in inspired air or decreased in alveolar ventilation) and decreased in respiratory alkalosis (e.g., in hyperventilation from anxiety, mechanical ventilator, or closed head injury [damaged respiratory center]).	Whole blood: Arterial F: 32-45 mm Hg M: 35-48 mm Hg Venous 6-7 mm Hg higher	Blood must not be exposed to air before or during measurement.
Bicarbonate (HCO_3^-) and total CO_2 (tCO_2)	For whole blood (HCO_3^-) is calculated from the equation given in pH section.	Increased in compensated respiratory acidosis and in metabolic acidosis; decreased in metabolic acidosis and in compensated respiratory alkalosis.	Whole blood, arterial: 21-28 mEq/L (21-28 mmol/L)	Blood must not be exposed to air before or during measurement.
Osmolality (Osmol), serum	Osmol depends on the amount of particles (solutes) dissolved in a solution; measurement based on relationship between solute concentration and freezing point; serum osmol assesses hydration status and solute load.	Serum Osmol increases in dehydration, diabetic coma, diabetic ketoacidosis; also estimated from the formula: $\text{mOsmol/L} = 2(\text{Na}^+) + (\text{Glucose mg/dL})/18 + (\text{BUN mg/dL})/2.8$	282-300 mOsm/kg H_2O (1 Osmol = 1 mol of solute particles; 1 kg serum/L)	Freezing point depression gives a more accurate estimate of osmol than the calculated value (e.g., in ketoacidosis).
Urinalysis: Sp.Gr.	Specimen midstream clean-catch if infection suspected, or regular collection. Dip Stick or laboratory testing for Sp.Gr.	One of a multiple of tests on a urine specimen. Sp.Gr. is a measure of concentration of particles and electrolytes in the urine.	Adult: 1.005-1.030 Sp.Gr. Newborn: 1.001-1.020 Sp.Gr.	Appearance can also give subjective indication of fluid concentration; darker color = higher concentration.
VII. Tests of Antioxidant Status and Oxidative Stress				
Water-Soluble Compounds	See Vitamin C above.			
Lipid-Soluble Compounds:	The carotenoids: lutein, xanthine zeaxanthin, alpha- and beta-carotene, and lycopene; carotenoids and coenzyme Q_{10} (ubiquinone-10) are measured chromatographically.	Reference ranges for these compounds vary greatly, depending on the method used for their assay.	See reference for carotenoid range under fat malabsorption.	Tests for carotenoids and coenzyme Q_{10} are not yet available for routine clinical use.

Total Antioxidant Capacity (e.g., ORAC, TEAC, FRAP)	ORAC: Oxygen radical absorbance capacity TEAC: Trolox-equivalent antioxidant capacity FRAP: Ferric-reducing ability of plasma.	These assays reflect the presence of all of plasma or serum antioxidants, including vitamins C and E, carotenoids, coenzyme Q ₁₀ , glutathione, uric acid, bilirubin, superoxide dismutase, catalase, glutathione peroxidase, and ALB.		These assays are now commercially available but are currently performed only in specialized laboratories. Testing botanicals also available.
Oxidative Stress Markers:	Free radical oxidation products of lipids.	8-Isoprostane (also called 8-epi prostaglandin F _{2a}) increases in plasma or urine of patients with lung disease, hypercholesterolemia, or diabetes mellitus. 8HDG represents whole-body cytosolic and nuclear free radical activity, including status of DNA. Lipid peroxides is a marker of membrane oxidative damage by reactive oxygen species (ROS) to PUFAs of cell membranes.	Examples: o-tyrosine nitro-tyrosine 8-isoprostane 4-hydroxynonenal malondialdehyde Lipid Peroxides 8-hydroxy-2'-deoxyguanosine (8-OHDG) (refer to Laboratory references)	8-Isoprostane assays are now commercially available. Markers of oxidative stress are currently assayed only in specialized laboratories.
VIII. Tests for Monitoring Nutrition Support				
CRP (see section V. hs-CRP)	CRP is an acute-phase protein used to assess inflammatory status.	Large increases in CRP are associated with development of a catabolic state during the stress response; CRP levels begin to fall when the anabolic phase is entered.	CRP <10 mg/L	Serial values rather than a single value must be used to specify the stage of the stress response.
Chemistry Panel with Phosphate and Mg ²⁺	Panel includes electrolytes, glucose, creatinine, BUN, and total CO ₂ (bicarbonate); see earlier discussion for additional test information.	Used to monitor carbohydrate tolerance, hydration status, and major organ system function.	See earlier discussion on phosphate and magnesium.	Very frequently ordered test panel.
Osmolality	(See discussion in VII. Blood Gases and Hydration Status.)			
Protein-Energy Balance	(See earlier discussion on PAB, RBP, Tf, ALB, nPCR, nitrogen balance, UUN, and TUN.)			
Minerals: Zn, Cu, Se, Cr	(See earlier discussion of serum zinc, serum copper, ceruloplasmin, and lymphocyte micronutrient testing.)			
Vitamins C, D, and A	(See earlier discussion of vitamins C, D, and A) Because vitamins C, 25-OH-D, and A are important in immune function and wound healing, they should be assessed regularly.	Note regarding TPN nutritional monitoring: Vitamin C levels can ↓ sharply in response to stress. Vitamin D and A nuclear receptors share the same connection with the RXR receptor, which have synergistic function and should be monitored congruently. ^{27,28}		Note regarding TPN nutritional monitoring. Systematic, regular monitoring protocol should be followed. 25-OH-D is produced in the liver and can be suppressed with hepatic stress conditions. ²⁹
Vitamin K ₁ & K ₂ status	(TPN only) (see earlier discussion); contribution of the gut flora to vitamin K status is absent during TPN, and basic TPN formulas are devoid of it.			Important to differentiate between vitamin K ₁ and K ₂ .

Continued

IX. Liver Function Tests				
BILI T/D (Direct and Indirect)	Total serum bilirubin represents both conjugated or direct bilirubin, and unconjugated or indirect bilirubin. Elevated levels suggest medical problem.	Conjugated bilirubin levels are elevated with cancer of pancreas or liver and bile duct obstruction; unconjugated bilirubin level elevated with hepatitis and jaundice anemias	Total bilirubin: 0.3-1 mg/dL (5.1-17 mmol/L) Direct bilirubin: 0.1-0.3 mg/dL; (1.7-5.1 mmol/L) Indirect bilirubin: 0.2-0.8 mg/dL (3.4-12 mmol/L)	Many medications are associated with elevated bilirubin levels.
ALT	Enzyme found primarily in the liver (also called serum glutamic pyruvic transaminase [SGPT]).	Injury to the liver results in elevated levels of ALT. Depressed in malnutrition.	4-36 U/L Infant: 2 x adult levels	Many medications and alcohol intake are associated with elevated ALT levels. ALT levels are often compared with AST for differential diagnosis.
GGT	Biliary excretory enzyme involved in transfer of amino acids across cell membranes.	Used to evaluate progression of liver disease and screening for alcoholism.	F: 4-25 U/L M: 12-38 U/L	Many medications are associated with elevated GGT levels.
ALP	Enzyme found primarily in the bone, liver, and biliary tract; increased in an alkaline environment.	Elevated levels noted in liver and bone disorders.	30-120 U/L	Nonspecific test; other tests need to confirm diagnosis. Many medications are associated with elevated ALP levels.
AST	Enzyme primarily found in the heart, liver, and skeletal muscle cells (also called serum glutamic oxaloacetic transaminase [SGOT]).	Diagnostic tool when coronary occlusive heart disease or hepatocellular disease is suspected.	0-35 U/L	Many medications are associated with elevated AST levels. AST levels are often compared with ALT for differential diagnosis.
A1AT	A1AT is a serine protease inhibitor secreted primarily by hepatocytes. Most common genetic A1AT variants are ZZ, SS, MZ, SZ. Measured by serum electrophoresis.	Decreased or absent Alpha-1-band in serum electrophoresis; A1AT is an acute-phase reactant associated with emphysema, COPD, and cirrhosis of the liver; A1AT elevated with states of inflammation, infection, or malignancy.	85-213 mg/dL (0.85-2.13 g/L) Homozygous + + variants: severe disease early in life. 80 known variants of A1AT gene: heterozygous ZZ and SS gene variants: majority have hepatic or pulmonary symptoms MZ and SZ milder gene variants: rarely have symptoms. ^{o,p}	There are 100 known variants of the A1AT gene. ^{o,p} If a person is not diagnosed with a severe form as a child, an individual may not be identified until an adult with end-stage lung and liver disease.
X. Thyroid Function Tests				
Thyroxine Total T ₄ and free T ₄	Measures the total amount of T ₄ in the blood; free T ₄ is the active form. See Chapter 30.	T ₄ increased in hyperthyroidism; T ₄ decreased in hypothyroidism and malnutrition.	T ₄ , Total F: 5-12 mcg/dL; (64-154 nmol/L) M: 4-12 mcg/dL (51-154 nmol/L) Free T ₄ = 0.7-1.9 ng/dL (10-23 pmol/L)	Tests are ordered to distinguish between euthyroidism, or hyperthyroidism and hypothyroidism. Can be related to iodine deficiencies.
Triiodothyronine T ₃ Total and Free T ₃	Measures the total amount of T ₃ in the blood; free T ₃ active form. See Chapter 30.	Hyperthyroidism-usually elevated; hypothyroidism-usually decreased and can show low function of thyroid peroxidase enzyme when T ₄ normal or high, and T ₃ low (poor conversion).	Total T ₃ 20-50 yr: 70-205 ng/dL (1.2-3.4 nmol/L) >50 yr: 40-180 ng/dL (0.6-2.8 nmol/L) Free T ₃ : 230-619 pg/mL	Tests are ordered to distinguish between euthyroidism, or hyperthyroidism and hypothyroidism. If low T ₃ levels, consider insufficient nutrient cofactors (selenium, vitamin E) for thyroid peroxidase enzyme conversion of T ₄ to T ₃ .

TSH	Used to monitor exogenous thyroid replacement or thyroid suppression; also used as a screening test for thyroid function. See Chapter 30.	Decreased TSH in hyperthyroidism; elevated TSH in hypothyroidism	0.5-5 mIU/L AACE Standards: Target TSH: 0.3-3.0 µIU/mL ^o	Tests are ordered to distinguish between euthyroidism, hyperthyroidism, and hypothyroidism. If depressed, use caution with iodine intake. If elevated, consider assessing nutrient cofactors: iodine, selenium, and vitamins E and A.
anti-TG	Anti-TG blood test used as a marker for autoimmune thyroiditis and related diseases. ³⁰ High prevalence of thyroid autoantibodies in celiac and rheumatoid arthritis patients	Anti-TG autoantibodies bind to thyroglobulin and affect thyroid hormone synthesis, storage and release. Recommend investigation of gluten intolerance if elevated anti-TG.	Titer <4 IU/mL Anti-TG often tested in conjunction with anti-TPO test.	Resulting disordered thyroid function seen most with common related conditions: Hashimoto's thyroiditis and autoimmune hypothyroid.
Anti-TPO or TPO-AB	Anti-TPO blood test used in the diagnosis of thyroid diseases, such as Hashimoto's thyroiditis or chronic lymphocytic thyroiditis (in children). High prevalence of thyroid autoantibodies in celiac and rheumatoid arthritis patients.	Thyroid microsomal antibodies act on section of the microsome in the thyroid cell and initiate inflammatory and cytotoxic effects on the thyroid follicle. Recommend investigation of gluten intolerance if elevated anti-TPO.	TPO-AB <9 IU/mL Anti-TPO often tested in conjunction with Anti-TG test.	Most sensitive assay for antimicrosomal antibody. Nutritional considerations are vitamin E and selenium co-factors for production of TPO enzyme.
XI. Tests for Metabolic Disease				
Amino Acidurias	Dietary treatment is the major therapy for many of these genetic diseases: phenylketonuria, cystinuria, maple syrup urine disease, tyrosinemia, homocystinuria, Hartnup disease. See Chapter 42. Urine or plasma amino acid testing.	Monitoring amino acid level in urine or serum is necessary to assess adequacy of treatment.	Examples: Phe: 2-6 g/L (120-360 mmol/L) Phe (during pregnancy): 2-6 mg/dL (120-360 mmol/L) Cys: 2-22 g/L (10-90 mmol/L) Val: 17-37 g/L (145-315 mmol/L) Tyr: 4-16 g/L (20-90 mmol/L)	There are several methods used to measure (e.g., phenylalanine); these usually do not have exactly equivalent reference ranges.
Organic Acids Panel	Urine organic acids panel; home collection of 10 mL sample of nocturnal and first morning urine, frozen and then shipped to laboratory. ⁹	Sensitive, broad range test that evaluates comprehensive functional markers for metabolic nutrient pathway functions that can suggest early markers for risk of disease or metabolic imbalances.	(See particular laboratory references)	Excellent for overview of metabolic function and noninvasive pediatric testing.
Diabetes Mellitus (See Chapter 29)				
Prediabetes Diagnosis	FBG	Prediabetes, blood glucose levels are higher than normal but not high enough for a diagnosis of diabetes.	Nondiabetic FBG = <99 mg/dL Impaired fasting glucose: 100-125 mg/dL	American Diabetes Association recommends testing for prediabetes in adults without symptoms who are overweight or obese, and who have one or more additional risk factors for diabetes.
Diabetes Diagnosis	1. Serum or whole blood glucose: after fasting 8-16 hours or on a random blood sample.	1. Two or more FBG levels >126 mg/dL are diagnostic; random level >200 mg/dL followed by fasting level >126 mg/dL are diagnostic. Fasting levels of 110 to 126 mg/dL indicate IGT.		1. Elevated glucose levels normally appear with physiologic stress; whole blood gives slightly lower values.

Continued

	<p>2. Glucose tolerance test (GTT); 75 g glucose (100 g during pregnancy) given after fasting; serum glucose measured by before and five times during the next 3 hours after oral dosing. Glucose measured by automated chemistry procedure.</p>	<p>2. Serum levels FBG >200 mg/dL at 2-hour point is diagnostic; 2-hour level <140 and all 0- to 2-hour levels <200 are normal; 140-199 at 2 hours indicates IGT. Gestational diabetes: fasting >105; 1-hour GTT >190; 2-hour GTT >165; and 3-hour GTT >145 mg/dL.</p>	<p>2. Serum: Fasting: <110 mg/dL (<6.1 mmol/L) 30 min: <200 mg/dL (<11.1 mmol/L) 1 hour: <200 mg/dL (<11.1 mmol/L) 2 hours: <140 mg/dL (<7.8 mmol/L) 3 hours: 70-115 mg/dL (<6.4 mmol/L) 4 hours: 70-115 mg/dL (<6.4 mmol/L) Urine: glucose negative</p>	<p>2. Often used for confirmation; ambulatory patient only; bed rest or stress impairs GTT; inadequate carbohydrate consumption before test invalidates results.</p>
Diabetes Monitoring	<p>1. Blood glucose—monitoring requires that the patient monitor blood glucose level.</p> <p>2. Serum fructosamine—assesses medium-term glucose control by measured glycated serum proteins; currently testing available in the laboratory and home tests.</p> <p>3. Serum glycated hemoglobin or HgbA1C—assesses longer-term glucose control.</p> <p>4. Porphyrin urine or whole blood testing for dioxin,³² a toxin with significant association with promoting diabetes.</p>	<p>1. Tight diabetes control requires frequent monitoring of glucose levels.</p> <p>2. Allows assessment of average glucose levels for previous 2-3 weeks.</p> <p>3. Allows assessment of average glucose levels for previous 2-3 months and verification of patient's serum glucose log.</p>	<p>1. 70-99 mg/dL (3.9-5.5 mmol/L)</p> <p>2. Normal levels: 1%-2% of total protein Ranges vary according to method used.</p> <p>3. Normal levels: Nondiabetic: 4%-5.9% Good diabetic control: 4%-7% Fair diabetic control: 6%-8% Poor diabetic control: >8% Mean blood sugar 205 mg/dL or greater is associated with increased risk of side effects</p>	<p>A combination of glucose monitoring (by patient) and laboratory measurement of glycated proteins are needed to effectively monitor glucose control; fructosamine must be interpreted in light of plasma protein half-lives, and HgbA1C must be interpreted in light of RBC half-life. Department of Defense study (July 2005) 47% percent increase in diabetes among veterans with the highest levels of dioxin.³²</p>

A1AT, Alpha 1 antitrypsin; AA, arachidonic acid; AACE, American Association of Clinical Endocrinologists; A/C ratio, albumin/globulin ratio; AGA, antigliadin antibodies; AHA/ACC/NHLBI, American Heart Association/American College of Cardiology/National Heart, Lung, and Blood Institute; ALA, alpha linolenic acid; ALB, albumin; ALCAT, Antigen Leucocyte Cellular Antibody Test; ALP, alkaline phosphatase; ALT, alanine amino transferase; Anti-TG, antithyroglobulin antibody; Anti-TPO, antithyroid peroxidase antibody; AS, absorption spectrophotometry; AST, aspartate aminotransferase; BAL, bronchoalveolar lavage; BCAA, branched-chain amino acid; BILI T/D, Bilirubin Total/Direct; BMI, body mass index; BUN, blood urea nitrogen; CAPD, continuous ambulatory peritoneal dialysis; CARO, carotene, serum total; CBC, complete blood count; CD, cardiac disease; CHD, coronary heart disease; CHOL, cholesterol; COPD, chronic obstructive pulmonary disease; Cr, chromium; CRP, C-reactive protein; CSF, cerebrospinal fluid; CVD, cardiovascular disease; DGLA, dihomo-gamma-linolenic acid; DGP, deamidated gliadin peptide antibody; DHA, docosahexaenoic acid; DM, diabetes mellitus; DNA, deoxyribonucleic acid; DPI, dietary protein intake; DRI, dietary reference intake; DRT, diet readiness test; EDTA, ethylenediaminetetraacetic acid; EFA, essential fatty acid; ELISA, enzyme-linked immunosorbent assay; EMA, endomysium antibody; EPA, eicosapentaenoic acid; FAD, flavin adenine dinucleotide; FIGLU, formiminoglutamic acid; FBG, fasting blood glucose; FBS, fasting blood sugar; FPG, fasting plasma glucose; FRAP, ferric-reducing ability of plasma; GH, growth hormone; GI, gastrointestinal; GLA, Gamma-linolenic acid; GLOB, globulin; GOT, glutamic-oxalacetic transaminase; GPT, glutamic-pyruvate transaminase; GR, glutathione reductase; GTT, glucose tolerance test; GU, urea generation rate; HBT-lactose, hydrogen breath test-lactose; HBT-fructose, hydrogen breath test-fructose; HCT, hematocrit; Hcy, homocysteine; Hgb, hemoglobin; HDL, high-density lipoproteins; HLA, human leukocyte antigen; HPLC, high performance liquid chromatography; HRT, hormone replacement therapy; hs-CRP, high-sensitivity C-reactive protein; I, iodine; ICA, ionized calcium; ICP-MS, inductively coupled plasma/mass spectrometry; IF, intrinsic factor; Ig, immunoglobulin; IGF, insulin-like growth factor; IGT, impaired glucose tolerance; IV, intravenously; KrU, residual renal urea clearance; Kt/Vurea, urea kinetics(kinetic dialyzer) x time(min)/volume urea(mL); LA, linoleic acid; LDL, low-density lipoprotein; LPP, lipoprotein particle; MCV, mean corpuscular volume; MLC, mixed lymphocyte culture; MMA, methylmalonic acid; MRT, Mediator Release Test; N, nitrogen; NCEP, National Cholesterol Education Program; NMN, methylnicotinamide; NSAID, nonsteroidal antiinflammatory drug; nPCR, normalized protein catabolic rate; OC, osteocalcin; ORAC, oxygen radical absorbance capacity; PAB, prealbumin; PCR, protein catabolic rate; PEM, protein-energy malnutrition; PLP, pyridoxal phosphate; PN, parenteral nutrition; PNA, protein equivalent of nitrogen appearance; PP, post prandial; PT, prothrombin time; PTH, parathyroid hormone; PTT, partial thromboplastin time; PUFA, polyunsaturated fatty acid; RBC, red blood cell; RBP, retinol-binding protein; RDW, RBC distribution width; ROS, reaction oxygen species; RXR, retinoid X receptor; sALB, serum albumin; SAME, s-adenosylmethionine; SNP, single nucleotide polymorphism; SPGR., Specific Gravity;

T₃, triiodothyronine; T₄, thyroxine; T1DM, type 1 diabetes mellitus; TEAC, trolox-equivalent antioxidant capacity; Tf, transferrin; Tf-sat, transferrin saturation; TG, triglyceride; TIBC, total iron-binding capacity; TLC, total lymphocyte count; TM, tetrathiomolybdate; TP, total protein; TPN, total parenteral nutrition; TPP, thiamin pyrophosphate; Trp, tryptophan; TTR, transthyretin; TSAT, transferrin saturation; tTG, tissue transglutaminase; TUN, total urinary nitrogen; U: Cr, urea/creatinine ratio; ucOC, undercarboxylated osteocalcin; UKM, urea kinetic modeling; UUN, urea urinary nitrogen; VLDL, very-low-density lipoprotein; WBC, white blood cell; XA, xanthurenic acid.

^aFactor = 5.95 for TPN; reflects severity of metabolic stress.

^bFactor = 5.95 for TPN; reflects severity of metabolic stress; TUN gives the most accurate estimation of total protein catabolism.

^cRed blood cells are separated from plasma by centrifugation and washed with saline; after hemolyzing the cells, the intracellular material is analyzed for vitamin availability.

^dNo biochemical tests have been developed to assess B₃ status; the fraction of whole blood niacin as nicotinamide adenine dinucleotide (NAD) is a potentially useful test (see Powers HJ: Current knowledge concerning optimum nutritional status of riboflavin, niacin, and pyridoxine, *Proc Nutr Soc* 58:435, 1999).

^eALT and GPT are the same enzyme; AST and GOT are the same enzyme.

^fPLP is a rate-limiting coenzyme in the transamination of amino acids (ALT and AST). PLP found primarily in liver and muscles.

^gMicrobiologic growth assays, the deoxyuridine suppression test, and recently developed research tests for folate and vitamin B₁₂ are not generally offered in the contemporary clinical laboratory.

^hMore sensitive procedures for measurement of vitamin K include serum chromatography and determination of the serum level of vitamin K-dependent bone protein called osteocalcin. Deficiency significantly increases the amount of abnormal forms of this protein. These tests are not yet widely available.

ⁱThese substances are measured by similar techniques when the concentration in urine or other body fluids is determined.

^jThese tests are combined with serum glucose, creatinine, and BUN on a test battery or panel. This set of tests is among the first and most frequently administered laboratory tests.

^kThe CBC includes the red cell count, the red cell indices, Hgb concentration, HCT, MCV, mean cell hemoglobin (MCH), mean cell hemoglobin concentration (MCHC), and white cell and platelet counts. Only HCT, Hgb, and MCV are discussed here (see Savage RA: The red cell indices: yesterday, today, and tomorrow, *Clin Lab Med* 13:773–785, 1993).

^lRanges are for adult men and premenopausal women. Pregnant women, infants, and children have different reference ranges.

Nutritional Implications of Selected Drugs

Pharmacology is the study of drugs and their interactions in the body. An interaction between a drug, nutrient, or food can alter the effectiveness of a drug as it moves from its site of administration into the blood and to the target tissues. This is called a *drug-nutrient interaction* (DNI) when there are specific changes to the pharmacokinetics (absorption, distribution, metabolism, or excretion) of a drug caused by foods and nutrients. A drug may also cause a nutrient depletion—either by disrupting absorption or increasing the excretion of one or more nutrients. Older adults and those who take multiple medications (polypharmacy) are at the greatest risk. Additionally, those who take medications along with dietary supplements may also be at increased risk for a DNI.

Many medications also cause side effects such as gastrointestinal (GI) distress, blood sugar imbalance, appetite changes, weight gain or loss, or organ toxicity. They can also affect taste, smell, and hydration status. It is important to evaluate every drug and dietary supplement a client is taking in order to assess for potential DNIs and/or side effects. In many cases these can be minimized or avoided if the diet is modified. Examples include avoidance of certain foods (such as grapefruit with many drugs), limiting certain nutrients (such as tyramine

with monoamine oxidase [MAO] antidepressants and calcium with levothyroxine), or altering the timing of foods (taking drugs either with or without food).

Some drugs have added ingredients, known as *excipients*, that may cause a DNI or side effect, so all drug ingredients should be evaluated when a patient has symptoms. Examples of potentially interactive excipients include alcohol, caffeine, lactose, sorbitol, aspartame, tyramine, and sulfites. Lastly, some drugs contain nutritionally significant ingredients including minerals (calcium, magnesium, or sodium), sugars, and fats that may contribute to a patient's overall nutrient status.

WebMD Drug Interaction Checker

The following is a list of common drugs and their nutritional implications.

Drug	Drug Effect	Nutritional Implications and Cautions
Selected Antiinfective Drugs		
Antibacterial Agents		
Penicillins	Short-term use: diarrhea Long-term use: oral candidiasis, diarrhea, epigastric distress, <i>Clostridium difficile</i> . Pen VK 250 mg tab contains 0.73 mEq of potassium. Pen VK 500 mg tab contains 1.44 mEq potassium. Pen VK Suspension 125 mg/5 mg = 0.42 mEq potassium. Pen VK Suspension 250 mg/5 mL = 0.85 mEq potassium. Zosyn 2.25 g = 125 mg Na. Zosyn 3.375 g = 192 mg Na. Zosyn 4.5 g = 256 mg Na.	Use caution with low potassium diets or in patients with renal failure. Augmentin: take with food to ↓ GI distress. Replace fluids & electrolytes for diarrhea. Probiotic is advised.
Macrolides	May cause GI distress (are promotility agents, erythromycin >> clarithromycin >> azithromycin), anorexia, stomatitis, dysgeusia, or diarrhea. May increase sedative effect of alcohol. Grapefruit may increase erythromycin levels leading to cardiac conduction abnormalities. May cause <i>Clostridium difficile</i> .	Take with food to ↓ GI distress. Eat frequent, small, appealing meals to counteract anorexia. Use mouth rinses, fresh mint, or lemon water for dysgeusia. Replace fluids & electrolytes for diarrhea. Avoid alcohol. Avoid grapefruit with erythromycin. Probiotic is advised.

Continued

Drug	Drug Effect	Nutritional Implications and Cautions
Sulfonamide Combination <ul style="list-style-type: none"> sulfamethoxazole/trimethoprim (Bactrim) 	May interfere with folate metabolism, especially with long-term use. May cause stomatitis, anorexia, nausea and vomiting, severe allergic reactions. May inhibit aldehyde dehydrogenase or the elimination of acetaldehyde resulting in disulfiram-type reaction. May increase potassium levels (generally at high doses) and hypoglycemia (more common in the elderly). May cause <i>Clostridium difficile</i> .	Take with food and 8 oz fluid to ↓ nausea, vomiting, and anorexia. Replace fluids & electrolytes for diarrhea. Supplement folic acid as needed. Discontinue and consult physician at first sign of allergic reaction. Avoid alcohol. Use with caution in patients with potassium supplements or in renal failure. May potentiate hypoglycemia in diabetic patients. Probiotic is advised.
Cephalosporins First Generation <ul style="list-style-type: none"> cephalexin (Keflex) cefazolin (Ancef) Second Generation <ul style="list-style-type: none"> cefprozil (Cefzil) cefuroxime (Ceftin) Third Generation <ul style="list-style-type: none"> ceftriaxone (Rocephin) Ceftazidime (Fortaz) cefdinir (Omnicef) cefepodoxime (Vantin) Fourth Generation <ul style="list-style-type: none"> cefepime (Maxipime) 	May cause stomatitis, sore mouth and tongue, and may interfere with eating. May cause diarrhea and <i>Clostridium difficile</i> . Food ↑ bioavailability of tablets and suspension (cefuroxime). Antacids (H ₂ blockers and PPIs), may ↓ bioavailability, avoid combination. Some cefuroxime products contain phenylalanine.	Replace fluids & electrolytes for diarrhea. Eat moist, soft, low-salt foods and cold foods such as ice chips, sherbet, and yogurt for stomatitis and sore mouth. Probiotic is advised. Take with a meal for optimal bioavailability. Take separately from H ₂ blockers or proton pump inhibitors or avoid combination (cefuroxime). Probiotic may be advised. Take cefpodoxime with food.
Fluoroquinolones <ul style="list-style-type: none"> ciprofloxacin (Cipro) levofloxacin (Levaquin) moxifloxacin (Avelox) 	Drug will bind to magnesium, calcium, zinc, and iron, forming an insoluble, unabsorbable complex. May cause <i>Clostridium difficile</i> . Cipro: Inhibits metabolism of caffeine and can therefore ↑ CNS stimulation. Drug may rarely precipitate in renal tubules.	Limit caffeine intake with ciprofloxacin. Take 2 hours before or 6 hours after antacids, Mg, Ca, Fe, Zn supplements, or multivitamin with minerals. Replace fluids electrolytes for diarrhea. Hold tube feeds 1-2 hours before and 1-2 hours after drug. Probiotic is advised. Take drug with 8 oz of fluid and maintain adequate hydration.
Antimicrobial Agents Oxazolidinone <ul style="list-style-type: none"> linezolid (Zyvox) 	Drug exhibits mild MAO inhibition. May cause taste change, oral candidiasis, and <i>Clostridium difficile</i> .	Avoid significant amounts (>100 mg) of high tyramine/pressor foods. See chart in 18th ed. of <i>Food Medication Interactions</i> . Eat small, frequent, appealing meals if tastes change. Replace fluids & electrolytes for diarrhea. Probiotic is advised.
Tetracyclines <ul style="list-style-type: none"> tetracycline (Sumycin) doxycycline (Vibramycin) 	Often used to treat Lyme disease; may cause anorexia. Binds to Mg, Ca, Zn, and Fe, forming an insoluble unabsorbable complex. May ↓ bacterial production of vitamin K in GI tract. Long-term use may cause B vitamin deficiencies. Combining with vitamin A may ↑ risk of benign intracranial hypertension. May cause <i>Clostridium difficile</i> .	Take supplements separately by 3 hours. Eat frequent, small, appealing meals to ↓ anorexia. Avoid excessive vitamin A while taking drug. Long-term use may warrant vitamins K and B supplementation. Probiotic is advised. Replace fluids & electrolytes for diarrhea. Tetracycline: Take drug 1 hour before or 2 hours after food or milk. Both can cause pill esophagitis, take with a full glass of water to ensure passage of pills into stomach.
Antiprotozoal/Antibacterial <ul style="list-style-type: none"> metronidazole (Flagyl) 	May cause anorexia, GI distress, stomatitis, and metallic taste in mouth. May cause disulfiram-like reaction when ingested with alcohol. Often used to treat <i>Clostridium difficile</i> .	Take with food to ↓ GI distress. Eat small, frequent, appealing meals to decrease anorexia. Avoid all alcohol during use and for 3 days after discontinuation. Probiotic is advised.
<ul style="list-style-type: none"> clindamycin (Cleocin) 	May cause weight loss, increased thirst, esophagitis, nausea, vomiting, cramps, flatulence, bloating, or diarrhea. May cause severe <i>Clostridium difficile</i> .	Take oral forms with food or 8 oz water to decrease esophageal irritation. Replace fluids & electrolytes for diarrhea. Probiotic is advised.
Nitrofurantoin <ul style="list-style-type: none"> nitrofurantoin (Macrobid) 	Peripheral neuropathy, muscle weakness, and wasting may occur with preexisting anemia, vitamin B deficiency, or electrolyte abnormalities. May cause <i>Clostridium difficile</i> .	Drug should be taken with food to maximize absorption, protein, and vitamin B complex. Avoid in G-6-PD deficiency because of increased risk of hemolytic anemia. Replace fluids & electrolytes for diarrhea. Probiotic is advised.
Antituberculars <ul style="list-style-type: none"> isoniazid (Nydrazid) 	Drug may cause pyridoxine (vitamin B ₆) and niacin (vitamin B ₃) deficiency resulting in peripheral neuropathy and pellagra. Drug has MAO inhibitor-like activity.	Avoid in malnourished individuals and others at ↑ risk for peripheral neuropathy. Supplement with 25-50 mg of pyridoxine and possibly B-complex if skin changes occur. Avoid foods high in tyramine (e.g., aged cheeses).

Drug	Drug Effect	Nutritional Implications and Cautions
<ul style="list-style-type: none"> rifampin (Rifadin) rifabutin 	<p>Drug may increase metabolism of vitamin D. Rare cases of osteomalacia have been reported. Food decreases absorption by 30%.</p> <p>Rifabutin is a less potent enzyme inducer than rifampin with less effects on vitamin D metabolism.</p>	<p>May need vitamin D supplement with long-term use. Take on an empty stomach.</p>
<ul style="list-style-type: none"> ethambutol (Myambutol) pyrazinamide (Rifater) 	<p>Drug may ↓ the excretion of uric acid, leading to hyperuricemia and gout.</p> <p>Myambutol: may g copper and zinc.</p>	<p>Maintain adequate hydration and purine-restricted diet.</p> <p>Myambutol: ↑ foods high in Cu and Zn; daily multivitamin with long term use.</p>
Antifungal Agents		
<ul style="list-style-type: none"> amphotericin B (Fungizone) 	<p>Drug may cause anorexia and weight loss.</p> <p>Drug causes loss of potassium, magnesium, and calcium.</p> <p>Nephrotoxic</p>	<p>Eat frequent, small, appealing meals high in magnesium, potassium, and calcium. May require PO/IV supplementation. Ensure adequate IV hydration pre and post infusion to reduce renal injury.</p>
<ul style="list-style-type: none"> ketoconazole (Nizoral) fluconazole (Diflucan) posaconazole (Noxafil) voriconazole (Vfend) 	<p>Drug does not dissolve at pH >5 (Ketoconazole)</p>	<p>Take with food to ↑ absorption. Take with acidic liquid (e.g., orange juice), especially individuals with achlorhydria or those on H₂ blockers or PPIs (for ketoconazole only).</p> <p>Posaconazole tablets (delayed release): Take with a full meal, preferably high-fat (>50g).</p> <p>Suspension: Give during or within 20 minutes following a full meal, liquid nutritional supplement, or an acidic carbonated beverage (e.g., ginger ale).</p> <p>Food decreases voriconazole absorption. Oral voriconazole should be taken 1 hour before or 2 hours after a meal.</p>
<ul style="list-style-type: none"> terbinafine (Lamisil) 	<p>Drug may cause taste changes or loss, dyspepsia, abdominal pain, diarrhea, weight loss, and headaches.</p> <p>May result in increased adverse effects of caffeine (headache, agitation, insomnia, diuresis).</p>	<p>Avoid taking with acidic foods such as applesauce or fruit-based foods. Limit alcohol and caffeine.</p>
Selected Antiviral Agents		
<ul style="list-style-type: none"> valganciclovir (Valcyte) 	<p>Cytomegalovirus antiviral agent. Suppresses bone marrow, renally eliminated.</p>	<p>Must take with a high-fat meal to maximize absorption.</p>
Selected Antithrombotic/Hematologic Drugs		
Anticoagulant Agents		
Vitamin K Antagonist		
<ul style="list-style-type: none"> warfarin (Coumadin) 	<p>Prevents the conversion of oxidized vitamin K to the active form. Produces systemic anticoagulation. May inhibit mineralization of newly formed bone.</p>	<p>Consistent intake of vitamin K-containing foods and supplements is required, not complete avoidance in order to achieve desired state of anticoagulation. Monitor bone mineral density in individuals on long-term therapy.</p> <p>Data are conflicting on whether consumption of cranberry and pomegranate juice/fruit with warfarin causes increased INR and bleeding episodes. However, it may be prudent to advise patients to avoid drinking large quantities of cranberry juice with warfarin. When concurrent consumption does occur, frequent monitoring for INR changes and for signs or symptoms of bleeding is recommended.</p> <p>The quantity of green and black tea consumed and the method of production affect the amount of vitamin K in the tea.</p> <p>Use caution when enteral nutrition is used in patients receiving warfarin, as there have been reports of development of warfarin resistance in patients receiving concurrent enteral feeding, even when using low vitamin K-containing products.</p> <p>Celery may potentiate the effect of anticoagulants.</p> <p>Apigenin, a constituent of celery, may inhibit thromboxane A₂ formation leading to reduced platelet aggregation (Teng et al, 1988). Celery contains coumarin derivatives, which may produce additional anticoagulant effects.</p> <p>Avoid high doses of fish oil, vitamin E, and herbal products with antiplatelet or anticoagulant effects.</p>

Drug	Drug Effect	Nutritional Implications and Cautions
Direct Thrombin Inhibitor <ul style="list-style-type: none"> dabigatran (Pradaxa) 	Drug may cause dyspepsia, abdominal pain, GERD, esophagitis, erosive gastritis, diarrhea, gastric hemorrhage, or GI ulcer. Alcohol may potentiate the effect, increasing the risk of bleeding.	Avoid alcohol and supplements, SJW can ↓ drug effectiveness. Avoid grapefruit, can increase dabigatran concentrations. Chewing can ↓ bioavailability by 75%. Take with food if GI distress occurs.
Factor Xa Inhibitors <ul style="list-style-type: none"> rivaroxaban (Xarelto) apixaban (Eliquis) edoxaban (Savaysa) betrixaban (Bevyxxa) 	Drug may cause abdominal pain, oropharyngeal pain, toothaches, dyspepsia, and anemia. Excess alcohol can ↑ bleeding risk.	Avoid high doses of fish oil, vitamin E, and herbal products with antiplatelet or anticoagulant effects. Avoid SJW as it can lead to decreased effectiveness. Avoid grapefruit/related citrus (limes, pomelo, Seville oranges) as they can increase risk of bleeding. Minimize alcohol intake.
Antiplatelet Agents Platelet Aggregation Inhibitors <ul style="list-style-type: none"> aspirin/salicylate (Bayer) 	Drug may cause GI irritation and bleeding. Drug may ↓ uptake of vitamin C and ↑ urinary loss.	Incorporate foods high in vitamin C and folate. Monitor electrolytes and hemoglobin to determine need for potassium or iron supplements. Avoid alcohol consumption.
<ul style="list-style-type: none"> clopidogrel (Plavix) prasugrel (Effient) ticagrelor (Brilinta) 	Drug may cause dyspepsia, nausea and vomiting, abdominal pain, GI bleeding/hemorrhage, diarrhea, and constipation.	Food ↑ bioavailability. Take with food if GI distress occurs. Avoid grapefruit/related citrus (limes, pomelo, Seville oranges). Replace fluids & electrolytes for diarrhea.
Selected Antihyperglycemic Drugs Insulin Sensitizing Agents Biguanide <ul style="list-style-type: none"> metformin (Glucophage) 	Drug may ↓ absorption of vitamin B ₁₂ and folic acid. May cause lactic acidosis. Drug does not cause hypoglycemia.	Follow American Diabetes Association dietary guidelines. ↑ Foods high in vitamin B ₁₂ and folate; supplement if necessary. Avoid alcohol to ↓ risk of lactic acidosis.
Thiazolidinedione (TZD) <ul style="list-style-type: none"> rosiglitazone (Avandia) pioglitazone (Actos) 	Drugs may lead to ↑ weight and insulin sensitivity, and ↓ gluconeogenesis. Avandia may ↑ total cholesterol, LDL, triglycerides, and ↓ HDL. Actos may g total cholesterol, LDL, triglycerides, and ↑ HDL. Rarely, drugs may cause hypoglycemia.	Black box warning: These agents cause or exacerbate congestive heart failure. Follow American Diabetes Association dietary guidelines. Reduce calorie intake if weight loss is the goal. Avoid SJW. Monitor blood lipid levels closely and encourage antiinflammatory diet to manage undesirable fluctuations.
Insulin Stimulating Agents Sulfonylureas <ul style="list-style-type: none"> glipizide (Glucotrol) glyburide (DiaBeta) glimepiride (Amaryl) 	Drug may cause ↑ or ↓ in appetite, weight gain, dyspepsia, nausea, diarrhea, or constipation. Drugs may lead to hypoglycemia. Food can decrease absorption. May enhance the effect of alcohol.	Follow American Diabetes Association dietary guidelines and encourage regular exercise. Time food intake according to pharmaceutical recommendations. Avoid alcohol. Take 30 minutes before meal to avoid erratic absorption.
Meglitinides <ul style="list-style-type: none"> repaglinide (Prandin) 	Drug stimulates the release of insulin and may lead to weight gain. May also cause nausea, vomiting, diarrhea, or constipation. Drug may cause hypoglycemia if meal not ingested.	Follow American Diabetes Association dietary guidelines and encourage exercise. Reduce calories if weight loss is the goal. Take 30 minutes before meal ingestion, dose should be skipped for that meal if not eating. Limit alcohol intake.
Enzyme Inhibitor Agents Alpha-Glucosidase Inhibitors <ul style="list-style-type: none"> miglitol (Glyset) acarbose (Precose) 	Drugs may delay the absorption of dietary disaccharides and complex carbohydrates. May also cause abdominal pain, diarrhea, and gas. Glyset: May reduce iron absorption. Drugs do not cause hypoglycemia.	Follow American Diabetes Association dietary guidelines. Avoid digestive enzymes and limit alcohol. Precose: Monitor liver enzymes (AST, ALT) quarterly during the first year. Glyset: Monitor iron levels and supplement as needed.
Dipeptidyl Peptidase-4 (DPP-4) Inhibitors (Gliptins) <ul style="list-style-type: none"> sitagliptin (Januvia) saxagliptin (Onglyza) linagliptin (Tradjenta) Alogliptin (Nesina) 	Drugs may lead to weight gain, abdominal pain, constipation, diarrhea, gastroenteritis, nausea, vomiting, and rarely, pancreatitis. Drug may cause hypoglycemia.	Follow American Diabetes Association dietary guidelines. ↓ Calories if weight loss is the goal. Onglyza: Avoid grapefruit/related citrus (limes, pomelo, Seville oranges). Onglyza/Tradjenta: Avoid SJW. Januvia: reports of pancreatitis. Nesina: reports of hepatotoxicity.

