Dietary Reference Intakes of Energy and Protein From Birth to 18 Years of Age per Day*

	Age	Estimated Energy Requirement	Protein (g)
Infants	0 to 3 months	$(89 \times \text{Weight [kg]} - 100) + 175 \text{ kcal}$	9.1
	4 to 6 months	$(89 \times \text{Weight [kg]} - 100) + 56 \text{ kcal}$	9.1
	7 to 12 months	$(89 \times \text{Weight [kg]} - 100) + 22 \text{ kcal}$	11
	13 to 36 months	$(89 \times \text{Weight [kg]} - 100) + 20 \text{ kcal}$	13
Boys	3 to 8 years	$88.5 - (61.9 \times \text{Age [yr]} + \text{PA} \times (26.7 \times \text{Weight [kg]} + 903 \times \text{Height [m]})) + 20 \text{ kcal}$	19
	9 to 18 years	$88.5 - (61.9 \times \text{Age [yr]} + \text{PA} \times (26.7 \times \text{Weight [kg]} + 903 \times \text{Height [m]})) + 25 \text{ kcal}$	34 to 52
Girls	3 to 8 years	$135.3 - (30.8 \times \text{Age [yr]} + \text{PA} \times (10.0 \times \text{Weight [kg]} + 934 \times \text{Height [m]})) + 20 \text{ kcal}$	19
	9 to 18 years	$135.3 - (30.8 \times \text{Age [yr]} + \text{PA} \times (10.0 \times \text{Weight [kg]} + 934 \times \text{Height [m]})) + 25 \text{ kcal}$	34 to 46

*PA, Physical activity level. Data from the Food and Nutrition Board, Institute of Medicine. *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids (macronutrients)*. Washington, DC: National Academies Press; 2002.

Source: *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids (2002/2005)* and *Dietary Reference Intakes for Water, Potassium, Sodium, Chloride, and Sulfate (2005)*. The report may be accessed via www.nap.edu

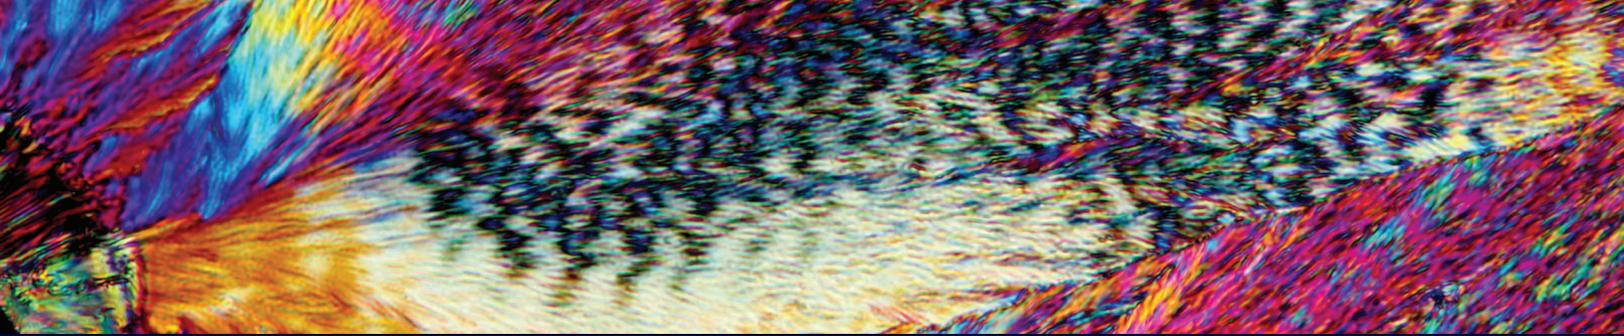

*NOTE: This table (taken from the DRI reports, see www.nap.edu) presents Recommended Dietary Allowances (RDA) in **boldface** type and Adequate Intakes (AIs) in ordinary type followed by an asterisk (*). An RDA is the average daily dietary intake level; sufficient to meet the nutrient requirements of nearly all (97-98%) healthy individuals in a group. It is calculated from an Estimated Average Requirement (EAR).

If sufficient scientific evidence is not available to establish an EAR, and thus calculate an RDA, an AI is usually developed. For healthy breastfed infants, an AI is the mean intake. The AI for other life stage and gender groups is believed to cover the needs of all healthy individuals in the groups, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of individuals covered by this intake.

^aTotal water includes all water contained in food, beverages, and drinking water.

^bBased on grams of protein per kilogram of body weight for the reference body weight (e.g., for adults 0.8 g/kg body weight for the reference body weight).

*This 15th edition is dedicated to the students, professors,
and practitioners who use this text.
We are also incredibly grateful to our authors for sharing