Drug	Drug Effect	Nutritional Implications and Cautions
Glucose Reabsorption Inhibitor Agents		
SGLT-2 Inhibitors (Gliflozins) <ul style="list-style-type: none"> • canagliflozin (Invokana) • dapagliflozin (Farxiga) • empagliflozin (Jardiance) • ertugliflozin (Steglatro) 	Drugs ↓ reabsorption of glucose and ↑ urinary glucose excretion. Drugs may lead to weight loss, polydipsia, ↑ LDL, hypovolemia, and dehydration. Drugs may cause hypoglycemia.	Follow American Diabetes Association dietary guidelines. Reduce calorie intake if weight loss is the goal. Monitor LDL and encourage appropriate fat intake. Invokana: Avoid SJW.
Selected Steroidal/Hormonal Drugs		
Corticosteroids		
<ul style="list-style-type: none"> • prednisone (Deltasone) • methylprednisolone (Medrol) • dexamethasone (Decadron) 	Drug induces protein catabolism, resulting in muscle wasting, atrophy of bone protein matrix, and delayed wound healing. Drug ↓ intestinal absorption of calcium; ↑ urinary loss of calcium, potassium, zinc, vitamin C, and nitrogen; causes sodium retention.	Maintain diet high in Ca, vitamin D, protein, K ⁺ , Zn, and vitamin C, and low in sodium. Ca and vitamin D supplements recommended to prevent osteoporosis with long-term use of drug.
Bisphosphonates		
<ul style="list-style-type: none"> • alendronate (Fosamax) • ibandronate (Boniva) • risedronate (Actonel) • zoledronic acid (Reclast) 	Drug may induce mild ↓ in serum calcium. Long-term use may cause zinc deficiency.	Pair with diet high in Ca or use Ca/vitamin D supplement. Monitor for signs of zinc deficiency. Drug must be taken 30 minutes to 1 hour before first intake of day with plain water only. Can cause pill-esophagitis; remain upright for 30 minutes after ingesting. Take zinc supplements 2 hours away from drug.
Female Hormones		
<ul style="list-style-type: none"> • estrogen (Premarin) • Oral contraceptives 	Drug may ↓ absorption and tissue uptake of vitamin C but may ↑ absorption of vitamin A. May inhibit folate conjugate and decrease serum folic acid. Drug may ↓ serum vitamin B ₆ , B ₁₂ , riboflavin, magnesium, zinc.	Maintain diet with adequate Mg, folate, vitamin B ₆ and B ₁₂ , riboflavin, and zinc. Calcium and vitamin D supplements may be advised with estrogen as hormone replacement for postmenopausal women.
Thyroid Hormones		
<ul style="list-style-type: none"> • levothyroxine (Synthroid) • liothyronine (Cytomel) 	Drug may cause appetite changes, weight loss, and nausea/diarrhea. Iron, calcium or magnesium may ↓ absorption of drug. Soy, walnuts, cottonseed oil, or high-fiber foods may also ↓ absorption.	Take Fe, Ca, or Mg supplements away from drug by ≥4 hours; take drug 2-3 hours before soy. Eat walnuts, cottonseed oil, or high-fiber foods away from medication. Use caution with grapefruit/related citrus (limes, pomelo, Seville oranges). Enteral nutrition may reduce bioavailability leading to hypothyroidism. Take on an empty stomach 30 minutes before a meal or 3-4 hours after last meal of the day.
Selected Cardiovascular Drugs		
Cardiac Glycoside Agent		
<ul style="list-style-type: none"> • digoxin (Lanoxin) 	Drug may ↑ urinary loss of magnesium and ↓ serum levels of potassium.	Monitor potassium and magnesium levels and use caution with calcium supplements and antacids. Take on an empty stomach and avoid consuming high amounts of bran as this may decrease digoxin absorption.
Beta Blocking Agents		
<ul style="list-style-type: none"> • metoprolol (Lopressor, Toprol XL) • atenolol (Tenormin) • bisoprolol (Blocadren) • nadolol (Corgard) • propranolol (Inderal) 	Do not stop taking abruptly unless under the close monitoring of the physician, can lead to rebound hypertension and cardiac ischemia. Drugs may mask signs of or prolong hypoglycemia. Drug may ↓ insulin release in response to hyperglycemia.	Monitoring of blood glucose levels for hypoglycemia or hyperglycemia may be recommended upon initiation of drugs. Take with food.
<ul style="list-style-type: none"> • carvedilol (Coreg) 	Drug may cause weight gain, nausea, vomiting, and diarrhea. May mask symptoms of diabetic hyperglycemia.	Avoid natural licorice and encourage low sodium diet; ↓ calories if weight loss is the goal. Patients with diabetes should monitor glucose regularly. Take with food to prevent orthostatic hypotension.

Continued

Drug	Drug Effect	Nutritional Implications and Cautions
ACE Inhibitor Agents <ul style="list-style-type: none"> enalapril (Vasotec) lisinopril (Zestril) benazepril (Lotensin) ramipril (Altace) 	Drugs may ↑ serum potassium. Drugs may cause abdominal pain, constipation, or diarrhea.	Caution with high-potassium diet or supplements. Avoid salt substitutes. Ensure adequate fluid intake. Avoid natural licorice. Limit alcohol.
Angiotensin II Receptor Antagonists <ul style="list-style-type: none"> losartan (Cozaar) valsartan (Diovan) irbesartan (Avapro) telmisartan (Micardis) 	Drugs may ↑ serum potassium.	Caution with high-potassium diet or supplements. Ensure adequate hydration. Avoid natural licorice and salt substitutes. Cozaar: Avoid grapefruit/related citrus (limes, pomelo, Seville oranges).
Calcium Channel Blocking Agents <ul style="list-style-type: none"> amlodipine (Norvasc) diltiazem (Cardizem) 	Drug may cause dysphagia, nausea, cramps, and edema. Drug may cause anorexia, dry mouth, dyspepsia, nausea, vomiting, constipation, and diarrhea.	If GI distress occurs, take with food. Avoid natural licorice. Reduce sodium intake. Grapefruit can modestly increase amlodipine levels; use caution with combination or avoid altogether. Avoid natural licorice. Strict adherence to a low-sodium diet may ↓ antihypertensive effect. Grapefruit can increase diltiazem levels; avoid grapefruit.
Alpha Adrenergic Agonist <ul style="list-style-type: none"> clonidine (Catapres) 	Drug commonly causes dizziness, drowsiness, and sedation.	Avoid alcohol and alcohol products. Drug ↑ sensitivity to alcohol, which may ↑ sedation caused by drug alone.
Peripheral Vasodilator <ul style="list-style-type: none"> hydralazine (Apresoline) 	Drug interferes with pyridoxine (vitamin B ₆) metabolism and may result in pyridoxine deficiency. Food and enteral nutrition decrease bioavailability.	Maintain a diet high in pyridoxine. Supplementation may be necessary. Enteral nutrition should be stopped prior to administration or take on an empty stomach.
Antiarrhythmic Agent <ul style="list-style-type: none"> amiodarone (Pacerone) 	Drug may cause anorexia, nausea, vomiting, taste changes, or increases in liver enzymes or thyroid hormones.	Avoid grapefruit/related citrus (limes, pomelo, Seville oranges) and SJW. Monitor hepatic and thyroid function. Contains 3 mg of inorganic iodide per 100 mg of amiodarone.
Selected Antihyperlipidemic Drugs HMG Co-A Reductase Inhibitors <ul style="list-style-type: none"> atorvastatin (Lipitor) simvastatin (Zocor) pravastatin (Pravachol) rosuvastatin (Crestor) 	Drug may cause significant reduction in CoQ ₁₀ . Drug lowers LDL cholesterol, raises HDL cholesterol.	Supplementation with CoQ ₁₀ has not been shown to ↓ statin myopathy but may still be advisable for repletion of the nutrient. Encourage antiinflammatory diet for optimal drug effect. Lipitor/Zocor: Avoid grapefruit/related citrus (limes, pomelo, Seville oranges). Concurrent use of red yeast rice may increase risk of side effects.
Fibric Acid Derivative <ul style="list-style-type: none"> gemfibrozil (Lopid) fenofibrate (Tricor) 	Drug decreases serum triglycerides. Lopid: Taste changes may occur.	Encourage antiinflammatory diet for optimal drug effect. Avoid alcohol. Lopid: Small meals are recommended.
Bile Acid Sequestrant <ul style="list-style-type: none"> cholestyramine (Questran) 	Drug binds fat-soluble vitamins (A, E, D, K), β-carotene, calcium, magnesium, iron, zinc, and folic acid.	Take fat-soluble vitamins in water-miscible form or take vitamin supplement at least 1 hour before first dose of drug daily. Maintain diet high in folate, Mg, Ca, Fe, Zn or supplement as needed. Monitor serum nutrient levels for long-term use.
Nicotinic Acid <ul style="list-style-type: none"> niacin (Niaspan) 	High dose may elevate blood glucose and uric acid.	Low-purine diet as recommended. Monitor blood glucose with diabetes.

Drug	Drug Effect	Nutritional Implications and Cautions
Selected Diuretic Drugs		
Loop Diuretics		
<ul style="list-style-type: none"> • furosemide (Lasix) • bumetanide (Bumex) 	Drug ↑ urinary excretion of sodium, potassium, magnesium, and calcium. Long-term use can lead to ↑ urinary zinc excretion.	Maintain diet high in zinc, potassium, magnesium, and calcium. Avoid natural licorice, which may counteract diuretic effect of drug. Monitor electrolytes; supplement as needed.
Thiazide Diuretic		
<ul style="list-style-type: none"> • hydrochlorothiazide (Hydrodiuril) • chlorothiazide (Diuril) • chlorthalidone (Hygroton) • metolazone (Zaroxyn) 	Drug ↑ urinary excretion of sodium, potassium, magnesium and ↑ renal resorption of calcium. Long-term use can lead to ↑ urinary zinc excretion.	Maintain diet high in zinc, potassium, and magnesium. Avoid natural licorice, which may counteract diuretic effect of drug. Monitor electrolytes and supplement as needed. Use caution with Ca supplements.
Potassium-Sparing Diuretics		
<ul style="list-style-type: none"> • triamterene (Dyrenium) • spironolactone (Aldactone) 	Drug ↑ renal resorption of potassium. Long-term use can lead to ↑ urinary zinc excretion.	Avoid salt substitutes. Use caution with potassium supplements. Avoid excessive potassium intake in diet. Monitor for signs of zinc deficiency.
Selected Analgesic Drugs		
Non-Narcotic Analgesics		
<ul style="list-style-type: none"> • acetaminophen (Tylenol) 	Drug may cause hepatotoxicity at high dose. Chronic alcohol ingestion ↑ risk of hepatotoxicity.	Maximum safe adult dose is ≤3 g/day. Avoid alcohol or limit to ≤2 drinks/day.
Non-Steroidal Antiinflammatory Drugs (NSAIDs)		
<ul style="list-style-type: none"> • ibuprofen (Motrin) • naproxen (Naprosyn) • meloxicam (Mobic) • ketorolac (Toradol) 	<p>Standard warning with NSAIDs:</p> <p>GI: ↑ risk of serious GI events (bleeding, ulceration, perforation of stomach and intestines) can occur at any time during use without warning. Elderly taking corticosteroids, antiplatelets, or anticoagulants are at greater risk.</p> <p>Renal: ↑ Risk of kidney injury.</p> <p>Cardiovascular: ↑ risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke.</p>	<p>Take drug with food or milk to decrease risk of GI toxicity.</p> <p>Avoid use in the elderly or in individuals with severe cardiovascular disease or renal disease.</p> <p>For chronic ongoing use, consider adding PPI to decrease risk of gastric ulceration.</p>
COX-2 Inhibitor		
<ul style="list-style-type: none"> • celecoxib (Celebrex) 	Drug may cause GI distress, weight gain, taste changes, dyspepsia, nausea, abdominal pain, diarrhea, and flatulence. Rare sudden, serious GI bleeding and colitis can occur.	If GI distress occurs, take with food and limit caffeine. High-fat meals can delay concentration, but ↑ absorption. Similar cardiovascular warnings as for NSAIDs.
Narcotic Analgesic Agents (Opioids)		
<ul style="list-style-type: none"> • morphine (MS Contin) • codeine/apap (Tylenol #3) • hydrocodone/apap (Norco) • oxycodone (OxyContin) • hydromorphone (Dilaudid) • fentanyl (Duragesic) • methadone (Dolophine) 	<p>Narcotics can be highly addictive and may cause severe dose-related sedation, respiratory depression, dry mouth, and constipation.</p> <p>Drugs cause slowing of digestion.</p>	<p>Monitor respiratory function and bowel function (not with paralytic ileus).</p> <p>Do not crush or chew sustained-release.</p> <p>OxyContin/Fentanyl/Methadone: Caution with grapefruit/related citrus (limes, pomelo, Seville oranges); do not take with SJW.</p> <p>Methadone causes QT prolongation; monitor ECG, Mg, and K and replete as necessary.</p> <p>Do not take with alcohol or other CNS depressants.</p>
Synthetic Opioid Analgesic		
<ul style="list-style-type: none"> • tramadol (Ultram) 	Drug may cause anorexia, dry mouth, dyspepsia, nausea/vomiting, abdominal pain, constipation, diarrhea, or gas.	Avoid alcohol. Use caution with SJW. Some products contain phenylalanine. Do not combine with alcohol.

Continued

Drug	Drug Effect	Nutritional Implications and Cautions
Selected Antidepressant Drugs		
Selective Serotonin Reuptake Inhibitors (SSRIs)		
<ul style="list-style-type: none"> sertraline (Zoloft) citalopram (Celexa) escitalopram (Lexapro) fluoxetine (Prozac) paroxetine (Paxil) 	<p>Drugs may ↑ weight, appetite, dry mouth, or anorexia. Many drug interactions with herbs and supplements may ↑ toxicity.</p> <p>Prozac: May cause weight loss; may g absorption of leucine.</p> <p>SSRI have antiplatelet effects increasing the risk for intestinal bleeding.</p>	<p>Avoid tryptophan, SJW. Additive effects may produce adverse effects or serotonin syndrome. Monitor weight trends as appropriate. Avoid alcohol. Black box warning: Antidepressants increased the risk compared with placebo of suicidal thinking and behavior (suicidality) in children, adolescents, and young adults (<24 year old) in short-term studies of MDD and other psychiatric disorders.</p> <p>Avoid taking with herbal products that have antiplatelet effects.</p> <p>Many drug interactions through CYP450 system, check interactions with all herbs and supplements.</p>
Serotonin Antagonist/Reuptake Inhibitor (SARI) & Serotonin-Norepinephrine Reuptake Inhibitors (SNRIs)		
<ul style="list-style-type: none"> trazodone (Desyrel) - SARI venlafaxine (Effexor XR) - SNRI desvenlafaxine (Pristiq) – SNRI duloxetine (Cymbalta) milnacipran (Savella) 	<p>Some herbal and natural products may ↑ toxicity.</p> <p>SNRI have antiplatelet effects increasing the risk for intestinal bleeding.</p>	<p>Alcohol may increase the sedative and psychomotor impairment as well as increase the risk of hepatotoxicity with duloxetine and milnacipran.</p> <p>Avoid tryptophan and SJW.</p> <p>Additive effects may produce adverse effects or serotonin syndrome.</p> <p>Avoid herbs that have antiplatelet effects.</p> <p>Many drug interactions through CYP450 system, check interactions with all herbs and supplements.</p>
Tricyclic Antidepressants (TCAs)		
<ul style="list-style-type: none"> amitriptyline (Elavil) nortriptyline (Pamelor) doxepin (Silenor) imipramine (Tofranil) 	<p>Drug may cause ↑ appetite (especially for carbohydrates/sweets) and weight gain. Causes dry mouth and constipation. High fiber may ↓ drug absorption.</p>	<p>Monitor caloric intake. Maintain consistent amount of fiber in diet. Avoid alcohol (increased sedation).</p>
Noradrenergic/Specific Serotonic Antidepressants (NaSSA)		
<ul style="list-style-type: none"> mirtazapine (Remeron) 	<p>Some herbal and natural products may ↑ toxicity.</p> <p>Drug can also be used as an appetite stimulant and may cause significant ↑ in appetite/weight gain. Dry mouth and constipation are common.</p>	<p>Avoid tryptophan and SJW.</p> <p>Additive effects may produce adverse effects or serotonin syndrome. Avoid combining with alcohol and cannabis.</p> <p>Some products contain phenylalanine.</p>
Norepinephrine/Dopamine Reuptake Inhibitor (NDRI)		
<ul style="list-style-type: none"> bupropion (Wellbutrin SR, XL) 	<p>Drug may cause anorexia, weight loss or gain, ↑ appetite, dry mouth, stomatitis, taste changes, dysphagia, pharyngitis, nausea/vomiting, dyspepsia, or GI distress. Lowers seizure threshold.</p>	<p>Minimize or avoid alcohol (lowers seizure threshold). Take with food to decrease GI irritation.</p> <p>Avoid mixing with SJW.</p>
Monoamine Oxidase Inhibitors (MAOIs)		
<ul style="list-style-type: none"> phenelzine (Nardil) 	<p>Drug may cause ↑ appetite (especially for carbohydrates and sweets) and weight gain. Risk for severe reaction with dietary tyramine.</p>	<p>Avoid foods high in tyramine, dopamine, tyrosine, phenylalanine, tryptophan, and caffeine during drug use and for 2 weeks after discontinuation to prevent hypertensive crisis. Monitor caloric intake to avoid weight gain.</p>
Mood Stabilizers		
<ul style="list-style-type: none"> lithium (Lithobid) 	<p>Sodium intake affects drug levels. May cause dry mouth, dehydration, and thirst, reflective of ↑ drug toxicity. Drug may cause GI irritation. Drug can cause nephrotoxicity.</p>	<p>Drink 2 to 3 L of fluid daily to avoid dehydration. Maintain consistent dietary sodium intake. Take with food to ↓ GI irritation. Limit caffeine.</p>

Drug	Drug Effect	Nutritional Implications and Cautions
Selected Antipsychotic & Antianxiety/Hypnotic Drugs		
Typical Antipsychotic Agent		
<ul style="list-style-type: none"> haloperidol (Haldol) 	May cause ↑ appetite, weight gain or loss, constipation, or dry mouth. Risk for tardive dyskinesia.	Monitor weight and calorie count. Tardive dyskinesia may interfere with biting, chewing, and swallowing. Avoid alcohol.
Atypical Antipsychotic Agents		
<ul style="list-style-type: none"> aripiprazole (Abilify) clozapine (Clozaril) olanzapine (Zyprexa) paliperidone (Invega) quetiapine (Seroquel) risperidone (Risperdal) ziprasidone (Geodon) 	<ul style="list-style-type: none"> Drugs may cause ↑ appetite and weight gain. May also cause ↑ blood sugar, Hgb A1C, or lipids/triglycerides, xerostomia, constipation. 	<ul style="list-style-type: none"> Monitor weight, fasting blood sugar, Hgb A1C, and lipids/triglycerides. Do not use in elderly dementia patients; increased risk of cerebrovascular events and greater mortality.
Antianxiety/Hypnotic Agents		
<ul style="list-style-type: none"> lorazepam (Ativan) alprazolam (Xanax) clonazepam (Klonopin) diazepam (Valium) temazepam (Restoril) zolpidem (Ambien) 	Drugs may cause significant sedation. Benzodiazepine drugs are highly addictive.	Avoid concurrent ingestion of alcohol, which will produce CNS depression. Limit or avoid caffeine, which may decrease the therapeutic effect of the drug. Use caution with drugs and herbal and natural products that cause CNS stimulation or sedation that can result in profound respiratory sedation, coma, and death. Avoid using in patients >65 years old.
Selected Anticonvulsant Drugs		
Carboxamides		
<ul style="list-style-type: none"> carbamazepine (Tegretol) 	Drug may ↓ biotin, folic acid, and vitamin D levels. Long-term therapy (>6 months) may cause loss of bone mineral density. May cause clinically significant hyponatremia.	Maintain diet high in folate and vitamin D. Calcium and vitamin D supplements may be necessary for long-term therapy. Use caution with grapefruit/related citrus (limes, pomelo, Seville oranges). Star fruit or pomegranate may ↑ drug levels and lead to toxicity. Avoid alcohol.
Hydantoin		
<ul style="list-style-type: none"> phenytoin (Dilantin) 	Drug may ↓ serum folic acid, calcium, vitamin D, biotin, and thiamine. Drug can cause gingival enlargement, altered taste, dysphagia, nausea, vomiting, and constipation. Alcohol intake decreases drug levels, increases seizure potential, and increases CNS depression. Ca and Mg may ↓ absorption.	May be paired with daily folic acid supplement; monitor levels. Consider Ca, vitamin D and B vitamin supplements with long-term use. Ca, Mg, or antacids should be taken 2 hours away from drug. Holding tube feeds 2 hours before & 2 hours after oral drug is recommended. If continuous tube feeds, switch to IV or may require doubling of the oral phenytoin dose. Avoid alcohol and SJW.
Barbiturate		
<ul style="list-style-type: none"> phenobarbital (Luminal) 	Drug may induce rapid metabolism of vitamin D, leading to vitamin D and calcium deficiencies. May also ↑ the metabolism of vitamin K and ↓ serum folic acid and vitamin B ₁₂ . Alcohol increases CNS depression and could lead to respiratory depression.	Encourage ↑ dietary intake of Ca, vitamin D, and folate. Consider Ca, vitamin D, folic acid, and vitamin B ₁₂ supplementation with long-term use. Avoid alcohol.
Valproic Acid Derivatives		
<ul style="list-style-type: none"> divalproex, valproic acid (Depakote) 	Causes competitive inhibition of intestinal SLC22A transport protein, leading to malabsorption of dietary carnitine.	Can cause symptomatic carnitine deficiency in susceptible patients. Supplement as necessary.
Gamma-Amino Butyric Acid (GABA) Analogs		
<ul style="list-style-type: none"> gabapentin (Neurontin) pregabalin (Lyrica) 	Drugs used for neuropathy, hot flashes, migraines, and as mood stabilizers. Mg can interfere with drug efficacy by ↓ absorption. Can cause ↑ weight and appetite, nausea, gingivitis, constipation, xerostomia, vomiting, and diarrhea.	Gabapentin: Take Mg supplements separately by 2 hours. Pregabalin: Administer with meals. Avoid alcohol to prevent additive CNS depression.

Continued

Drug	Drug Effect	Nutritional Implications and Cautions
Fructose Derivative <ul style="list-style-type: none"> • topiramate (Topamax) • lamotrigine (Lamictal) 	May cause weight loss, anorexia, dry mouth, gingivitis, taste changes, GERD, nausea, dyspepsia, constipation, or diarrhea.	Topiramate: Encourage adequate fluid intake to ↓ risk of kidney stones. Replace fluids & electrolytes for diarrhea. Avoid alcohol.
Selected Anti-Dementia Drugs Cholinesterase Inhibitors <ul style="list-style-type: none"> • donepezil (Aricept) • rivastigmine (Exelon) 	Drug is highly cholinergic; may cause weight loss, diarrhea, nausea/vomiting, ↑ gastric acid, and GI bleeding.	Take with food to prevent GI irritation. Monitor food intake and weight trends.
NMDA Receptor Antagonist <ul style="list-style-type: none"> • memantine (Namenda) 	Drug is cleared from the body almost exclusively by renal excretion. Urine pH >8 decreases renal excretion by 80%.	Avoid diet that alkalinizes the urine (predominantly milk products, citrus fruit) to avoid drug toxicity.
Selected Gastrointestinal Drugs H₂ Receptor Antagonist <ul style="list-style-type: none"> • ranitidine (Zantac) • famotidine (Pepcid) 	Drug may reduce the absorption of vitamin B ₁₂ and iron.	Monitor iron studies, vitamin B ₁₂ level on long-term therapy. Supplement as needed.
Proton Pump Inhibitors <ul style="list-style-type: none"> • omeprazole (Prilosec) • lansoprazole (Prevacid) • esomeprazole (Nexium) • pantoprazole (Protonix) • dexlansoprazole (Dexilant) 	<p>Long-term ↓ acid secretion may inhibit the absorption of iron and vitamin B₁₂; ↓ calcium absorption may lead to osteoporosis. Low Mg may occur.</p> <p>Inhibition of acid secretion may also ↑ the risk of <i>Clostridium difficile</i>. Some studies have also shown correlation between PPI therapy, SIBO, and IBS.</p>	<p>Monitor iron studies, vitamin B₁₂, magnesium levels, and bone density with long-term use; supplement as needed. Consider alternatives in those with a diagnosis of SIBO and/or IBS.</p> <p>Prilosec: Avoid SJW and ginkgo. Hold tube feeds 1 hour before and 1 hour after drug.</p>
Prokinetic Agent <ul style="list-style-type: none"> • metoclopramide (Reglan) 	Drug ↑ gastric emptying; may change insulin requirements in persons with diabetes; may ↑ CNS depressant effects of alcohol. Drug may cause tardive dyskinesia with extended use.	Monitor blood glucose in persons with diabetes carefully when drug is initiated. Avoid alcohol. Tardive dyskinesia may interfere with biting, chewing, swallowing.
Selected Antineoplastic Drugs Folate Antagonist <ul style="list-style-type: none"> • methotrexate (Trexall) 	<p>Drug inhibits dihydrofolate reductase; decreased formation of active folate. Drug may cause GI irritation or injury (stomatitis, gingivitis, GI hemorrhage, intestinal perforation), diarrhea, nausea/vomiting, anorexia.</p> <p>All antineoplastic drugs are cytotoxic; potential to damage intestinal mucosa.</p> <p>Drug also used as an antirheumatic.</p>	Maintain diet high in folate and vitamin B ₁₂ . Daily folic acid supplement may be recommended with antirheumatic doses but is not advised with antineoplastic. Leucovorin rescue may be necessary with antineoplastic doses. Alcohol may increase the risk of hepatotoxicity; avoid alcohol.
Alkylating Agent <ul style="list-style-type: none"> • cyclophosphamide (Cytoxan) 	<p>Drug metabolite causes bladder irritation, acute hemorrhagic cystitis.</p> <p>All antineoplastic drugs are cytotoxic; potential to damage intestinal mucosa.</p> <p>Decreases appetite.</p>	Maintain high fluid intake (2-3 L daily) to induce frequent voiding.
Epidermal Growth Factor Inhibitor <ul style="list-style-type: none"> • erlotinib (Tarceva) 	Drug may cause anorexia, weight loss, stomatitis, nausea, vomiting, diarrhea. Rarely, GI bleeding can occur.	Avoid SJW and grapefruit/related citrus (limes, pomelo, Seville oranges). Hold tube feeds 2 hour before and 1 hour after drug.

Drug	Drug Effect	Nutritional Implications and Cautions
Selected Anti-Parkinson's Drugs		
Dopamine Precursor		
<ul style="list-style-type: none"> carbidopa/levodopa (Sinemet) 	Carbidopa protects levodopa against pyridoxine-enhanced peripheral decarboxylation to dopamine. Can cause xerostomia.	Pyridoxine supplements >10-25 mg daily may ↑ carbidopa requirements and ↑ adverse effects of levodopa. High protein diet (>2 g/kg) can decrease the efficacy of L-dopa.
Dopamine Agonist		
<ul style="list-style-type: none"> bromocriptine (Parlodel) 	Drug may cause GI irritation, nausea, vomiting, and GI bleeding.	Take with food to prevent GI irritation. Take at bedtime to ↓ nausea.
MAO-B Inhibitor		
<ul style="list-style-type: none"> selegiline (Eldepryl) 	Drug selectively inhibits MAO-B at 10 mg or less per day. Drug loses selectivity at higher doses.	Avoid high-tyramine foods at doses >10 mg/day. May precipitate hypertension.
COMT Inhibitor		
<ul style="list-style-type: none"> entacapone (Comtan) 	Drug chelates iron, which for some patients may ↓ serum iron and make the drug less effective.	Monitor iron levels. Take iron supplement as needed 2-3 hours away from drug. Avoid alcohol.
Selected Attention-Deficit/Hyperactivity Disorder (ADHD) Treatment Drugs		
CNS Stimulants		
<ul style="list-style-type: none"> methylphenidate (Ritalin, Concerta) dextroamphetamine & amphetamine (Adderall) 	Drugs may cause anorexia, weight loss, and ↓ growth in children. Dry mouth, metallic taste, and GI upset can occur. May be habit forming.	Monitor children's weight/growth; ensure adequate calories. Limit caffeine & alcohol. Ritalin/Concerta: Avoid SJW. Adderall: High-dose vitamin C and acidifying foods may ↓ absorption and ↑ excretion.
Selected Immunosuppressants		
<ul style="list-style-type: none"> tacrolimus (Prograf, Envarsus XR) cyclosporine (Neoral, Sandimmune) 	Inhibits calcineurin to suppress T-lymphocyte activation. Can cause kidney injury, hyperglycemia, hyperkalemia, hypomagnesemia, hyperlipidemia. Also anorexia, constipation, diarrhea. CYP 3A4 substrate.	Monitor potassium; may need low K diet. Monitor Mg and replete as needed. Check fasting blood sugar and lipids at regular intervals. Avoid grapefruit and other herbs that can inhibit 3A4. For Envarsus XR, must avoid alcohol.
<ul style="list-style-type: none"> mycophenolate (Cellcept, Myfortic) 	Inhibits inosine monophosphate dehydrogenase, preventing de novo guanosine nucleotide synthesis thereby inhibiting T and B cells. Causes nausea, diarrhea, constipation, vomiting, anorexia, and dyspepsia.	Take with food to decrease GI upset. Avoid taking Ca/mg containing antacids within 2 hrs.
<ul style="list-style-type: none"> sirolimus (Rapamune) 	mTOR inhibitor that halts cell-cycle progression. Antiproliferative. Causes hypercholesterolemia, increased blood sugars, stomatitis, diarrhea, and constipation. Impairs wound healing.	Avoid grapefruit. Check lipids and blood sugars at regular intervals.

ACE, Angiotensin-converting enzyme; ALT, alanine amino transferase; AST, aspartate aminotransferase; CNS, central nervous system; Co-A, coenzyme A; COMT, catechol-o-methyl transferase; ECG, electrocardiogram; G-6-PD, glucose-6-phosphate dehydrogenase; GI, gastrointestinal; GERD, gastroesophageal reflux disease; HDL, high-density lipoprotein; Hgb A1C, hemoglobin A1c; HMG, 3-hydroxy-3-methyl-glutaryl; IBS, irritable bowel syndrome; INR, international normalized ratio; LDL, low-density lipoprotein; MAO, monoamine oxidase; MDD, major depressive disorder; mTOR, mammalian target of rapamycin; NMDA, N-methyl-D-aspartate; NSAID, nonsteroidal antiinflammatory drug; PPI, proton pump inhibitors; PKU, phenylketonuria; ↑↑ increase/decrease; SIBO, small intestine bacterial overgrowth; SJW, St. John's Wort. Nutritional Facts on Fluid and Hydration

Adequate hydration is essential for life. Body water is necessary to regulate body temperature, transport nutrients, moisten body tissues, compose body fluids, and make waste products soluble for excretion. As the most plentiful substance in the human body, water is also the most plentiful nutrient in the diet. The amount of water recommended for an individual varies with age, activity, medical condition, and physical condition. The water in juice, tea, milk, decaffeinated coffee, and carbonated beverages contributes the majority of water in the diet. Solid foods also contribute water to the diet but usually are not counted in the amount of water provided per day.

Water deficiency, or dehydration, is characterized by dark urine; decreased skin turgor; dry mouth, lips, and mucous membranes; headache; a coated, wrinkled tongue; dry or sunken eyes; weight loss; a lowered body temperature; and increased serum sodium, albumin, blood urea nitrogen (BUN), and creatinine values. Dehydration may be caused by inadequate intake in relation to fluid requirements or excessive fluid losses caused by fever, increased urine output (often related to diuretic therapy), diarrhea,

draining wounds, ostomy output, fistulas, environmental temperature, or vomiting. Concentrated or high-protein tube feeding formulas may increase the water requirement.

Thirst is often the first noticeable sign of the need for more water. However, athletes or workers exercising or working physically in hot climates may be significantly dehydrated before they realize they are thirsty. In these situations they should be drinking at regular intervals; they may not be able to rely on thirst to determine their need to drink.

Water excess or overhydration may be the result of inadequate output or excessive intake. Overhydration is characterized by increased blood pressure; decreased pulse rate; edema; and decreased serum sodium, potassium, albumin, BUN, and creatinine values. Fluid restrictions may be necessary for certain medical conditions such as kidney or cardiac disease. For those on fluid restrictions, the fluid needs should be calculated on an individual basis. The usual diet provides approximately 1080 mL (36 oz), a little more than a quart of fluid per day.

Approximate Fluid Content of Common Foods

Food	Fluid Ounces	Household Measure	Metric Measure
Juice	2	¼ cup	60 mL
	3	⅓ cup	90 mL
	4	½ cup	120 mL
	8	1 cup	240 mL
Coffee, tea, decaffeinated coffee	6	⅔ cup	180 mL
Gelatin	4	½ cup	120 mL
Ice cream, sherbet	3	⅓ cup	90 mL
Soup	6	⅔ cup	180 mL
Liquid coffee creamer	1	2 Tbsp	30 mL

©2003, State of California Department of Developmental Services, revised 2004.

Estimating Daily Fluid Requirements for Healthy Individuals

Children	Body Weight	Daily Fluid Requirement
Infants		140 to 150 mL/kg
Children		
Method 1		50 to 60 mL/kg
Method 2	3 to 10 kg of body weight	100 mL/kg
	11 to 20 kg of body weight	1000 mL + 50 mL/kg >10
	More than 20 kg	1500 mL + 20 mL/kg >20

Continued

Estimating Daily Fluid Requirements for Healthy Individuals—cont'd

Children	Body Weight	Daily Fluid Requirement
Adults*		
Method 1	30 to 35 mL per weight in kilograms	
Method 2	1 mL fluid per calorie consumed	
Method 3	First 10 kg of body weight	100 mL/kg
	Second 10 kg of body weight	+50 mL/kg
	Remaining kg of body weight (age <50)	+20 mL/kg
	Remaining kg of body weight (age >50)	+15 mL/kg
Method 4	Age in years	
	16-30 (active)	40 mL/kg
	20-55	35 mL/kg
	55-75	30 mL/kg
	>75	25 mL/kg

*The 1 mL of fluid per calorie method should be used with caution because it will underestimate the fluid needs of those with low-calorie needs. Persons who are significantly obese may best be evaluated by Method 3 because it adjusts for high body weight.

From the California Diet Manual, ©2003, State of California Department of Developmental Services, revised 2004, 2010.

Note: 3 oz is approximately $\frac{1}{3}$ cup; 6 oz is approximately $\frac{2}{3}$ cup.

Enteral (Tube Feeding) Formulas for Adults Marketed in the United States

This table is meant to be a general reference for types of enteral products marketed in the U.S. It does not reflect precise values for specific formulas as products and formulations are subject to change.

Consult Abbott Nutrition, <https://www.abbottnutrition.com/>, Nestlé Nutrition, <https://www.nestle-nutrition.com>, and Functional Formularies (whole foods-based formula), <https://www.functional-formularies.com>, or Kate Farms (whole foods-based formula), <https://www.katefarms.com> for current, detailed information.

Enteral Formulas	kcal/mL	Protein (g/L)	CHO (g/L)	Fat (g/L)	mOsm/kg water	Water (mL/L)	Notes
Whole foods-based (commercial)	1.06	48	132	40	340	854	Contains chicken, peas, carrots, tomatoes, cranberry juice with added vitamins/minerals. Some formulas are plant based (vegetarian) and contain protein from legumes, nut butter, and quinoa.
Polymeric, standard	1-1.5	44-68	144-216	35-65	300-650	760-1260	Suitable for most patients; higher caloric density products provide less volume; some contain fiber
Polymeric, high-protein	1-1.2	53-63	130-160	26-39	340-490	818-839	Higher protein content relative to energy; some contain fiber
Polymeric, low-electrolyte	1.8-2	35-81	161-290	83-100	600-960	700-736	Volume restricted; lower concentrations of some vitamins/minerals
Polymeric, modified carbohydrate	1-1.5	40-83	96-100	48-75	280-875	859-854	Proprietary carbohydrate blends; some with pureed fruits and vegetables and without sugar alcohols; some with fiber
Polymeric, reduced carbohydrate	1.5	63-68	100-106	93-95	330-785	535-785	Lower carbohydrate with MCT oil; marketed as possible option to reduce diet-induced carbon dioxide production
Peptide-based	1-1.5	40-94	78-188	39-64	345-610	759-848	Di- and tripeptides from whey or casein; MCT oil; some with MCT combined with fish oil; some with fructooligosaccharides; varying protein to energy ratios
Critical care (polymeric or free amino acid options)	1-1.5	50-78	134-176	28-94	460-630	759-868	Various formulations marketed as support for the immune system and healing; some with omega-3 fatty acids, fiber, and/or free amino acids
Modular Additives	kcal	Protein (g)	CHO (g)	Fat (g)			
Liquid protein & carbohydrate/30 mL	100	10	14 (glycerin)	0			Hydrolyzed collagen fortified with tryptophan
Powdered protein/7 g	25	6	0	0			Whey protein
Fat & carbohydrate blend/10 g	49	0	7.3	2.2			Cornstarch, vegetable oil, MCT oil

CHO, Carbohydrates; MCT, medium-chain triglyceride.

Sample Stepwise Method to Calculate a Parenteral Nutrition (PN) Formula

1. Determine total calories needed (see energy equations in Chapter 2)
2. Determine total protein need: Recommendations—Range of 1 to 2 g protein/kg or provide 20% of total calories as protein
3. Determine total fat needs: Recommendations—1 g/kg/day or 20% to 30% of total calories
4. Balance kcals with carbohydrate (dextrose)

PN FORMULA

Ex: Female, Ht: 65 in (165 cm), Wt: 145 lb (65.9 kg), Age: 43
 Recommended Energy Intake: 1800 calories (kcal)/day with 1.4 g protein/kg (moderate stress)

Macronutrients:

1. Protein (amino acids) = 90 g
 (Using a 10% amino acid solution—100 g amino acids/liter)
 EX: 20% of 1800 kcal = 360 kcal from protein divided by 4 kcal/g = 90 g protein = 900 mL
2. Fat (lipid emulsion) = ~45 g
 (Using 20% lipid emulsion that provides 2 kcal/mL)
 Ex: 25% of 1800 kcal = 450 kcal = 225 mL

3. Balance of kcals as carbohydrate = 990 kcal = 291 g
 (Using 70% dextrose = 700 g/1000mL 3.4 kcal/g = 2380 kcal/1000 mL)
 Ex: 990 kcal needed \times 2380 kcal/1000mL = 415 mL

Macronutrients:

10% amino acids	= 900 mL
20% lipid	= 225 mL
70% dextrose	= 415 mL
Total	= 1540 mL

4. Micronutrients:
 add multivitamin infusion (MVI) + trace elements = 12 to 15 mL = 1555 mL
5. Electrolytes/additives: (~100 mL) = 100 mL = 1665 mL
 (to balance—based on current laboratories*)
6. Total nutritional fluids: 1665 mL
7. Fluids needs 2000 mL/day = add 335 mL sterile water to equal = 2000 mL/day

*Laboratories that are significantly below normal due to disease fluctuations may need to be treated outside the PN solution.

Dietary Approaches to Stop Hypertension (DASH) Diet

The DASH diet is an eating pattern that reduces high blood pressure. It is not the traditional low-salt diet. DASH uses foods high in the minerals calcium, potassium, and magnesium, which, when combined, help lower blood pressure. It is also low in fat and high in fiber, an eating style recommended for everyone.

The Healthy Eating Pattern is the template for the DASH eating pattern, with inclusion of ½ to 1 serving of nuts, seeds, and legumes daily; limited fats and oils; and use of nonfat or low-fat milk. The eating pattern is reduced in saturated fat, total fat, cholesterol, and sweet and sugar-containing beverages and provides abundant servings of fruits and vegetables.

Although the DASH eating plan is naturally lower in salt because of the emphasis on fruits and vegetables, all adults should still make an effort to reduce packaged and processed foods and high-sodium snacks (such as salted chips, pretzels, and crackers) and use less or no salt at the table.

DASH can be an excellent way to lose weight. Because weight loss can help lower blood pressure, it is often suggested. In addition to following DASH, try adding in daily physical activity such as walking or other exercise. You may want to check with your doctor first.

THE DASH DIET				
Food Group	1600 kcal Servings/Day	2000 kcal Servings/Day	2600 kcal Servings/Day	3100 kcal Servings/Day
Grains (whole grains)	6	7-8	10-11	12-13
Vegetables	3-4	4-5	5-6	6
Fruits and juices	4	4-5	5-6	6
Milk, nonfat or low-fat	2-3	2-3	3	3-4
Meats, poultry, and fish	1-2	2 or less	6	2-3
Nuts, seeds, and legumes	3/week	½-1	1	1
Fats and oils	2	2-3	3	4
Sweets	0	5/week	Less than 2	2
DIETARY GUIDELINES				
Food Group	Servings/Day	Serving Sizes	Examples	Significance of Each Food Group
Grains	6-13	1 slice bread ½ cup (1 oz) dry cereal* ½ cup cooked rice, pasta, or cereal and fiber	Whole-wheat bread, English muffin, pita bread, bagel, cereals, grits, oatmeal, crackers, unsalted pretzels, and popcorn	Major sources of energy
Vegetables	3-6	1 cup raw, leafy vegetable ½ cup cooked vegetable 6 oz vegetable juice	Tomatoes, potatoes, carrots, peas, kale, squash, broccoli, turnip greens, collards, spinach, artichokes, beans, sweet potatoes	Rich sources of potassium, magnesium, antioxidants, and fiber
Fruits	4-6	6 oz fruit juice 1 medium fruit ¼ cup dried fruit ½ cup fresh, frozen, or canned fruit	Apricots, bananas, dates, grapes, oranges and juice, tangerines, strawberries, mangoes, melons, peaches, pineapples, prunes, raisins, grapefruit and juice	Important sources of energy, potassium, magnesium, and fiber
Low-fat dairy	2-4	8 oz milk, 1 cup yogurt, or 1.5 oz cheese	Fat-free or 1% milk, fat-free or low-fat buttermilk, yogurt, or cheese	Major sources of calcium, vitamin D, and protein
Meat, poultry, fish	1-3	3 oz cooked meats, poultry, or fish 1 egg white†	Select only lean meats; trim away visible fats, broil, roast, boil, instead of frying; remove skin from poultry	Rich sources of protein, zinc, and magnesium

Continued

DIETARY GUIDELINES				
Food Group	Servings/Day	Serving Sizes	Examples	Significance of Each Food Group
Nuts, seeds, legumes	3/wk–1/day	1.5 oz (½ cup) nuts, ½ oz or 2 Tbsp seeds, ½ cup cooked legumes	Almonds, filberts, mixed nuts, walnuts, sunflower seeds, kidney beans, lentils	Rich sources of energy, magnesium, protein, monounsaturated fats, and fiber
Fat	2-4	1 tsp soft margarine, vegetable oil, 1 Tbsp low-fat mayonnaise or salad dressing, or 2 Tbsp light salad dressing [†]	Soft margarine, low fat mayonnaise, vegetable oil, light salad dressing	The DASH study had 27% of calories as fat, including fat in or added to foods. Sweets should be low in fat

National Institutes of Health, National Heart, Lung, and Blood Institute: *Your guide to lowering your blood pressure with DASH*, 2006, U.S. Department of Health and Human Services, NIH Publication No. 06-4082.

^{*}Serving sizes vary between ½ cup and 1 ¼ cup, depending on cereal type. Check the product's Nutrition Facts label.

[†]Because eggs are high in cholesterol, limit egg yolk intake to no more than four per week; two egg whites have the same protein content as 1 oz of meat.

[‡]Fat content changes serving amount for fats and oils. For example, 1 Tbsp of regular salad dressing equals one serving; 1 Tbsp of a low-fat dressing equals one-half serving; 1 Tbsp of a fat-free dressing equals zero servings.

SAMPLE MENU		
Breakfast	Lunch	Dinner
1 cup calcium-fortified orange juice ¾ cup Raisin Bran 1 cup skim milk Mini whole-wheat bagel 1 ½ tsp soft margarine 1 cup coffee 2 tsp sugar	3-oz boneless skinless chicken breast 2 slices reduced-fat cheese 2 large leaves lettuce 2 slices tomato 1 Tbsp light mayonnaise 2 slices whole wheat bread 1 medium apple ½ cup raw carrot sticks 1 cup iced tea	1 cup spaghetti with vegetarian/low-sodium tomato sauce 3 Tbsp Parmesan cheese ½ cup green beans 1 cup spinach, raw ½ cup mushrooms, raw 2 Tbsp croutons 2 Tbsp low-fat Italian dressing 1 slice Italian bread ½ cup frozen yogurt
Midmorning Snack	Midafternoon Snack	
1 cup apple juice 2 oz walnuts	1 large banana	
Nutritional Analysis:	Calories: 1980 Protein: 78 g Fat: 56 g Saturated fat: 13 g Carbohydrates: 314 g	Sodium: 2377 mg Potassium: 4129 mg Fiber: 32 g Magnesium: 517 g

Exchange Lists and Carbohydrate Counting for Meal Planning

HOW THE EXCHANGE LIST WORKS WITH MEAL PLANNING

There are three main groups of foods in this exchange list. They are based on the three major nutrients: carbohydrates, protein (meat and meat substitutes), and fat. Each food list contains foods grouped together because they have similar nutrient content and serving sizes. Each serving of a food has about the same amount of carbohydrate, protein, fat, and calories as the other foods on the same list. Carbohydrate counting is used more often than the full exchange list, although the full exchange list can be useful for overall dietary balance and calorie counts.

- Foods on the **Carbohydrates** list, **Fruits** list, **Milk** list, and **Sweets, Desserts, and Other Carbohydrates** list are similar because they contain 12 to 15 grams of carbohydrate per serving.
- Foods on the **Fat** list and **Meat and Meat Substitutes** list usually do not have carbohydrate (except for the plant-based meat substitutes such as beans and lentils).

- Foods on the Starchy Vegetables list (part of the **Carbohydrates** list and including foods such as potatoes, corn, and peas) contain 15 grams of carbohydrate per serving.
- Foods on the **Nonstarchy Vegetables** list (such as green beans, tomatoes, and carrots) contain 5 grams of carbohydrate per serving.
- Some foods have so little carbohydrate and calories that they are considered “free,” if eaten in small amounts. You can find these foods on the **Free Foods** list.
- Foods that have different amounts of carbohydrates and calories are listed as **Combination Foods** (such as lasagna) or **Fast Foods**.

Foods are listed with their serving sizes, which are usually measured after cooking. When you begin, measuring the size of each serving will help you learn to “eyeball” correct serving sizes. The following chart shows the amount of nutrients in one serving from each list:

Food List	Carbohydrate (grams)	Protein (grams)	Fat (grams)	Calories
Carbohydrates				
Carbohydrates: breads, cereals and grains, starchy vegetables, crackers and snacks, and beans, peas, and lentils	15	0-3	0-1	80
Fruits	15	—	—	60
Milk				
Fat-free, low-fat, 1%	12	8	0-3	100
Reduced fat, 2%	12	8	5	120
Whole	12	8	8	160
Sweets, desserts, and other carbohydrates	15	Varies	Varies	Varies
Nonstarchy Vegetables	5	2	—	25
Meat and Meat Substitutes				
Lean	—	7	0-3	45
Medium-fat	—	7	4-7	75
High-fat	—	7	8+	100
Plant-based proteins	Varies	7	Varies	Varies
Fats	—	—	5	45
Alcohol	Varies	—	—	100

CARBOHYDRATES

Cereals, grains, pasta, breads, crackers, snacks, starchy vegetables, and cooked beans, peas, and lentils are carbohydrates. In general, one carbohydrate is:

- 1/2 cup of cooked cereal, grain, or starchy vegetable
- 1/2 cup of cooked rice or pasta

- 1 oz of a bread product, such as 1 slice of bread
- 3/4 oz to 1 oz of most snack foods (some snack foods may also have extra fat)

Nutrition Tips

1. A choice on the **Carbohydrates** list has 15 grams of carbohydrate, 0 to 3 grams of protein, 0 to 1 grams of fat, and 80 calories.

2. For maximum health benefits, eat three or more servings of whole grains each day. A serving of whole grain is about $\frac{1}{2}$ cup of cooked cereal or grain, 1 slice of whole-grain bread, or 1 cup of whole-grain cold breakfast cereal.

Selection Tips

1. Choose low-fat carbohydrates as often as you can.
2. Starchy vegetables, baked goods, and grains prepared with fat count as one carbohydrate and one fat.

3. For many starchy foods (bagels, muffins, dinner rolls, buns), a general rule of thumb is 1 oz equals one serving. Always check the size you eat. Because of their large size, some foods have a lot more carbohydrate (and calories) than you might think. For example, a large bagel may weigh 4 oz and equal four carbohydrate servings.
4. For specific information, read the Nutrition Facts panel on the food label.

Carbohydrates

Food	Serving Size	Food	Serving Size
Bread		Starchy Vegetables	
Bagel, large (about 4 oz)	$\frac{1}{4}$ (1 oz)	Cassava	$\frac{1}{3}$ cup
Biscuit, 2 $\frac{1}{2}$ inches across [†]	1	Corn	$\frac{1}{2}$ cup
Bread		On cob, large	$\frac{1}{2}$ cob (5 oz)
Reduced-calorie*	2 slices (1 $\frac{1}{2}$ oz)	Hominy, canned*	$\frac{3}{4}$ cup
White, whole-grain, pumpernickel, rye, unfrosted raisin	1 slice (1 oz)	Hummus	$\frac{1}{3}$ cup
Chapati, small, 6 inches across	1	Mixed vegetables with corn, peas, or pasta*	1 cup
Cornbread, 1 $\frac{3}{4}$ inch cube [†]	1 (1 $\frac{1}{2}$ oz)	Parsnips*	$\frac{1}{2}$ cup
English muffin	$\frac{1}{2}$	Peas, green*	$\frac{1}{2}$ cup
Hot dog bun or hamburger bun	$\frac{1}{2}$ (1 oz)	Plantain, ripe	$\frac{1}{3}$ cup
Naan, 8 inches by 2 inches	$\frac{1}{4}$	Potato	
Pancake, 4 inches across, $\frac{1}{4}$ inch thick	1	Baked with skin	$\frac{1}{4}$ large (3 oz)
Pita, 6 inches across	$\frac{1}{2}$	Boiled, all kinds	$\frac{1}{2}$ cup or $\frac{1}{2}$ medium (3 oz)
Roll, plain, small	1 (1 oz)	French fried (oven-baked)	1 cup (2 oz)
Stuffing, bread [†]	$\frac{1}{3}$ cup	Mashed, with milk and fat [†]	$\frac{1}{2}$ cup
Taco shell, 5 inches across [†]	2	Pumpkin, canned, no sugar added*	1 cup
Tortilla, corn, 6 inches across	1	Spaghetti/pasta sauce	$\frac{1}{2}$ cup
Tortilla, flour, 6 inches across	1	Squash, winter (acorn, butternut, delicata) [†]	1 cup
Tortilla, flour, 10 inches across	$\frac{1}{3}$ tortilla	Succotash*	$\frac{1}{2}$ cup
Waffle, 4-inch square or 4 inches across [†]	1	Yam, sweet potato, plain	$\frac{1}{2}$ cup
Cereals and Grains		Crackers and Snacks	
Barley, cooked	$\frac{1}{3}$ cup	Crackers	
Bran, dry		Animal crackers	8
Oat*	$\frac{1}{4}$ cup	Graham cracker, 2 $\frac{1}{2}$ -inch square	3
Wheat*	$\frac{1}{2}$ cup	Matzo	$\frac{3}{4}$ oz
Bulgur (cooked)*	$\frac{1}{2}$ cup	Melba toast, about 2-inch by 4-inch piece	4 pieces
Cereals		Oyster crackers	20
Bran*	$\frac{1}{2}$ cup	Round-butter type [†]	6
Cooked (grits, oats, oatmeal)	$\frac{1}{2}$ cup		
Puffed	1 $\frac{1}{2}$ cup		
Shredded wheat, plain	$\frac{1}{2}$ cup		
Sugar-coated	$\frac{1}{2}$ cup		
Unsweetened, ready-to-eat	$\frac{3}{4}$ cup		
Couscous	$\frac{1}{3}$ cup		
Granola			
Low-fat	$\frac{1}{4}$ cup		
Regular [†]	$\frac{1}{4}$ cup		
Granola bar	1		

Carbohydrates—cont'd

Food	Serving Size	Food	Serving Size
Rye crisps	4	Chips	Fat-free or baked (tortilla, potato), baked pita chips 15-20 (3/4 oz)
Saltine-type	6		
Sandwich-style, cheese or peanut butter filling†	3	Regular (tortilla, potato)†	9-13 (3/4 oz)
Whole-wheat regular†	2-5 (3/4 oz)	Beans, Peas, and Lentils	The Choices on this List Count as One Carbohydrate + One Lean Meat.
Whole-wheat lower fat or crispbreads*	2-5 (3/4 oz)		
Popcorn (Microwave Popped)		Baked beans*	1/3 cup
With butter†*	3 cups	Beans, cooked (black, garbanzo, kidney, lima, navy, pinto, white)*	1/2 cup
No fat added*	3 cups	Lentils, cooked (brown, green, red, yellow)*	1/2 cup
Lower fat*	3 cups	Peas, cooked (black-eyed, split)*	1/2 cup
Pretzels	3/4 oz	Refried beans, canned†*	1/2 cup
Rice cakes, 4 inches across	2		

*More than 3 grams of dietary fiber per serving.

†Extra fat or prepared with added fat. (Count as one carbohydrate + one fat.)

‡480 milligrams or more of sodium per serving.

FRUIT

Fresh, frozen, canned, and dried fruits and fruit juices are on this list. In general, 1 fruit choice is:

- 1/2 cup of canned or fresh fruit or unsweetened fruit juice
- 1 small fresh fruit (4 oz)
- 2 tablespoons of dried fruit

Nutrition Tips

1. A choice on the **Fruits** list has 15 grams of carbohydrate, 0 grams of protein, 0 grams of fat, and 60 calories.
2. Fresh, frozen, and dried fruits are good sources of fiber. Fruit juices contain very little fiber. Choose fruits instead of juices whenever possible.
3. Citrus fruits, berries, and melons are good sources of vitamin C.

Selection Tips

1. Use a food scale to weigh fresh fruits. Practice builds portion skills.
2. The weight listed includes skin, core, seeds, and rind.
3. Read the Nutrition Facts on the food label. If one serving has more than 15 g of carbohydrate, you may need to adjust the size of the serving.
4. Portion sizes for canned fruits are for the fruit and a small amount of juice (1 to 2 tablespoons).
5. Food labels for fruits may contain the words *no sugar added* or *unsweetened*. This means that no sucrose (table sugar) has been added; it *does not* mean the food contains no sugar.
6. Fruit canned in *extra light syrup* has the same amount of carbohydrate per serving as the *no sugar added* or *the juice pack*. All canned fruits on the **Fruits** list are based on one of these three types of pack. Avoid fruit canned in heavy syrup.

Fruit

Food	Serving Size	Food	Serving Size
Apple		Dates	3
Unpeeled, small	1 (4 oz)	Dried fruits (blueberries, cherries, cranberries, mixed fruit, raisins)	2 Tbsp
Dried	4 rings	Figs	Dried 1 1/2
Applesauce, unsweetened	1/2 cup		
Apricots		Fresh*	1 1/2 large or 2 medium (3 1/2 oz)
Canned	1/2 cup	Fruit cocktail	1/2 cup
Dried	8 halves	Grapefruit	Large 1/2 (11 oz)
Fresh*	4 whole (5 1/2 oz)		
Banana, extra small	1 (4 oz)	Sections, canned	3/4 cup
Banana, regular	1	Grapes, small	17 (3 oz)
Blackberries*	3/4 cup	Guava*	1/2
Blueberries	3/4 cup	Honeydew melon	1 slice or 1 cup cubed (10 oz)
Cantaloupe, small	1/3 melon or 1 cup cubed (11 oz)	Kiwi*	1 (3 1/2 oz)
Cherries		Kumquats*	5 (3 1/2 oz)
Sweet, canned	1/2 cup	Mandarin oranges, canned	3/4 cup
Sweet fresh	12 (3 oz)	Mango, small	1/2 fruit (5 1/2 oz) or 1/2 cup

Continued

Fruit—cont'd			
Food	Serving Size	Food	Serving Size
Nectarine, small	1 (5 oz)	Dried (prunes)	3
Orange, small*	1 (6½ oz)	Fresh, small	2 (5 oz)
Papaya	½ fruit or 1 cup cubed (8 oz)	Pomegranate*	½
Peaches		Raspberries*	1 cup
Canned	½ cup	Strawberries*	1¼ cup whole berries
Fresh, medium	1 (6 oz)	Tangerines, small*	2 (8 oz)
Pears		Watermelon	1 slice or 1¼ cups cubes (6½ oz)
Canned	½ cup	Fruit Juice	
Fresh, large	½ (4 oz)	Apple juice/cider	½ cup
Persimmon, medium	2	Fruit juice blends, 100% juice, unsweetened	⅓ cup
Pineapple		Grape juice	⅓ cup
Canned	½ cup	Grapefruit juice	½ cup
Fresh	¾ cup	Orange juice	½ cup
Plums		Pineapple juice	½ cup
Canned	½ cup	Prune juice	⅓ cup

*More than 3 grams of dietary fiber per serving.

MILK

Different types of milk and nondairy beverages are on this list. However, two types of milk products are found in other lists:

- Cheeses are on the **Meat and Meat Substitutes** list (because they are rich in protein).
- Cream and other dairy fats are on the **Fats** list.

Milks and yogurts are grouped in three categories (fat-free/low-fat, reduced-fat, or whole) based on the amount of fat they have. The following chart shows you what one milk choice contains:

Milk				
	Carbohydrate (grams)	Protein (grams)	Fat (grams)	Calories
Fat-free (skim), low-fat (1%)	12	8	0-3	100
Reduced-fat (2%)	12	8	5	120
Whole	12	8	8	160

Nutrition Tips

1. Milk and yogurt are good sources of calcium and protein.
2. The higher the fat content of milk and yogurt, the more saturated fat and cholesterol it has.
3. Children over the age of 2 and adults should choose lower-fat varieties such as skim, 1%, or 2% milks or yogurts.

Selection Tips

1. 1 cup equals 8 fluid oz or ½ pint.
2. If you choose 2%, or whole-milk foods, be aware of the extra fat.

Milk and Yogurts

Food	Serving Size	Count As
Fat-free (skim) or low-fat (1%)		
Milk, buttermilk, acidophilus milk, Lactaid	1 cup	1 fat-free milk
Evaporated milk	½ cup	1 fat-free milk
Chocolate milk	1 cup	1 fat-free milk + 1 carbohydrate
Eggnog	⅓ cup	1 carbohydrate
Yogurt, plain or Greek	⅔ cup (6 oz)	1 fat-free milk
Yogurt with fruit or juice	⅔ cup (6 oz)	1 fat-free milk + 1 carbohydrate
Yogurt, low carbohydrate (less than 6 grams carbohydrate per choice)	⅔ cup (6 oz)	½ fat-free milk
Reduced-fat (2%)		
Milk, acidophilus milk, kefir, Lactaid	1 cup	1 reduced-fat milk
Chocolate milk	1 cup	1 reduced-fat milk + 1 carbohydrate
Eggnog	⅓ cup	1 carbohydrate + 1 fat
Yogurt, plain or Greek	⅔ cup (6 oz)	1 reduced-fat milk
Yogurt with fruit or juice	⅔ cup (6 oz)	1 reduced-fat milk + 1 carbohydrate

Milk and Yogurts—cont'd		
Food	Serving Size	Count As
Whole		
Milk, buttermilk, goat's milk	1 cup	1 whole milk
Evaporated milk	1/2 cup	1 whole milk
Chocolate milk	1 cup	1 whole milk + 1 carbohydrate
Eggnog	1/2 cup	1 carbohydrate + 2 fats
Yogurt, plain or Greek	8 oz	1 whole milk
Yogurt with fruit or juice	2/3 cup (6 oz)	1 whole milk + 1 carbohydrate
Non-Dairy Beverages		
Almond milk		
Original	1 cup	1/2 carbohydrate + 1/2 fat
Flavored	1 cup	1 carbohydrate + 1/2 fat
Cashew milk		
Original	1 cup	1/2 carbohydrate + 1 fat
Flavored	1 cup	1 carbohydrate + 1 fat
Hemp milk		
Original	1 cup	1 carbohydrate + 1 fat
Flavored	1 cup	2 carbohydrates + 1 fat
Rice milk		
Original	1 cup	2 carbohydrates + 1 fat
Flavored	1 cup	2 carbohydrates + 1 fat
Soy milk		
Original	1 cup	1/2 carbohydrate + 1 fat
Flavored	1 cup	1 carbohydrate + 1 fat

SWEETS, DESSERTS, AND OTHER CARBOHYDRATES

You can substitute food choices from this list for other carbohydrate-containing foods (such as those found on the **Carbohydrates**, **Fruit**, or **Milk** lists) in your meal plan, even though these foods have added sugars or fat.

Common Measurements

Dry:

- 3 tsp = 1 Tbsp
- 4 oz = 1/2 cup
- 8 oz = 1 cup

Liquid:

- 4 Tbsp = 1/4 cup
- 8 oz = 1/2 pint

Nutrition Tips

1. A serving from this list has 15 grams of carbohydrate, variable grams of protein, variable grams of fat, and variable calories.
2. The foods on this list do not have as many vitamins, minerals, and fiber as the choices on the **Carbohydrates**, **Fruits**, or **Milk** lists. When choosing sweets, desserts, and other carbohydrate foods, you should also eat foods from other food lists to balance out your meals.
3. Many of these foods do not equal a single choice. Some will also count as one or more fat choices.
4. If you are trying to lose weight, choose foods from this list less often.
5. The serving sizes for these foods are small because of their fat content.

Selection Tips

1. Read the Nutrition Facts on the food label to find the serving size and nutrient information.
2. Many sugar-free, fat-free, or reduced-fat products are made with ingredients that contain carbohydrates. These types of food usually have the same amount of carbohydrates as the regular foods they are replacing. Talk with your registered dietitian nutritionist (RDN) and find out how to fit these foods into your meal plan.

Sweets, Desserts, and Other Carbohydrates

Food	Serving Size	Count As	Food	Serving Size	Count As
Beverages, Soda, and Energy/Sports Drinks			Brownies, Cake, Cookies, Gelatin, Pie, and Pudding		
Cranberry juice cocktail	1/2 cup	1 carbohydrate	Brownie, small, unfrosted	1 1/4-inch square, 7/8-inch high (about 1 oz)	1 carbohydrate + 1 fat
Energy drink	1 can (8.3 oz)	2 carbohydrates	Cake		
Fruit juice or lemonade	1 cup (8 oz)	2 carbohydrates	Angel food, unfrosted	1/12 of cake (about 2 oz)	2 carbohydrates
Hot Chocolate			Frosted	2-inch square (about 2 oz)	2 carbohydrates + 1 fat
Regular	1 envelope added to 8 oz water	1 carbohydrate + 1 fat	Unfrosted	2-inch square (about 2 oz)	1 carbohydrate + 1 fat
Sugar-free or light	1 envelope added to 8 oz water	1 carbohydrate			
Soft drink (soda), regular	1 can (12 oz)	2 1/2 carbohydrates			
Sports drink	1 cup (8 oz)	1 carbohydrate

Sweets, Desserts, and Other Carbohydrates—cont'd

Food	Serving Size	Count As	Food	Serving Size	Count As
Cookies			Cranberry sauce, jellied	1/4 cup	1 1/2 carbohydrates
Chocolate chip	2 cookies (2 1/4 inches across)	1 carbohydrate + 2 fats	Gravy, mushroom, canned [†]	1/2 cup	1/2 carbohydrate + 1/2 fat
Gingersnap	3 cookies	1 carbohydrate	Salad dressing, fat-free, low fat, cream-based	3 Tbsp	1 carbohydrate
Sandwich, with cream filling	2 small (about 2/3 oz)	1 carbohydrate + 1 fat	Sweet and sour sauce	3 Tbsp	1 carbohydrate
Sugar-free	3 small or 1 large (3/4-1 oz)	1 carbohydrate + 1-2 fats	Donuts, Muffins, Pastries, and Sweet Breads		
Vanilla wafer	5 cookies	1 carbohydrate + 1 fat	Banana nut bread	1-inch slice (1 oz)	2 carbohydrates + 1 fat
Cupcake, frosted	1 small (about 1 3/4 oz)	2 carbohydrates + 1-1 1/2 fats	Donuts		
Fruit cobbler	1/2 cup (3 1/2 oz)	3 carbohydrates + 1 fat	Cake, plain	1 medium (1 1/2 oz)	1 1/2 carbohydrates + 2 fats
Pie			Glazed	3 3/4 inches across (2 oz)	2 carbohydrates + 2 fats
Commercially prepared fruit, 2 crusts	1/6 of 8-inch pie	3 carbohydrates + 2 fats	Muffin (4 oz)	1/4 muffin (1 oz)	1 carbohydrate + 1/2 fat
Pumpkin or custard	1/3 of 8-inch pie	1 1/2 carbohydrates + 1 1/2 fats	Sweet roll or Danish	1 (2 1/2 oz)	2 1/2 carbohydrates + 2 fats
Pudding			Frozen Bars, Frozen Desserts, Frozen Yogurt, and Ice Cream		
Regular (made with reduced-fat milk)	1/2 cup	2 carbohydrates	Frozen pops	1	1/2 carbohydrate
Sugar-free or sugar- and fat-free (made with fat-free milk)	1/2 cup	1 carbohydrate	Fruit juice bars, frozen, 100% juice	1 bar (3 oz)	1 carbohydrate
Candy, Spreads, Sweets, Sweeteners, Syrups, and Toppings			Ice Cream		
Candy bar, chocolate/peanut	2 "fun size" bars (1 oz)	1 1/2 carbohydrates + 1 1/2 fats	Fat-free	1/2 cup	1 1/2 carbohydrates
Candy, hard	3 pieces	1 carbohydrate	Light	1/2 cup	1 carbohydrate + 1 fat
Chocolate "kisses"	5 pieces	1 carbohydrate + 1 fat	No sugar added	1/2 cup	1 carbohydrate + 1 fat
Coffee Creamer			Regular	1/2 cup	1 carbohydrate + 2 fats
Dry, flavored	4 tsp	1/2 carbohydrate + 1/2 fat	Sherbet, sorbet	1/2 cup	2 carbohydrates
Liquid, flavored	2 Tbsp	1 carbohydrate	Yogurt, Frozen		
Fruit snacks, chewy (pureed fruit concentrate)	1 roll (3/4 oz)	1 carbohydrate	Fat-free	1/3 cup	1 carbohydrate
Fruit spreads, 100% fruit	1 1/2 Tbsp	1 carbohydrate	Regular	1/2 cup	1 carbohydrate + 0-1 fat
Honey	1 Tbsp	1 carbohydrate	Granola Bars, Meal Replacement Bars/Shakes, and Trail Mix		
Jam or jelly, regular	1 Tbsp	1 carbohydrate	Granola or snack bar, regular or low-fat	1 bar (1 oz)	1 1/2 carbohydrates
Sugar	1 Tbsp	1 carbohydrate	Meal replacement bar	1 bar (1 1/3 oz)	1 1/2 carbohydrates + 0-1 fat
Syrup			Meal replacement bar	1 bar (2 oz)	2 carbohydrates + 1 fat
Chocolate	2 Tbsp	2 carbohydrates	Meal replacement shake, reduced calorie	1 can (10-11 oz)	1 1/2 carbohydrates + 0-1 fat
Light (pancake type)	2 Tbsp	1 carbohydrate	Trail Mix		
Maple	1 Tbsp	1 carbohydrate	Candy/nut-based	1 oz	1 carbohydrate + 2 fats
Condiments and Sauces			Dried fruit-based	1 oz	1 carbohydrate + 1 fat
Barbecue sauce	3 Tbsp	1 carbohydrate			

[†]480 mg or more of sodium per serving.

NONSTARCHY VEGETABLES

Vegetable choices include vegetables in this **Nonstarchy Vegetables** list and the **Starchy Vegetables** list found within the **Carbohydrates** list. Vegetables with small amounts of carbohydrate and calories are on the **Nonstarchy Vegetables** list. Vegetables contain important nutrients. Try to eat at least two to three nonstarchy vegetable choices each day (as well as choices from the **Starchy Vegetables** list). In general, one nonstarchy vegetable choice is:

- 1/2 cup of cooked vegetables or vegetable juice
- 1 cup of raw vegetables

If you eat 3 cups or more of raw vegetables or 1 1/2 cups of cooked vegetables in a meal, count them as one carbohydrate choice.

Nutrition Tips

1. A choice on this list (1/2 cup cooked or 1 cup raw) equals 5 grams of carbohydrate, 2 grams of protein, 0 grams of fat, and 25 calories.
2. Fresh and frozen vegetables have less added salt than canned vegetables. Drain and rinse canned vegetables to remove some salt.

3. Choose dark green and dark yellow vegetables each day. Spinach, broccoli, romaine, carrots, chilies, squash, and peppers are great choices.
4. Brussels sprouts, broccoli, cauliflower, greens, peppers, spinach, and tomatoes are good sources of vitamin C.
5. Eat vegetables from the cruciferous family several times each week. Cruciferous vegetables include bok choy, broccoli, Brussels sprouts, cabbage, cauliflower, collards, kale, kohlrabi, radishes, rutabaga, turnip, and watercress.

Selection Tips

1. Canned vegetables and juices are also available without added salt.
2. A 1-cup portion of broccoli is a portion about the size of a regular light bulb.
3. Starchy vegetables such as corn, peas, winter squash, and potatoes that have more calories and carbohydrates are on the **Starchy Vegetables** section in the **Carbohydrates** list.
4. The tomato sauce referred to in this list is different from spaghetti/pasta sauce, which is on the **Starchy Vegetables** list.

Nonstarchy Vegetables

Amaranth or Chinese spinach	Chayote*	Peppers (all varieties)*
Artichoke	Coleslaw, packaged, no dressing	Radishes (breakfast, daikon, watermelon)
Artichoke hearts	Cucumber	Rutabaga
Asparagus	Eggplant	Sauerkraut†
Baby corn	Gourds (bitter, bottle, luffa, bitter melon)	Spinach
Bamboo shoots	Green onions or scallions	Sprouts (alfalfa, broccoli, clover, mung bean, radish, soybean)
Beans (green, wax, Italian)	Greens (dandelion, collard, kale, mustard, turnip)	Squash (summer, crookneck, zucchini)
Bean sprouts	Hearts of palm	Sugar pea snaps
Beets	Jicama	Swiss chard*
Borscht†	Kohlrabi	Tomato, fresh or canned
Broccoli	Leeks	Tomato sauce†
Brussels sprouts*	Mixed vegetables (without corn, peas, or pasta)	Tomato/vegetable juice†
Cabbage (purple, green, bok choy, Chinese)	Mushrooms, all kinds, fresh	Turnips
Carrots*	Okra	Water chestnuts
Cauliflower	Onions (green, pearl, red, shallots, sweet, white, yellow)	Watercress
Celery	Pea pods	Yard-long beans

*More than 3 grams of dietary fiber per serving.

†480 milligrams or more of sodium per serving.

MEAT AND MEAT SUBSTITUTES

Meat and meat substitutes are rich in protein. Foods from this list are divided into four groups based on the amount of fat they contain. These groups are lean meat, medium-fat meat, high-fat meat, and plant-based proteins. The following chart shows you what one choice includes:

Meat and Meat Substitutes

	Carbohydrate (grams)	Protein (grams)	Fat (grams)	Calories
Lean meat	—	7	0-3	45
Medium-fat meat	—	7	4-7	75
High-fat meat	—	7	8+	100
Plant-based protein	Varies	7	Varies	Varies

Nutrition Tips

1. Read labels to find foods low in fat and cholesterol. Try for 3 grams of fat or less per serving.
2. Read labels to find “hidden” carbohydrate. For example, hot dogs actually contain a lot of carbohydrate. Most hot dogs are also high in fat but are often sold in lower-fat versions.

3. Whenever possible, choose lean meats.
 - a. Select grades of meat that are the leanest.
 - b. Choice grades have a moderate amount of fat.
 - c. Prime cuts of meat have the highest amount of fat.
4. Fish such as herring, mackerel, salmon, sardines, halibut, trout, and tuna are rich in omega-3 fats, which may help reduce risk for heart disease. Choose fish (not commercially fried fish fillets) two or more times each week.
5. Bake, roast, broil, grill, poach, steam, or boil instead of frying.

Selection Tips

1. Trim off visible fat or skin.
2. Roast, broil, or grill meat on a rack so that the fat will drain off during cooking.
3. Use a nonstick spray and a nonstick pan to brown or fry foods.
4. Some processed meats, seafood, and soy products contain carbohydrates. Read the food label to see if the amount of carbohydrates in the serving size you plan to eat is 12 to 15 grams. If so, count it as one carbohydrate choice and one or more meat choice.
5. Meat or fish that is breaded with cornmeal, flour, or dried breadcrumbs contain carbohydrates. Count 3 Tbsp of one of these dry grains as 15 grams of carbohydrate.

Lean Meats and Meat Substitutes

Food	Amount
Beef: Select or Choice grades trimmed of fat: ground round, roast (chuck, rib, rump), round, sirloin, steak (cubed, flank, porterhouse, T-bone), tenderloin	1 oz
Beef jerky [†]	1 oz
Cheeses with 3 grams of fat or less per oz	1 oz
Cottage cheese	1/4 cup
Egg substitutes, plain	1/4 cup
Egg whites	2
Fish, fresh, frozen, or canned, plain: catfish, cod, flounder, haddock, halibut, orange roughy, salmon, tilapia, trout, tuna	1 oz
Fish, smoked: herring or salmon (lox) [†]	1 oz
Game: buffalo, ostrich, rabbit, venison	1 oz
Hot dog with 3 grams of fat or less per oz [†] (8 dogs per 14 oz package) (Note: May be high in carbohydrate)	1
Lamb: chop, leg, or roast	1 oz
Organ meats: heart, kidney, liver (Note: May be high in cholesterol)	1 oz
Oysters, fresh or frozen	6 medium
Pork, Lean	
Canadian bacon [†]	1 oz
Rib or loin chop/roast, ham, tenderloin	1 oz
Poultry, without skin: Cornish hen, chicken, domestic duck or goose (well-drained of fat), turkey	1 oz
Processed sandwich meats with 3 grams of fat or less per oz: chipped beef, deli thin-sliced meats, turkey ham, turkey kielbasa, turkey pastrami	1 oz
Salmon, canned	1 oz
Sardines, canned	2 medium
Sausage with 3 grams of fat or less per oz [†]	1 oz
Shellfish: clams, crab, imitation shellfish, lobster, scallops, shrimp	1 oz
Veal, loin chop, roast	1 oz
Medium-Fat Meat and Meat Substitutes	
Beef: corned beef, ground beef, meatloaf, prime grades trimmed of fat (prime rib), short ribs, tongue	1 oz
Cheeses with 4-7 grams of fat per oz: feta, mozzarella, pasteurized processed cheese spread, reduced-fat cheeses, string	1 oz
Egg (Note: High in cholesterol, so limit to 3 per week)	1
Fish, any fried product	1 oz
Lamb: ground, rib roast	1 oz
Pork: cutlet, shoulder roast	1 oz
Poultry: chicken with skin; dove, pheasant, wild duck, or goose; fried chicken; ground turkey	1 oz
Ricotta cheese	2 oz or 1/4 cup
Sausage with 4-7 grams of fat per oz [†]	1 oz
Veal, cutlet (no breading)	1 oz

[†]480 milligrams or more of sodium per serving.

The following foods are high in saturated fat, cholesterol, and calories and may raise blood cholesterol levels if eaten on a regular basis. Try to eat three or fewer servings from this group per week.

High-Fat Meat and Meat Substitutes

Food	Amount
Bacon	
Pork [†]	2 slices (16 slices per lb or 1 oz each, before cooking)
Turkey [†]	3 slices (1/2 oz each before cooking)
Cheese, regular: American, bleu, brie, cheddar, hard goat, Monterey jack, queso, and Swiss	1 oz
Hot dog: beef, pork, or combination (10 per lb-sized package) ^{††}	1
Hot dog: turkey or chicken (10 per lb-sized package) [†]	1
Pork: ground, sausage, spareribs	1 oz
Processed sandwich meats with 8 grams of fat or more per oz: bologna, pastrami, hard salami	1 oz
Sausage with 8 grams fat or more per oz: bratwurst, chorizo, Italian, knockwurst, Polish, smoked, summer ^{††}	1 oz

[†]Extra fat or prepared with added fat. (Add an additional fat choice to this food.)

^{††}480 milligrams or more of sodium per serving.

Because carbohydrate content varies among plant-based proteins, you should read the food label.

Plant-Based Proteins

Food	Amount	Count As
"Bacon" strips, soy-based	3 strips	1 medium-fat meat
Baked beans [*]	1/3 cup	1 carbohydrate + 1 lean meat
Beans, cooked: black, garbanzo, kidney, lima, navy, pinto, white [*]	1/2 cup	1 carbohydrate + 1 lean meat
"Beef" or "sausage" crumbles, soy-based [*]	2 oz	1/2 carbohydrate + 1 lean meat
"Chicken" nuggets, soy-based	2 nuggets (1 1/2 oz)	1/2 carbohydrate + 1 medium-fat meat
Edamame [*]	1/2 cup	1/2 carbohydrate + 1 lean meat
Falafel (spiced chickpea and wheat patties)	3 patties (about 2 inches across)	1 carbohydrate + 1 high-fat meat

Plant-Based Proteins—cont'd

Food	Amount	Count As
Hot dog, soy-based	1 (1½ oz)	½ carbohydrate + 1 lean meat
Hummus*	⅓ cup	1 carbohydrate + 1 high-fat meat
Lentils, brown, green, or yellow*	½ cup	1 carbohydrate + 1 lean meat
Meatless burger, soy-based*	3 oz	½ carbohydrate + 2 lean meats
Meatless burger, vegetable- and starch-based*	1 patty (about 2½ oz)	1 carbohydrate + 2 lean meats
Nut spreads: almond butter, cashew butter, peanut butter, soy nut butter	1 Tbsp	1 high-fat meat
Peas, cooked: black-eyed and split peas*	½ cup	1 carbohydrate + 1 lean meat
Refried beans, canned**	½ cup	1 carbohydrate + 1 lean meat
“Sausage” patties, soy-based	1 (1½ oz)	1 medium-fat meat
Soy nuts, unsalted	¾ oz	½ carbohydrate + 1 medium-fat meat
Tempeh	¼ cup	1 medium-fat meat
Tofu	4 oz (½ oz)	1 medium-fat meat
Tofu, light	4 oz (½ oz)	1 lean meat

*More than 3 grams of dietary fiber per serving.
 †480 milligrams or more of sodium per serving.

FATS

Fats are divided into three groups, based on the main type of fat they contain:

- **Unsaturated fats** (omega-3, monounsaturated, and polyunsaturated) are primarily vegetable and are liquid at room temperature. These fats have good health benefits.
 - **Omega-3 fats** are a type of polyunsaturated fat and can help lower triglyceride levels and the risk of heart disease.
 - **Monounsaturated fats** also help lower cholesterol levels and may help raise high-density lipoprotein (HDL) (good) cholesterol levels.
 - **Polyunsaturated fats** can help lower cholesterol levels.
- **Saturated fats** have been linked with heart disease. They can raise low-density lipoprotein (LDL) (bad) cholesterol levels and should be eaten in small amounts. Saturated fats are solid at room temperature.
- **Trans fats** are made in a process that changes vegetable oils into semisolid fats. These fats can raise blood cholesterol levels and should be eaten in small amounts. Partially hydrogenated and hydrogenated fats are types of man-made trans fats and should be avoided. Trans fats are also found naturally occurring in some animal products such as meat, cheese, butter, and dairy products.

Nutrition Tips

1. A choice on the **Fats** list contains 5 grams of fat and 45 calories.
2. All fats are high in calories. Limit serving sizes for good nutrition and health.

3. Limit the amount of fried foods you eat.
4. Nuts and seeds are good sources of unsaturated fats if eaten in moderation. They have small amounts of fiber, protein, and magnesium.
5. Good sources of omega-3 fatty acids include:
 - a. Fish such as albacore tuna, halibut, herring, mackerel, salmon, sardines, and trout.
 - b. Flaxseeds, chia seeds, and English walnuts.
 - c. Oils such as canola, soybean, flaxseed, and walnut.

Selection Tips

1. Read the Nutrition Facts on food labels for serving sizes. One fat choice is based on a serving size that has 5 grams of fat.
2. The food label also lists total fat grams, saturated fat, and trans fat grams per serving. When most of the calories come from saturated fat, the food is part of the Saturated Fats list.
3. When selecting fats, consider replacing saturated fats with monounsaturated fats and omega-3 fats.

Fats and oils have mixtures of unsaturated (polyunsaturated and monounsaturated) and saturated fats. Foods on the Fats list are grouped together based on the major type of fat they contain. In general, one fat choice equals:

 - 1 teaspoon of vegetable oil or butter
 - 1 tablespoon of regular salad dressing

Fats	
Food	Serving Size
Monounsaturated Fats	
Avocado, medium	2 Tbsp (1 oz)
Nut butters: almond butter, cashew butter, peanut butter (smooth or crunchy)	1½ tsp
Nuts	
Almonds	6 nuts
Brazil	2 nuts
Cashews	6 nuts
Filberts (hazelnuts)	5 nuts
Macadamia	3 nuts
Mixed (50% peanuts)	6 nuts
Peanuts	10 nuts
Pecans	4 halves
Pistachios	16 nuts
Oil: canola, olive, peanut	1 tsp
Olives	
Black (ripe)	8 large
Green, stuffed	10 large
Polyunsaturated Fats	
Mayonnaise	
Reduced-fat	1 Tbsp
Regular	1 tsp
Mayonnaise-Style Salad Dressing	
Reduced-fat	1 Tbsp
Regular	2 tsp
Non-Dairy Spread, stick or tub	1 tsp

Continued

Fats—cont'd	
Food	Serving Size
Nuts	
Walnuts, English	4 halves
Pignolia (pine nuts)	1 Tbsp
Oil: canola, corn, cottonseed, flaxseed, grape seed, safflower, soybean, sunflower	1 tsp
Salad Dressing	
Reduced-fat (Note: May be high in carbohydrate) [†]	2 Tbsp
Regular [†]	1 Tbsp
Seeds	
Chia, flaxseed (whole), pumpkin, sunflower, sesame	1 Tbsp
Tahini or sesame paste	2 tsp
Saturated Fats	
Bacon, cooked, regular, or turkey	1 slice
Butter	
Stick	1 tsp
Whipped	2 tsp
Butter Blend made with Oil	
Reduced-fat or light	1 Tbsp
Regular	1½ tsp
Coconut, sweetened, shredded	2 Tbsp
Coconut Milk	
Light	⅓ cup
Regular	1½ Tbsp
Cream	
Half and half	2 Tbsp
Heavy	1 Tbsp
Light	1½ Tbsp
Whipped	2 Tbsp
Whipped, pressurized	¼ cup
Cream Cheese	
Reduced-fat	1½ Tbsp (¾ oz)
Regular	1 Tbsp (½ oz)
Lard	1 tsp
Oil: coconut, palm, palm kernel	1 tsp
Salt pork	¼ oz
Shortening, solid	1 tsp
Sour Cream	
Reduced-fat or light	3 Tbsp
Regular	2 Tbsp

[†]480 milligrams or more of sodium per serving.

FREE FOODS

A “free” food is any food or drink choice that has less than 20 calories and 5 grams or less of carbohydrate per serving.

Selection Tips

1. Most foods on this list should be limited to three servings (as listed here) per day. Spread out the servings throughout the day. If you eat all three servings at once, it could raise your blood glucose level.
2. Food and drink choices listed here without a serving size can be eaten whenever you like.

Free Foods	
Food	Serving Size
Low Carbohydrate Foods	
Cabbage, raw	½ cup
Candy, hard (sugar-free)	1 piece
Carrots, cauliflower, or green beans, cooked	¼ cup
Cranberries, sweetened with sugar substitute	½ cup
Cucumber, sliced	½ cup
Gum, sugar free	1 stick
Jam or jelly, light or no sugar added	2 tsp
Rhubarb, sweetened with sugar substitute	½ cup
Salad greens	1 cup raw
Sugar substitutes (artificial sweeteners)	
Syrup, sugar-free	2 Tbsp
Modified Fat Foods with Carbohydrate	
Cream cheese, fat-free	1 Tbsp (½ oz)
Creamers	
Nondairy, liquid	1 Tbsp
Nondairy, powdered	2 tsp
Mayonnaise	
Fat-free	1 Tbsp
Reduced-fat	1 tsp
Mayonnaise-Style Salad Dressing	
Fat-free	1 Tbsp
Reduced-fat	1 tsp
Salad Dressing	
Fat-free or low-fat	1 Tbsp
Fat-free, Italian	2 Tbsp
Sour cream, fat-free or reduced-fat	1 Tbsp
Whipped Topping	
Light or fat-free	2 Tbsp
Regular	1 Tbsp
Condiments	
Barbecue sauce	2 tsp
Honey mustard	1 Tbsp
Horseradish	1 tsp
Ketchup	1 Tbsp
Lemon juice	1 Tbsp
Miso	1½ tsp
Mustard	1 Tbsp
Parmesan cheese, freshly grated	1 Tbsp
Pickle relish	1 Tbsp
Salsa	¼ cup

Free Foods—cont'd

Food	Serving Size
Soy sauce, light or regular [†]	1 Tbsp
Sweet and sour sauce	2 tsp
Sweet chili sauce	2 tsp
Taco sauce	1 Tbsp
Vinegar	1 Tbsp
Pickles	
Dill [‡]	1½ medium
Sweet, bread and butter	2 slices
Sweet, gherkin	¾ oz

[†]480 milligrams or more of sodium per serving.

Drinks/Mixes

Any food on this list—without a serving size listed—can be consumed in any moderate amount:

- Bouillon, broth, consommé[‡]
- Bouillon or broth, low-sodium
- Carbonated or mineral water
- Club soda
- Cocoa powder, unsweetened (1 Tbsp)
- Coffee, unsweetened or with sugar substitute
- Diet soft drinks, sugar-free
- Drink mixes, sugar-free
- Tea, unsweetened or with sugar substitute
- Tonic water, diet
- Water
- Water, flavored, carbohydrate free

Seasonings

Any food on this list can be consumed in any moderate amount:

- Flavoring extracts (e.g., vanilla, almond, peppermint)
- Garlic
- Herbs, fresh or dried
- Nonstick cooking spray
- Pimento
- Spices
- Hot pepper sauce
- Wine, used in cooking
- Worcestershire sauce

COMBINATION FOODS

Many of the foods you eat are mixed together in various combinations, such as casseroles. These “combination” foods do not fit into any one choice list. This is a list of choices for some typical combination foods. This list will help you fit these foods into your meal plan. Ask your RDN for nutrient information about other combination foods you would like to eat, including your own recipes.

Combination Foods

Food	Serving Size	Count As
Entrees		
Casserole type (tuna noodle, lasagna, spaghetti with meatballs, chili with beans, macaroni and cheese) [‡]	1 cup (8 oz)	2 carbohydrates + 2 medium-fat meats

Combination Foods—cont'd

Food	Serving Size	Count As
Stews (beef/other meats and vegetables) [‡]	1 cup (8 oz)	1 carbohydrate + 1 medium-fat meat + 0-3 fats
Tuna salad or chicken salad	½ cup (31/2 oz)	½ carbohydrate + 2 lean meats + 1 fat
Frozen Meals/Entrees		
Burrito (beef and bean) ^{†*}	1 (5 oz)	3 carbohydrates + 1 lean meat + 2 fats
Entree or meal with more than 340 calories [‡]	Generally 14-17 oz	3 carbohydrates + 3 medium-fat meats + 3 fats
Entree or meal with less than 340 calories [‡]	About 8-11 oz	2-3 carbohydrates + 1-2 lean meats
Pizza		
Cheese/vegetarian, thin crust [‡]	¼ of a 12 inch (4½-5 oz)	2 carbohydrates + 2 medium-fat meats
Meat topping, thin crust [‡]	¼ of a 12 inch (5 oz)	2 carbohydrates + 2 medium-fat meats + 1½ fats
Pocket sandwich [‡]	1 (4½ oz)	3 carbohydrates + 1 lean meat + 1-2 fats
Pot pie [‡]	1 (7 oz)	2½ carbohydrates + 1 medium-fat meat + 3 fats
Salads (Deli-Style)		
Coleslaw	½ cup	1 carbohydrate + 1½ fats
Macaroni/pasta salad	½ cup	2 carbohydrates + 3 fats
Potato salad [‡]	½ cup	1½-2 carbohydrates + 1-2 fats
Soups		
Asian noodle (pho, ramen) [‡]	1 cup	2 carbohydrates + 2 fats
Bean, lentil, or split pea [‡]	1 cup	1 carbohydrate + 1 lean meat
Chowder (made with milk) [‡]	1 cup (8 oz)	1 carbohydrate + 1 lean meat + 1½ fats
Instant [‡]	6 oz prepared	1 carbohydrate
With beans or lentils [‡]	8 oz prepared	2½ carbohydrates + 1 lean meat
Miso soup [‡]	1 cup	½ carbohydrate + 1 fat
Rice (congee)	1 cup	1 carbohydrate
Tomato (made with water) [‡]	1 cup (8 oz)	1 carbohydrate
Vegetable beef, chicken noodle, or other broth-type [‡]	1 cup (8 oz)	1 carbohydrate

*More than 3 grams of dietary fiber per serving.

[‡]600 milligrams or more of sodium per serving (for combination food main dishes/meals).

FAST FOOD

The choices in the **Fast Food** list are not specific fast food meals or items but are estimates based on popular foods. You can get specific

nutrition information for almost every fast food or restaurant chain. Ask the restaurant or check its website for nutrition information about your favorite fast foods.

Fast Food			Fast Food		
Food	Serving Size	Count As	Food	Serving Size	Count As
Asian			Sandwiches		
Beef/chicken/shrimp with vegetables in sauce [†]	1 cup (about 5 oz)	1 carbohydrate + 1 lean meat + 1 fat	Cheese/vegetarian, thin crust [†]	1/4 of a 12 inch (about 6 oz)	2 1/2 carbohydrates + 2 medium-fat meats + 1 1/2 fats
Egg roll, meat [†]	1 (about 3 oz)	1 carbohydrate + 1 lean meat + 1 fat	Chicken sandwich, grilled [†]	1	3 carbohydrates + 4 lean meats
Fried rice, vegetarian	1/2 cup	1 1/2 carbohydrates + 1 1/2 fats	Chicken sandwich, crispy [†]	1	3 1/2 carbohydrates + 3 medium-fat meats + 1 fat
Meat and sweet sauce (orange chicken) [†]	1 cup	3 carbohydrates + 3 medium-fat meats + 2 fats	Fish sandwich with tartar sauce	1	2 1/2 carbohydrates + 2 medium-fat meats + 2 fats
Noodles and vegetables in sauce (chow mein, lo mein) ^{†*}	1 cup	1 carbohydrate + 1 medium-fat meat + 1 1/2 fats	Hamburger		
Soup, hot and sour	1 cup	1/2 carbohydrate + 1/2 fat	Large with cheese [†]	1	2 1/2 carbohydrates + 4 medium-fat meats + 1 fat
Breakfast Sandwiches			Regular	1	2 carbohydrates + 1 medium-fat meat + 1 fat
Egg, cheese, meat, English muffin [†]	1 sandwich	2 carbohydrates + 2 medium-fat meats	Soy (meatless)	1	1/2 carbohydrate + 2 lean meats
Sausage biscuit sandwich [†]	1 sandwich	2 carbohydrates + 2 high-fat meats + 3 1/2 fats	Veggie and grain	1	1 carbohydrate + 2 lean meats
Main Dishes/Entrees			Hot dog with bun [†]	1	1 carbohydrate + 1 high-fat meat + 1 fat
Burrito			Submarine Sandwiches		
Bean and cheese ^{†*}	1 (about 8 oz)	3 1/2 carbohydrates + 1 medium-fat meats + 1 fats	Less than 6 grams fat [†]	6-inch sub	3 carbohydrates + 2 lean meats
Beef and beans ^{†*}	1 (about 8 oz)	3 carbohydrates + 3 medium-fat meats + 3 fats	Regular [†]	6-inch sub	3 1/2 carbohydrates + 2 medium-fat meats + 1 fat
Chicken breast, breaded and fried [†]	1 (about 5 oz)	1 carbohydrate + 4 medium-fat meats	Salads		
Chicken drumstick, breaded and fried	1 (about 2 oz)	2 medium-fat meats	Salad, main dish (grilled chicken type, no dressing or croutons) ^{†*}	Salad	1 carbohydrate + 4 lean meats
Chicken nuggets [†]	6 (about 3 1/2 oz)	1 carbohydrate + 2 medium-fat meats + 1 fat	Salad, side, no dressing or cheese	Small (about 5 oz)	1 vegetable
Chicken thigh, breaded and fried [†]	1 (about 4 oz)	1/2 carbohydrate + 3 medium-fat meats + 1 1/2 fats	Sides/Appetizers		
Chicken wings, hot [†]	6 (5 oz)	5 medium-fat meats + 1 1/2 fats	Falafel patties	3	1 carbohydrate + 1 high-fat meat
Spaghetti with meatballs	1 cup	2 carbohydrates + 2 medium-fat meats	French fries, restaurant style [†]	Small	3 carbohydrates + 3 fats
Taco, hard or soft shell (meat and cheese)	1 small	1 carbohydrate + 1 medium-fat meat + 1 1/2 fats		Medium	4 carbohydrates + 4 fats
Taco salad with chicken and tortilla bowl	16 oz	3 1/2 carbohydrates + 4 medium-fat meat + 3 fats		Large	5 carbohydrates + 6 fats
Pizza			Hummus	1/3 cup	1 carbohydrate + 1 medium-fat meat
Cheese, pepperoni, regular crust [†]	1/8 of a 14 inch (about 4 oz)	2 1/2 carbohydrates + 1 medium-fat meat + 1 1/2 fats			

Fast Food—cont'd					
Food	Serving Size	Count As	Food	Serving Size	Count As
Nachos with cheese [†]	Small (about 4½ oz)	2⅓ carbohydrates + 4 fats	Desserts		
Onion rings [†]	1 serving (about 3 oz)	2½ carbohydrates + 3 fats	Milkshake, any flavor	12 oz	6 carbohydrates + 2 fats
Refried beans ^{†*}	½ cup	1 carbohydrate + 1 lean meat	Soft-serve ice cream cone	1 small	2½ carbohydrates + 1 fat

*More than 3 grams of dietary fiber per serving.

†Extra fat or prepared with extra fat.

‡600 milligrams or more of sodium per serving (for fast food main dishes/meals).

ALCOHOL

Nutrition Tips

1. In general, one alcohol choice (½ oz absolute alcohol) has about 100 calories.

Selection Tips

1. If you choose to drink alcohol, you should limit it to one drink or fewer per day for women, and two drinks or fewer per day for men.

2. To reduce your risk of low blood glucose (hypoglycemia), especially if you take insulin or a diabetes pill that increases insulin, always drink alcohol with food.
3. While alcohol, by itself, does not directly affect blood glucose, be aware of the carbohydrate (for example, in mixed drinks, beer, and wine) that may raise your blood glucose.
4. Check with your RDN if you would like to fit alcohol into your meal plan.

Alcohol		
Alcoholic Beverage	Serving Size	Count As
Beer		
Light (4.2%)	12 fl oz	1 alcohol equivalent + ½ carbohydrate
Regular (4.9%)	12 fl oz	1 alcohol equivalent + 1 carbohydrate
Distilled spirits: vodka, rum, gin, whiskey 80 or 86 proof	1½ fl oz	1 alcohol equivalent
Liqueur, coffee (53 proof)	1 fl oz	1 alcohol equivalent + 1 carbohydrate
Sake	1 fl oz	½ alcohol equivalent
Wine		
Dessert (sherry)	3½ fl oz	1 alcohol equivalent + 1 carbohydrate
Dry, red or white (10%)	5 fl oz	1 alcohol equivalent

1500	5	2		9	2 - 3
2000	5 - 6	2		11	5
2500	8	3		17	8
3000	10	4		17	10

The Ketogenic Diet

The ketogenic diet is a high-fat diet that is low in carbohydrate, adequate in protein, and mimics fasting.^{1,2} Under the condition of reduced carbohydrate and increased fat intake, fats are converted into ketone bodies in the liver, resulting in a state of ketosis. Ketone bodies are then utilized as the main energy source by the brain and other organs, instead of the usual energy source, glucose.¹

A ketogenic diet is an evidence-based and effective treatment primarily for epilepsy that has been utilized and researched for nearly 100 years. Dating back to biblical times, fasting has been noted to treat epilepsy.¹ In the early 1920s, Dr. Russell Wilde at the Mayo Clinic suggested that a high-fat and low-carbohydrate diet can mimic fasting and produce ketosis.^{1,2} The diet was developed and utilized for the treatment of epilepsy, but the use of the diet decreased with the introduction of additional antiseizure medications in 1930s.² The diet gained increased popularity again in 1990s. The increase in its popularity has been attributed to the efforts of Jim Abraham's family, who, in 1994, founded the Charlie Foundation. The Charlie Foundation is a not-for-profit organization established in the United States to educate the public on the use of ketogenic diets for the treatment of epilepsy after the founder's son, Charlie Abrahams, became seizure-free on the diet. Since then, numerous studies have been published on the use of the ketogenic diet. In 2017, the American College of Nutrition awarded the Charlie Foundation with the Humanitarian Award for being "an organization that has worked selflessly and effectively in the broader field of nutrition to benefit humanity."³

Less restrictive variations of ketogenic diet have been developed, including modified Atkins diet (MAD), low glycemic index treatment (LGIT), and medium chain triglyceride (MCT) oil diet (see [Tables 1 and 2](#)). The diet type is chosen by the medical team based on individual diet needs, preferences, medical history, and age of each patient.⁴ Overall, more than 50% of patients with epilepsy will develop greater than 50% seizure reduction and some will become seizure-free on a ketogenic type diet.²

A classic ketogenic diet is the strictest type of a ketogenic diet. Patients are usually young children and are admitted to the hospital for the diet initiation. All meal ingredients are weighed on a gram scale with 0.1 gram accuracy. The diet ratio is calculated for every meal and snack (see [Table 3](#)). There is commonly 3 to 4 parts of fat for every 1 part of the sum of protein and net carbohydrates (net carbohydrates = total carbohydrates minus fiber).¹ For example, if a meal contains 40 grams fat, 7 grams protein, and 3 grams net carbohydrates, it has 4:1 ratio, because $40:(7 + 3) = 40:10 = 4:1$. A 2016 review of randomized controlled studies showed that with a 4:1 ratio classic ketogenic diet, up to 55% patients became seizure-free and up to 85% had a reduction in seizures.⁵ Although 4:1 and 3:1 ratios are the most commonly used, lower diet ratios that accommodate more carbohydrates and contain less fat are used as well and are called a modified ketogenic

diet. Lower-ratio diet may provide higher compliance and less side effects; however, diet efficacy can be reduced. The KetoDietCalculator™ (<https://www.KetoDietCalculator.org>) is a free online program that is used to calculate meal plans.

The MCT oil diet incorporates MCT oil, which is absorbed faster and results in a higher level of ketosis, allowing for more carbohydrates in the diet. The MCT oil diet and classic ketogenic diet have shown to have similar effectiveness and tolerability.⁶

MAD and LGIT utilize household measurements or estimate portion sizes instead of using a gram scale and calculate total amount of net carbohydrate allowance per day instead of calculating a diet ratio for every meal and snack¹ (see [Tables 4 and 5](#)). These diets are usually initiated in a home setting.^{1,4} These less restrictive forms of ketogenic diet produce less side effects and may be easier to follow, thus increasing compliance.² The diet is considered a better fit for older children and adults.⁷ However, the MAD and LGIT appear to be slightly less effective than the classic ketogenic diet.²

The diet is contraindicated for some individuals, especially those with carnitine or fatty acid oxidation disorders, failure to thrive, eating disorders, history of kidney stones, gastrointestinal (GI) disorders, major organ dysfunction, and dyslipidemia among others (see [Table 6](#)).^{2,4} The exact mechanism of the diet action is unknown, but its effectiveness is due to a combination of several factors, including decreased inflammation and changes in blood glucose levels and neurotransmitters.² Emerging research suggests that changes in the microbiota may also play a role.⁸

The multidisciplinary team approach, with a neurologist, a nurse, and a dietitian trained in ketogenic diets, is key to the successful diet initiation and maintenance.² Pharmacists and social workers also play an important role in supporting the patient and the family on the diet and assuring compliance.^{2,4} Many potential side effects of the diet can be prevented by appropriate diet initiation, laboratory monitoring, and nutrient supplementation (see [Tables 7, 8](#)).^{2,4}

Although the diet has been originally used for the treatment of epilepsy, it has since been studied and utilized in a variety of other conditions, including cancer, Alzheimer's disease, Parkinson's disease, weight loss, traumatic brain injury, mitochondrial disorders, autism, diabetes, migraines, bipolar disorder, multiple sclerosis, and amyotrophic lateral sclerosis³ with varying levels of success. The utilization of ketogenic diets in the treatment of cancer, especially brain tumors, is promising but requires additional research.^{9,10} For example, the use of a ketogenic diet in the treatment of gliomas is considered experimental but generally safe according to the available research.⁹ There is a need for more research to help better understand the safety, tolerability, effectiveness, and appropriate administration of ketogenic diets for cancer^{9,10} and other disorders.

TABLE 1 Example of Approximate Macronutrient Composition of Available Ketogenic Diet Therapies^a

^aNote: Ratio and specific macronutrient composition can vary on each type of ketogenic diet. The above images serve as a visual comparison of diet compositions. Images obtained from The Charlie Foundation for Ketogenic Therapies www.CharlieFoundation.org website.

TABLE 2 Comparison of Macronutrient Composition and Initiation Requirements Between Various Ketogenic Diets and the 2015–2020 Dietary Guidelines for Americans^a

Diet	Fat	Carbohydrate	Protein	Hospital Admission
	range (%)			
2015-2020 Dietary Guidelines for Americans	20-35	45-65	10-35	No
Ketogenic diet ratio ^b				
4:1	90	2-4	6-8	Yes
3:1	85-90	2-5	8-12	Varies
2:1	80-85	5-10	10-15	Varies
Modified Atkins diet (1:1 ratio ^b)	60-65	5-10	25-35	No
Low glycemic index treatment (1:1 ratio ^b)	60-70	20-30	10-20	No
Medium-chain triglyceride diet (1:1 ratio ^b)	60-70	20-30	10	Yes

^aBased on data from the Charlie Foundation for Ketogenic Therapies and U.S. Department of Health and Human Services.

^bRatio refers to grams of (fat) : (net carbohydrates + protein).

Note: Kosssoff 2018 guidelines do not recommend hospital admission for most, though individual cases may vary.

TABLE 3 Sample Menu for the Classic Ketogenic Diet, 3:1 Ratio^a

	Grams Net Carbohydrate	Fat (in Grams)
Breakfast		
Egg Scramble (To prepare: Melt butter in frying pan; scramble all items together on medium heat.)		
71 g raw egg mixed well	0.51	6.75
17 g heavy cream	0.51	6.12
28 g butter	0.02	22.71
29 g feta cheese	1.2	6.17
21 g spinach	0.3	0.08
10 g mushrooms, chopped	0.23	0.02
10 g olive oil	0	22.71
Breakfast Subtotal:	2.76	64.56
Lunch		
Cobb Salad (To prepare: Toss all salad ingredients together in a bowl, top with olive oil and red wine vinegar.)		
72 g mixed greens	0.9	0.22
18 g avocado, sliced	0.33	2.77
68 g hard-boiled egg, chopped	0.76	7.21
14 g finely chopped bacon	0.42	6.3
15 g hard cheese shredded	0.27	4.55
31 g olive oil	0	31
15 g red wine vinegar	0	0
Lunch Subtotal:	2.68	52.05
Dinner		
Chicken and Zucchini "Pasta" (To prepare: Slice zucchini thinly into "noodles" and sauté in olive oil. Mix half the pesto into the zucchini and spread the other half on top of chicken. Basil Pesto recipe available at https://www.ketodietcalculator.org .)		
39 g baked chicken breast	0	1.4
80 g sliced or spiraled zucchini	1.69	0.26
28 g olive oil	0	28
32 g basil pesto	0.62	16.7
Dinner Subtotal:	2.76	46.36
Snacks		
<i>Celery & Cream Cheese</i>		
10 g stalk of celery, sliced	0.14	0
30 g full-fat cream cheese	1.1	10.3
Snacks Subtotal:	1.24	0
Daily Total:	9.44	173.27

^aApproximate daily total: 1700 kcal; (173.27 g fat): (9.44 g net carbohydrate + 45 g protein) = 3:1 diet ratio.

Nutrition information obtained from: <https://www.ketodietcalculator.org>. (Roehl K, Sewak SL: Practice paper of the Academy of Nutrition and Dietetics: classic and modified ketogenic diets for treatment of epilepsy, J Acad Nutr Diet 117(8):1279 -1292, 2017.)

TABLE 4 Sample Menu for the Modified Atkins Diet^a

	Grams Net Carbohydrate	Fat (in Servings ^b)
Breakfast		
Egg Scramble (To prepare: Melt butter in frying pan; scramble all items together on medium heat.)		
2 large eggs	1	1
2 Tbsp heavy cream	½	1
1 Tbsp butter	0	1
¼ cup feta cheese	2	½
½ cup spinach	½	0
½ cup mushrooms, chopped	1	0
Breakfast Subtotal:	5	3½
Lunch		
Cobb Salad (To prepare: Toss all salad ingredients together in a bowl, top with olive oil and red wine vinegar.)		
1½ cups mixed greens	½	0
½ cup avocado, sliced	2	1
1 hard-boiled egg, sliced	1	½
1 Tbsp finely chopped bacon	0	½
¼ cup blue cheese or cheddar cheese, shredded	1	1
2 Tbsp olive oil	0	2
1 Tbsp red wine vinegar	0	0
Lunch Subtotal:	4½	5
Dinner		
Chicken and Zucchini "Pasta" (To prepare: Slice zucchini thinly into "noodles" and sauté in olive oil. Mix half the pesto into the zucchini and spread the other half on top of chicken.)		
1 medium baked chicken breast	0	0
1 cup sliced or spiraled zucchini	2½	0
1 Tbsp olive oil	0	1
2 Tbsp pesto	1	1
Dinner Subtotal:	3½	2
Snacks		
<i>Celery & Cream Cheese</i>		
1 stalk of celery, sliced	1	1
2 Tbsp full-fat cream cheese	2	0
½ cup sugar-free gelatin	½	0
Snacks Subtotal:	3½	1
Daily Total:	16½	11½

^aApproximate daily total: 1700 kcal, 16½ g net carbohydrate, 75 g protein, 150 g fat (11½ servings).

^b1 serving = 14 g of fat.

(Roehl K, Sewak SL: Practice paper of the Academy of Nutrition and Dietetics: classic and modified ketogenic diets for treatment of epilepsy, J Acad Nutr Diet 117(8):1279 -1292, 2017.)

TABLE 6 Contraindications for the Use of Ketogenic Diet, Absolute and Relative, With Suggested Workups for Relative Concerns

Contraindication/Concern	Action
Absolute	Do not initiate ketogenic diet
Carnitine deficiency (primary)	
Carnitine palmitoyltransferase (CPT) I or II deficiency	
Carnitine translocase deficiency	
Beta-oxidation defects	
• Medium-chain acyl dehydrogenase deficiency (MCAD)	
• Long-chain acyl dehydrogenase deficiency (LCAD)	
• Short-chain acyl dehydrogenase deficiency (SCAD)	
• Long-chain 3-hydroxyacyl-CoA deficiency	
• Medium-chain 3-hydroxyacyl-CoA deficiency	
Pyruvate carboxylase deficiency	
Porphyria	
Surgical focus identified by neuroimaging and video-electroencephalography (EEG) monitoring	
Propofol concurrent use (risk of propofol infusion syndrome may be higher)	• Consult with physician
Relative Contraindications	• Obtain gastrointestinal consult
• Inability to maintain adequate nutrition or hydration	• Obtain swallow evaluation
• Failure to thrive	• Consider need for gastrostomy tube placement
• Dysphagia	• Increase fat/kcal before initiation
• Gastrointestinal issues (chronic diarrhea, vomiting, reflux)	• Trial of 4:1 ketogenic formula

TABLE 6 Contraindications for the Use of Ketogenic Diet, Absolute and Relative, With Suggested Workups for Relative Concerns

Contraindication/Concern	Action
<ul style="list-style-type: none"> • Not able to meet fluid goals • Extreme picky eating/limited food acceptance 	<ul style="list-style-type: none"> • Provide recipes/foods to trial • Behavioral feeding consult
Concerning medical history <ul style="list-style-type: none"> • Extreme dyslipidemia • Cardiomyopathy • Renal disease/renal calculi • Liver disease • Baseline metabolic acidosis 	<ul style="list-style-type: none"> • Obtain cardiology, nephrology, or hepatology consult for clearance • Adjust fluid minimums • Add citrate, consider bicitrate to alkalyze urine, avoid drugs such as topiramate and zonisamide • Taper off contraindicated medications if possible, increase fluid minimums, consider beginning with lower diet ratio
Social constraints <ul style="list-style-type: none"> • Access to food and kitchen • Caregiver noncompliance • Multiple caregivers/unstable home environment 	<ul style="list-style-type: none"> • Connect family with social worker to discuss access to services, for example (but not limited to) durable medical equipment; Special Supplemental Program for Women, Infants, and Children; respite care; in home supportive services; formula company's assistance programs • Registered dietitian nutritionist can discuss meal and food options that may be feasible for family

TABLE 7 Dietary Supplements for Orally Fed Patients on Ketogenic Diet

Recommended supplements: ^a <ul style="list-style-type: none"> • Multivitamin with minerals and trace minerals, especially selenium • Calcium with vitamin D (meeting daily recommended dietary allowance [RDA] requirements) Optional supplements to consider based on specific patient needs: <ul style="list-style-type: none"> • Vitamin D (above RDA) • Oral citrates • Laxatives (Miralax, mineral oil, glycerin suppository) • Additional selenium, magnesium, zinc, phosphorus, iron, copper • Carnitine • Probiotic • Eicosapentaenoic acid/docosahexaenoic acid • Medium chain triglyceride oil • Table salt/light salt • Digestive enzymes

^aAll supplements should be provided as carbohydrate-free when possible.

Table created by Maggie Moon, MS, RDN, combined data from: Roehl K, Sewak SL: Practice paper of the Academy of Nutrition and Dietetics: classic and modified ketogenic diets for treatment of epilepsy, *J Acad Nutr Diet* 117(8):1279-1292, 2017; and Kossoff EH, Zupec-Kania BA, Auvin S, et al: Optimal clinical management of children receiving dietary therapies for epilepsy: updated recommendations of the International Ketogenic Diet Study Group, *Epilepsia Open* 3(2):175-192, 2018. doi:10.1002/epi4.12225.

Medical, social, and nutrition history should be taken into account when determining whether a patient is an appropriate candidate for a ketogenic diet. It is important to take a comprehensive look at the patient's family history, genetics (including increased cardiovascular risk), and lifestyle and to communicate any potential risks and benefits of following any restrictive diet, such as a ketogenic diet.

The International Dysphagia Diet Standardisation Initiative (IDDSI)

INTRODUCTION AND BACKGROUND

The clinical disorder of swallowing, known as dysphagia, is addressed by multiple professionals at different phases of diagnosis, treatment, and management. The clinical management must be approached as an interdisciplinary venture in that a primary mechanism is through diet texture modification (Lam et al, 2017). The communication between speech-language pathologists (SLPs) and nutrition professionals supports the identification of food preferences, the modifications to food to support safe oropharyngeal transit, and the active consideration of an individual's quality of life.

How does the existing classification system under the National Dysphagia Diet (NDD) fit in this framework?

A universal language for the various diet textures had been attempted under the National Dysphagia Diet (NDD) initiative in 2002. At that time the American Dietetic Association, now the Academy of Nutrition and Dietetics (AND), through the National Dysphagia Diet Task Force (NDDTF), described terminology related to dysphagia, texture, and viscosity of common food and liquid modifications, and created an implementation strategy using the NDD for hospitals.

Though a task force composed of dietetic professionals and SLPs existed, the resulting framework was not peer-reviewed by the American Speech-Language-Hearing Association (ASHA). Though widely used, the framework was not considered an evidenced-based standard for SLPs (NDDTF, 2002). Resulting research addressed concerns of fidelity within implementation and consistency across settings. However, the framework also made apparent that multiple key components were absent in the medical language used to diagnose and manage dysphagia. Therefore the resulting widespread use of the NDD system was adopted in practice by SLPs. Important recommendations that resulted from the NDDTF were as follows:

- a need for scientific foundations of diet texture modification;
- a need for consistency in food preparation;
- consideration of texture modifications for both liquids and solids;
- prescriptive integration for the diagnosis, treatment, and management of dysphagia;
- standardization of practice;
- application within health care facilities and in the transition home; and
- and continuity among all settings.

The diet classifications were established using an exemplary food item within each category with the understanding that the diet descriptions needed to have flexibility to address all possible foods (NDDTF, 2002). However, one limitation of the framework immediately recognized was the inability to specifically categorize all foods (McCullough et al, 2003). Further, the NDD did not provide testing methods to determine classification with certainty.

Food textures were characterized on levels with anchor foods to aid in characterization:

- Level 1, or dysphagia puree;
- Level 2, or dysphagia mechanically altered;
- Level 3, or dysphagia advanced; and
- Regular, or all foods allowed.

In a similar manner, specifications for viscosity of fluids were outlined as follows:

- Thin liquids, described as 1 to 50 centipoise
- Nectar-like, described as 51 to 350 centipoise
- Honey-like, described as 351 to 1750 centipoise
- Spoon-thick, described as >1750 centipoise

Initial intentions included correlation of a standardized severity scale, such as the Dysphagia Outcome and Severity Scale (DOSS), to aid in classification. The idea behind this was to support an evidence-based decision component for the use of a particular diet texture (McCullough et al, 2003). However, ASHA never supported the use of a scale to determine a specific texture modification as this would diminish the role of clinical judgment and expertise of SLPs in assessing the swallow mechanism (McCullough et al, 2003). Therefore the standard of practice remained a combination of testing methods paired with clinical judgment.

Emergence of a New International Dysphagia Diet Standardisation Initiative (IDDSI)

Within the use of the NDD, dysphagia management professionals expressed concerns relating to characterizations of foods not found on the exemplary list or not matching closely enough with the exemplary item (Lam et al, 2017). Continued challenges persisted in managing the difficulties with the consistency of preparation to attain a specified level and subsequent quality control assessments. Managing external factors on foods when textures are modified, and availability of commercially produced modified diets in maintaining described textures, were also of concern (Cichero, 2014). Finally, despite attempts at a consistent language, the terminology of the NDD still seemed to vary across and within settings, which created uncertainty (Lam et al, 2017).

Rather than modify the existing framework by overlaying standardized components, a team of diverse professionals reviewed existing research, professional concerns related to implementation and use, and patient reports of use and confusion to create a new framework (Cichero, 2014). Professionals represented included dietitians, SLPs, food scientists, physicians, occupational therapists, engineers, and nurses (IDDSI, 2018). The initial goal was directed toward patient safety and better treatment of dysphagia by tracking outcomes (Cichero et al, 2013). This goal expanded to include a system across the life span, cultural terms and uses, detailed definitions, accessible and

inexpensive testing, input of professionals involved in food preparation, and publication-level standardization of use (Cichero et al, 2017).

The resulting framework addressed gaps in research related to inconsistent descriptions and uses for diet texture modifications. Steele et al (2015) noted combining “nectar-thick” and “slightly thicker than thin” to encapsulate research for swallowing impaired individuals who required modification to their liquid. Even more so, solids were sometimes minimally categorized as “soft,” “hard,” or “puree,” a significant reduction from even the NDD framework recommendations (Steele et al, 2015). As such, research attempting to understand the therapeutic and physiologic benefits of modified diets were unable to address basic questions related to consistency across multiple settings, carryover of findings into new settings, and actual consistency of foods tested (Steele et al, 2015). What resulted was better insight into patient safety

and professional oversight for diet texture modification, and consequently, an entirely new framework.

DEVELOPMENT

In 2013, the committee members created the International Dysphagia Diet Standardisation Initiative (IDDSI) to address the need for a standardized global terminology (IDDSI, 2017). Within their research and experimentation methods, the committee defined eight distinctive groups across liquids and solids, as well as the intersection of liquids and solids. The continuum is identified by number, description, and color coding to support users across language differences, global cuisines, education level, and food service industry familiarity (IDDSI, 2017). See Figure 1.

Another inclusion element is that the dysphagia continuum is now across all age groups. The framework incorporates aspects of pediatric dysphagia management as well as adults with considerations for food preparation and testing inside and outside of medical facilities. Unlike prior attempts at a standardized system, the IDDSI committee expanded considerations for cultural foods (Cichero et al, 2017). This consideration allowed for the development of different testing methods and a departure from terminology that would only be understood by professionals within the medical or food service industry (Cichero et al, 2017).

As such, the resulting labels are defined in multiple ways to support users of varied training and education in food preparation. Each level is defined by its number, 0 to 7. The direction of the triangle identifies the food as a solid or a liquid with the presence of two triangles for textures which are present in both areas (IDDSI, 2017). Information is

available to support clinical decision making for the use of a particular texture. However, no texture is mandated for a particular clinical presentation. The key component for each diet texture is the testing method available to accurately identify the uncertain food item within a category description (IDDSI, 2017). The ability to test any food item and classify it within the framework allows for the IDDSI framework to be implemented consistently in any setting. Simple training for family members allows for transition to the home setting with carryover of the recommended diet texture.

FRAMEWORK

One of the unique components of the IDDSI framework is the ease of testing available. This component allows for the framework to apply to any potential food without relying on exemplar foods as the standard.

The tests used are the Flow Test, Fork Drip Test, Fork Pressure Test, Spoon Tilt Test, Chopstick Test, and the Finger Test.

- The Flow Test involves using a 10 mL syringe where fluid is filled to the 10 mL line and then allowed to flow for 10 seconds. The remaining amount of fluid defines the consistency.
- The Fork Drip Test requires a standard fork. Food is scooped onto the fork, and classification is based on how it drips, if at all, through the tines.
- The Fork Pressure Test involves using a standard fork which typically has a 4 mm space between each tine. This spacing serves as a measurement for adults as “bite-sized.” Using the tines on the food and a thumb pressed on the solid portion of the fork, the pressure required to blanch the fingernail is comparable to the lingual pressure required within a swallow. The way the food changes, or not, determines the food texture level.
- The Spoon Tilt Test involves a standard spoon used to scoop food in a small mound. The spoon can then be tipped slightly. The manner of which the food falls off the spoon and its ability to maintain shape on the plate, or not, define the consistency.
- The Chopstick Test is similar to the Finger Test where the food is picked up and squeezed between the chopsticks. The ability to hold shape, or not, defines the consistency.

The first three levels describe liquids only. Within the framework these triangles are right-side up and identify these consistencies as only liquids. These levels are best tested and differentiated with a 10 mL syringe (i.e., the Flow Test). The three levels are differentiated by how much fluid is left in the syringe after 10 seconds.

- 0 – Thin: no residue
- 1 – Slightly Thick: will leave 1 to 4 mL in the syringe
- 2 – Mildly Thick: will leave 4 to 8 mL in the syringe

The expectations for thin, level 0, is for the liquid to flow “like water” (IDDSI, 2017). As such, a thin liquid can pass through a teat, a nipple, a cup, or a straw without difficulty. The expectation for slightly thick, level 1, is for the liquid to be a little thicker than water (IDDSI, 2017). The thickness described is commercially found in “anti-regurgitation infant formula” (IDDSI, 2017). This level requires a little more effort to pass through a straw, syringe, teat, or nipple than a level 0 would require. A level 2, or mildly thick, liquid should easily flow off a spoon, but sipping from a standard straw would require effort given the slower flow (IDDSI, 2017). IDDSI (2017) recommends this level if tongue control is slightly reduced, or if the individual is unable to manage faster flowing fluids as would be found in a level 0.

The next two levels, 3 and 4, comprise the overlap of liquids and solids; these levels maintain two triangles, one right-side up and one upside-down on the framework (see Figure 1). As such, the availability of testing options increases if the item being tested is meeting a liquids requirement versus a solids texture. Available methods for testing include the Flow Test, the Fork Drip Test, the Spoon Tilt Test, the Chopstick Test, and the Finger Test.

- 3 – Liquidized/Moderately Thick:
 - Flow Test: >8 mL will remain in the syringe.
 - Fork Drip Test: Dollops through the prongs, fork does not leave a pattern on the surface, and food will spread out on the plate.
 - Spoon Tilt Test: Will not stick to the spoon when poured from the spoon.
 - Chopstick Test: Not suitable.
 - Finger Test: Not suitable.
- 4 – Pureed/Extremely Thick:
 - Flow Test: Not suitable.
 - Fork Drip Test: Fork tines will leave a clear pattern on the surface; no lumps in the food; food will sit in a mound on the plate; food may seep between tines, but it will not drip continuously.

- Spoon Tilt Test: Food will hold a shape on the spoon, and it will hold together and fall off the spoon all at once. It may spread out a little bit on a plate.
- Chopstick Test: Not suitable.
- Finger Test: Difficult, but able to hold a small sample between fingers. When rubbing fingers together, no noticeable residue will remain.

Levels 3 and 4 integrate foods and liquids that share properties. A level 3 liquid could be drunk from a cup or sipped through a straw with effort. A level 3 cannot hold shape, so serving on a plate or eating with a fork would not be appropriate. No chewing or oral processing is required for this food (IDDSI, 2017). IDDSI (2017) recommends this texture for individuals with pain on swallow or the need for extra time for oral control. A level 4 is differentiated in that it can be eaten with a fork, and it will hold its shape on a plate. A key component for a level 4 is that it must be cohesive but not sticky. IDDSI differentiates between cohesion and adhesion when identifying foods in level 4. Consider a scoop of chocolate pudding versus a scoop of peanut butter. Both are cohesive (i.e., stick together), but peanut butter is adhesive as well, so it will leave significant residue on the spoon whereas pudding will leave minimal residue. IDDSI (2017) recommends a level 4 when tongue control is significantly reduced; the texture requires no chewing or biting.

The remaining three levels, 5 through 7, define solids. As such, the triangle is upside-down on the framework for these levels. The availability of testing options includes the Fork Pressure Test, Fork Drip Test, Spoon Tilt Test, Chopstick test, and Finger Test. The Flow Test is not appropriate for this level.

- 5 – Minced and Moist:
 - Fork Pressure Test: Food will easily separate when pressed; little pressure (i.e., nail blanching not required) will mash food out of its presented shape.
 - Fork Drip Test: Food will sit in a pile on the fork without falling through the tines.
 - Spoon Tilt Test: When the spoon is tilted, food should easily fall off. It may spread slightly on a plate.
 - Chopstick Test: When chopsticks are pressed together, food can be scooped or held in position.
 - Finger Test: When placed between the fingers, the food can be held in place. The food will leave the fingers wet.
- 6 – Soft and Bite-Sized:
 - Fork Pressure Test: A fork can be used to cut the food. When using pressure and the thumbnail blanches, the sample will change shape and is unable to return to prior shape.
 - Spoon Pressure Test: A spoon can be used to cut the food. When using pressure and the thumbnail blanches, the sample will change shape and not return to the prior shape.
 - Chopstick Test: Can break the food into smaller pieces.
 - Finger Test: With pressure between the thumb and index finger to blanch the nail, the food will change shape and be unable to return to its prior shape.
- 7 – Regular:
 - There are no tests for this level as all foods are acceptable.

Levels 5 and 6 create differentiation from prior systems in the specificity of food size. For a level 5, adult-sized food is to be within 4 mm lump sizes, or the space between the tines of a fork (IDDSI, 2017). For pediatric populations, this is 2 mm (IDDSI, 2017). Minimal oral processing in terms of chewing is required for this level, with the tongue being necessary to support bolus transit. For a level 6, the adult-sized piece is 1.5 cm, or a standard fork’s width (IDDSI, 2017). For pediatric populations, this size is reduced to 8 mm (IDDSI, 2017). A level 6 mandates the need for chewing and enough lingual control for bolus movement and transit. Level 7 is meant to include foods that are naturally hard or soft, may include chewy, sticky, crunchy, combined textures, variable sizes (i.e., seeds), and layers of

complexity (i.e., pith inside skin) (IDDSI, 2017). Foods considered to be regular have no tests because there are no exclusions or exceptions.

Another unique aspect of the IDDSI framework is in the consideration of “transitional food” (IDDSI, 2017). These foods are defined as items that change from one texture to another when moisture or changes in temperature are presented to the food item. As such, minimal chewing may support modifying the bolus, but often the lingual pressure is sufficient. Tests may be applied after the modification (i.e., moisture or temperature change). The results would be as follows:

- Fork Pressure Test: With a “bite-size” portion, the fork pressure for blanching the thumbnail should result in the sample changing shape, or it has melted into a different shape.
- Chopstick Test: With a “bite-size” portion, the food will break apart with the pressure from squeezing the chopsticks together.
- Finger Test: With a “bite-size” portion, the food will break apart with the pressure from squeezing the fingers together.

Implementation and Utilization: Where and How Is the IDDSI Being Utilized?

While this is continually changing, IDDSI.org tracks policy related to implementation. As such, Australia, Canada, and the United States have scheduled adoption of the IDDSI framework as the standard by May 1, 2019 (IDDSI, 2018; AND, n.d.). Discussions for implementation are in process in Belgium, Brazil, China, Denmark, France, Germany, Ireland, Israel, Japan, the Netherlands, New Zealand, Norway, Poland, Slovenia, Sweden, South Africa, Thailand, and Turkey (IDDSI, 2018). The United Kingdom has an adoption date of April 2019 (IDDSI, 2018). The United States has endorsed the need for creating an implementation process. This commitment has been led by joint work of the Academy and the ASHA.

Challenges: How Do We Understand Patient Choice Within This Framework? How Do We Implement to Fidelity? How Do We Address Exceptions?

Many challenges that arise result from applying the IDDSI framework to individuals who do not have dysphagia. Though common practice to qualify a diet texture in the absence of dysphagia, the IDDSI framework was not created to capture diet modifications for purposes outside of dysphagia management and risk reduction (Cichero et al, 2013). Therefore the diet textures do not address elements of nutritional adequacy or quantity measurements in the context of thickened fluids (Cichero et al, 2013). Further, as was a concern for the NDD, the IDDSI is not meant to be prescriptive in coordination with a standardized swallow function test to determine a particular diet texture (Cichero et al, 2013). The levels are defined in a particular manner with specific testing results that aid in classification. Once the presence of dysphagia is established, clinical expertise and judgment identify appropriate textures based on physiologic presentations. As such, there are no exceptions if the IDDSI framework is implemented correctly (IDDSI, 2018).

Patient choice remains an integral element of dysphagia management. Discussing with the patient and family the risks associated with a diet texture outside of the recommended levels is meant to be a professional discussion between a provider and a patient.

Training food service providers in the different levels and how to test them will aid in increasing staff knowledge and understanding of the IDDSI framework (Garcia et al, 2018). A continued challenge in medical settings is the consistency of implementation for diet texture modifications. This challenge involves training food service staff so they understand how to prepare foods in levels 5 and 6, how to cut into bite-size to attain a level 6, how to mix fluids to attain a level 2 or 3, and

how to use sauces within the different levels. Furthermore, in institutional food service, holding times in warmers and steam tables can affect the food texture and must be taken into consideration. These challenges have carried over from prior systems, such as the NDD, and remain a challenge of implementation under the IDDSI (Garcia et al, 2018). The role of testing supports accuracy of diet texture modifications (Garcia et al, 2018).

Renal Diet for Dialysis

Your diet depends on your kidney function. Most of the information here relates to people on dialysis. What is right for others is not always right for you. As your kidney function changes, your diet may change as well. This guide will help you do two things: plan nutritious meals you enjoy and keep your body working at its best. Your renal dietitian will work with you to make any changes needed to your usual meal plan, but this will provide helpful guidelines.

1. Increase Protein

You will need to eat a high-protein diet. Your protein needs are based on your weight. Most people need at least 6 to 8 oz of protein per day.

2. Limit Potassium

Most foods contain some potassium, but fruits and vegetables are the easiest to control. Limit high potassium foods to 1 serving from the high, 2 from the medium and 2-3 from the low list per day (see list on following page).

Do not use salt substitute or “lite” salt because they are made with potassium.

3. Limit Salt

Limit the salt you eat. Don’t add salt during cooking or at the table. Avoid high-salt foods such as frozen meals; canned or dried foods; “fast foods”; and salted meats such as ham, sausage, and luncheon meats. Use salt-free spices or spice mixes such as Mrs. Dash instead of salt to add flavor to your food.

4. Limit Phosphorus

Use only one serving of milk or dairy food per day. A serving is usually ½ to 1 cup. Take phosphate binders such as Tums, PhosLo, Renagel, or Fosrenol with your meals as prescribed by your doctor.

5. Fluid

A safe amount of fluid to drink is different for everyone. It depends on how much urine you are making. Try not to drink more than 3 cups (24 oz) of fluid each day plus the amount equal to your urine output. If you are limiting your salt intake, you should not feel thirsty.

Fluids include all beverages and foods that are liquid at room temperature such as Jell-O, ice cream, popcicles, ice, and soup.

6. Poor Appetite and Weight Loss

It is common to have a poor appetite if you are new to dialysis. If your appetite has been poor, try eating small frequent meals and

extra snacks. Try adding high-calorie fats such as butter, non-hydrogenated margarine, and oils; sauces and gravies; and sour cream, cream cheese, or whipped cream for extra calories. Adding rice, pasta, bread, and rolls to meals also adds calories. Talk to your dietitian about adding a high calorie nutritional supplement.

PROTEIN

When on dialysis, you need to eat a high-protein diet. This is because you lose protein during each dialysis treatment. To stay healthy, you need to eat enough protein for your daily needs and also make up for the amount lost during dialysis. Meat, fish, poultry, eggs, and other animal foods provide most of the protein in your diet, although some vegetarian foods are acceptable options too (see list below). Your body uses protein to build and repair muscles, skin, blood, and other tissues.

ALBUMIN

Albumin is a protein found in blood. Each month a laboratory test measures your albumin. It is a good way to know how healthy you are. Your albumin level should be more than 3.4 mg/dL. To maintain a healthy albumin level, make sure to eat enough protein. Find your weight on the chart below to identify the number of servings you need each day.

PROTEIN SERVINGS FOR YOU

If you weigh:	You need:
40 kg	4-5 servings
50 kg	5-6 servings
60 kg	6-7 servings
70 kg	7-8 servings
80 kg	8-9 servings
90 kg	9-10 servings
Your weight: _____ kg	
You need: _____ protein servings each day	

ONE SERVING OF PROTEIN

1 egg
 1 oz cooked meat, fish, poultry
 ¼ cup cooked or canned fish, seafood
 ½ cup tofu
 1 cup milk
 1 oz cheese
 ¼ cup cottage cheese
 ¾ cup pudding or custard
 2 Tbsp peanut butter
 1 scoop protein powder
 ½ protein bar

COMMON SERVING SIZES

Most people eat protein foods in portions larger than one serving. Here are some examples:

Average hamburger patty (3 oz) = 3 protein servings
 Small beefsteak (3 in × 4 in) = 4 protein servings
 Half chicken breast (3 oz) = 3 protein servings
 Chicken drumstick or thigh (2 oz) = 2 protein servings
 Average pork chop (3 oz) = 3 protein servings
 Fish fillet (3 in × 3 in) = 3 protein servings

ESTIMATING SERVING SIZES

Here are some other easy ways to estimate protein serving sizes:

- Your whole thumb is about the size of 1 oz.
- Three stacked dice are about the size of 1 oz.
- A deck of cards is about the size of 3 oz.
- The palm of your hand is about the size of 3 to 4 oz.
- Your clenched fist is about the size of 1 cup.

TIPS FOR EATING MORE PROTEIN

Some people on dialysis dislike the taste of protein. Some people find cooking smells unpleasant. Still others are not able to eat enough protein each day.

The following tips will be helpful:

- Use gravy, sauces, seasonings, or spices to improve or hide flavors.
- Prepare meals ahead of time or stay away from kitchen smells if they spoil your appetite.
- Eat cooked protein foods cold. Try cold fried chicken, a roast beef sandwich, or shrimp salad.
- Add cut-up meats or beans to soups or salads.
- Use more eggs. Try hardboiled eggs, egg salad sandwiches, custards, or quiches. Stir beaten eggs into casseroles and soups.
- Try other protein foods such as angel food cake, peanut butter, or bean salads.
- Eat a protein bar. Your nutritionist can help you choose one.
- Use a protein powder. Your nutritionist can help you choose one and give you ideas for using it.

NUTRITIONAL SUPPLEMENTS

Nutritional supplements provide extra calories and protein. In general, use one can of supplement as a snack each day. Add one extra can for each meal you miss.

Not all nutritional supplements are safe for dialysis patients. Check with your nutritionist before using any supplement. Some of the supplements that are used by people on dialysis are listed below.

MALNUTRITION

If you are not eating enough high-protein foods, your albumin level will drop below the recommended level.

If your albumin level is low, the cells in your body cannot hold fluid well. This leads to swelling (edema) and low blood pressure during dialysis. Low albumin increases your risk of death. Patients with albumin levels above four have the lowest death rate.

It is also important to eat enough calories. Your nutritionist can help you make sure you are getting plenty of protein and calories.

EXERCISE

Try to be active in some way each day (e.g., walk, swim, garden, stretch). Using your muscles helps keep them strong. Protein that is stored in your muscles helps support your albumin level.

POTASSIUM FOR PEOPLE ON HEMODIALYSIS

- Most foods have some potassium, but fruits and vegetables are the easiest form to control in your diet. The following list groups vegetables and fruits by the amount of potassium in one serving.
- Remember, there are no foods that you cannot eat on your diet. What is important is the amount of foods you eat and how often you eat them. Keep this list handy for shopping or eating out.
- If there are fruits and vegetables you enjoy that are not on the list, ask your nutritionist about them.

MOST PEOPLE ON HEMODIALYSIS MAY HAVE

- One serving per day from the high-potassium group
 - Two servings per day from the medium-potassium group
 - Two to three servings per day from the low-potassium group
- This is approximately 2000 to 3000 mg of potassium per day with the other foods you eat. Check the serving size for each food, listed in parentheses next to the item.

SOAKING VEGETABLES AND BEANS

Soaking works well for high-potassium foods such as potatoes, parsnips, sweet potatoes, winter squash, and beans. The procedure for soaking follows.

1. Peel vegetables and slice thinly ($\frac{1}{8}$ inch). Rinse well. Place them in a bowl of warm water, using four times more water than vegetable. For example, soak 1 cup of sliced vegetables in 4 cups of water. Soak at least 1 hour. Drain and rinse again.
2. Vegetables that have been soaked this way can then be fried, mashed, scalloped, put in soups or stews, or served fresh. If you are boiling the food, use four times more water than food and cook as usual.
3. Dried beans should be cooked and then chopped and soaked, using the preceding directions. Canned beans can simply be chopped, rinsed, and soaked.

	Low-Potassium Foods 5-150 mg	Medium-Potassium Foods 150-250 mg	High-Potassium Foods 250-500 mg
	Food Category		
Fruits	Applesauce (½ cup) Blackberries (½ cup) Blueberries (1 cup) Grapefruit (½ cup) Pears, canned (½ cup) Pineapple (½ cup) Plums, canned (½ cup) Raspberries (½ cup) Rhubarb, cooked (½ cup) Strawberries (½ cup) Tangerine (1)	Apple (1 medium), cherries (8-10) Fruit cocktail (½ cup) Grapes (10-15) Mango (½ medium) Melons: cantaloupe, honeydew (½ cup), papaya (½ cup) Peaches, canned (½ cup) Pear, fresh (1 medium) Plums (2) Watermelon (1 cup)	Apricots (3) Avocados (¼) Banana (1 medium) Dates (5) Figs (3) Kiwi (1) Nectarine (1 medium) Orange (1 medium) Peach, fresh (1 medium) Prunes (5) Raisins and dried fruit (¼ cup)
Vegetables	Asparagus (4 spears) Bean sprouts (½ cup) Cabbage (½ cup) Cauliflower (½ cup) Corn (½ cup) Cucumber (½) Green and wax beans (½ cup) Lettuce (1 cup) Okra (3 pods) Onions (½ cup) Peas (½ cup) Radishes (5) Rutabagas (½ cup) Summer squash (½ cup) Turnips (½ cup) Water chestnuts (4)	Broccoli (½ cup) Brussels sprouts (4-6) Beets (½ cup) Carrots (½ cup) Celery (½ cup) Eggplant (½ cup) Mixed vegetables (½ cup) Mushrooms (½ cup) Peanut butter (2 Tbsp) Pepper, green (1) Potato chips (10) Soaked potatoes (½ cup)	Artichoke (1 medium) Beans: lima, kidney, navy, pinto (½ cup) Greens: beet, collard, mustard, spinach, turnip (½ cup) Lentils, split peas, chickpeas, black-eyed peas (½ cup) Nuts: all kinds (½ cup) Parsnips (½ cup) Potatoes (½ cup or 1 small) Pumpkin (½ cup) Spinach (½ cup) Tomato (1 medium) Tomato sauce, tomato salsa (¼ cup) Winter squash (½ cup) Yams, sweet potatoes (½ cup)
Juices	Apple juice (½ cup) Cranberry juices (1 cup) Grape juice, frozen (1 cup) Tang, Hi-C and other fruit drinks (1 cup), Kool-Aid (1 cup) Lemonade and limeade (1 cup) Peach or pear nectar (½ cup)	Apricot nectar (½ cup) Grape juice, canned (½ cup) Grapefruit juice (½ cup) Pineapple juice (½ cup)	Pomegranate juice (½ cup) Prune juice (½ cup) Tomato juice (½ cup) V-8 juice (½ cup)

OTHER HIGH-POTASSIUM FOODS

- Milk is high in potassium. Limit milk to 1 cup per day unless you are told to do otherwise.
- Supplements such as Ensure Plus also contain a lot of potassium. Always speak to your nutritionist before using supplements.
- Most salt substitutes and “lite” salt products are made with potassium. Do not use these products. If you are unsure, ask your nutritionist.

SHAKING THE SALT HABIT

Salt, or sodium chloride, is found in convenience and preserved foods. Foods that do not spoil easily are usually high in sodium. The more sodium you eat, the thirstier you will be. The following list of foods is grouped by sodium levels.

Following a low-sodium diet can be challenging. This list of sodium levels of foods is meant to help you learn what foods and how much of them you can enjoy.

Remember, there are no foods that you cannot eat on your diet. What is important is the amount of foods you eat and how often you eat them. Keep this list handy for shopping or dining.

MOST PEOPLE ON DIALYSIS MAY HAVE

- 1 serving per day from the high group
 - 3 servings per day from the medium group
 - As many servings as desired from the low group*
- *Your daily sodium should not exceed 2000 mg of sodium per day. Check the serving size for each and the sodium content.

RINSING CANNED FOODS TO LOWER SODIUM (CANNED VEGETABLES, CHUNK OR FLAKED FISH OR SHELLFISH, POULTRY, OR MEATS)

1. Empty can into colander or sieve.
2. Drain brine and discard.
3. Break up chunks into flakes or smaller pieces.
4. Rinse under running water for 1 min.
5. Drain food until most moisture is gone.

	Low-Sodium Foods 1-150 mg	Medium-Sodium Foods 150-250 mg	High-Sodium Foods 250-700 mg
Breads and cereals	Breads, white, whole grain Cakes, cookies, crepes, doughnuts Cereals: cooked, granola, puffed rice, puffed wheat, Shredded Wheat, Sugar Pops, Sugar Smacks, Sugar Crisps Crackers: graham, low salt, melba toast Macaroni, noodles, spaghetti, rice Corn tortillas	Food Category Biscuits, rolls, muffins: homemade (1) Pancakes (1) "Ready-to-eat" cereals (¾ cup) Saltine crackers (6) Sweet roll (1)	All Bran (¼ cup) Instant mixes: noodles, potatoes, rice (½ cup) Instant mixes: biscuits, breads, muffins, rolls (1 serving) Flour tortillas Waffles (1)
Condiments	Butter, margarine, oil Horseradish, mustard, spices, herbs, sugar, syrup, Tabasco, vinegar, Worcestershire	Bacon (2 slices) Catsup, steak sauce (1 Tbsp) Commercial salad dressing (1 Tbsp) Gravy (2 Tbsp) Low-sodium soy sauce (2 tsp) Mayonnaise (2 Tbsp) Pickle relish (2 Tbsp) Sweet pickles (2 small)	Salt (¼ tsp)
Dairy products	Cheeses: cream, Monterey, mozzarella, ricotta, low-salt types Cream: half-and-half, sour, whipping Custard, ice cream, sherbet Milk: all kinds, yogurt Nondairy creamer	Cheeses (1-oz slice) Cottage cheese (½ cup) Pudding (¾ cup)	Buttermilk (1 cup) Processed cheeses and cheese spreads (1 slice or 2 Tbsp)
Main dishes	All unprocessed meats, fish, poultry Eggs Peanut butter Tuna: low-sodium or rinsed		Broth (½ cup) Canned fish, meat (¼ cup) Canned soups (½ cup) Hot dog (1) Luncheon meat (1 slice) Canned entrees (e.g., pork and beans, spaghetti, stew) (1 cup) Sausage (1 oz)
Fruits and vegetables	All fresh or frozen vegetables All fruits and juices Canned tomatoes, tomato paste Canned vegetables: low-sodium or rinsed	Vegetables (½ cup) Juices: tomato, vegetable (½ cup)	Canned tomato sauce or puree (¼ cup) Frozen vegetables with special sauce (½ cup) Sauerkraut (¼ cup)
Beverages and snacks	Beer, wine, coffee, tea Candy: all kinds Fruit drinks, Popsicles, soda pop, Kool-Aid, Tang Low-salt products: without potassium substitutes Unsalted nuts, unsalted popcorn	Potato and corn chips (1 cup) Snack crackers (5-10)	Commercial dips (¼ cup) Dill pickle chips (3 slices) Olives (5) Salted nuts (½ cup)

PHOSPHORUS

Low-Phosphorus Diet

When phosphorus is high for too long, bones become brittle and weak. You may have joint and bone pain. Extra phosphorus may go into your soft tissue, causing hard or soft lumps. Also, you may have severe itching.

The good news is that with diet, binders, and good dialysis, you can keep your phosphorus level under control.

Phosphorus is a mineral found in most foods. Dialysis does not remove it easily. Your phosphorus level depends on the foods you eat and your medications. Keeping your phosphorus at a safe level will help keep your bones healthy.

Each month your phosphorus level will be measured. High phosphorus is a common problem for people on dialysis. A good phosphorus level in your blood is between 3 and 6 g/dL.

High-Phosphorus Foods

Phosphorus is found in most foods you eat, especially protein foods. The foods that are highest in phosphorus are milk and things made from milk (dairy foods).

By limiting these foods you can cut down on the phosphorus you are eating. Most people on dialysis can have one serving daily from this list of dairy foods. The serving size is also noted.

You can also eat part of a serving of different foods to add up to one serving.

Milk (1 cup)
 Cheese (2 oz)
 Cottage cheese (2/3 cup)
 Yogurt (1 cup)
 Ice cream (1½ cup)
 Frozen yogurt (1½ cup)
 Milkshake (1 cup)
 Hot chocolate (1 cup)
 Pudding or custard (1 cup)

Other High-Phosphorus Foods

When your phosphorus level is high, you may need to limit these foods to once a week.

Bran cereals (1 oz)
 Dried beans or peas (½ cup cooked)
 Chili (½ cup)
 Nuts (½ cup)
 Frozen waffles (1)

Phosphorus and Potassium

High-phosphorus foods are often high in potassium as well. This is another reason to limit dairy foods and other high-phosphorus foods.

Phosphate Binders

Phosphate binders are pills you take when you eat. Binders help keep phosphorus in your food from going into your blood.

Your doctor will decide which binder is best for you and how many you should take each time you eat.

It is important to take all your binders planned for each day.

You can take your binders just before you start a meal, during the meal, or right after eating.

If you forget to take them or skip a meal, it may be difficult to get your full binder dose. Ask your doctor what to do if this happens.

It may take some hard work to remember to take binders each time you eat. Try these ideas:

- Each morning take out the number of binders you need that day. Put them in a small container to carry with you. It should be empty at the end of the day.

- Carry a spare container of binders for when you travel or eat out.
- Take your binders with high-protein snacks such as sandwiches or dairy foods.
- Binders may cause constipation. Talk with your nutritionist about ideas to help with bowel movements.
- There are many types of binders. If you don't like the kind you are taking, talk with your doctor, pharmacist, or nutritionist about other kinds.

Lower Phosphorus Ideas

Following are some lower phosphorus choices you can make in the place of milk and other creamy dairy products. Check those you will try.

- Use nondairy creamer such as Mocha Mix, Coffee Rich, or rice or soy milk on cereal, for creamy sauces or soups, and in shakes.
- Try soy cheese or soy yogurt. They are available in a variety of flavors.
- Use cream cheese in the place of regular cheese or cottage cheese.
- Use sour cream or imitation sour cream on fruits or to replace yogurt in dips.
- Try a nondairy frozen ice cream made from soy, rice, or nondairy creamer such as Mocha Mix.
- Enjoy sorbet or sherbet instead of ice cream.

High Phosphorus Levels

Following are some reasons for a high phosphorus level. Check the ones that you think may apply to you:

- Eating too many high-phosphorus foods
- Forgetting to take your binders
- Not taking all the phosphate binders ordered for you
- Not taking your phosphate binders at the right times

Even if you follow your diet and take your binders, your phosphorus level may be high. When calcium and phosphorus are out of balance, your parathyroid gland becomes overactive. High levels of parathyroid hormone damage your bones. Your doctor can test for this problem and recommend treatment.

The Antiinflammatory Diet

DIETARY APPROACHES TO REDUCE INFLAMMATION

Inflammation is thought to underlie most chronic health conditions including metabolic syndrome, type 2 diabetes, cancer, cardiovascular disease, arthritis, autoimmune diseases, atopic conditions, inflammatory bowel disease, and cognitive decline. Various nutrients, foods, and dietary patterns have been shown to reduce inflammatory markers as well as subjective and objective measures of inflammation.

Multiple iterations of an antiinflammatory diet exist: Dietary Approaches to Stop Hypertension (DASH), Mediterranean, Mediterranean-DASH Intervention for Neurodegenerative Delay (MIND), vegetarian, food allergy elimination, calorie restriction, intermittent fasting, and low histamine. In most cases, overall dietary and lifestyle habits are more important to consider rather than any single change. Which diet

is right for any individual often depends on trial and error (Casas et al, 2016; Kaluza et al, 2019).

The Dietary Inflammatory Index (DII) has been developed and validated as a tool to evaluate the overall inflammatory potential of the diet based on evaluation of over 6500 peer-reviewed research articles. The DII consists of 45 foods, spices, nutrients, and bioactive compounds in relation to six inflammatory biomarkers: IL-1 β , IL-4, IL-6, IL-10, TNF- α , and C-reactive protein (Garcia-Arellano et al, 2015; Shivappa et al, 2014). In recent studies, dietary patterns with a higher DII have been associated with an increased risk of cancer, asthma, cardiovascular disease, low bone density, depression, and metabolic syndrome (Bergmans and Malecki, 2017; Fowler and Akinyemiju, 2017; Neufcourt et al, 2015; Shivappa et al, 2016).

Dietary components with the most antiinflammatory effects are included as negative numbers in the Overall Inflammatory Effect Score as shown in the table below.

Food Parameters in the Dietary Inflammatory Index and Overall Inflammatory Effect Score			
Food Parameter	Overall Inflammatory Effect Score	Food Parameter	Overall Inflammatory Effect Score
Alcohol (g)	-0.278	Riboflavin (mg)	-0.068
Vitamin B ₁₂ (μ g)	0.106	Saffron (g)	-0.140
Vitamin B ₆ (mg)	-0.365	Saturated fat (g)	0.373
β -Carotene (μ g)	-0.584	Se (μ g)	-0.191
Caffeine (g)	-0.110	Thiamin (mg)	-0.098
Carbohydrate (g)	0.097	<i>Trans</i> fat (g)	0.229
Cholesterol (mg)	0.110	Turmeric (mg)	-0.785
Energy (kcal)	0.180	Vitamin A (RE)	-0.401
Eugenol (mg)	-0.140	Vitamin C (mg)	-0.424
Total fat (g)	0.298	Vitamin D (μ g)	-0.446
Fiber (g)	-0.663	Vitamin E (mg)	-0.419
Folic acid (μ g)	-0.190	Zn (mg)	-0.313
Garlic (g)	-0.412	Green/black tea (g)	-0.536
Ginger (g)	-0.453	Flavan-3-ol (mg)	-0.415

Adapted from Shivappa N, Steck SE, Hurley TG, et al: Designing and developing a literature-derived, population-based dietary inflammatory index, *Public Health Nutr* 17:1689–1696, 2014.

The following recommendations reflect an effort to consolidate similarities among the various antiinflammatory diets.

CONSUME AN ABUNDANCE OF FRUITS, VEGETABLES, HERBS, AND SPICES

Colorful fruits and vegetables contain a myriad of antiinflammatory phytochemicals and fiber and are thought to be the cornerstone of an antiinflammatory diet due to their ability to down-regulate markers such as C-reactive protein (CRP), Nuclear Factor-kappa Beta (NFkB), histamine, and other inflammatory cytokines in vivo and in vitro.

Most plant-based foods contain antiinflammatory properties, but the following fruits and vegetables appear to be the most anti-inflammatory based on their mention in research: cruciferous vegetables, onions, berries, purple grapes, cherries, citrus fruits, tomatoes, and pomegranates. Antiinflammatory herbs and spices include: green and black tea, turmeric, garlic, ginger, rosemary, oregano, fenugreek, caraway, anise, cocoa, mint, clove, coriander, cinnamon, nutmeg, red chili powder, lemongrass, fennel, saffron, black pepper, parsley, sage, dill, bay leaf, and basil (Aggarwal and Shishodia, 2004; Galland, 2010; Habauzit and Morand, 2012; Jiang et al, 2014; Jungbauer and Medjakovic, 2012; Panahi et al, 2016).

ENCOURAGE A LOW GLYCEMIC DIET PATTERN

Excessive amounts of refined carbohydrates and sugars may be proinflammatory. Regular consumption of these high glycemic foods can increase blood glucose and insulin levels, which, when chronically elevated, can trigger an inflammatory response. Choosing low glycemic foods has been shown to reduce post-prandial glucose and insulin levels and modestly lower concentrations of insulin-like growth factor (IGF) and improve the inflammatory and adipokine (inflammatory proteins secreted by adipose tissue) profiles (Neuhaus et al, 2012; Runchey et al, 2012). It is important to look at the glycemic load of a food versus the glycemic index because the glycemic load is a better indicator of the actual portion of food. See Appendix 28. For example, beets have a high glycemic index: 64, but a low glycemic load: 5.

High Glycemic Foods	Low Glycemic Foods
Cookies, cakes, pastries, [†] chips, white flour breads, crackers, tortillas, pasta, white rice	Whole and unprocessed grains, (like oats, brown rice, quinoa, whole wheat) high-fiber or whole grain pastas
Fruit juice and dried fruits	Fresh fruit
White (russet potatoes) mashed or baked without the skin	Sweet potatoes, pumpkin, squashes, beans and lentils, nuts and seeds
Sugar-sweetened sodas and other beverages	Most vegetables**

*cookies, cakes etc., can be made using low glycemic ingredients like oats and nuts, which can reduce their glycemic load.

**Consuming large amounts of certain juiced vegetables like carrots or beets will produce a higher glycemic load.

INCLUDE NUTS AND SEEDS OR NUT AND SEED BUTTERS EVERY DAY

Nuts and seeds not only provide antiinflammatory and valuable phenolic compounds, but they provide a beneficial ratio of polyunsaturated

fats (omega-6 and omega-3) that helps to support a healthy inflammatory response in the body. Consume a variety of nuts in order to gain the spectrum of nutrients that each has to offer. Especially beneficial are pumpkin seeds, sunflower seeds, almonds, cashews, Brazil nuts, flaxseed, sesame seeds, and walnuts.

ADJUST THE QUALITY AND QUANTITY OF DIETARY FAT AND OILS

Increase:

Unsaturated fats high in omega-3 fatty acids (alpha-linolenic acid), which are antiinflammatory. Best sources include coldwater fish, flax, chia and hemp seeds, and walnuts. Flaxseed, walnut and expeller pressed canola oils are excellent plant sources of omega-3 fatty acids but should not be heated. Choose brands that use low-heat processing for best quality.

Monounsaturated fats:

Use extra virgin olive oil as the main ingredient for sauces, salad dressings, and marinades. It can also be used for low-heat sautéing.

Avocados can replace cheese or mayonnaise on sandwiches, and can be added to dips, smoothies, and salads.

Decrease:

Red meats contain arachidonic acid and saturated fats, which can increase inflammation if eaten in excess, especially in those with a higher body mass index (BMI) (Chai et al, 2017).

Processed foods and oils are high in omega-6 fatty acids (linoleic acid) such as soybean, corn, safflower, and sunflower oils. Omega-6 fatty acids can increase proinflammatory markers in the body if eaten in excess. Many of these oils are common in highly processed foods. Deep fried foods or oils heated (and reheated) to high temperatures may result in oxidation and trans fat formation causing a pro-inflammatory effect.

Avoid:

Hydrogenated fats and trans fats that are found in many baked and prepackaged foods and are in hydrogenated vegetable shortening and many margarines. Trans fat consumption has been shown to increase markers of systemic inflammation and is particularly associated with coronary artery disease. Trans fats were banned in processed foods in the United States in July 2015, and manufacturers had 3 years to completely remove it.

SUPPORT A HEALTHY MICROBIOME

Preliminary studies suggest that consumptions of fermented foods (probiotics) and plant fibers (prebiotics) may help reduce inflammation by supporting a healthy microbiome in the gut (Hiippala et al, 2018). Fermented and cultured foods are an excellent source of probiotic bacteria. Sources include miso, sauerkraut, yogurt, kefir, kimchi, tempeh, and kombucha (a fermented beverage). Prebiotic foods feed the good bacteria and are also important for gut health. Inulin and fructooligosaccharides are examples of prebiotics and can be found in bananas, asparagus, maple syrup, onions, garlic, chicory, artichoke, and many other plant foods.

ELIMINATE FOODS THAT CAUSE SYMPTOMS OF ALLERGY AND INTOLERANCE

Adverse reactions to food can induce the production of a variety of inflammatory mediators including immunoglobulins, cytokines, and histamine. Reactions can be either immediate or delayed, and their intensity may depend on dose and individual tolerance. Risk may depend on timing and composition of food exposure in early life, diet quality, and gastrointestinal microflora balance.

AVOID CHEMICALS

Many industrial chemicals and pesticides can irritate or disrupt the immune system and cause inflammation. Choose organic or low pesticide foods and “green” personal care and cleaning products to reduce exposure. Many canned foods contain bisphenol A in their linings. Bisphenol A (BPA), which is also found in many plastic bottles and food containers, is an endocrine disrupter, impairs the action of insulin in the body, and upregulates inflammatory pathways (Valentino et al, 2013). Seek out “BPA-Free” cans and use glass containers and bottles as often as possible. Refer online to the Environmental Working Group for more information.

DRINK ALCOHOL IN MODERATION

Alcohol can have the effect of both increasing and decreasing markers of inflammation, depending on the individual person and the amount consumed. High intake, especially for prolonged periods, can increase inflammatory cytokines (Miller et al, 2011). In the PREDIMED trial, moderate alcohol consumption was associated with improved lipid profiles, blood pressure, endothelial function, and reduced reactive oxygen species (ROS) and was associated with about a one drink equivalent (10 g) per day. Red wine is the most commonly featured as antiinflammatory.

CALORIE RESTRICTION AND INTERMITTANT FASTING

Modification of dietary patterns including calorie restriction (CR) and intermittent fasting (IF) have been studied for their effect on inflammation, longevity, and metabolic health. CR involves a reduction of calories by 20% to 40% while maintaining a consistent meal pattern. In multiple animal models, CR has led to significant lengthening of lifespan and reduction of inflammatory markers (González, 2012). In humans, CR has shown improvements in metabolic health, but the effect on longevity is still under investigation. Studies have demonstrated a similar metabolic and antiinflammatory benefits with the use of IF. Although several methods exist, the most common application of IF includes a 13-hour overnight fast (also called prolonged nightly fasting) and alternate-day fasting where participants alternate fasting with ad libitum eating (Patterson and Sears, 2017). Both of these interventions should be employed with care to ensure they are used appropriately. While most of the research is positive, there is theoretically a potential for harm in certain populations, especially those with disordered eating or in those with critical illness.

REDUCE STRESS AND IMPROVE SLEEP

High stress levels and lack of adequate sleep are both associated with inflammation. Elevated circulating cortisol levels found under conditions of psychological stress are associated with elevated inflammatory cytokines. Sustained sleep deprivation has also been associated with an inflammatory state and an elevation of CRP, TNF- α , interleukin (IL)-1 β , IL-2, IL-4, and monocyte chemo-attractant protein-1 (MCP-1) (Axelsson et al, 2013; Richardson and Churilla, 2017). Intentionally practicing stress reduction techniques such as meditation has been shown to reduce the inflammatory response in human experimental models (Kox et al, 2014).

EXAMPLE OF AN ANTIINFLAMMATORY 1-DAY DIET BASED ON THE DASH, MIND, AND MEDITERRANEAN MEAL PATTERNS

Breakfast: Vegetable frittata with onions, garlic, basil, spinach, artichoke hearts, and tomato. Baked sweet potato wedges. Herbal tea.

Lunch: Lentil vegetable soup and a green salad with arugula, purple cabbage, red onion, cucumber, carrot, walnuts, and a mustard vinaigrette. Whole grain bread or crackers. Green tea with lemon.

Snack: Greek yogurt with berries.

Dinner: Lemon dill baked fish over brown rice with garlic sautéed kale and a glass of red wine.

Dessert: Dark chocolate and cherries.

The Mediterranean Diet

SIGNIFICANCE

The Mediterranean diet emulates both the traditional diet and lifestyle of countries bordering the Mediterranean Sea. It is known as one of the healthiest dietary patterns in the world, specifically for its prevention of various chronic diseases. The diet places emphasis on the consumption of fruits, vegetables, nuts, seeds, whole grains, legumes, fish, lean meats, red wine (in moderation), and olive oil, and minimizes consumption of red meat and sugar. Additionally, the diet prioritizes daily physical activity, as well as getting adequate sleep, spending time with friends and family, and living a low-stress lifestyle. While the diet is specific to the Mediterranean region, its principles can easily be adapted to incorporate foods and recipes characteristic of other global cuisines.

One of the greatest risk factors for developing chronic diseases is inflammation. Eating a Mediterranean diet pattern has been demonstrated to reduce the following inflammatory markers: C-reactive protein (CRP), IL-1 β , IL-4, IL-5, IL-6, IL-7, IL-18, TNF- α , TGF β , COX-2, fibrinogen, and homocysteine. Notable antiinflammatory components of the Mediterranean diet include polyphenols, omega-3 fatty acids, fiber, and various phytochemicals including anthocyanin and lycopene (Donovan et al, 2017). Significant associations have also been demonstrated between consuming a Mediterranean diet and physical function, mental function, health-related quality of life for men and women, and life satisfaction for women (Zaragoza-Martí et al, 2018). Additionally, by choosing to include olive oil, vegetables, legumes, fish, nuts, and wine in food patterns, dependence on polypharmacy significantly decreases. Specifically, a high adherence to the Mediterranean diet is inversely associated with overall number of medications used for controlling health conditions (Vicinanza et al, 2018).

Common Health Conditions Managed With the Mediterranean Diet

- Cardiovascular disease
- Cancer
- Diabetes
- Reproductive Health
- Brain Health

Foods and Lifestyle Factors Emphasized

- *Fruits and vegetables:* Incorporating a colorful variety of fruits and vegetables into the diet ensures adequate consumption of many vitamins, minerals, and phytonutrients. Snack on vegetables in the morning and include them on half of the plate at lunch and dinner. Enjoy fruits and vegetables both in their cooked and raw forms.
 - Fruits to include: Apples, apricots, bananas, blackberries, blueberries, cantaloupe, cherries, clementines, cranberries, dates, figs, goji berries, grapefruit, grapes, lemons, limes, mango, marionberries, melons, nectarines, oranges, papaya, peaches, pears, persimmons, pineapples, plums, pomegranates, prunes, raspberries, star fruit, strawberries, tangerines, watermelon

- Vegetables to include: Artichokes, arugula, asparagus, avocados, bean sprouts, beets, bell peppers, bok choy, broccoli, broccolini, Brussels sprouts, cabbage, carrots, cauliflower, celeriac, celery, chicory, collards, cucumbers, daikon, dandelion greens, eggplant, fennel, jicama, kale, leeks, lettuce, mushrooms, mustard greens, nettles, okra, olives, onions, peas, peppers, purslane, radicchio, radishes, scallions, shallots, spinach, tomatoes, watercress, zucchini
- *Nuts and seeds:* Nuts and seeds are both rich sources of essential fats, protein, fiber, and vitamins and minerals, including calcium, magnesium, B vitamins, and vitamin E. Nuts and seeds are healthiest when consumed in their raw, natural form or in butters made without hydrogenated oils. Choose them for a snack or to accompany a favorite meal.
 - Nuts to include: Almonds, cashews, hazelnuts, peanuts, pecans, pine nuts, pistachios, walnuts
 - Seeds to include: Chia, flax, hemp, pumpkin, sesame, sunflower
- *Whole grains and starches:* Unlike refined grains, whole grains consist of complex carbohydrates and are richer sources of fiber, essential fats, B vitamins, antioxidants, and phytonutrients. They provide lasting energy throughout the day, balance blood sugar, and regulate appetite.
 - Whole grains and starches to include: Amaranth, barley, brown rice, buckwheat, bulgur, corn, couscous, durum, farro, millet, oats, polenta, potatoes, pumpkin, quinoa, rice, rutabaga, rye, spelt, sweet potatoes, squash (acorn, buttercup, butternut, carnival, delicata, kabocha, spaghetti), turnips, wheat berries, whole wheat bread
- *Legumes:* This plant-based protein is a great meat alternative, for it is also rich in fiber, vitamins, minerals, antioxidants, and phytonutrients that help fight inflammation.
 - Legumes to include: Beans (adzuki, black, black eyed, cannellini, fava, garbanzo, green, kidney, pinto, red), edamame, lentils (black, brown, French, green, red, yellow), split peas
- *Lean animal protein:* When following a Mediterranean eating pattern, meat is eaten as an accent on the plate and not the main dish. Smaller portions of less than 3 oz are usually consumed, which is equivalent to the size of a deck of cards. Alternative protein sources include eggs, fish, and seafood. It is recommended to consume fish and seafood at least two times per week.
 - Lean animal protein to include: Chicken, turkey
 - Eggs to include: Chicken, duck, quail
 - Fish to include: Cod, flounder, salmon, sardines, sea bass, tilapia, tuna, yellowtail
 - Seafood to include: Clams, crab, lobster, mussels, oysters, shrimp
- *Healthy fats:* The Mediterranean diet emphasizes the consumption of fats at every meal and snack. Nuts and seeds can be added to any dish, as they are rich in both healthy fats and protein. Choose oils high in omega-3, monounsaturated, and polyunsaturated fatty acids to dress salads, and incorporate avocado and olives into meals. Dairy products usually only accompany main dishes in small portions or are eaten in fermented forms such as kefir and yogurt.

- Healthy fats to include: Avocado, cheese, coconut, milk, nuts (see above), oils (avocado, coconut, flaxseed, grapeseed, hemp seed, olive, safflower, sunflower seed, sesame, walnut), olives (kalamata, niçoise, picholine), seeds (see above), yogurt
- *Herbs and spices*: Cooking with these seasonings not only enhances the flavor of food but also increases its nutrient content by contributing vitamins, minerals, and antioxidants and protective phytonutrients.
 - Herbs to include: Basil, bay leaf, cilantro, lavender, mint, parsley, rosemary, sage, tarragon, thyme
 - Spices to include: Anise, chili peppers, cinnamon, clove, cumin, fennel, garlic, ginger, marjoram, oregano, pepper, turmeric, za'atar
- *Beverages to include*: Herbal tea, water, coffee, and a small glass of red wine, which contains beneficial antioxidants and phytonutrients.

EXAMPLES OF A 1-DAY MEAL PLAN BASED ON THE MEDITERRANEAN DIET

Breakfast: Shakshuka with baked eggs, onions, garlic, tomatoes, crumbled feta served with cooked quinoa or whole wheat bread. Season with paprika and cumin. Black coffee, tea, or water.

Lunch: Veggie wrap with whole wheat tortilla, spinach, cucumber, shredded carrots, hummus, avocado. Eat with a piece of fruit. Water or tea.

Snack: Hardboiled egg with grapes and mixed nuts.

Dinner: Paella with shrimp, brown rice, bell pepper, stewed tomatoes, onion, garlic, extra virgin olive oil. Season with saffron. Water, tea, or one small glass of red wine.

Nutritional Facts on Alcoholic Beverages

According to the 2015 National Survey on Drug Use and Health, 86% of U.S. adults 18 and older report drinking alcohol at some time in their life; 26% report binge drinking in the past month, and 7% report excessive drinking in the past month. An estimated 15 million adults in the United States have alcohol use disorder according to the National Institute on Alcohol Abuse and Alcoholism (National Institutes of Health [NIH], 2019). Recent studies have disputed the overall health benefits of drinking alcohol, although some research demonstrates a small positive effect of moderate drinking on cardiovascular risk and mortality (Centers for Disease Control [CDC], 2019). A growing body of evidence suggests that regular alcohol intake, especially if excessive, is associated with liver disease, hypertension and left ventricular function, multiple forms of cancer (breast, mouth, esophagus, larynx, throat), as well as motor vehicle accidents, violence, and sexual assault (CDC, 2019).

The 2015–2020 Dietary Guidelines for Americans (DGA) recommend moderate drinking for those who do drink alcohol and do not recommend that individuals start drinking for any potential health

benefit if they do not drink already. The DGA guidelines recommend the following:

- Alcoholic beverages should not be consumed by some individuals, including those who cannot control their alcohol intake, women of childbearing age who may become pregnant, pregnant and lactating women, children and adolescents, individuals taking medications that can interact with alcohol, and those with specific medical conditions.
- Those who choose to drink alcoholic beverages should do so sensibly and in moderation—defined as the consumption of up to one drink per day for women and up to two drinks per day for men.
- Combining alcohol and caffeine is not recommended. This can lead to excessive drinking because caffeine can mask the effects of alcohol.
- Alcoholic beverages should be avoided by individuals engaging in activities that require attention, skill, or coordination, such as driving or operating machinery.

Each beverage portrayed above represents one U.S. standard drink (also known as an alcoholic drink-equivalent). The percent of pure alcohol, expressed here as alcohol by volume (alc/vol), varies within and across beverage types.

ALCOHOL AND CALORIE CONTENT IN SELECTED ALCOHOLIC BEVERAGES

This table is a guide to estimate the alcohol percentage and calories from various alcoholic beverages. A sample serving volume and the calories in that drink are shown for beer, wine, and distilled spirits.

Image: National Institutes of Health, National Institute on Alcohol Abuse and Alcoholism: *Rethinking drinking*. Available at: <https://www.rethinkingdrinking.niaaa.nih.gov/How-much-is-too-much/What-counts-as-a-drink/Whats-A-Standard-Drink.aspx>. Accessed February 4, 2019.

Higher alcohol content (higher percent alcohol or higher proof) and mixing alcohol with other beverages such as sweetened soft drinks, fruit juice, or cream increase the amount of calories in the beverage. Alcoholic beverages supply calories but provide few essential nutrients apart from small amounts of B vitamins in some beer (USDA, 2019; Cronometer, 2019).

One standard drink equivalent contains ~14 grams of alcohol. This equates to roughly 12 ounces of regular beer (6%–14% alcohol), 5 ounces of wine (12% alcohol), and 1.5 ounces of distilled spirits (hard alcohol 40% alcohol).

Beverage	Serving (oz)	Alcohol (%)	Calories (Approximate)
Beer and Cider			
Regular	12	5%	120-150
Microbrew/Craft beer	12	6%-14%	160-250
Gluten Free Beer	12	4%-5%	120-200
Light beer	12	4%-5%	100
Nonalcoholic beer	12	Trace	100-130
Hard Cider	12	3.4%-8.5%	140-200
Hard Lemonade	11.2	5%	220
Distilled Spirits (gin, vodka, rum, brandy, whisky, scotch)			
80 Proof	1.5	40%	90-100
100 Proof	1.5	50%	105-120
Wine			
White	4	10%-12%	80-100
Zinfandel and Shiraz	4	14%-16%	115-120
Red	4	12%-15%	85-100
Rose	4	11.5%-13.5%	85-110
Wine cooler	12	4%-6%	200
Champagne	4	12%	100
Sweet wine	4	12%	130
Sherry, port, muscatel	2	17%-21%	75-90
Sake	4	17%-21%	150
Cordials, liqueurs	2-3	24%	160

National Institutes of Health (NIH), National Institute on Alcohol Abuse and Alcoholism: *What is a standard drink?* Available at: <https://www.niaaa.nih.gov/alcohol-health/overview-alcohol-consumption/what-standard-drink>. Accessed February 3, 2019.

USDA: *Nutrient database standard release*. Available at: <https://ndb.nal.usda.gov/ndb/search/list>. Accessed. February 3, 2019.

The caloric contribution from alcohol of an alcoholic beverage can be estimated by multiplying the number of ounces by the proof and then again by the factor 0.8. For beers and wines, kilocalories from alcohol can be estimated by multiplying ounces by percentage of alcohol (by volume) and then by the factor 1.6.

Nutritional Facts on Caffeine-Containing Products

Caffeine is similar in structure to adenosine, a chemical found in the brain that slows down its activity. Because the two compete, the more caffeine is consumed, the less adenosine is available, up to a point. Caffeine temporarily heightens concentration and wards off fatigue. Within 30 to 60 minutes of drinking a cup of coffee, caffeine reaches peak concentrations in the bloodstream and takes 4 to 6 hours for its effects to wear off. The average American adult

consumes about 200 mg of caffeine a day, and many may consume twice that level. It is generally safe to consume no more than the equivalent amount of caffeine in 1 to 2 cups of coffee daily during pregnancy or lactation. Individuals with heart disease and hypertension may benefit from a reduction in caffeine consumption. To reduce caffeine and its stimulant effects, monitor intake from foods and beverages listed below.

Selected Food and Beverage Sources of Caffeine	
Caffeine-Containing Products	Serving (mg)
Coffee	
Starbucks coffee (in store), 16 oz	330
Starbucks coffee (at home), 16 oz	260
Brewed, drip method, 6 oz	103
Brewed, percolator method, 6 oz	75
Instant, 1 rounded tsp	57
Flavored, regular and sugar-free, 6 oz	26-75
Espresso, 1 oz	40
Café Latte, short (8 oz) or tall (12 oz) (Starbucks)	35
Decaffeinated, 6 oz	2
Tea	
Black or green tea, 16 oz	60-100
3-minute brew, 12 oz	72
Lipton, Arizona, or Snapple tea, 16 oz	30-60
Instant, 1 rounded tsp in 8 oz of water	25-35
Tea, green brewed, 8 oz	30
Tea, bottles (12 oz) or from instant mix, 8 oz	14
Decaffeinated, 5-minute brew, 6-oz cup	1
Carbonated Beverages	
7-Eleven Big Gulp cola, 64 oz	190
Mountain Dew MDX or Vault, 12 oz	120
Diet Pepsi Max, 20 oz	70
Mountain Dew, 12 oz, regular or diet	54
Mellow Yellow, 12 oz, regular or diet	52
Regular or diet cola, cherry colas, Dr. Pepper, Mr. Pibb, 12 oz	35-50
Decaffeinated drinks, 12 oz	Trace
Caffeine-Containing Products	Serving (mg)
Cocoa and Chocolate	
Chocolate, baking, unsweetened, 1 oz	58
Chocolate, sweet, semisweet, dark, milk, 1 oz	8-20
Milk chocolate bar, 1.5 oz	10
Chocolate milk, 8 oz	8
Cocoa beverage, 6-oz cup	4
Chocolate-flavored syrup, 1 oz	5
Chocolate pudding, ½ cup	4-8
Energy Drinks	
Rockstar (16 oz)	160
Red Bull (8.3 oz)	80
Full Throttle (16 oz)	160
Monster (16)	160
Jolt (8 oz)	80
Miscellaneous	
NoDoz, Maximum Strength (1), or Vivarin (1)	200
Pit Bull Energy Bar, 2 oz	165
Excedrin (2)	130
NoDoz, Regular Strength (1)	100
Water, caffeinated (Edge 2 O), (8 oz)	70
Anacin (2)	65
Bud Extra Beer, 10 oz	55
Propel Invigorating water	50
Bai Antioxidant Infusion (16 oz)	70
Crystal Light Energy (1 packet)	60
Starbucks Refresher (12 ounces)	50

Nutritional Facts on Essential (Omega) Fatty Acids

Essential fatty acids (EFAs) are fatty acids that are required in the human diet. They must be obtained from food because human cells have no biochemical pathways capable of producing them internally. There are two closely related families of EFAs: **omega-3 (Ω-3 or ω-3)** and **omega-6 (Ω-6 or ω-6)**. Only one substance in each of these families is truly essential, because, for example, the body can convert one ω-3 to another ω-3 but cannot create ω-3 endogenously.

In the body essential fatty acids serve multiple functions. In each of these the balance between dietary ω-3 and ω-6 strongly affects function. They are modified to make the eicosanoids (affecting inflammation and many other cellular functions); the endogenous cannabinoids (affecting mood, behavior, and inflammation); the lipoxins from ω-6 EFAs and resolvins from ω-3 (in the presence of aspirin, down-regulating inflammation); the isofurans, isoprostanes, hepxilins, epoxyeicosatrienoic acids, and neuroprotectin D; and the lipid rafts (affecting cellular signaling). They also act on deoxyribonucleic acid (activating or inhibiting transcription factors for nuclear factor-κB [NFκB], a proinflammatory cytokine).

Between 1930 and 1950, arachidonic and linolenic acids were termed *essential* because each was more or less able to meet the growth requirements of rats given fat-free diets. Further research has shown that human metabolism requires both fatty acids. To some extent any ω-3 and any ω-6 can relieve the worst symptoms of fatty acid deficiency. However, in many people the ability to convert the ω-3 α-linolenic acid (ALA) to the ω-3 eicosapentaenoic (EPA) and docosahexaenoic acid (DHA) is only 5% efficient. Therefore it is important to

incorporate the EPA and DHA directly into the diet, usually as fish or a fish oil supplement. Particular fatty acids such as DHA are needed at critical life stages (e.g., infancy and lactation) and in some disease states.

The essential fatty acids are:

- ALA (18:3)-ω-3
- Linoleic acid (18:2)- ω-6

These two fatty acids cannot be synthesized by humans because humans lack the desaturase enzymes required for their production. They form the starting point for the creation of longer and more desaturated fatty acids, which are also referred to as long-chain polyunsaturates:

Ω-3 FATTY ACIDS:

- EPA (20:5) eicosapentaenoic acid
- DHA (22:6) docosahexanoic acid
- ALA (18:) alpha-linolenic acid

Ω-6 FATTY ACIDS:

- Gamma-linolenic acid (GLA) (18:3)
- Dihomo-γ-linolenic acid (DGLA) (20:3)
- Arachidonic acid (AA) (20:4)

Ω-9 Fatty acids are not essential in humans, because humans possess all the enzymes required for their synthesis.

ADEQUATE INTAKES FOR Ω-3 FATTY ACIDS FOR CHILDREN AND ADULTS				ADEQUATE INTAKES FOR Ω-6 FATTY ACIDS FOR CHILDREN AND ADULTS			
Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)	Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)
1-3	0.7	N/A	N/A	1-3	7	N/A	N/A
4-8	0.9	N/A	N/A	4-8	10	N/A	N/A
9-13	1.2 for boys, 1 for girls	N/A	N/A	9-13	12 for boys, 10 for girls	N/A	N/A
14-18	1.6 for boys, 1.1 for girls	1.4	1.3	14-18	16 for boys, 11 for girls	13	13
19+	1.6 for men, 1.1 for women	1.4	1.3	19+	17 for men, 12 for women	13	13

N/A, Not applicable.

DIETARY SOURCES

Some of the food sources of ω -3 and ω -6 fatty acids are fish and shellfish, flaxseed (linseed), soya oil, canola (rapeseed) oil, hemp oil, chia seeds, pumpkin seeds, sunflower seeds, leafy vegetables, and walnuts.

EFA play a part in many metabolic processes, and there is evidence to suggest that low levels of EFAs or the wrong balance of types among the EFAs may be a factor in a number of illnesses.

Plant sources of ω -3s do not contain EPA and DHA. This is thought to be the reason that absorption of EFAs is much greater from animal rather than plant sources.

EFA content of vegetable sources varies with cultivation conditions. Animal sources vary widely, both with the animal's feed and that the EFA makeup varies markedly with fats from different body parts.

OMEGA-3 FATTY ACIDS

There is some evidence that suggests that ω -3s may:

- Help lower elevated triglyceride levels. High triglyceride levels can contribute to coronary heart disease.

- Reduce the blood's tendency to clot, which may relate to the clotting that occurs with the initial atherosclerotic plaque.
- Reduce the inflammation involved in conditions such as rheumatoid arthritis.
- Improve symptoms of depression and other mental health disorders in some individuals.

Dietary sources of ω -3 fatty acids include fish oil and certain plant and nut oils. Fish oil contains both DHA and EPA, whereas some nuts (English walnuts) and vegetable oils (canola, soybean, flaxseed and linseed, olive) contain only the ω -3 ALA.

There is evidence from multiple large-scale population (epidemiologic) studies and randomized controlled trials that intake of recommended amounts of DHA and EPA in the form of fish or fish oil supplements lowers triglycerides and raises HDL cholesterol. However, high doses may have harmful effects such as an increased risk of bleeding. Some species of fish carry a higher risk of environmental contamination such as with methyl mercury. Refer to the U.S. Environmental Protection Agency for more information about safely consuming fish: <https://www.epa.gov/fish-tech>.

Common Food Sources of Omega-3 Fats

Omega-3 Fat	Food Source
ALA	Ground flaxseed and walnuts and soybeans Flaxseed (ground), walnut, soybean and canola oils, and nonhydrogenated canola and soy margarines
DHA and EPA	Mackerel, salmon, herring, trout and sardines, and other fish and shellfish Marine algae supplements
Fish or Other Food Source	Omega-3 Content in a 4-oz Serving
English walnuts	6.8 g
Chinook salmon	3.6 g
Sockeye salmon	2.3 g
Mackerel	1.8-2.6 g
Herring	1.2-2.7 g
Rainbow trout	1.0 g
Wheat germ and oat germ	0.7-1.4 g
Halibut	0.5-1.3 g
White tuna	0.97 g
Light tuna	0.35 g
Whiting	0.9 g
Spinach	0.9 g
Flounder	0.6 g
King crab	0.6 g
Shrimp	0.5 g
Tofu	0.4 g (less in "lite" tofu)
Clam	0.32 g
Cod	0.3 g
Scallop	0.23 g
Supplements*	
Cod liver oil	800-100 mg/tsp
Fish oil	1200-1800 mg/tsp
Omega-3 fatty acid concentrate	~250 mg/capsule

Enhancing Intake of Omega-3 Fats

- Eat fish at least two times each week.
- Include canned fish in your diet (examples: salmon, sardines, light tuna). Try sardines on toast.
- Add ground flaxseed to foods such as hot or cold cereal or yogurt (flaxseed must be ground for the fatty acids to be fully available for absorption).
- Add walnuts to salads, cereals, baking (examples, muffins, cookies, breads), and pancakes or have on their own as a snack.
- Have fresh or frozen soybeans (edamame) as a vegetable at meals or as a snack.
- Use soybean oil or canola oil in salad dressings and recipes.
- Use nonhydrogenated margarine made from canola or soybean as a spread or in baking.
- Cook with ω -3 eggs. Enjoy scrambled, hardboiled, poached, or over easy.
- Use other ω -3 fortified products such as milk, yogurt, nutritional beverages, bars, cereal, bread, and pasta.
- Substitute $\frac{1}{4}$ cup ground flaxseed for $\frac{1}{4}$ cup flour in bread, pizza dough, muffin, cookie, or meatloaf recipes.
- Replace 1 egg with 1 Tbsp ground flaxseed blended with 3 Tbsp water in recipes.

*Exact omega-3 content varies per manufacturer. Check label.

EPA, Eicosapentaenoic; *DHA*, docosahexaenoic acid.

National Institutes of Health Office of Dietary Supplements Fact Sheets for Health Professionals: Omega-3 Fatty Acids. Nutritional Facts on a High-Fiber Diet

This diet is a modification of the regular diet. The purpose of this diet is to decrease transit time through the intestine, promote more frequent bowel movements, and promote softer stools. A high fiber diet may be prescribed as a treatment for diverticulosis, irritable bowel syndrome, hemorrhoids, or constipation. A high-fiber diet is also prescribed for weight loss, cardiovascular disease, and diabetes. It includes all the foods on a regular diet, with emphasis on the proper planning and selection of foods to increase the daily intake of fiber. Fluid intake should be also increased. The Academy of Nutrition and Dietetics recommends that the average adult have a daily fiber intake of 20 to 35 g from a variety of sources. For children, the child's age plus 5 g of fiber is recommended daily. In cases of severe constipation, more fiber is recommended. Following the guidelines for the Mediterranean diet will provide a high fiber diet.

Dietary Reference Intakes for Fiber for Children and Adults

Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)
1-3	19	N/A	N/A
4-8	25	N/A	N/A
9-13	31 for boys, 26 for girls	N/A	N/A
14-18	38 for boys, 26 for girls	28	29
19+	38 for men, 25 for women	28	29

N/A, Not applicable.

Although numerous over-the-counter fiber supplements are available, food sources provide many nutrients and are the preferred method of increasing dietary fiber. Adequate liquid consumption (at least eight 8-oz glasses per day) is recommended. Fiber should be added to the diet slowly because of possible cramps, bloating, and diarrhea with a sudden fiber increase. Maximum therapeutic benefits of fiber are obtained after several months of compliance. There are two components of dietary fiber, each providing health benefits: insoluble and soluble.

Types of Dietary Fiber

Type of Fiber	Components of Cells	Food Sources	Health Benefits
Soluble fibers	Gums, mucilages, pectin, certain hemicelluloses	Vegetables, fruits, barley; legumes, oats, and oat-bran	Decrease total blood cholesterol. Guard against diabetes. Prevent constipation. May help manage irritable bowel syndrome. May protect against colon cancer and gallstones.
Insoluble fibers	Cellulose, lignin, some hemicelluloses	Whole-wheat products, wheat and corn bran, and many vegetables (including cauliflower, green beans, potatoes, and skins of root vegetables)	May prevent diverticular disease. Prevents constipation. May delay glucose absorption (probably insignificant). May increase satiety and therefore assist with weight loss. Lower cholesterol. May protect against colon cancer.

GUIDELINES FOR HIGH-FIBER DIET

1. Increase consumption of whole-grain breads, cereals, flours, and other whole-grain productions to 6 to 11 servings daily.
2. Increase consumption of vegetables, legumes and fruits, nuts, and edible seeds to 5 to 8 servings daily.
3. Consume high-fiber cereals, granolas, and legumes as needed to bring fiber intake to 25 g or more daily.
4. Increase consumption of fluids to at least 2 L (or approximately 2 qt) daily.
5. For a high-fiber diet of approximately 24 g of dietary fiber: use 12 or more servings of the foods from the groups below (each food contains approximately 2 g of dietary fiber). For example, ½ cup of baked beans (8 Tbsp) would count as 4 servings.

EACH OF THESE FOODS IN THIS AMOUNT CONTAINS 2 G OF DIETARY FIBER

Apple, 1 small	Strawberries, ½ cup
Orange, 1 small	Pear, ½ small
Banana, 1 small	Cherries, 10 large
Peach, 1 medium	Plums, 2 small
Whole-wheat bread, 1 slice	Oatmeal, dry, 3 Tbsp
All Bran, 1 Tbsp	Shredded wheat, ½ biscuit
Rye bread, 1 slice	Wheat bran, 1 tsp
Corn flakes, ⅔ cup	Grape-nuts, 3 Tbsp
Cracked wheat bread, 1 slice	Puffed wheat, 1½ cup
Broccoli, ½ stalk	Potato, 2-in diameter
Lettuce, raw, 2 cups	Celery, 1 cup
Brussels sprouts, 4	Tomato, raw, 1 medium
Green beans, ½ cup	Corn on the cob, 2 in
Carrots, ⅔ cup	Baked beans, canned, 2 Tbsp

SELECTED FOOD SOURCES OF FIBER		
Food	Grams per Serving	% Daily Value*
Navy beans, cooked, ½ cup	9.5	38
Bran ready-to-eat cereal (100%), ½ cup	8.8	35
Kidney beans, canned, ½ cup	8.2	33
Split peas, cooked, ½ cup	8.1	32
Lentils, cooked, ½ cup	7.8	31
Black beans, cooked, ½ cup	7.5	30
Pinto beans, cooked, ½ cup	7.7	31
Lima beans, cooked, ½ cup	6.6	26
Artichoke, globe, cooked, 1 each	6.5	26
White beans, canned, ½ cup	6.3	25
Chickpeas, cooked, ½ cup	6.2	24
Great northern beans, cooked, ½ cup	6.2	24
Cowpeas, cooked, ½ cup	5.6	22
Soybeans, mature, cooked, ½ cup	5.2	21
Bran ready-to-eat cereals, various, 1 oz	2.6-5.0	10-20
Crackers, rye wafers, plain, 2 wafers	5.0	20
Sweet potato, baked, with peel, 1 medium (146 g)	4.8	19
Asian pear, raw, 1 small	4.4	18
Green peas, cooked, ½ cup	4.4	18
Whole-wheat English muffin, 1 each	4.4	18
Pear, raw, 1 small	4.3	17

SELECTED FOOD SOURCES OF FIBER		
Food	Grams per Serving	% Daily Value*
Bulgur, cooked, ½ cup	4.1	16
Mixed vegetables, cooked, ½ cup	4.0	16
Raspberries, raw, ½ cup	4.0	16
Sweet potato, boiled, no peel, 1 medium (156 g)	3.9	15.5
Blackberries, raw, ½ cup	3.8	15
Potato, baked, with skin, 1 medium	3.8	15
Soybeans, green, cooked, ½ cup	3.8	15
Stewed prunes, ½ cup	3.8	15
Figs, dried, ¼ cup	3.7	14.5
Dates, ¼ cup	3.6	14
Oat bran, raw, ¼ cup	3.6	14
Pumpkin, canned, ½ cup	3.6	14
Spinach, frozen, cooked, ½ cup	3.5	14
Shredded wheat ready-to-eat cereals, various, ≈1 oz	2.8-3.4	11-13
Almonds, 1 oz	3.3	13
Apple with skin, raw, 1 medium	3.3	13
Brussels sprouts, frozen, cooked, ½ cup	3.2	13
Whole-wheat spaghetti, cooked, ½ cup	3.1	12
Banana, 1 medium	3.1	12
Orange, raw, 1 medium	3.1	12
Oat bran muffin, 1 small	3.0	12
Guava, 1 medium	3.0	12
Pearled barley, cooked, ½ cup	3.0	12
Sauerkraut, canned, solids, and liquids, ½ cup	3.0	12
Tomato paste, ¼ cup	2.9	11.5
Winter squash, cooked, ½ cup	2.9	11.5
Broccoli, cooked, ½ cup	2.8	11
Parsnips, cooked, chopped, ½ cup	2.8	11
Turnip greens, cooked, ½ cup	2.5	10
Collards, cooked, ½ cup	2.7	11
Okra, frozen, cooked, ½ cup	2.6	10
Peas, edible-podded, cooked, ½ cup	2.5	10

*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine whether a food contains a lot or a little of a specific nutrient. The DV for fiber is 25 g. The percent DV (%DV) listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving. %DVs are based on a 2000-calorie diet.

Food sources of dietary fiber ranked by grams of dietary fiber per standard amount. (All are ≥10% of adequate intake for adult women, which is 25 g/day.)

Glycemic Index (GI) and Glycemic Load (GL) of Selected Foods*

The glycemic index (GI) is a measure of the predicted rise in blood glucose of a variety of carbohydrate foods on a scale of 1–100 as compared to pure glucose, which has a value of 100. The GI ranking is as follows: high GI >70; moderate GI 56–69; and low GI <55 (University of Sydney, 2019). Foods with a high GI cause a rapid rise in blood glucose, whereas lower GI foods cause blood glucose to rise more slowly which could be helpful in managing conditions such as diabetes, cardiovascular disease, and obesity (Augustin et al, 2015).

The glycemic load (GL) takes this measurement one step further and looks at the predicted rise in blood glucose in a typical portion of carbohydrate food using this equation: $GI \times \text{grams carbohydrate in a typical portion of food} \div 100$. The ranking is as follows: high GL ≥ 20 ; medium GL 11–19; and low GL ≤ 10 (Monro and Shaw, 2008).

Additional factors that affect the GI and the GL include portion eaten, whether it was eaten on an empty stomach or not, and overall macronutrient and fiber content of the meal. Pairing a high GI food with some fat and protein will lead to a slower rise in blood glucose.

	GI	GL		GI	GL
Breakfast Cereals					
Kashi Seven Whole Grains	65	16	"Grainy" breads (avg)	49	6
Kellogg's All-Bran	30	4	Pita bread	57	10

Nutritional Facts on a High-Protein Diet

A diet high in protein is recommended most often for increased needs for healing. A diet of 1.2 g/kg to 1.5 g/kg is recommended for healing by the National Pressure Injury Advisory Panel. It is now recommended for people on dialysis and for those with some types of liver disease. Diets as high as 2.0 g/kg have been recommended after major trauma. High-protein diets of 1.6g/kg are recommended for athletes who are building muscle. Historically, a high-protein diet has been defined as one with at least 100 g of protein per day. This has been replaced by recommendations based on weight. How to accurately determine protein needs in an obese person remains debatable. A high-protein diet of 1.75 g/kg of ideal body weight (IBW) is sometimes beneficial for treating those with obesity.

BEST FOOD SOURCES OF PROTEIN

1 cup = 240 mL; 1 ounce = 28 grams

Meat: most types of meat provide 7 g per ounce

Fish and shellfish: 7 g per ounce

Eggs: 6 to 7 g per egg, depends on the egg size

Cow's milk: 8 g per cup

Goat's milk: 9 g per cup

Soy milk: 7 to 8 g per cup

Nonfat milk powder: 8 grams per 3 Tbsp. (24g)

Plain yogurt: 6 to 7 g per ½ cup

Greek yogurt: 11 to 15 g per ½ cup

Cheese: 7 g per ¼ cup of cottage cheese OR 1 ounce hard cheese.

Peanut butter or nut butter: 8 g per 2 Tbsp. (34g)

Tofu: 4.6 g per ounce

Lentils: 10 g per ½ cup, cooked

Chickpeas: 8 g per ½ cup, cooked

Quinoa: 4 g per ½ cup, cooked

Teff: 5 g per ½ cup, cooked

Chia seeds: 5 g per ounce

Hemp seeds: 9 grams per 3 Tbsp. (30g)

PROTEIN SUPPLEMENTS

Nonfat dry milk (NFDM) may be added to cooked foods to increase protein intake. However when it is added, carbohydrate is also added as the sugar lactose. NFDM can be added to regular milk to create more concentrated milk. Protein powders are a popular way to increase the protein content of the diet, either by adding it to foods or by using it in smoothies or shakes. Whey-based supplements are the most common because they are water-soluble and provide complete protein. Soy-based supplements are also popular, especially for those avoiding animal products. For other vegetable protein sources, see Appendix 30. There are now hundreds of products available, most with other added nutrients.

It is important to note that almond milk, hemp milk, oat milk, and coconut milk in their fluid forms are relatively low in protein. If used for high-nutrition impact drinks, an added source of powdered protein may be necessary to meet nutrition goals.

Nutritional Facts on Vegetarian Eating

A well-planned vegetarian diet can meet nutritional needs and can be a healthy way to meet the dietary guidelines. Vegetarian diets are chosen for nutritional, religious, ecologic, or personal reasons. It is the position of the Academy of Nutrition and Dietetics (AND) that “appropriately planned vegetarian diets are healthful, nutritionally adequate and provide health benefits in the prevention and treatment of certain diseases” (Melina et al, 2016).

The Academy’s practice guideline contains recommendations, based on scientific evidence, designed to assist in the appropriate nutrition care for vegetarians. The guideline includes recommendations for children, adolescents, adults, and women who are pregnant or lactating, providing more than 30 nutrition recommendations related to vegetarian nutrition, including:

- Macronutrients, including protein
- Micronutrients, including vitamin B₁₂
- Knowledge, beliefs, and motivations
- Diet diversity
- Nutrition counseling
- Treatment of hyperlipidemia, obesity, type 2 diabetes
- Adherence to a vegetarian diet

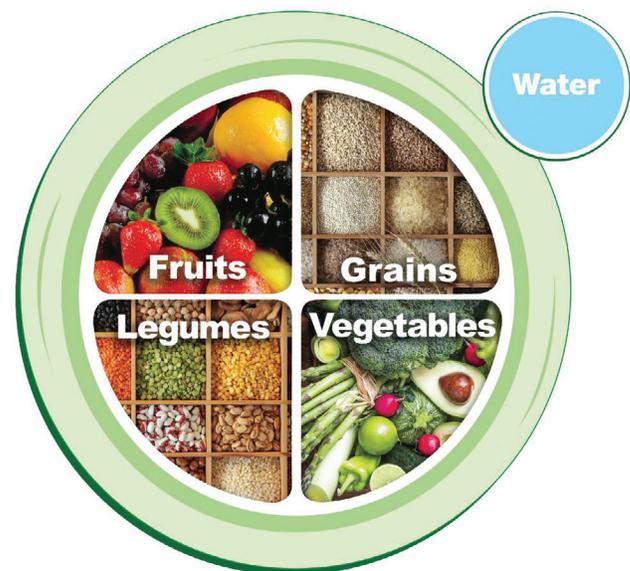

Vegetarian adaptations of the U.S. Department of Agriculture (USDA) food patterns were included in the 2010 *Dietary Guidelines for Americans*, with sample vegetarian food patterns that allow for additional flexibility in food group choices. However, those adaptations did not modify the underlying structure of the patterns but substituted the same amounts of plant foods for animal foods in each food group. In contrast, the current Healthy Vegetarian Pattern in the 2015 U.S. Dietary Guidelines includes changes in food group composition and amounts, based on assessing the food choices of vegetarians. The Healthy Vegetarian Pattern is similar in meeting nutrient standards to the Healthy U.S.-Style Pattern, but somewhat higher in calcium and fiber and lower in vitamin D due to differences in the foods included.

Vegetarian diets are usually classified into one of the following three types:

1. Lacto-ovo-vegetarian is a modification of the diet that eliminates all dietary sources of animal protein except dairy products and eggs. This is the most common type of vegetarian diet and is the easiest of the vegetarian diets to prepare.
2. Lacto-vegetarian is a modification of the diet that eliminates all dietary sources of animal protein except dairy products. This requires that baked products be made without eggs and the elimination of egg noodles.
3. Strict vegetarian (vegan diet) is a modification of the diet that eliminates all dietary sources of animal protein.

Adequacy: The more restrictive the diet, the more challenging it is to ensure adequacy. Lacto-ovo and lacto-vegetarian diets require the same planning as any other diet. The vegan diet is a little more difficult but can be adequate with some planning. The Power Plate is a tool developed by Physicians Committee for Responsible Medicine to assist in planning a nutritionally complete vegan diet and can be accessed at PCRM.org.

The Sustainable Power Plate

SustainablePowerPlate.org

NUTRIENTS TO CONSIDER WHEN PLANNING A VEGETARIAN MENU

Protein

Foods that provide approximately 7 grams of protein per serving:

¼ cup cottage cheese	½ cup legumes, cooked
1 cup cow's milk, goat's milk or soymilk	¼ cup soybeans
1 oz cheese	¾ cup of almonds
⅓ cup mixed nuts	¼ cup tofu (soy cheese)
1 egg	¾ cup yogurt
2 Tbsp peanut butter	¼ cup plain, Greek style yogurt
	1 cup of quinoa

Foods that contain the essential amino acids are considered complete proteins. However, foods that are incomplete proteins can be combined to make a complete protein. These are known as complementary proteins. They do not have to be eaten together at the same meal. The most common combination of complementary proteins is beans (legumes) combined with rice or corn.

Calcium: All vegetarians, especially young women, should ensure adequate calcium intake for development and maintenance of strong bones. In place of dairy products, choose abundant amounts of dark, leafy greens (e.g., kale, mustard and turnip greens, collards); bok choy; broccoli; legumes; tofu processed with calcium; dried figs; sesame seeds; and calcium-fortified cereals and juices can be incorporated into the diet. The following foods provide approximately the same amount of calcium as 1 cup of cow's milk (approximately 300 mg).

1 cup calcium-fortified orange juice, soy milk, nut milk, grain, or hemp milk	2-3 cups cooked dried beans
¼ cup sesame seeds or 2 Tbsp. sesame butter (Tahini)	1 cup almonds
1 cup collards or kale, cooked	1.5 oz chia seeds
	¾ cup blanched nettles
	3 ounces (100g) extra firm tofu made with calcium

Iron: Iron deficiency rates are similar between vegetarians and nonvegetarians. When consumed along with foods rich in vitamin C, plant sources of iron are better absorbed. High-iron foods include legumes, dark-green vegetables (i.e., spinach and beet greens), dried fruits, prune juice, blackstrap molasses, pumpkin seeds, soy nuts, and iron-fortified breads and cereals.

Vitamin B₁₂: Found only in animal foods, vitamin B₁₂ is not a nutrient of great concern for vegetarians who regularly consume eggs or dairy products (lacto-ovo-vegetarians). However, vegans should include vitamin B₁₂-fortified foods such as fortified soy milk and

commercial breakfast cereals, or a B₁₂ supplement in their diets. Vitamin B₁₂ is also found in some brands of Brewer's yeast (check the label).

Vitamin D: In the United States, the primary source of vitamin D is dairy products, most of which are fortified with vitamin D. However, cheese and yogurt do not have to be made from vitamin D-fortified milk and thus are not reliable sources of vitamin D. The other main source results from sunlight exposure, causing vitamin D to be synthesized in the skin. See Appendix 38. If dairy products are not consumed and direct sunlight exposure is limited, supplementation is warranted. Foods containing vitamin D include fortified cow's milk, soy milk, rice milk, or nut milk. Supplementation (at least 1000 IU/day) is needed for individuals who do not consume milk products or who spend little time in the sun.

Zinc: Because zinc is found in higher amounts in animal foods, the vegetarian diet may be limited. The following foods can be included in the diet to increase zinc intake:

Wheat germ

Tofu

Nuts including cashews and almonds

Seeds including sunflower, flax, pumpkin (pepitas), and chia seeds

Dried beans

Breakfast cereals, fortified

To follow the Dietary Guidelines for Americans Healthy Vegetarian Eating Pattern, identifying an appropriate calorie level is the first step (see table below). Then choose a variety of foods in each group and subgroup over time in recommended amounts, and limit choices that are not in nutrient-dense forms so that the overall calorie limit is not exceeded.

Calorie Level of Pattern	1000	1200	1400	1600	1800	2000
Food Group	Daily Amount of Food From Each Group (vegetable and protein foods subgroup amounts are per week)					
Vegetables	1 c-eq	1½ c-eq	1½ c-eq	2 c-eq	2½ c-eq	2½ c-eq
Dark-green vegetables (c-eq/wk)	½	1	1	1½	1½	1½
Red and orange vegetables (c-eq/wk)	2½	3	3	4	5½	5½
Legumes (beans and peas) (c-eq/wk)	½	½	½	1	1½	1½
Starchy vegetables (c-eq/wk)	2	3½	3½	4	5	5
Other vegetables (c-eq/wk)	1½	2½	2½	3½	4	4
Fruits	1 c-eq	1 c-eq	1½ c-eq	1½ c-eq	1½ c-eq	2 c-eq
Grains	3 oz-eq	4 oz-eq	5 oz-eq	5½ oz-eq	6½ oz-eq	6½ oz-eq
Whole grains (oz-eq/day)	1½	2	2½	3	3½	3½
Refined grains (oz-eq/day)	1½	2	2½	2½	3	3
Dairy	2 c-eq	2.5 c-eq	2.5 c-eq	3 c-eq	3 c-eq	3 c-eq
Protein Foods	1 oz-eq	1½ oz-eq	2 oz-eq	2½ oz-eq	3 oz-eq	3½ oz-eq
Eggs (oz-eq/wk)	2	3	3	3	3	3
Legumes (beans and peas) (oz-eq/wk)	1	2	4	4	6	6
Soy products (oz-eq/wk)	2	3	4	6	6	8
Nuts and seeds (oz-eq/wk)	2	2	3	5	6	7
Oils	15 g	17 g	17 g	22 g	24 g	27 g
Limit on Calories for Other Uses, calories (% of calories)	190 (19%)	170 (14%)	190 (14%)	180 (11%)	190 (11%)	290 (15%)

U.S. Dietary Guidelines 2015-2020 Appendix 5. USDA Food Patterns: Healthy Vegetarian Eating Pattern. <https://health.gov/dietaryguidelines/2015/guidelines/appendix-5/>. Accessed February 7, 2019.

SPECIAL NOTES

Pregnancy and Lactation: Well-planned vegan and lacto-ovo-vegetarian eating patterns adequately provide for the nutritional needs of pregnant and lactating women. Folate supplements are recommended for all pregnant women, including vegetarians. Vegans must ensure daily intake of 2 mcg of vitamin B₁₂ daily during pregnancy and 2.6 mcg during lactation, whether through supplements or fortified foods. Women with limited sun exposure should include vitamin D–fortified foods and possibly a vitamin D supplement. Caution should be used with vitamin D supplementation because excess vitamin D can cause fetal abnormalities.

Infants, Children, and Adolescents: According to the Academy, well-planned vegan and lacto-ovo-vegetarian eating patterns adequately provide for the nutritional needs of infants, children, and adolescents. Because of the high bulk of low-fat vegetarian eating patterns, it may be difficult for children and adolescents to consume enough food to provide for their energy needs. Frequent meals and snacks with nutrient-dense foods can help meet energy and nutrient needs. If sun exposure is limited, vitamin D–fortified foods or supplements should be used. For vegan children, a reliable source of vitamin B₁₂ should be included in their diets. To provide for growth, calcium, iron, and zinc intakes deserve special attention. It is recommended that parents of vegetarian infants and youth consult a registered dietitian nutritionist (RDN) with expertise in the vegetarian eating pattern.

Meal Pattern: Lacto-Vegetarian

Breakfast	Lunch	Dinner	Snack
½ cup orange juice	Vegetarian chili	Quinoa patties	½ peanut butter sandwich and
Whole grain cereal and milk	Corn bread	Brown rice	8 oz milk
Berry yogurt parfait	Green salad	Fresh spinach served with lemon and butter if desired	
	Fresh fruit	Banana pudding made with coconut milk	

Meal Pattern: Lacto-Ovo-Vegetarian

Breakfast	Lunch	Dinner	Snack
Fresh fruit	Egg salad sandwich on whole wheat bread with lettuce	Black bean burritos with cheese, avocado, and salsa	Apple and cheese
½ cup oat-meal served with Greek yogurt	Cup of tomato soup	Lettuce salad	
1 cup (8 oz) milk	Carrot sticks	Peanut butter cookie and 8 oz milk	
	Fresh fruit		

Meal Pattern: Vegan

Breakfast	Lunch	Dinner	Snack
½ cup orange juice (calcium fortified)	Bean burritos served with guacamole and salsa	Tofu-vegetable stir-fry (include bok choy and spinach for calcium) Top with cashews	½ peanut butter sandwich or ½ cup of edamame
3 whole grain pancakes topped with walnuts, applesauce, and cinnamon	Green salad with oil and vinegar salad dressing	Brown rice	
1 cup fortified soy milk or soy yogurt	1 fresh apple and 1 cup fortified soymilk	Cardamom-flavored chia pudding made with soymilk	
		Beverage of choice

Nutritional Facts on Folic Acid, Vitamin B₆, and Vitamin B₁₂

FOLATE

Folate is a water-soluble B vitamin that occurs naturally in food. Folic acid is the synthetic form of folate that is found in supplements and is added to fortified foods. Folate, formerly known as folacin, is the generic term to refer to both folate and folic acid. Folate functions as an enzyme in single carbon transfers and is involved in the production and maintenance of new cells, which is especially important during periods of rapid cell division and growth such as infancy, adolescence, and pregnancy. Folate is needed to make deoxyribonucleic acid (DNA) and ribonucleic acid, the building blocks of cells. Both adults and children need folate to make normal red blood cells and prevent anemia. Folate is also essential for the conversion of homocysteine to methionine in the synthesis of s-adenosyl-methionine, and important methyl donor.

A genetic mutation of a folate-metabolizing enzyme (5,10-methylenetetrahydrofolate reductase [MTHFR]) results in the inability to convert dietary folate or folic acid into the active form, 5-methyltetrahydrofolate (5-MTHFA). The result is folate deficiency unless folate is consumed in the methylated form as methyltetrahydrofolic acid (MTHFA).

Recommended Intakes

Intake recommendations for folate and other nutrients are provided in the dietary reference intakes (DRIs) developed by the Food and

Nutrition Board (FNB), Institute of Medicine (IOM) of the National Academies (formerly National Academy of Sciences). DRI is the general term for a set of reference values used for planning and assessing nutrient intakes of healthy people.

The table lists the current RDAs for folate as micrograms (mcg) of dietary folate equivalents (DFEs). The FNB developed DFEs to reflect the higher bioavailability of folic acid than that of food folate. At least 85% of supplemental folic acid is estimated to be bioavailable when taken with food, whereas only about 50% of folate naturally present in food is bioavailable. Based on these values, the FNB defined DFE as follows:

- 1 mcg DFE = 1 mcg food folate
- 1 mcg DFE = 0.6 mcg folic acid from fortified foods or dietary supplements consumed with foods
- 1 mcg DFE = 0.5 mcg folic acid from dietary supplements taken on an empty stomach

For infants from birth to 12 months of age, AIs were established that are equivalent to the mean intake of folate in healthy, breastfed infants in the United States. For a list of tolerable upper intake levels (UL), see the DRI table on the inside cover of this book.

Recommended Dietary Allowances (RDAs) for Folate

Age	Male	Female	Pregnant	Lactating
Birth to 6 months*	65 mcg DFE*	65 mcg DFE*	N/A	N/A
7-12 months*	80 mcg DFE*	80 mcg DFE*	N/A	N/A
1-3 years	150 mcg DFE	150 mcg DFE	N/A	N/A
4-8 years	200 mcg DFE	200 mcg DFE	N/A	N/A
9-13 years	300 mcg DFE	300 mcg DFE	N/A	N/A
14-18 years	400 mcg DFE	400 mcg DFE	600 mcg DFE	500 mcg DFE
19+ years	400 mcg DFE	400 mcg DFE	600 mcg DFE	500 mcg DFE

N/A, Not applicable.

*Adequate intake (AI)

Tolerable upper intake level (UL): 0-12 mos not determined; 1-3y 300 mcg/d; 4-8y 400 mcg/d; 9-13y 600 mcg/d; 14-18y (also for pregnancy and lactation) 800 mcg/d; 19+ (also for pregnancy and lactation) 1000 mcg/d.

Selected Food Sources of Folate and Folic Acid

Food	mcg DFE per Serving	Percent DV*	Food	mcg DFE per Serving	Percent DV*
Beef liver, braised, 3 ounces	215	54	Peanuts, dry roasted, 1 ounce	41	10
Spinach, boiled, ½ cup	131	33	Wheat germ, 2 tablespoons	40	10
Black-eyed peas (cowpeas), boiled, ½ cup	105	26	Tomato juice, canned, ¾ cup	36	9
Breakfast cereals, fortified with 25% of the DV [†]	100	25	Crab, Dungeness, 3 ounces	36	9
Rice, white, medium-grain, cooked, ½ cup [†]	90	23	Orange juice, ¾ cup	35	9
Asparagus, boiled, 4 spears	89	22	Turnip greens, frozen, boiled, ½ cup	32	8
Spaghetti, cooked, enriched, ½ cup [†]	83	21	Orange, fresh, 1 small	29	7
Brussels sprouts, frozen, boiled, ½ cup	78	20	Papaya, raw, cubed, ½ cup	27	7
Lettuce, romaine, shredded, 1 cup	64	16	Banana, 1 medium	24	6
Avocado, raw, sliced, ½ cup	59	15	Yeast, baker's, ¼ teaspoon	23	6
Spinach, raw, 1 cup	58	15	Egg, whole, hard-boiled, 1 large	22	6
Broccoli, chopped, frozen, cooked, ½ cup	52	13	Vegetarian baked beans, canned, ½ cup	15	4
Mustard greens, chopped, frozen, boiled, ½ cup	52	13	Cantaloupe, raw, 1 wedge	14	4
Green peas, frozen, boiled, ½ cup	47	12	Fish, halibut, cooked, 3 ounces	12	3
Kidney beans, canned, ½ cup	46	12	Milk, 1% fat, 1 cup	12	3
Bread, white, 1 slice [†]	43	11	Ground beef, 85% lean, cooked, 3 ounces	7	2
			Chicken breast, roasted, ½ breast	3	1

*DV = Daily value. The Food and Drug Administration (FDA) developed DVs to help consumers compare the nutrient contents of products within the context of a total diet. The DV for folate is 400 mcg for adults and children aged 4 and older. However, the FDA does not require food labels to list folate content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient.

[†]Fortified with folic acid as part of the folate fortification program.

VITAMIN B₆

Vitamin B₆ is a water-soluble vitamin that exists in three major chemical forms: pyridoxine, pyridoxal, and pyridoxamine and their respective esters. Pyridoxal 5[′] phosphate (PLP) and pyridoxamine 5[′] phosphate (PMP) are the active coenzyme forms of vitamin B₆. Vitamin B₆ is naturally present in many foods, is added to others, and also exists as a dietary supplement.

Vitamin B₆ performs a wide variety of functions in the body. It is needed for more than 100 enzymes involved in protein metabolism and is essential for red blood cell metabolism. The nervous and immune systems need vitamin B₆ to function efficiently, and it is also needed for the conversion of tryptophan (an amino acid) to niacin. A vitamin B₆ deficiency can result in a form of anemia that is similar to iron deficiency anemia.

Through its involvement in protein metabolism and cellular growth, vitamin B₆ is important to the immune system. It helps maintain the health of lymphoid organs (thymus, spleen, and lymph nodes) that make white blood cells. It is also important for maintaining normal blood glucose levels.

Recommended Intakes

Intake recommendations for vitamin B₆ and other nutrients are provided in the DRIs developed by the FNB of the IOM of the National Academies.

Recommended Dietary Allowances for Vitamin B₆ for Children and Adults

Age (years)	Males (mg/day)	Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0-6 mo	0.1*	0.1*	N/A	N/A
7-12 mo	0.3*	0.3*	N/A	N/A
1-3	0.5	0.5	N/A	N/A
4-8	0.6	0.6	N/A	N/A
9-13	1.0	1.0	N/A	N/A
14-18	1.3	1.2	1.9	2.0
19-50	1.3	1.3	1.9	2.0
51+	1.7	1.5	N/A	N/A

N/A, Not applicable.

*Adequate intake (AI). AI for vitamin B₆ is equivalent to the mean intake of vitamin B₆ in healthy, breastfed infants.

Tolerable upper intake level (UL): 0-12 mos not determined; 1-3y 30 mg/d; 4-8y 40 mg/d; 9-13y 60 mg/d; 14-18y (also for pregnancy and lactation) 80 mg/d; 19+ (also for pregnancy and lactation) 100 mg/d.

Substantial proportions of the naturally occurring pyridoxine in fruits, vegetables, and grains exist in glycosylated forms that exhibit reduced bioavailability.

Selected Food Sources of Vitamin B₆

Food	Milligrams (mg) per Serving	Percent DV*
Chickpeas, canned, 1 cup	1.1	55
Beef liver, pan fried, 3 ounces	0.9	45
Tuna, yellowfin, fresh, cooked, 3 ounces	0.9	45
Salmon, sockeye, cooked, 3 ounces	0.6	30
Chicken breast, roasted, 3 ounces	0.5	25
Breakfast cereals, fortified with 25% of the DV for vitamin B ₆	0.5	25
Potatoes, boiled, 1 cup	0.4	20
Turkey, meat only, roasted, 3 ounces	0.4	20
Banana, 1 medium	0.4	20
Marinara (spaghetti) sauce, ready to serve, 1 cup	0.4	20
Ground beef, patty, 85% lean, broiled, 3 ounces	0.3	15
Waffles, plain, ready to heat, toasted, 1 waffle	0.3	15
Bulgur, cooked, 1 cup	0.2	10
Cottage cheese, 1% low-fat, 1 cup	0.2	10
Squash, winter, baked, ½ cup	0.2	10
Rice, white, long-grain, enriched, cooked, 1 cup	0.1	5
Nuts, mixed, dry-roasted, 1 ounce	0.1	5
Raisins, seedless, ½ cup	0.1	5
Onions, chopped, ½ cup	0.1	5
Spinach, frozen, chopped, boiled, ½ cup	0.1	5
Tofu, raw, firm, prepared with calcium sulfate, ½ cup	0.1	5
Watermelon, raw, 1 cup	0.1	5

*DV = Daily value. DVs were developed by the Food and Drug Administration (FDA) to help consumers compare the nutrient contents of products within the context of a total diet. The DV for vitamin B₆ is 2 mg for adults and children age 4 and older. However, the FDA does not require food labels to list vitamin B₆ content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient.

VITAMIN B₁₂

Vitamin B₁₂ is a member of the vitamin B complex. It contains cobalt; thus it is also known as *cobalamin*. Methylcobalamin and 5-deoxyadenosylcobalamin are the active forms of vitamin B₁₂. Like folate, vitamin B₁₂ is involved in the conversion of homocysteine to methionine.

Vitamin B₁₂ is necessary for the synthesis of red blood cells, the maintenance of the nervous system, DNA synthesis, and growth.

Deficiency can cause anemia. Vitamin B₁₂ neuropathy, involving the degeneration of nerve fibers and irreversible neurologic damage, can also occur.

Proper vitamin B₁₂ absorption requires the presence of hydrochloric acid (HCL) and gastric protease, which cause its release from the protein it is bound to in food, allowing it to be absorbed. B₁₂ then combines with intrinsic factor (IF), secreted by the stomach's parietal cells, and travels down the gastrointestinal (GI) tract where it is absorbed as the B₁₂-IF complex in the distal ileum. Because HCL production tends to diminish with age, B₁₂ supplementation where the B₁₂ is already separated from the protein molecule and is in its free form can be useful in treating or preventing a deficiency. Total body store of B₁₂ is 2 to 5 mg in adults. Approximately 80% of this is stored in the liver.

Along with folate and vitamin B₆, vitamin B₁₂ is helpful in lowering the level of the amino acid homocysteine in the blood. It has been hypothesized that at high levels homocysteine might damage coronary arteries or make it easier for blood-clotting cells to clump together and form a clot. This could increase risks for a heart attack or stroke.

The table below lists the current RDAs for vitamin B₁₂ in micrograms (mcg). For infants aged 0 to 12 months, there are AIs that are equivalent to the mean intake of vitamin B₁₂ in healthy, breastfed infants.

Recommended Dietary Allowances for Vitamin B₁₂ for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
0-6 mo	0.4*	N/A	N/A
7-12 mo	0.5*	N/A	N/A
1-3	0.9	N/A	N/A
4-8	1.2	N/A	N/A
9-13	1.8	N/A	N/A
14 +	2.4	2.6	2.8

N/A, Not applicable.

*Adequate intake (AI)

Tolerable upper intake level (UL) not established for B₁₂.

Vitamin B₁₂ is found primarily in animal foods such as fish, meat, poultry, eggs, and dairy products. However, it is also synthesized by bacteria, and there has been considerable research into proposed plant sources of vitamin B₁₂. Fermented soy products, seaweeds, and algae (spirulina) have all been suggested as containing significant B₁₂. However, the present consensus is that any B₁₂ present in plant foods is likely to be unavailable to humans; thus these foods should not be relied on as safe sources. Vegans need B₁₂ from fortified foods or as a supplement. Fortified breakfast cereals are a readily available source of vitamin B₁₂ with high bioavailability for vegans. Some nutritional yeast products also contain vitamin B₁₂. Fortified foods vary in formulation, so it is important to read product labels.

Many vegan foods are supplemented with B₁₂.

Selected Food Sources of Vitamin B₁₂

Food	Micrograms (mcg) per Serving	Percent DV*
Clams, cooked, 3 ounces	84.1	1,402
Liver, beef, cooked, 3 ounces	70.7	1,178
Breakfast cereals, fortified with 100% of the DV for vitamin B ₁₂ , 1 serving	6.0	100
Trout, rainbow, wild, cooked, 3 ounces	5.4	90
Salmon, sockeye, cooked, 3 ounces	4.8	80
Trout, rainbow, farmed, cooked, 3 ounces	3.5	58
Tuna fish, light, canned in water, 3 ounces	2.5	42
Cheeseburger, double patty and bun, 1 sandwich	2.1	35
Haddock, cooked, 3 ounces	1.8	30
Breakfast cereals, fortified with 25% of the DV for vitamin B ₁₂ , 1 serving	1.5	25
Beef, top sirloin, broiled, 3 ounces	1.4	23
Milk, low-fat, 1 cup	1.2	18
Yogurt, fruit, low-fat, 8 ounces	1.1	18
Cheese, Swiss, 1 ounce	0.9	15
Beef taco, 1 soft taco	0.9	15
Ham, cured, roasted, 3 ounces	0.6	10
Egg, whole, hard boiled, 1 large	0.6	10
Chicken, breast meat, roasted, 3 ounces	0.3	5

*DV = Daily value. DVs were developed by the Food and Drug Administration (FDA) to help consumers determine the level of various nutrients in a standard serving of food in relation to their approximate requirement for it. The DV for adults and children aged 4 and older is 6.0 mcg. The %DV listed on the Nutrition Facts label states the percentage of the DV provided per serving. However, the FDA does not require food labels to list vitamin B₁₂ content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient, but foods providing lower percentages of the DV also contribute to a healthful diet.

Nutritional Facts on Choline

Choline is an essential nutrient synthesized in the liver but must be consumed through diet to adequately meet human needs. It is found in many foods but is most concentrated in meat, poultry, fish, and eggs. Choline supports the structural integrity of cells as a precursor to two essential membrane phospholipids, phosphatidylcholine and sphingomyelin. It also supports the synthesis of ceramide and diacylglycerol, which are important in cell signaling as intracellular messengers. Choline has a role in stimulating the synthesis of catecholamine neurotransmitters and is a precursor for acetylcholine, which is needed for muscle control, memory, mood, circadian rhythm, and other neurologic functions.

Additionally, phosphatidylcholine is needed for the formation and secretion of very-low-density lipoprotein (VLDL) from the liver; therefore a choline deficiency can lead to nonalcoholic fatty liver disease (NAFLD) and nonalcoholic steatohepatitis (NASH).

Choline acts as a methyl donor, modulating gene expression as well as many metabolic steps, including homocysteine metabolism. Homocysteine accumulation is associated with elevated risk of cardiovascular disease (CVD). Betaine, a metabolite of choline, serves as the methyl donor for up to 60% of the methylation needed to convert homocysteine back to methionine. Yet research suggests high choline

intake coupled with certain intestinal microbiota may also increase risk for CVD. Choline and phosphatidylcholine can be converted to trimethylamine (TMA) by the microbiota, which is converted to trimethylamine-N-oxide (TMAO) in the liver. Elevated TMAO has been linked with increased CVD risk, but more research is needed to elucidate the relationship between choline, microbiota composition, and CVD risk (Bu and Wang, 2018).

GROUPS WITH INCREASED CHOLINE NEEDS

Most pregnant women consume less than the AI of choline, and it is rarely included in prenatal supplements. Higher choline intake may be especially important for pregnant women with impaired methylation status resulting from low folic acid or vitamin B₁₂ intake or a single nucleotide polymorphism (SNP) for methylenetetrahydrofolate dehydrogenase.

Other SNPs can also raise the risk for choline deficiency, such as one for the enzyme phosphatidylethanolamine N-methyltransferase (PEMT). PEMT governs de novo choline synthesis. When impaired, individuals are more susceptible to a choline deficiency and resulting organ dysfunction. Estrogen induces PEMT; therefore this SNP is of greatest concern for postmenopausal women. Other SNPs that correlate with race can modify choline requirements. Those of European descent are more likely to have four SNPs that elevate risk for organ dysfunction when consuming a low-choline diet.

Another group at risk of developing choline-insufficiency-induced organ damage are adult and pediatric patients receiving long-term total parenteral nutrition (TPN). Currently, routine TPN formulations lack choline.

Finally, because choline is a methyl donor nutrient with critical roles in neuronal functions, cognitive processes, and DNA methylation, it may be particularly important for developing children as well as older adults facing neurologic decline and diseases such as Alzheimer's disease.

EXCESSIVE CHOLINE INTAKE

Excessive choline intake is characterized by fishy body odor, vomiting, extreme sweating and salivation, hypotension, and liver toxicity.

Dietary Reference Intakes: Adequate Intakes (AIs) for Choline for Children and Adults

Age (years)	Male (mg/day)	Female (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
Birth-6 mo	125	125		
7-12 mo	150	150		
1-3	200	200		
4-8	250	250		
9-13	375	375		
14-18	550	400	450	550
19+	550	425	450	550

Tolerable upper intake level (UL): 0-12 mos not determined; 1-3y 1 g/d; 4-8y 1 g/d; 9-13y 2 g/d; 14-18y (also for pregnancy and lactation) 3 g/d; 19+ (also for pregnancy and lactation) 3.5 g/d.

Food Sources of Choline			Food Sources of Choline		
Food	Milligrams (mg) per Serving	% Daily Value*	Food	Milligrams (mg) per Serving	% Daily Value*
Beef kidney, 3 oz	436	79	Cod, Atlantic, cooked, 3 oz	71	13
Pork chitterlings, 3 oz	400	73	Chicken, light meat, 3 oz	71	13
Beef liver, 3 oz	362	65	Pork loin, 3 oz	65	11
Beef liver, pan fried, 3 oz	356	65	Brussels sprouts, boiled, 1 cup	63	11
Chicken liver, 3 oz	277	50	Broccoli, boiled, 1 cup	63	11
Wheat germ, toasted, 1 cup	202	37	Mushrooms, shiitake, cooked, ½ cup	58	11
Beef heart, 3 oz	195	35	Potato, red, baked, with skin, 1 large	57	10
Peas, green, split, raw, ½ cup	154	28	Cauliflower, boiled, 1 cup	48	8
Egg, hard boiled	147	27	Beans, kidney, canned, ½ cup	45	8
Egg yolk, 1 large	140	25	Milk, (whole or skim), 1 cup	35	6
Shrimp, 3 oz	115	21	Quinoa, cooked, ½ cup	22	4
Oysters, 3 oz	110	20	Peanut butter, smooth, 2 tablespoons	20	4
Soybeans, roasted, ½ cup	107	19	Cheese, cheddar, 1.5 oz	7	1.3
Chickpeas, raw, ½ cup	99	18	Cheese, mozzarella, 1.5 oz	7	1.3
Beef, trim cut, cooked, 3 oz	97	18	Egg white, 1 large	0.04	0.007
Chicken, dark meat, 3 oz	84	15			
Salmon, pink, canned, 3 oz	73	13			
Chicken breast, roasted, 3 oz	72	13			

*DV 5 Daily value. DVs were developed by the Food and Drug Administration (FDA) to help consumers determine the level of various nutrients in a standard serving of food in relation to their approximate requirement for it. The DV for adults and children aged 4 and older is 6.0 mcg. The %DV listed on the Nutrition Facts label states the percentage of the DV provided per serving. However, the FDA does not require food labels to list vitamin B12 content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient, but foods providing lower percentages of the DV also contribute to a healthful diet.

Drug Nutrient Interaction: Methotrexate

Methotrexate inhibits methyl group donation from folate derivatives. Therefore patients taking methotrexate may need more choline to compensate (akin to folate deficiency).

Nutritional Facts on Biotin

Biotin is an essential nutrient that is naturally present in some foods and available as a dietary supplement. Biotin is a water-soluble B vitamin and functions as a cofactor for five carboxylase enzymes needed for important steps in the metabolism of amino acids, glucose, and fatty acids. Biotin is also used in histone modification, gene regulation, and cell signaling. While some biotin found in foods is in the free form, most biotin is bound to protein. Once released and processed by enzymes in the gastrointestinal tract, free biotin is absorbed in the small intestine and predominantly stored in the liver.

There is not currently sufficient data available to derive an estimated average requirement and recommended dietary allowance for biotin, resulting in only an established adequate intake (AI) for biotin. The Food and Nutrition Board has determined the AI for all age groups by taking the amount of biotin in human breastmilk consumed by infants and extrapolating AI to the other groups using body weight.

Daily Reference Intakes: Adequate Intakes (AIs) for Biotin for Children and Adults

Age	Males and Females	Pregnancy	Lactation
0-6 months	5 mcg	N/A	N/A
7-12 months	6 mcg	N/A	N/A
1-3 years	8 mcg	N/A	N/A
4-8 years	12 mcg	N/A	N/A
9-13 years	20 mcg	N/A	N/A
14-18 years	25 mcg	30 mcg	35 mcg
19+ years	30 mcg	30 mcg	35 mcg

N/A, Not applicable.

Tolerable upper intake level (UL) has not been established for biotin.

Biotin is found in appreciable amounts in organ meats, egg, fish, and meat, but is also found in seeds, nuts, and some vegetables. Raw egg whites contain a glycoprotein, avidin, that inhibits biotin's absorption in the gastrointestinal tract. Individuals consuming large amounts of raw egg whites may be at risk for biotin deficiency. Cooking egg whites denatures the avidin, preventing this interference. In healthy individuals eating a normal mixed diet, biotin deficiency is rare. There are currently no upper limits set for biotin due to lack of evidence of

toxicity at high exposures. However, high levels of biotin supplementation may interfere with clinical tests, such as producing falsely normal or abnormal results on thyroid function tests.

Selected Food Sources of Biotin*

Food	Biotin (mcg)
Beef liver, cooked, 3 ounces	30.8
Egg, whole, cooked	10.0
Salmon, pink, canned in water, 3 ounces	5.0
Pork chop, cooked, 3 ounces	3.8
Hamburger patty, cooked, 3 ounces	3.8
Sunflower seeds, roasted, ¼ cup	2.6
Sweet potato, cooked, ½ cup	2.4
Almonds, roasted, ¼ cup	1.5
Tuna, canned in water, 3 ounces	0.6
Spinach, boiled, ½ cup	0.5
Broccoli, fresh, ½ cup	0.4
Cheddar cheese, mild, 1 ounce	0.4
Milk, 2%, 1 cup	0.3
Plain yogurt, 1 cup	0.2
Oatmeal, 1 cup	0.2
Banana, ½ cup	0.2
Whole-wheat bread, 1 slice	0.0
Apple, ½ cup	0.0

*Biotin does not currently have a daily value (DV) but will have a DV of 30 mcg for adults and children age 4+ on updated Nutrition and Supplement Facts labels starting in January 2020.

Nutritional Facts on Vitamin A and Carotenoids

Vitamin A includes a group of compounds that affect vision, bone growth, reproduction, cell division, immunity, and healthy surface linings of the respiratory tract and mucous membranes. There are two categories of vitamin A, depending on whether the food source is an animal or a plant. Vitamin A found in animal foods is called *preformed vitamin A* and is absorbed as retinol. Sources include liver, whole milk, and some fortified food products. In the body retinol can be made into retinal and retinoic acid (other active forms of vitamin A).

Plant sources of vitamin A provide the provitamin A, called *carotenoids*. They can be made into retinol in the body and then into the other active forms of vitamin A. In the United States, approximately 26% to 34% of vitamin A consumed is in the form of provitamin A carotenoids. Common provitamin A carotenoids, which give plants their color, are β -carotene, α -carotene, and β -cryptoxanthin. Among these, β -carotene is most efficiently made into retinol. The darker the color of a fruit or vegetable, the greater is its carotenoid content.

Vitamin A deficiency rarely occurs in the United States. Vitamin A deficiency is more common in developing countries, where access to sufficient animal and beta-carotene containing plant sources is limited. Vitamin A deficiency is a leading cause of preventable blindness in children. Children with measles or diarrhea can significantly benefit from increased vitamin A. Fat malabsorption can result in diarrhea and prevent normal absorption of vitamin A; this may result in vitamin A deficiency in celiac disease, Crohn's disease, and pancreatic disorders. The best absorbed form of vitamin A is in the oil form such as in cod liver oil.

Excess intake of retinol (preformed vitamin A) can be toxic to the liver and can lead to birth defects. The tolerable upper limit (UL) for adults is 3000 RAE/10,000 IU. This does not apply to intake of vitamin A derived from carotenoids.

All dietary sources of vitamin A are converted to retinol. Intake recommendations for vitamin A in foods are expressed as micrograms of retinol activity equivalents (RAEs) as a way to standardize the variation in bioactivities of retinol and provitamin A carotenoids, and account for the differences based on source. International units (IU) are a helpful guideline, but conversion rates also vary based on source:

- 1 IU retinol = 0.3 mcg RAE
- 1 IU beta-carotene from dietary supplements = 0.15 mcg RAE
- 1 IU beta-carotene from food = 0.05 mcg RAE
- 1 IU alpha-carotene or beta-cryptoxanthin = 0.025 mcg RAE

Recommended Daily Allowances

Age (years)	Males and Females (mcg RAEs/IU/day)	Pregnancy (mcg RAEs/IU/day)	Lactation (mcg RAEs/IU/day)
0-6 mo	400*/1333	N/A	N/A
0-7 mo	500*/1666	N/A	N/A
1-3	300/1000	N/A	N/A
4-8	400/1333	N/A	N/A
9-13	600/2000	N/A	N/A
14-18	900/3000 for boys 700/2333 for girls	750/2500	1200/4000
19+	900/3000 for men 700/2333 for women	770/2566	1300/4333

N/A, Not applicable; RAE, retinol activity equivalent.

*Adequate intakes

Tolerable upper intake level (UL): 0-12 mos 600 mcg/ 2000 IU/d; 1-3y 600 mcg/2000 IU/d; 4-8y 900 mcg/ 3000 IU/d; 9-13y 1700 mcg/ 5666 IU/d; 14-18y (also for pregnancy and lactation) 2800 mcg/ 9333/d; 19+ (also for pregnancy and lactation) 3000 mcg/ 10000 IU/d.

FOOD SOURCES OF VITAMIN A

Selected Animal Sources of Vitamin A

Food	Vitamin A (IU)	% Daily Value
Liver, beef, cooked, 3 oz	27,185	545
Liver, chicken, cooked, 3 oz	12,325	245
Cod Liver Oil, 1Tbs	4080	13,600
Milk, fortified skim, 1 cup	500	10
Cheese, cheddar, 1 oz	284	6
Milk, fortified whole (3.25% fat), 1 cup	249	5
Egg, whole, large	266	5.6
Egg substitute, ¼ cup	226	5
Egg yolk, large	216	4.5

Selected Plant Sources of Vitamin A (from β -Carotene)

Food	Vitamin A (IU)	% Daily Value*	Food	Vitamin A (IU)	% Daily Value*
Sweet potato, 1 medium	28,058	561	Papaya, cubes, 1 cup	1532	30
Carrot juice, canned, ½ cup	22,567	450	Mango, sliced, 1 cup	1262	25
Carrots, boiled, slices, ½ cup	13,418	270	Oatmeal, instant, fortified, plain, prepared with water, 1 cup	1252	25
Spinach, frozen, boiled, ½ cup	11,458	230	Peas, frozen, boiled, ½ cup	1050	20
Kale, frozen, boiled, ½ cup	9558	190	Tomato juice, canned, 6 oz	819	15
Carrots, 1 raw (7½ in)	8666	175	Peaches, canned, juice pack, halves or slices, ½ cup	473	10
Vegetable soup, canned, chunky, ready-to-serve, 1 cup	5820	115	Peach, 1 medium	319	6
Cantaloupe, cubes, 1 cup	5411	110	Pepper, sweet, red, raw, 1 ring (3 inches diameter by ¼ inch thick)	313	6
Spinach, raw, 1 cup	2813	55			
Apricots with skin, juice pack, ½ cup	2063	40			
Apricot nectar, canned, ½ cup	1651	35			

*Daily values (DVs) are reference numbers based on the RDA. They were developed to help consumers determine whether a food contains a lot or a little of a nutrient. The DV for vitamin A is 5000 IU. Most food labels do not list vitamin A content. The %DV column in this table indicates the percentage of the DV provided in one serving. A food providing 5% or less of the DV is a low source, whereas a food that provides 10% to 19% of the DV is a good source. A food that provides 20% or more of the DV is high in that nutrient. It is important to remember that foods that provide lower percentages of the DV also contribute to a healthful diet.

Carotenoids in Fruits and Vegetables (mole %)

	Neoxanthins and Violaxanthins	Lutein and Zeaxanthin	Lutein	Zeaxanthin	Cryptoxanthins	Lycopenes	α -Carotene	β -Carotene

Table from Sommerburg O, Keunen JE, Bird AC, et al: Fruits and vegetables that are sources for lutein and zeaxanthin: the macular pigment in human eyes, *Br J Ophthalmol* 82:907–910, 1998.

The contents of the major carotenoids are given in mole %. The amounts of the carotenoids were shown in seven major groups, as (1) neoxanthins and violaxanthins (neoxanthin, violaxanthin, and their related isomers, lutein 5, 6 epoxide), (2) lutein, (3) zeaxanthin, (4) cryptoxanthins (α-cryptoxanthin, β-cryptoxanthins, and related isomers), (5) lycopenes (lycopene and related isomers), (6) alpha-carotenes, and (7) β-carotene (all *trans* β-carotene and *cis* isomers). Lutein and zeaxanthin are given combined and as single amounts. The data are sorted by the combined amount of lutein and zeaxanthin.

Nutritional Facts on Vitamin C

Vitamin C is a nutrient naturally present in foods (mainly fruits and vegetables) and is also known by the chemical name of its principal form, L-ascorbic acid or, simply, ascorbic acid. Unlike most animals, humans are unable to synthesize vitamin C. Vitamin C is principally known as a water-soluble antioxidant, preventing the damaging effects of free radicals, and it regenerates other antioxidants in the body including vitamin E or alpha-tocopherol.

Vitamin C is required for the biosynthesis of collagen, L-carnitine, and certain neurotransmitters; it is also involved in protein metabolism. Collagen is an essential component of connective tissue, which plays a vital role in wound healing, and it plays an important role in immune function. It also improves the absorption of nonheme iron, the form of iron present in plant-based foods. Vitamin C prevents scurvy, characterized by fatigue or lassitude, widespread connective tissue weakness, and capillary fragility.

The recommended dietary allowances (RDAs) for vitamin C are based on its known physiologic and antioxidant functions in white blood cells and are much higher than the amount required for protection from deficiency. For infants from birth to 12 months, the Food and Nutrition Board (FNB) established an adequate intake (AI) for vitamin C that is equivalent to the mean intake of vitamin C in healthy, breastfed infants.

Recommended Dietary Allowances (RDAs) for Vitamin C for Children and Adults

Age (years)	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0-6 mo	40	N/A	N/A
7-12 mo	50	N/A	N/A
1-3	15	N/A	N/A
4-8	25	N/A	N/A
9-13	45	N/A	N/A
14-18	75 for boys, 65 for girls	80	115
19+	90 for men, 75 for women	85	120
Smokers	Individuals who smoke require 35 mg/day more vitamin C than nonsmokers.		

N/A, Not applicable.

Tolerable upper intake level (UL): 0-12 mos not determined; 1-3y 400 mg/d; 4-8y 650 mg/d; 9-13y 1200 mg/d; 14-18y (also for pregnancy and lactation) 1800 mg/d; 19+ (also for pregnancy and lactation) 2000 mg/d.

Fruits and vegetables are the best sources of vitamin C, especially citrus fruits, red and green peppers, kiwi fruit, and tomatoes and tomato juice. Other good food sources include broccoli, strawberries, Brussels sprouts, and cantaloupe. Some fortified breakfast cereals are also good sources of vitamin C.

The vitamin C content of food can be lessened by prolonged storage and by cooking because ascorbic acid is water soluble and is destroyed by heat. Steaming or microwaving vegetables rather than boiling them may reduce cooking losses. Fortunately, many of the best food sources of vitamin C, such as fruits and vegetables, are usually consumed raw.

Selected Food Sources of Vitamin C

Food	Milligrams (mg) per Serving	Percent (%) DV*
Red pepper, sweet, raw, ½ cup	95	158
Orange juice, ¾ cup	93	155
Orange, 1 medium	70	117
Grapefruit juice, ¾ cup	70	117
Kiwifruit, 1 medium	64	107
Green pepper, sweet, raw, ½ cup	60	100
Broccoli, cooked, ½ cup	51	85
Strawberries, fresh, sliced, ½ cup	49	82
Brussels sprouts, cooked, ½ cup	48	80
Grapefruit, ½ medium	39	65
Broccoli, raw, ½ cup	39	65
Tomato juice, ¾ cup	33	55
Cantaloupe, ½ cup	29	48
Cabbage, cooked, ½ cup	28	47
Cauliflower, raw, ½ cup	26	43
Potato, baked, 1 medium	17	28
Tomato, raw, 1 medium	17	28
Spinach, cooked, ½ cup	9	15
Green peas, frozen, cooked, ½ cup	8	13

*DV = Daily value. DVs were developed by the Food and Drug Administration (FDA) to help consumers compare the nutrient contents of products within the context of a total diet. The DV for vitamin C is 60 mg for adults and children aged 4 and older. The FDA requires all food labels to list the percent DV for vitamin C. Foods providing 20% or more of the DV are considered to be high sources of a nutrient.

Dietary Supplements

Supplements typically contain vitamin C in the form of ascorbic acid, which has equivalent bioavailability to that of naturally occurring ascorbic acid in foods, such as orange juice and broccoli. Other forms of vitamin C supplements include sodium ascorbate; calcium ascorbate; other mineral ascorbates; ascorbic acid with bioflavonoids; and combination products, such as Ester-C, which contains calcium ascorbate, dehydroascorbate, calcium threonate, xylonate, and lyxonate. It is not established whether Ester-C is more bioavailable or effective than ascorbic acid in improving vitamin C status.

Nutritional Facts on Vitamin E

Vitamin E is a naturally occurring fat-soluble vitamin that exists in eight different forms: alpha-, beta-, gamma-, and delta-tocopherol, and alpha-, beta-, gamma-, and delta-tocotrienol that have varying levels of biological activity. Alpha- (or α -) tocopherol appears to be the most active form and is the only form that is recognized to meet human requirements. Serum concentrations of alpha-tocopherol depend on the liver, which takes up the nutrient after absorption of all the forms from the small intestine. The liver then preferentially secretes only alpha-tocopherol and metabolizes and excretes the other vitamin E forms. As a result, blood and cellular concentrations of other forms of vitamin E are lower than those of alpha-tocopherol and thus have been less studied.

Vitamin E has powerful antioxidant activities, which protect cells from the damaging effects of free radicals. Free radicals combine with oxygen and form reactive oxygen species (ROS) that damage cells. Free radicals are produced endogenously when the body metabolizes food to energy. Exogenous sources come from exposure to cigarette smoke, air pollution, and ultraviolet radiation from the sun. ROS are part of signaling mechanisms among cells, and antioxidant vitamin E protects the cells against free radical damage. Scientists are investigating whether, by limiting free-radical production and possibly through other mechanisms, vitamin E might help prevent or delay the chronic diseases associated with free radicals. Besides functioning as an antioxidant, vitamin E is also involved in immune function and, as shown primarily by in vitro studies of cells, cell signaling, regulation of gene expression, and other metabolic processes.

Vitamin E in supplements is usually sold as α -tocopherol acetate, a form of α -tocopherol that protects its ability to function as an antioxidant. The synthetic form is labeled *dl*, whereas the natural form is labeled *d*. The synthetic form is only half as active as the natural form. It is important to include foods high in vitamin E on a daily basis to get enough vitamin E from foods alone. Vegetable oils, nuts, green leafy vegetables, and fortified cereals are common food sources of vitamin E.

Recommended Dietary Allowances (RDAs) for Vitamin E of α -Tocopherol Equivalents (TE) for Children and Adults

Age	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0-6 mo	4 mg (6 IU)*	N/A	N/A
7-12 mo	6 mg (7.5 IU)*	N/A	N/A
1-3 years	6 (9 IU)	N/A	N/A
4-8 years	7 (10.4 IU)	N/A	N/A
9-13 years	11 (16.4 IU)	N/A	N/A
14-18 years	15 (22.4 IU)	15 (22.4 IU)	19 (28.4 IU)
19+ years	15 (22.4 IU)	15 (22.4 IU)	19 (28.4 IU)

N/A, Not applicable.

*Adequate intake (AI)

Tolerable upper intake level (UL): 0-12 mos not determined; 1-3y 200 mg/d; 4-8y 300 mg/d; 9-13y 600 mg/d; 14-18y (also for pregnancy and lactation) 800 mg/d; 19-50 (also for pregnancy and lactation) 1000 mg/d.

Vitamin E content of food is stated as milligrams of α -tocopherol, milligrams of α -tocopherol equivalents (mg α -TE), or as international units (IUs) on supplement labels. 1 unit = 0.67 α -TE in the *d* form and approximately 1/2 of that in the *dl* or synthetic form. The vitamin E content of foods and dietary supplements is listed on labels in IUs, a measure of biological activity rather than quantity. Naturally sourced vitamin E is called *d*-alpha-tocopherol; the synthetically produced form is *dl*-alpha-tocopherol. Conversion rules are as follows:

- To convert from mg to IU: 1 mg of alpha-tocopherol is equivalent to 1.49 IU of the natural form or 2.22 IU of the synthetic form.
- To convert from IU to mg: 1 IU of alpha-tocopherol is equivalent to 0.67 mg of the natural form or 0.45 mg of the synthetic form.

Numerous foods provide vitamin E. Nuts, seeds, and vegetable oils are among the best sources of alpha-tocopherol, and significant amounts are available in green leafy vegetables and fortified cereals (see the table below). Most vitamin E in American diets is in the form of gamma-tocopherol from soybean, canola, corn, and other vegetable oils and food products.

Selected Food Sources of Vitamin E (α -Tocopherol)

Food	Milligrams (mg) per Serving	Percent DV*
Wheat germ oil, 1 tablespoon	20.3	100
Sunflower seeds, dry roasted, 1 ounce	7.4	37
Almonds, dry roasted, 1 ounce	6.8	34
Sunflower oil, 1 tablespoon	5.6	28
Safflower oil, 1 tablespoon	4.6	25
Hazelnuts, dry roasted, 1 ounce	4.3	22
Peanut butter, 2 tablespoons	2.9	15

Corn oil, 1 tablespoon	1.9	10
Spinach, boiled, 1/2 cup	1.9	10
Broccoli, chopped, boiled, 1/2 cup	1.2	6
Soybean oil, 1 tablespoon	1.1	6
Kiwifruit, 1 medium	1.1	6
Mango, sliced, 1/2 cup	0.7	4
Tomato, raw, 1 medium	0.7	4
Spinach, raw, 1 cup	0.6	3

*DV = Daily value. DVs were developed by the Food and Drug Administration (FDA) to help consumers compare the nutrient content of different foods within the context of a total diet. The DV for vitamin E is 30 IU (approximately 20 mg of natural alpha-tocopherol) for adults and children age 4 and older. However, the FDA does not require food labels to list vitamin E content unless a food has been fortified with this nutrient. Foods providing 20% or more of the DV are considered to be high sources of a nutrient, but foods providing lower percentages of the DV also contribute to a healthful diet.

Nutritional Facts on Vitamin K

Vitamin K refers to a family of compounds with a common chemical structure. These compounds include phyloquinone (vitamin K₁) and a series of menaquinones known as vitamin K₂. They are further designated as MK-4 through MK-13 depending on the length of their individual side chains. Vitamin K is fat soluble and is naturally present in some foods, is produced by the bacteria naturally present in the gastrointestinal tract, and is available as a dietary supplement. Vitamin K₁, the main dietary form of vitamin K, is present mainly in green leafy vegetables. Menaquinones, primarily of bacterial origin, are found in some animal-based foods and in fermented foods. Natto, a Japanese fermented soy food, is an excellent source of vitamin K₂. Menaquinones are also produced by the naturally occurring bacteria in the gut. However, MK-4 is unique in that it is produced from phyloquinone by a conversion process that does not involve bacteria.

Vitamin K functions as a coenzyme for vitamin K-dependent carboxylase, an enzyme required for the synthesis of proteins involved in hemostasis (blood clotting) and bone metabolism, and other diverse physiologic functions. Prothrombin (clotting factor II) is a vitamin K-dependent protein in plasma that is directly involved in blood clotting.

Matrix Gla-protein is another vitamin K-dependent protein present in vascular smooth muscle, bone, and cartilage. Matrix Gla-protein is the focus of considerable scientific research because it might help reduce abnormal calcification. Osteocalcin is another vitamin K-dependent protein, and it is present in bone and may be involved in bone mineralization or turnover.

Antibiotics may interfere with this normal production. Circumstances that may lead to vitamin K deficiency include liver disease,

serious burns, health problems that can prevent the absorption of vitamin K (such as gallbladder or biliary disease, which may alter the absorption of fat), cystic fibrosis, celiac disease, Crohn's disease, and chronic antibiotic therapy. Excess vitamin E can inhibit vitamin K activity and precipitate signs of deficiency. The classic sign of a vitamin K deficiency is a prolonged prothrombin time, which increases the risk of spontaneous hemorrhage. Because vitamin K is stored in the liver, clinical deficiencies are rare.

Vitamin K is needed to make clotting factors that help the blood to clot and prevent bleeding. The amount of vitamin K in food may affect drug therapy, such as that from warfarin or other anticoagulants. Warfarin (Coumadin) and some anticoagulants used primarily in Europe antagonize the activity of vitamin K and, in turn, prothrombin. For this reason, individuals who are taking these anticoagulants need to maintain consistent vitamin K intakes. When taking these medications, it is necessary to eat a normal, balanced diet, maintaining a consistent amount of vitamin K and avoiding large changes in vitamin K intake.

In general, leafy green vegetables and certain legumes and vegetable oils contain high amounts of vitamin K. Foods that contain a significant amount of vitamin K include beef liver, green tea, turnip greens, broccoli, kale, spinach, cabbage, asparagus, and dark-green lettuce. Chlorophyll, which is water soluble, is the substance in plants that gives them their green color and provides vitamin K; thus chlorophyll supplements need to be considered when assessing vitamin K intake. Foods that appear to contain low amounts of vitamin K include roots, bulbs, tubers, the fleshy portion of fruits, fruit juices and other beverages, and cereal grains and their milled products.

Dietary Reference Intakes: Adequate Intakes (AIs) for Vitamin K for Children and Adults

Nutritional Facts on Vitamin D

Vitamin D is a fat-soluble vitamin that is naturally present in very few foods, is added to some foods, is available as a nutritional supplement, and is made when ultraviolet light, specifically UVB rays from the sun, strike the skin and stimulate its synthesis. Both the vitamin D that is absorbed from food and supplements, and the vitamin D that is made by the skin, is biologically inert. It must be hydroxylated twice in the body—first into 25(OH)D (calcidiol) by the liver, and again into 1,25(OH)₂D₂ (calcitriol) by the kidney.

Vitamin D is needed for the absorption of calcium from the small intestine and for the functioning of calcium in the body. Vitamin D also acts like a hormone and has many functions unrelated to its co-functions with calcium absorption and bone growth and remodeling. Besides being in bone, receptors for vitamin D have been identified in the gastrointestinal tract, brain, breast, nerve, and many other tissues. Vitamin D maintains adequate serum calcium and phosphate concentrations to prevent hypocalcemic tetany. It also modulates cell growth, neuromuscular and immune function, and reduction of inflammation. Many genes that encode for the regulation of cell proliferation, differentiation, and apoptosis are modulated by vitamin D. Recommended dietary allowances (RDAs) were established for vitamin D in 2011 and are presented in [Table 1](#).

VITAMIN D SYNTHESIZED FROM SUNLIGHT EXPOSURE

Vitamin D made in the skin lasts twice as long in the blood as vitamin D ingested from the diet. The skin not only makes vitamin D upon

exposure to UVB rays but also makes other photoproducts that cannot be obtained from food or supplements. It is unknown if any of these products have unique benefits to health, but research continues in this area.

UVB light cannot pass through glass; exposure of the skin to sunlight through glass will not result in vitamin D synthesis. Another deterrent to vitamin D synthesis by the skin is sunscreen. A sunscreen with an SPF 15 reduces skin synthesis of vitamin D by 95%, and an SPF 30 reduces it by 99%.

How much sun exposure is the correct amount to maintain optimal vitamin D levels in the body? A person sunbathing in a bathing suit will have received a dose of between 10,000 and 25,000 IU of vitamin D when he or she has sunbathed long enough to be slightly pink 24 hours later (technically called a minimal erythemal dose or “1 MED.”) Exposing 25% of the body (arms and legs) for ¼ to ½ the time it takes to get slightly pink will allow the body to make 2000 to 4000 IU of vitamin D with each exposure.

The amount of time necessary for sunlight exposure to produce adequate vitamin D depends on the person’s skin type (pale skin requires less time than dark skin with a lot of the burn-protecting pigment melanin), season of the year (the lower the sun on the horizon in the winter, the greater the time needed), the latitude (within + or – 35 degrees from the equator, the most vitamin D can be produced when skin is exposed to UVB rays), and the time of day (more vitamin D is synthesized by the skin when the sun is directly overhead between 11 AM and 3 PM). A person should be exposed to sunlight two to three times per week from March through October in northern climates to accumulate enough vitamin D to get through the winter with adequate vitamin D. See Holick (2010) for tables of time of sun exposure needed to make adequate amounts of vitamin D. Several apps are also available to determine this—Vitamin D Calculator, Vitamin D Pro, and D-Minder.

VITAMIN D IN FOODS

Vitamin D is measured in international units (IUs). 1 mcg = 40 IU of vitamin D or calciferol. IUs are used on food and supplement labels and both are used in the 2011 RDAs for vitamin D. The vitamin D in foods is measured as calciferol. There are only a few food sources of vitamin calciferol. Fish such as salmon, tuna, and mackerel and fish oils are one of the few natural sources of vitamin D. Beef liver, cheese, and egg yolks contain small amounts of vitamin D₃, a metabolite of vitamin D, which appears to be approximately five times more potent than the parent vitamin (calciferol) in raising serum 25(OH)D concentrations. At the present time, the USDA’s Nutrient Database does not include this vitamin D metabolite when reporting the vitamin D content of foods. Actual vitamin D intakes in the U.S. population may be underestimated for this reason.

Mushrooms are the only plant food known to contain vitamin D, and the amount varies widely depending on the type of mushroom and amount of sunlight exposure during growth. Commercially raised

TABLE 1 Recommended Dietary Allowances (RDAs) for Vitamin D

Age	Male	Female	Pregnancy	Lactation
0-12 months*	400 IU (10 mcg)	400 IU (10 mcg)	N/A	N/A
1-13 years	600 IU (15 mcg)	600 IU (15 mcg)	N/A	N/A
14-18 years	600 IU (15 mcg)	600 IU (15 mcg)	600 IU (15 mcg)	600 IU (15 mcg)

Tolerable upper intake level (UL): 0-6 mos 25 mcg/d; 7-12 mos 38 mcg/d; 1-3y 63 mcg/d; 4-8y 75 mcg/d; 9-13y 100 mcg/d; 14-18y (also for pregnancy and lactation) 100 mcg/d; 19-50 (also for pregnancy and lactation) 100 mcg/d.

TABLE 2 Selected Food Sources of Vitamin D

Food	IUs per Serving*	Percent DV**	Food	IUs per Serving*	Percent DV**
Cod liver oil, 1 tablespoon	1360	340	Milk, nonfat, reduced fat, and whole, vitamin D-fortified, 1 cup	115	29-31
Swordfish, cooked, 3 ounces	566	142	Yogurt, fortified, with 20% of the DV for vitamin D, 6 ounces (some yogurts are more heavily fortified—check label)	80	20
Salmon (sockeye), cooked, 3 ounces	447	112	Margarine, fortified, 1 tablespoon	60	15
Mushrooms, maitake, raw, 3 ounces	943	235	Sardines, canned in oil, drained, 2 sardines	46	12
Mushrooms, portabella, exposed to UV light, raw, 3 ounces	375	94	Liver, beef, cooked, 3 ounces	42	11
Mushrooms, chanterelle, raw, 3 ounces	15	4	Egg, 1 large (vitamin D is found in yolk)	41	10
Mushrooms, shiitake, raw, 3 ounces	178	45	Ready-to-eat cereal, fortified with 10% of the DV for vitamin D, 0.75-1 cup (more heavily fortified cereals might provide more of the DV)	40	10
Mushrooms, white, raw, 3 ounces	6	2	Cheese, Swiss, 1 ounce	6	2
Tuna fish, canned in water, drained, 3 ounces	100	39			
Orange juice fortified with vitamin D, 1 cup (check product labels, as amount of added vitamin D varies)	137	34			

DV, Daily value; UV, ultraviolet.

*IUs 5 international units.

**DV for vitamin D is 400 IU (10 mcg).

mushrooms are now being grown with controlled UVB exposure so that they synthesize and thus contain much more vitamin D than if grown in the wild. In fact, grown with lots of UVB exposure, four to five button or crimini mushrooms may contain as much as 400 IU of vitamin D.

Good sources of vitamin D are fortified foods and beverages such as milk; fortified soy, rice, and nut beverages; some yogurts and margarine; fortified breakfast cereals, fortified orange juice and other juices; and fortified products (check the labels on these foods). These fortified foods supply most of the calcium in the American diet. Cow's milk in the United States is voluntarily fortified to 100 IU/cup and in Canada is fortified by law to 35 to 40 IU/100 mL (84 to 96 IU/cup). Yogurt, cheese, cottage cheese, quark, and other milk products, unless made with vitamin D fortified milk (which is not required) or are fortified with vitamin D during production, are not good sources of vitamin D. See Table 2 for the vitamin D content of selected foods.

VITAMIN D IN SUPPLEMENTS

In supplements, as well as in fortified foods, vitamin D is available in two forms, D₂ (ergocalciferol) and D₃ (cholecalciferol). Vitamin D₂ is manufactured by the UV irradiation of ergosterol in yeast, and vitamin D₃ is manufactured by the irradiation of 7-dehydrocholesterol from lanolin and the chemical conversion of cholesterol. Both forms

effectively raise serum 25(OH)D levels. Firm conclusions about any different effects of these two forms of vitamin D cannot be drawn at this time. However, it appears that at nutritional doses vitamins D₂ and D₃ are equivalent, but at high doses vitamin D₂ appears to be less potent. <https://ods.od.nih.gov/factsheets/VitaminD-HealthProfessional/>. It also appears that frequent smaller dosing (daily) rather than much, much larger bolus dosing (weekly or monthly) of vitamin D may be more effective in improving 25(OH)D levels.

Nutritional Facts on Calcium

Calcium, the most abundant mineral in the body, is found in some foods, is added to others, is available as a dietary supplement, and is present in some medications such as antacids. Less than 1% of total body calcium supports critical metabolic functions required for vascular contraction and vasodilation, muscle function, nerve transmission, intracellular signaling, and hormonal secretion. The remaining 99% of the body's calcium supply is stored in the bones and teeth where it supports their structure and function.

Serum calcium is very tightly regulated and does not fluctuate with changes in dietary intakes; the body uses bone tissue as a reservoir for and source of calcium, in order to maintain constant concentrations of calcium in blood, muscle, and intercellular fluids. The website <https://ods.od.nih.gov/factsheets/Calcium-HealthProfessional> is an excellent resource for additional calcium nutrition information.

Recommended Dietary Allowances (RDAs) for Calcium				
Age	Male	Female	Pregnancy	Lactating
0-6 months*	200 mg	200 mg		
7-12 months*	260 mg	260 mg		
1-3 years	700 mg	700 mg		
4-8 years	1000 mg	1000 mg		
9-13 years	1300 mg	1300 mg		
14-18 years	1300 mg	1300 mg	1300 mg	1300 mg
19-50 years	1000 mg	1000 mg	1000 mg	1000 mg
51-70 years	1000 mg	1200 mg		
71+ years	1200 mg	1200 mg		

*Adequate intake (AI)

Tolerable upper intake level (UL): 0-6 mos 1000 mg/d; 7-12 mos 1500 mg/d; 1-3y 2500 mg/d; 4-8y 2500 mg/d; 9-13y 3000 mg/d; 14-18y (also for pregnancy and lactation) 3000 mg/d; 19-50 (also for pregnancy and lactation) 2500 mg/d; 51+ 2000 mg/d.

CALCIUM IN FOODS

There are many dietary sources of calcium, but low-fat milk or yogurt or fortified substitutes are the most efficient and readily available. The lactose in mammalian milks appears to improve the absorption of calcium from milk. Lactose-free milk and soy, nut, rice, and other grain milks fortified with calcium and vitamin D are now available. They are usually fortified to 300 mg calcium per cup, equivalent to the amount of calcium in cow's or goat's milk, but the nutrition label should be checked.

In addition to milk, a variety of foods and calcium-fortified juices contain calcium and can help children, teens, and adults get sufficient

levels of calcium in their diets. If it is difficult to get the recommended amounts of calcium from foods alone, a combination of food sources and supplements may be needed.

The absorption of calcium from the gut is increased when there is high body need such as during pregnancy and lactation, growth in infancy, childhood and adolescence, and when there is adequate vitamin D. Absorption is decreased by the presence of phytic acid and oxalic acid containing foods in the gut, alcohol, and caffeine.

Selected Food Sources of Calcium

Food	Milligrams per Serving	Food	Milligrams per Serving
Dairy Foods		Fruit	
Milk, with added calcium, 1 cup	420	Kale, raw, chopped, ½ cup	50
Milk, whole, 2%, 1% skim, 1 cup	300	Mustard greens, boiled, ½ cup	76
Yogurt, low fat, plain, ¾ cup	300	Chinese broccoli (gai lan), ½ cup	44
Cheese, processed slices, 2 slices	265	Broccoli, raw, ½ cup	21
Yogurt, fruit on the bottom, ¾ cup	250	Fruit	
Processed cheese spread, 3 Tbsp	250	Orange, 1 med	55
Cheese, hard, 1 oz	240	Dried figs, 2 med	54
Milk, evaporated, ¼ cup	165	Nondairy Drinks	
Cottage cheese, ¾ cup	120	Calcium enriched orange juice, 1 cup	300
Frozen yogurt, soft serve, ½ cup	100	Fortified rice milk, 1 cup	300
Ice cream, ½ cup	85	Fortified almond milk, 1 cup	300
Macaroni and cheese, prepared as per box instructions, ½ cup	80	Fortified soy milk, 1 cup	300
Beans and Bean Products		Regular soy milk, 1 cup	20
Soy cheese substitutes, 1 oz	0-200	Grains	
Tofu, firm, made with calcium sulfate, 3½ oz	125	Amaranth, raw, ½ cup	150
White beans, ½ cup	100	Whole wheat flour, 1 cup	40
Navy beans, ½ cup	60	Pizza, cheese, 1 small slice (1 oz)	120
Black turtle beans, canned, ½ cup	42	Macaroni and cheese, boxed mix, prepared as per label, 1 cup	80
Pinto beans, chickpeas, ½ cup	40	Other	
Nuts and Seeds		Blackstrap molasses, 1 Tbsp	80
Almonds, dry roasted, ¼ cup	95	Regular molasses, 1 Tbsp	41
Whole sesame seeds (black or white), 1 Tbsp	90	Asian Foods	
Tahini (sesame seed butter), 1 Tbsp	63	Sea cucumber, fresh, 3 oz	285
Brazil, hazelnuts, ¼ cup	55	Shrimp, small, dried, 1 oz	167
Almond butter, 1 Tbsp	43	Dried fish, smelt, 2 Tbsp	140
Meats, Fish, and Poultry		Seaweed, dry (hijiki), 10 g	140
Sardines, canned, 3½ oz (8 med)	370	Seaweed, dry (agar), 10 g	76
Salmon, canned with bones, 3 oz	180	Boiled bone soup, ½ cup	Negligible
Oysters, canned, ½ cup	60	Laver, nori, and wakame seaweeds are low in calcium.	
Shrimp, canned, ½ cup	40	Native Foods	
Turnip greens, boiled, ½ cup	99	Oolichan, salted, cooked, 3 oz	210
Okra, frozen, ½ cup	75	Fish head soup, 1 cup	150
Chinese cabbage or bok choy, ½ cup	75	Native American ice cream (whipped soapberries), ½ cup	130

CALCIUM SUPPLEMENTS

Calcium carbonate is the most common and least expensive calcium supplement. It can be difficult to digest and causes gas and constipation in some people. Calcium carbonate is 40% elemental calcium; 1000 mg will provide 400 mg of calcium. This supplement should be taken with food to aid in absorption. Taking magnesium with it can help prevent constipation.

Calcium citrate is more easily absorbed, easier to digest, and less likely to cause constipation and gas than calcium carbonate. It is a better choice for those with malabsorption diseases and in the

elderly. However, it is less concentrated, providing approximately 21% elemental calcium; 1000 mg will provide 210 mg of calcium. It is more expensive than calcium carbonate, and more of it must be taken to get the same amount of calcium, but it is better absorbed. It can be taken with or without food.

Calcium phosphate costs more than calcium carbonate but less than calcium citrate. It is easily absorbed and is less likely to cause constipation and gas.

Calcium lactate and calcium aspartate are both more easily digested but more expensive than calcium carbonate.

As the dose of calcium supplement increases, the percentage absorbed decreases. Because it appears that absorption is highest with dosages of <500 mg at a time, it is best to take calcium supplements in at least two dosages per day.

CALCIUM IN MEDICATIONS

Many over-the-counter antacids such as Tums and Rolaids contain calcium carbonate because of calcium carbonate's ability to neutralize stomach acid. Depending on the product, each chewable pill or soft chew contains 200 to 300 mg of elemental calcium, which can be a significant source of calcium supplementation for the person with normal levels of stomach acid.

Nutritional Facts on Chromium

Chromium is known to enhance the action of insulin; chromium was identified as the active ingredient in the “glucose tolerance factor” many years ago. Chromium also appears to be directly involved in carbohydrate, fat, and protein metabolism, but more research is needed to determine the full range of its roles in the body.

Chromium is widely distributed in the food supply, but most foods provide only small amounts (less than 2 mcg per serving). Meat and whole-grain products, as well as some fruits, vegetables, and spices, are relatively good sources, but Brewer’s yeast is by far the most concentrated food source. Foods high in simple sugars (such as sucrose and fructose) are low in chromium. Dietary intakes of chromium cannot be reliably determined because the content of the mineral in foods is substantially affected by agricultural and manufacturing processes and food-composition databases are inadequate. Chromium values in foods are approximate and should only serve as a guide. It appears that chromium picolinate and chromium nicotinate used in supplements are more bioavailable than chromic chloride.

Dietary reference intakes for chromium are adequate intakes (AIs). See table below.

Dietary Reference Intakes (AIs) for Chromium for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
0-6 months	0.2		
7-12 months	5.5		
1-3	11	N/A	N/A
4-8	15	N/A	N/A
9-13	25 for boys 21 for girls	N/A	N/A
14-18	35 for men 24 for women	29	44
19+	35 for men 25 for women	30	45
50+	30 for men 29 for women	N/A	N/A

N/A, Not applicable.

Tolerable upper intake level not determined.

Selected Food Sources of Chromium

Food	Micrograms per Serving
Broccoli, ½ cup	11
Grape juice, 1 cup	8
English muffin, whole wheat, 1	4
Potatoes, mashed, 1 cup	3
Garlic, dried, 1 tsp	3
Basil, dried, 1 Tbsp	2
Beef cubes, 3 oz	2
Orange juice, 1 cup	2
Turkey breast, 3 oz	2
Whole wheat bread, 2 slices	2
Red wine, 5 oz	1-13
Apple, unpeeled, 1 med	1
Banana, 1 med	1
Green beans, ½ cup	1

DV = Daily value. DVs were developed by the Food and Drug Administration (FDA) to help consumers compare the nutrient contents of products within the context of a total diet. The DV for chromium is 120 mcg. The percentage DV listed on the label indicates the percentage of the DV provided in one serving. A food providing 5% of the DV or less is a source, whereas a food that provides 10% to 19% of the DV is a good source. A food that provides 20% or more of the DV is high in that nutrient.

Nutritional Facts on Iodine

Iodine is an important mineral that is naturally found in some foods and added to others (primarily iodized salt). It is most concentrated in foods from the ocean. More than 70 countries, including the United States and Canada, have salt iodization programs.

Iodine is an essential component of thyroid hormones, thyroxine (T_4) and triiodothyronine (T_3), which help regulate metabolic rate, body temperature, growth, reproduction, blood cell production, muscle function, nerve function, and even gene expression. Iodine appears to have physiologic functions including a role in the immune response and possibly a beneficial effect on mammary dysplasia and fibrocystic breast disease.

The most useful clinical tool for measuring thyroid function and thus iodine sufficiency is to measure thyroid-stimulating hormone (TSH), which is released from the pituitary gland and stimulates thyroid hormone production and release. If the TSH is high, thyroid function should be evaluated further. Selenium-dependent enzymes are also required for the conversion of thyroxine (T_4) to the biologically active thyroid hormone, triiodothyronine (T_3); thus deficiencies of selenium, vitamin A, or iron may also affect iodine status. Another method to assess iodine status is the urinary iodine excretion test.

DEFICIENCY

Iodine deficiency is an important health problem throughout much of the world. Most of the earth's iodine is found in its oceans and soils; thus parts of the world away from the oceans exposed for millions of years longer have iodine-deficient soils, and the foods grown in these soils have low iodine content. Thus large percentages of people eating foods from those iodine-deficient soils, and not able to consume fish, can become iodine deficient unless public health measures are taken. Iodine deficiency can cause developmental and cognitive delay, hypothyroidism, goiter, and varying degrees of other growth and developmental abnormalities. Iodine is now recognized as the most common cause of preventable brain damage in the world, with millions living in iodine-deficient areas.

The major source of dietary iodine in the United States is iodized salt, which has been fortified with iodine. In the United States, assume that any salt in processed foods is iodized unless the product label shows that it is not iodized. In the United States and Canada, iodized salt contains 77 mcg of iodine per gram of salt. Iodine is also added in the diet because it is used in the feed of animals and in many processed or preserved foods as a stabilizer and as a component of red food dyes.

Diets that exclude iodized salt, fish, and seaweed have been found to contain very little iodine. Urinary iodine excretion studies suggest that iodine intakes are declining in the United States, possibly as a result of increased adherence to dietary recommendations to reduce salt intake.

GOITROGENS

Substances that interfere with iodine use or thyroid hormone production are known as goitrogens and occur in some foods. Some species of millet and cruciferous vegetables (e.g., cabbage, broccoli, cauliflower, and Brussels sprouts) contain goitrogens, and the soybean isoflavones genistein and daidzein have also been found to inhibit thyroid hormone synthesis. Most of these goitrogens are not of clinical importance unless they are consumed raw and in large amounts or there is a coexisting iodine or selenium deficiency. Cooking food will decrease the goitrogenic effect.

Recommended Dietary Allowances (RDAs) for Iodine

Age	Male mcg/day	Female mcg/day	Pregnancy mcg/day	Lactation mcg/day
0-6 months	110*	110*	N/A	N/A
7-12 months	130*	130*	N/A	N/A
1-3 years	90	90	N/A	N/A
4-8 years	90	90	N/A	N/A
9-13 years	120	120	N/A	N/A
14-18 years	150	150	220	290
19+	150	150	220	290

N/A, Not applicable.

*Adequate intake (AI).

Tolerable upper intake level (UL): 0-12 mos not determined; 1-3y 200 mcg/d; 4-8y 300 mcg/d; 9-13y 600 mcg/d; 14-18y (also for pregnancy and lactation) 900 mcg/d; 19+ (also for pregnancy and lactation) 1,100 mcg/d.

The World Health Organization, United Nations Children's Fund, and the International Council for the Control of Iodine Deficiency Disorders recommend a slightly higher iodine intake for pregnant women of 250 mcg per day.

The iodine contents of some common foods containing iodine are given in the table below. As already mentioned, the iodine content of fruits and vegetables depends on the soil in which they were grown; the iodine content of animal foods, outside of those from the ocean, depends on where they were raised and which plants they consumed. Therefore these values are average approximations.

Selected Food Sources of Iodine			
Food	Serving	Micrograms (mcg) per Serving	% Daily Value*
Salt (iodized)	1 g	47.5	31.3%
Cod	3 oz	99	66
Shrimp	3 oz	35	23
Fish sticks	2 fish sticks (2 oz)	54	36
Tuna, canned in oil	3 oz (½ can)	17	11
Milk (cow's), reduced fat	1 cup (8 fluid oz)	56	37
Egg, boiled	1 large	24	16
Navy beans, cooked	½ cup	35	23
Potato with peel, baked	1 medium	63	42
Seaweed	1 g, dried	Variable; 16 to 2984; may be greater than 18,000 mcg (18 mg)	11 to 1989

*DVs were developed by the Food and Drug Administration (FDA) to help consumers to compare the nutrient content of products. The DV for iodine is 150 mcg for adults and children 4 years and older. Foods containing 20% or more of the DV are considered to be excellent sources. However, the FDA does not require food labels to list iodine content unless the food has been fortified with iodine.

Nutritional Facts on Iron

Iron is a nutrient found in trace amounts in every cell of the body. Iron is part of hemoglobin in red blood cells and myoglobin in muscles. The role of both of these molecules is to carry oxygen. Iron also makes up part of many proteins and enzymes in the body. Iron deficiency anemia is common in children, adolescent girls, and women of childbearing age. It is usually treated with an iron-rich diet as well as iron supplements. Iron exists in foods in two forms: heme iron and nonheme iron. Vitamin C-containing foods (see Appendix 35) enhance the absorption of nonheme iron and should be consumed at the same time as an iron-rich food or meal. The presence of heme iron in the meal also enhances the absorption of nonheme iron. Substances that decrease the absorption of nonheme iron are as follows:

Oxalic acid, found in raw spinach and chocolate

Phytic acid, found in wheat bran and beans (legumes)

Tannins, found in commercial black or pekoe teas

Polyphenols, found in coffee

Calcium carbonate supplements

Heme iron found in animal foods is absorbed more efficiently than nonheme iron. The richest dietary sources of heme iron are oysters, liver, lean red meat (especially beef), poultry (the dark red meat), tuna, and salmon. Less rich sources are lamb, pork, shellfish, and eggs (especially the yolks).

Nonheme iron is harder for the body to absorb. Sources of nonheme iron are iron-fortified cereals, dried beans, whole grains (wheat, millet, oats, brown rice), legumes (lima beans, soybeans, dried beans and peas, kidney beans), nuts (almonds, Brazil nuts), dried fruits (especially prunes, raisins, apricots), vegetables, and greens (broccoli, spinach, kale, collards, asparagus, dandelion greens). See Table: Selected Food Sources of Iron.

Breastmilk contains a highly bioavailable form of iron that is well absorbed by infants, but the amount is not enough to meet the needs of the infant older than 4 to 6 months, so a food source of iron (usually as infant cereal) should be offered to the older infant.

Recommended Dietary Allowances for Iron for Children and Adults

Age	Male	Female	Pregnancy	Lactation
0-6 months	0.27 mg*	0.27 mg*		
7-12 months	11 mg	11 mg		
1-3 years	7 mg	7 mg		
4-8 years	10 mg	10 mg		
9-13 years	8 mg	8 mg		
14-18 years	11 mg	15 mg	27 mg	10 mg
19-50 years	8 mg	18 mg	27 mg	9 mg
51+ years	8 mg	8 mg		

*Adequate intake (AI)

Tolerable upper intake level (UL): 0-12 mos 40 mg; 1-3y 40 mg/d; 4-8y 119 mg/d; 9-13y 40 mg/d; 14-18y (also for pregnancy and lactation) 45 mg/d; 19+ (also for pregnancy and lactation) 45 mg/d.

Selected Food Sources of Iron

Food	Milligrams Per Serving	% Daily Value*
Clams, canned, drained, 3 oz	2.28	12.67
Fortified ready-to-eat cereals (various), ≈1 oz	1.8-19.2	10-107
Oysters, eastern, wild, cooked, moist heat, 3 oz	8	44
Organ meats (liver, giblets), various, cooked, 3 oz†	5.2-9.9 1.77-33.46	29-55 9.83-185.9
Fortified instant cooked cereals (various), 1 packet	3.40-10.55	18.9-58.6
Soybeans, mature, cooked, ½ cup	4.4	24
White beans, canned, ½ cup	3.9	22
Molasses, 1 Tbsp	3.5	19
Lentils, cooked, ½ cup	3.3	18
Spinach, cooked from fresh, ½ cup	3.2	18
Beef, chuck, blade roast, lean, cooked, 3 oz	3.1	17
Beef, bottom round, lean, 0 in fat, all grades, cooked, 3 oz	2.8	15.5
Kidney beans, cooked, ½ cup	2.6	14
Sardines, canned in oil, drained, 3 oz	2.5	14
Beef, rib, lean, ¼ in. fat, all grades, 3 oz	2.4	13
Chickpeas, cooked, ½ cup	2.4	13
Pumpkin and squash seed kernels, roasted, 1 oz	2.3	12.7
Duck, meat only, roasted, 3 oz	2.3	13

Lima beans, cooked, ½ cup	2.2	12
Soybeans, green, cooked, ½ cup	2.3	13
Navy beans, cooked, ½ cup	2.2	12
Refried beans, ½ cup	2.1	11.5
Beef, top sirloin, lean, 0 in fat, all grades, cooked, 3 oz	2.0	11
Tomato paste, ¼ cup	2.0	11

DV = Daily value.

*DVs were developed by the Food and Drug Administration to help consumers compare the nutrient content of products. The % DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving. The DV for iron is 18 mg. Foods containing 20% or more of the DV are considered to be excellent sources of the nutrient. †High in cholesterol.

TIPS FOR INCREASING IRON INTAKE

The amount of iron the body absorbs varies depending on several factors. For example, the body will absorb more iron from foods when iron stores are low and will absorb less when stores are sufficient. In addition, use these tips to enhance absorption:

- Include heme and nonheme iron at the same meal
- Include a vitamin C rich food in a meal
- Drink coffee or tea between meals rather than with a meal
- Cook acidic foods in cast iron pots, which can increase the iron content of food up to 30 times.

WHAT ABOUT TOO MUCH IRON?

It is unlikely that a healthy person would take iron at toxic (too high) levels. However, children can sometimes develop iron toxicity by eating iron supplements, mistaking them for candy. Symptoms include the following: fatigue, anorexia, dizziness, nausea, vomiting, headache, weight loss, shortness of breath, and grayish color to the skin.

Hemochromatosis is a genetic disorder that affects the regulation of iron absorption. Treatment consists of a low-iron diet, no iron supplements, and phlebotomy (blood removal) on a regular basis.

Excess storage of iron in the body is known as hemosiderosis. The high iron stores come from eating excessive iron supplements or from receiving frequent blood transfusions, not from increased iron intake in the diet.

To reduce the iron from dietary sources, review the list of foods and exclude or severely limit their intake until the iron overload is alleviated. Pay particular attention to sports drinks, energy bars, fortified cereals, and multivitamin mineral supplements that have significant amounts of added iron.

Nutritional Facts on Magnesium

The mineral magnesium is important for every organ in the body, particularly the heart, muscles, and kidneys. It also contributes to the composition of teeth and bones. Most important, it is a cofactor in hundreds of enzyme systems, contributing to energy production and deoxyribonucleic acid (DNA) synthesis, and it helps regulate calcium levels, as well as copper, zinc, potassium, vitamin D, and other important nutrients in the body.

DIETARY SOURCES

Rich sources of magnesium include tofu, legumes, whole grains, green leafy vegetables, wheat bran, Brazil nuts, soybean flour, almonds,

cashews, blackstrap molasses, pumpkin and squash seeds, pine nuts, and black walnuts. Other good dietary sources of this mineral include peanuts, whole-wheat flour, oat flour, beet greens, spinach, pistachio nuts, shredded wheat, bran cereals, oatmeal, bananas, baked potatoes (with skin), chocolate, and cocoa powder. Many herbs, spices, and seaweeds supply magnesium, such as agar seaweed, coriander, dill weed, celery seed, sage, dried mustard, basil, cocoa powder, fennel seed, savory, cumin seed, tarragon, marjoram, and poppy seed. See Table: Selected Food Sources of Magnesium.

Recommended Dietary Allowance (RDA) for Magnesium for Children and Adults				
Age	Males and Females (mg/day)	Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0-6 months	30	30	N/A	N/A
7-12 months	75	75	N/A	N/A
1-3	80	80	N/A	N/A

Nutritional Facts on Potassium

A potassium-rich diet is useful for cardiac patients who are trying to lower their blood pressure using diet. If diuretics are also used, it is important to know if potassium is retained or depleted by the diuretic, and it should be monitored. Most patients with chronic kidney disease or on renal dialysis may need to restrict potassium in their diets. Because potassium is lost in sweat, athletes need to pay attention to the potassium in their diets.

There is no recommended dietary allowance (RDA) for potassium. Dietary reference intake (DRI) is a general term for a set of reference values used to plan and assess nutrient intakes of healthy people. The DRIs for potassium are stated as adequate intakes (AIs). For breastfed infants, the AI is the mean intake; for older individuals, the AI is believed to cover the needs of all individuals in the group, but there is a lack data to be more specific. AIs are given in the following table.

Dietary Reference Intakes: Adequate Intakes (AIs) for Potassium for Children and Adults

Age	Males and Females (mg/day)	Pregnancy (g/day)	Lactation (g/day)
0-6 months	400	N/A	N/A
7-12 months	860	N/A	N/A
1-3 years	2000	N/A	N/A
4-8 years	2300	N/A	N/A
9-13 years	3000	N/A	N/A
14-18 years	3400	2600	2500
19+ years	3400	2900	2800

N/A, Not applicable.

There is no tolerable upper intake level for healthy people.

Selected Food Sources of Potassium

Food	Milligrams (mg) per Serving	% Daily Value*	Food	Milligrams (mg) per Serving	% Daily Value*
Sweet potato, baked, 1 potato (146 g)	694	19.8	Tomato juice, ¾ cup	395	11.3
Tomato paste, ¼ cup	669	19	Milk, nonfat, 1 cup	382	10.9
Beet greens, cooked, ½ cup	655	18.7	Pork chop, center loin, cooked, 3 oz	382	10.9
Potato, baked, flesh, 1 potato (156 g)	610	17.4	Rainbow trout, farmed, cooked, 3 oz	382	10.9
White beans, canned, ½ cup	595	17	Apricots, dried, uncooked, ¼ cup	378	10.8
Yogurt, plain, nonfat, 8-oz container	579	16.5	Orange juice, ¾ cup	372	10.6
Tomato puree, ½ cup	549	15.7	Buttermilk, cultured, low-fat, 1 cup	370	10.5
Clams, canned, 3 oz	534	15.3	Cantaloupe, ¼ med	368	10.5
Yogurt, plain, low-fat, 8-oz container	531	15.2	1%-2% milk, 1 cup	366	10.4
Prune or carrot juice, ¾ cup	530	15.1	Honeydew melon, 1/8 med	365	10.4
Soy or lima beans, green, cooked, ½ cup	485	13.9	Lentils, cooked, ½ cup	365	10.4
Halibut or yellowfin tuna, cooked, 3 oz	449	12.8	Tomato sauce, ½ cup	364	10.4
Winter squash, cooked, ½ cup	448	9.5	Pork loin, rib (roasts), lean, roasted, 3 oz	358	10.2
Bananas, 1 med	422	12.1	Plantains, cooked, ½ cup slices	358	10.2
Spinach, cooked, ½ cup	419	12	Kidney beans or split peas, cooked, ½ cup	358	10.2
Peaches, dried, uncooked, ¼ cup	398	11.4	Yogurt, plain, whole milk, 8-oz container	352	10.0
Prunes, stewed, ½ cup	398	11.4	Cod, Pacific, cooked, 3 oz	246	7.0
Rockfish, Pacific, cooked, 3 oz	397	11.3			

*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine whether a food contains a lot or a little of a specific nutrient. The DV for potassium is 3500 mg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving. Percent DVs are based on a 2000-calorie diet.

Nutritional Facts on Selenium

Selenium is incorporated into proteins to make selenoproteins, which are important antioxidant enzymes. The antioxidant properties of selenoproteins prevent cellular damage from free radicals. Other selenoproteins help regulate thyroid function and play a role in the immune system. Selenium, as a nutrient that functions as an antioxidant, may be protective against some types of cancer and heart disease.

Plant foods are the major dietary sources of selenium. The content of selenium in food depends on the selenium content of the soil where plants are grown or animals are raised. Soil in Nebraska and the Dakotas has very high levels of selenium. The southeast coastal areas in the United States have very low levels; selenium deficiency is often reported in these regions. Selenium is also found in some meats and seafood. Animals that eat grains or plants that were grown in selenium-rich soil have higher levels of selenium in their muscle. In the United States, meats, bread, and Brazil nuts are common sources of dietary selenium. Most food labels do not list the selenium content of a food; however, if they do, it is listed as a % Daily value (DV).

Dietary Reference Intakes for Selenium for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
1-3	20	N/A	N/A
4-8	30	N/A	N/A
9-13	40	N/A	N/A
14-18	55	60	70
19+	55	60	70

N/A, Not applicable.

Tolerable upper intake level (UL): 0-6 mos 45 mcg; 7-12 mos 60 mcg; 1-3y 90 mcg/d; 4-8y 150 mcg/d; 9-13y 280 mcg/d; 14-18y (also for pregnancy and lactation) 400 mcg/d; 19+ (also for pregnancy and lactation) 400 mcg/d.

Selected Food Sources of Selenium

Food	Micrograms per Serving	% DV*	Food	Micrograms per Serving	% DV*
Brazil nuts, dried, unblanched, 1 oz	544	777	Macaroni, elbow, enriched, boiled, 1 cup	37	53
Tuna, yellowfin, cooked, dry heat, 3 oz	92	131	Egg, whole, 1 med	15	21
Ground beef, 25% fat, cooked, oz	18	26	Cottage cheese, 1% fat, 1 cup	20	29
Spaghetti sauce, marinara, 1 cup	4	6	Oatmeal, instant, fortified, cooked, 1 cup	13	19
Corn Flakes, 1 cup	2	3	Milk, 1 %, 1 cup	8	11
Turkey, light meat, roasted, 3 oz	31	44	Lentils, boiled, 1 cup	6	9
Spinach, frozen, boiled, 1 cup	11	16	Bread, whole wheat, 1 slice	13	19
Chicken breast, meat only, roasted, 3 oz	22	31	Rice, brown, long grain, cooked, 1 cup	19	27
Noodles, enriched, boiled, ½ cup	19	27	Cashew nuts, dry roasted, 1 oz	3	4

DV = Daily value.

*DVs were developed by the Food and Drug Administration to help consumers compare the nutrient content of products.

The % DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving. The DV for selenium for adults and children aged 4 and over is 70 mcg. Foods containing 20% or more of the DV are considered to be excellent sources of the nutrient.

Sodium in Food

The National Academies of Sciences updated the AI's for sodium in March, 2019 and are as follows: 110 mg for infants 6-12 mos; 800 mg for children 1-3; 1000 mg for ages 4-8; 1200 mg for 9-13; and 1500 mg for 14 and older. Both the National Academies and the 2015–2020 U.S. Dietary Guidelines specify an upper limit of 2300 mg/day of sodium for adults. This is approximately a teaspoon of table salt. In the past this level of sodium was considered to be a restriction. Currently, the average American eats almost double the recommended daily amount of sodium, so sodium restrictions continue to be commonly prescribed for patients with heart disease, kidney disease, and liver disease.

The sodium in food is added in processing. Virtually no food is naturally high in sodium (see selected food list below). Food manufacturers have been responding to the call from health professionals and consumers to lower the amount of sodium in processed foods, but processed foods remain the main source of sodium in the U.S. diet.

SPECIAL CONSIDERATIONS

A therapeutic sodium-restricted meal plan should be prescribed in terms of milligrams of sodium desired on a daily basis. The following are the commonly used levels of sodium restrictions:

No added salt (NAS): This is the least restrictive of the sodium-restricted diets. Table salt should not be used, and salt should not be added in cooking. High-sodium foods such as smoked, cured, or dried meats and cheeses; condiments and seasonings; salted snacks; and canned and dried soups and bouillon are restricted. The NAS diet provides no more than 3000 mg of sodium daily. It is desirable to be closer to the 2300 mg of sodium when possible.

2000 mg sodium: This diet may be appropriate for people with some types of liver disease and renal disease. It is no longer recommended for patients with heart failure. This diet *eliminates* processed and prepared foods and beverages that are high in sodium. In addition to limiting all the foods in the NAS diet, baked products must also be limited. Milk and milk products are limited to 16 oz daily. Only salt-free commercially prepared foods should be used.

GUIDELINES FOR SODIUM RESTRICTION

Salt substitutes containing potassium chloride should be recommended only if approved by a physician. Potassium is generally contraindicated for patients with renal disease and for people on potassium sparing diuretics. Salt-free, herb-based seasoning products are readily available in most grocery stores and should be suggested instead.

- Instruct patients/clients on reading the Nutrition Facts food label for sodium content of foods.
- Encourage patients to prepare food at home without adding salt and to limit eating in restaurants.

- Recommend baked products that use sodium-free baking powder, potassium bicarbonate (instead of sodium bicarbonate or baking soda), and salt-free shortening in place of those containing sodium.
- Limit or avoid obviously salted foods such as bouillon, soup and gravy bases, canned soups and stews, bread and rolls with salt toppings, salted crackers, salted nuts or popcorn, potato chips, pretzels, and other salted snack foods. Avoid buying vegetables prepared in sauce.
- Limit or avoid smoked or cured meats, such as bacon, bologna, cold cuts, other processed meats, chipped or corned beef, frankfurters, ham, kosher or kosher-style meats, and canned meat poultry.
- Limit or avoid salted and smoked fish such as cod, herring, and sardines.
- Limit or avoid sauerkraut, olives, pickles, relishes, kimchi, and other vegetables prepared in brine, tomato, and vegetable cocktail juices.
- Limit or avoid seasonings such as celery salt, garlic salt, Worcestershire sauce, fish sauce, and soy sauce. Reduced sodium versions of items like soy sauce can still be very high in sodium.
- Serve cheeses in limited amounts. Swiss cheese and cream cheese are relatively low in sodium.
- Monitor the sodium content of various medications, including over-the-counter brands.

The front of the food package can be used to quickly identify foods that may contain less sodium, but it is important to understand the terminology. For example, look for foods with claims such as:

- **Salt/Sodium-Free** → Less than 5 mg of sodium per serving
- **Very Low Sodium** → 35 mg of sodium or less per serving
- **Low Sodium** → 140 mg of sodium or less per serving
- **Reduced Sodium** → At least 25% less sodium than in the original product
- **Light in Sodium or Lightly Salted** → At least 50% less sodium added than in the regular product
- **No-Salt-Added or Unsalted** → No salt is added during processing, but not necessarily sodium-free. Check the Nutrition Facts label.

Seasoning without salt: Flavorings or seasonings will make food more appetizing. For example:

- Lemon or vinegar is excellent with fish or meat and with many vegetables such as broccoli, asparagus, green beans, or salads.
- Meat may be seasoned with onion, garlic, green pepper, nutmeg, ginger, dry mustard, sage, cumin and marjoram. It may be cooked with fresh mushrooms or unsalted tomato juice. Curries made without salt are a good way to season meats and lentils.
- Cranberry sauce, applesauce, or jellies make appetizing accompaniments to meats and poultry.
- Vegetables can be flavored by the addition of onion, mint, ginger, mace, dill seed, parsley, green pepper, or fresh mushrooms.
- Unsalted cottage cheese can be flavored with minced onion, chopped chives, raw green pepper, grated carrots, chopped parsley, or crushed pineapple.
- A number of salt-free seasonings for use in cooking are available in the spice section of most supermarkets.

Sodium Content of Selected Common Foods			
1 cup of whole or reduced fat milk	107 mg	1 avocado	11 mg
1 slice whole-wheat bread	110-170 mg	1 small potato with skin, baked	12 mg
1 hamburger bun	300-375 mg	1 cup chopped broccoli, raw	30 mg
1 slice American cheese	270-280 mg	½ cup broccoli in cheese sauce (Green Giant)	420 mg
1 slice Swiss cheese (nonprocessed)	50-65 mg	1 cup brown rice, cooked	8 mg
2 oz mozzarella cheese, part skim	350 mg	1 cup white rice, cooked	0 mg
2 oz cream cheese	178 mg	1 cup prepared rice pilaf (Rice-A-Roni)	970 mg
3 oz corned beef (brisket)	900-1100 mg	1 cup pasta, enriched	3-8 mg
3 oz lean ground beef	55-60 mg	1 large egg, raw	71 mg
3 oz chicken, raw broiler without the skin	65 mg	1 large olive, ripe	65 mg
1 slice bacon, pork	185 mgR	1 tbsp olive oil	0 mg
1 cup kidney beans, cooked without salt	2 mg	2 tbsp ranch dressing	270 mg
1 cup canned kidney beans, drained	230-250 mg	2 tbsp balsamic vinegar	8 mg
1 tbsp soy sauce (tamari)	1000 mg	2 tbsp sour cream, cultured	8 mg
1 tbsp reduced-sodium soy sauce	450 mg	12 oz cola, regular	11 mg
1 cup chopped celery, raw	80 mg	1 slice cheese pizza (Domino's)	565 mg
1 cup chopped onion, raw	6 mg	1 slice pepperoni pizza (Pizza Hut)	769 mg
1 tbsp garlic	0 mg	1 Big Mac (McDonald's)	460 mg
1 med banana	1 mg	1 6-in. Subway Club on white bread	720 mg

Nutritional Facts on Zinc

Zinc is an essential mineral that is found in almost every cell. It stimulates the activity of approximately 100 enzymes, which are substances that promote biochemical reactions in the body. Zinc supports immunity; is needed for wound healing; helps maintain the sense of taste and smell; is needed for deoxyribonucleic acid (DNA) synthesis; and supports normal growth and development during pregnancy, childhood, and adolescence.

Zinc is found in a wide variety of foods. Oysters and Alaskan crab are some of the best food sources of zinc, but red meat and poultry provide the majority of zinc in the American diet. Other good food sources include beans, nuts, certain seafood, whole grains, fortified breakfast cereals, and dairy products.

Because zinc absorption is greater from a diet high in animal protein than a diet rich in plant proteins, vegetarians may become deficient if they are not monitored carefully. Phytates from whole-grain breads, cereals, legumes, and other products can decrease zinc absorption.

Recommended Dietary Allowance (RDA) for Zinc for Children and Adults

Age	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
0-6 months	2	N/A	N/A
7-12 months	2	N/A	N/A
1-3	3	N/A	N/A
4-8	5	N/A	N/A
9-13	8	N/A	N/A
14-18	11 for boys, 9 for girls	12	13
19+	11 for men, 8 for women	11	12

N/A, Not applicable.

DV = Daily value. The DV for zinc is 15 mg.

Tolerable upper intake level (UL): 0-6 mos 4 mg; 7-12 mos 5 mg; 1-3y 7 mg/d; 4-8y 12 mg/d; 9-13y 23 mg/d; 14-18y (also for pregnancy and lactation) 34 mg/d; 19+ (also for pregnancy and lactation) 40 mg/d.

Selected Food Sources of Zinc

Food	Milligrams (mg) per Serving	% Daily Value*
Oysters, battered and fried, 6 med	16.0	100
RTE breakfast cereal, fortified with 100% of the DV for zinc per serving, ¾ cup serving	15.0	100
Beef shank, lean only, cooked 3 oz	8.9	60
Beef chuck, arm pot roast, lean only, cooked, 3 oz	7.1	47
Beef tenderloin, lean only, cooked, 3 oz	4.8	30
Beef, eye of round, lean only, cooked, 3 oz	4.0	25
RTE breakfast cereal, fortified with 25% of the DV for zinc per serving, ¾ cup	3.8	25
Pork shoulder, lean, cooked, 3 oz	3.5	25
Baked beans, canned, plain or vegetarian, ½ cup	2.9	19
Chicken leg, meat only, roasted, 1 leg	2.7	20
Pork tenderloin, lean only, cooked, 3 oz	2.5	15
Pork loin, sirloin roast, lean only, cooked, 3 oz	2.2	15
Yogurt, plain, low fat, 1 cup	2.2	15
Baked beans, canned, with pork, ½ cup	1.8	10
Cashews, dry roasted without salt, 1 oz	1.6	10
Yogurt, fruit, low fat, 1 cup	1.6	10
Chickpeas, mature seeds, canned, ½ cup	1.5	9
Pecans, dry roasted without salt, 1 oz	1.4	10
Oatmeal, instant, low sodium, 1 packet	1.3	9
Cheese, Swiss, 1 oz	1.2	8
Mixed nuts, dry roasted with peanuts, 1 oz	1.1	8
Walnuts, black, dried, 1 oz	1.0	6
Almonds, dry roasted, without salt, 1 oz	1.0	6
Milk, fluid, any kind, 1 cup	0.9	6
Chicken breast, meat only, roasted, ½ breast with bone and skin removed	0.9	6
Cheese, cheddar, 1 oz	0.9	6
Cheese, mozzarella, part skim, low moisture, 1 oz	0.9	6
Beans, kidney, California red, cooked, ½ cup	0.9	6

RTE, Ready to eat.

*DV = Daily value: developed by the Food and Drug Administration to help consumers compare the nutrient content of products. Foods containing 20% or more of the DV are considered to be excellent sources.

Sources: *Dietary Reference Intakes for Calcium, Phosphorus, Magnesium, Vitamin D, and Fluoride* (1997); *Dietary Reference Intakes for Thiamin, Riboflavin, Niacin, Vitamin B₆, Folate, Vitamin B₁₂, Pantothenic Acid, Biotin, and Choline* (1998); *Dietary Reference Intakes for Vitamin C, Vitamin E, Selenium, and Carotenoids* (2000); *Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicon, Vanadium, and Zinc* (2001); *Dietary Reference Intakes for Water, Potassium, Sodium, Chloride, and Sulfate* (2005); and *Dietary Reference Intakes for Calcium and Vitamin D* (2011). These reports may be accessed via www.nap.edu.

***Note:** This table (taken from the DRI reports, see www.nap.edu) presents Recommended Dietary Allowances (RDAs) in **boldface** type and Adequate Intakes (AIs) in **lightface** type followed by an asterisk (*). An RDA is the average daily dietary intake level; sufficient to meet the nutrient requirements of nearly all (97-98%) healthy individuals in a group. It is calculated from an Estimated Average Requirement (EAR). If sufficient scientific evidence is not available to establish an EAR, and thus calculate an RDA, an AI is usually developed. For healthy breastfed infants, an AI is the mean intake. The AI for other life stage and gender groups is believed to cover the needs of all healthy individuals in the groups, but lack of data or uncertainty in the data prevent being able to specify with confidence of the percentage of individuals covered by this intake.

^aAs retinol activity equivalents (RAEs). 1 RAE = 1 mcg of retinol, 12 mcg of β-carotene, 24 mcg of α-carotene, or 24 mcg of β-cryptoxanthin. The RAE for dietary provitamin A carotenoids is twofold greater than retinol equivalents (REs), whereas the RAE for preformed vitamin A is the same as the RE for vitamin A.

^bAs cholecalciferol. 1 mcg of cholecalciferol = 40 IU of vitamin D.

^cUnder the assumption of minimal sunlight.

^dAs α-tocopherol. α-Tocopherol includes RRR-α-tocopherol, the only form of α-tocopherol that occurs naturally in foods, and the 2*R*-stereoisomeric forms of α-tocopherol (RRR-, RSR-, RRS-, and RSS-α-tocopherol) that occur in fortified foods and supplements. It does not include the 2*S*-stereoisomeric forms of α-tocopherol (SRR-, SSR-, SRS-, and SSS-α-tocopherol), also found in fortified foods and supplements.

^eAs niacin equivalents (NEs). 1 mg of niacin = 60 mg of tryptophan; 0-6 months = preformed niacin (not NE).

^fAs dietary folate equivalents (DFEs). 1 DFE = 1 mcg of food folate = 0.6 mcg of folic acid from fortified food or as a supplement consumed with food = 0.5 mcg of a supplement taken on an empty stomach.

^gAlthough AIs have been established for choline, there are few data to assess whether a dietary supply of choline is needed at all stages of the life cycle, and it may be that the choline requirement can be met by endogenous synthesis at some of these stages.

^hLife-stage groups for infants were 0-5.9 and 6-11.9 months.

ⁱBecause 10% to 30% of older people may malabsorb food-bound B₁₂, it is advisable for those older than 50 years to meet their RDA mainly by consuming foods fortified with B₁₂ or a supplement containing B₁₂.

^jIn view of evidence linking folate intake with neural tube defects in the fetus, it is recommended that all women capable of becoming pregnant consume 400 mcg from supplements or fortified foods in addition to intake of food folate from a varied diet.

^kIt is assumed that women will continue consuming 400 mcg from supplements or fortified food until their pregnancy is confirmed and they enter prenatal care, which ordinarily occurs after the end of the periconceptual period—the critical time for formation of the neural tube.

Sources: *Dietary Reference Intakes for Calcium, Phosphorus, Magnesium, Vitamin D, and Fluoride* (1997); *Dietary Reference Intakes for Thiamin, Riboflavin, Niacin, Vitamin B₆, Folate, Vitamin B₁₂, Pantothenic Acid, Biotin, and Choline* (1998); *Dietary Reference Intakes for Vitamin C, Vitamin E, Selenium, and Carotenoids* (2000); and *Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicon, Vanadium, and Zinc* (2001); *Dietary Reference Intakes for Water, Potassium, Sodium, Chloride, and Sulfate* (2005); and *Dietary Reference Intakes for Calcium and Vitamin D* (2011). These reports may be accessed via www.nap.edu.

NOTE: This table (taken from the DRI reports, see www.nap.edu) presents Recommended Dietary Allowances (RDAs) in **boldface** type and Adequate Intakes (AIs) in **lightface** type followed by an asterisk (*). An RDA is the average daily dietary intake level sufficient to meet the nutrient requirements of nearly all (97–98 percent) healthy individuals in a group. It is calculated from an Estimated Average Requirement (EAR). If sufficient scientific evidence is not available to establish an EAR, and thus calculate an RDA, an AI is usually developed. For healthy breastfed infants, an AI is the mean intake. The AI for other life-stage and gender groups is believed to cover the needs of all healthy individuals in the groups, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of individuals covered by this intake.

^aLife-stage groups for infants were 0–5.9 and 6–11.9 months.

Dietary Reference Intakes (DRIs): Acceptable Macronutrient Distribution Ranges

Food and Nutrition Board, Institute of Medicine, National Academies

Macronutrient	RANGE (PERCENT OF ENERGY)		
	Children, 1-3 yr	Children, 4-18 yr	Adults
Fat	30-40	25-35	20-35
<i>n</i> -6 polyunsaturated fatty acids ^a (linoleic acid)	5-10	5-10	5-10
<i>n</i> -3 polyunsaturated fatty acids ^a (α-linolenic acid)	0.6-1.2	0.6-1.2	0.6-1.2
Carbohydrate	45-65	45-65	45-65
Protein	5-20	10-30	10-35

Source: *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids* (2002/2005). The report may be accessed via www.nap.edu.

^aApproximately 10% of the total can come from longer-chain *n*-3 or *n*-6 fatty acids.

Dietary Reference Intakes (DRIs): Acceptable Macronutrient Distribution Ranges

Food and Nutrition Board, Institute of Medicine, National Academies

Macronutrient	Recommendation
Dietary cholesterol	As low as possible while consuming a nutritionally adequate diet
Trans fatty acids	As low as possible while consuming a nutritionally adequate diet
Saturated fatty acids	As low as possible while consuming a nutritionally adequate diet
Added sugars ^a	Limit to no more than 25% of total energy

Source: *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids* (2002/2005). The report may be accessed via www.nap.edu.

^aNot a recommended intake. A daily intake of added sugars that individuals should aim for to achieve a healthful diet was not set.

Dietary Reference Intakes (DRIs): Tolerable upper Intake Levels, Vitamins*

NOTE: A Tolerable Upper Intake Level (UL) is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to a lack of suitable data, ULs could not be established for vitamin K, thiamin, riboflavin, vitamin B₁₂, pantothenic acid, biotin, and carotenoids. In the absence of a UL, extra caution may be warranted in consuming levels above recommended intakes. Members of the general population should be advised not to routinely exceed the UL. The UL is not meant to apply to individuals who are treated with the nutrient under medical supervision or to individuals with predisposing conditions that modify their sensitivity to the nutrient.

*The tolerable upper intake levels for the following nutrients have not been determined: vitamin K, thiamin, riboflavin, vitamin B₁₂, pantothenic acid, biotin, and the carotenoids. The levels have not been determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.

^aAs preformed vitamin A only.

^bAs α -tocopherol; applies to any form of supplemental -tocopherol.

^cThe ULs for vitamin E, niacin, and folate apply to synthetic forms obtained from supplements, fortified foods, or a combination of the two.

^d β -Carotene supplements are advised only to serve as a provitamin A source for individuals at risk of vitamin A deficiency.

NOTE: A Tolerable Upper Intake Level (UL) is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to a lack of suitable data, ULs could not be established for vitamin K, thiamin, riboflavin, vitamin B₁₂, pantothenic acid, biotin, and carotenoids. In the absence of a UL, extra caution may be warranted in consuming levels above recommended intakes. Members of the general population should be advised not to routinely exceed the UL. The UL is not meant to apply to individuals who are treated with the nutrient under medical supervision or to individuals with predisposing conditions that modify their sensitivity to the nutrient.

^aAlthough the UL was not determined for arsenic, there is no justification for adding arsenic to food or supplements.

^bThe ULs for magnesium represent intake from a pharmacological agent only and do not include intake from food and water.

^cAlthough silicon has not been shown to cause adverse effects in humans, there is no justification for adding silicon to supplements.

^dAlthough vanadium in food has not been shown to cause adverse effects in humans, there is no justification for adding vanadium to food and vanadium supplements should be used with caution. The UL is based on adverse effects in laboratory animals and this data could be used to set a UL for adults but not children and adolescents.

^eND = Not determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.
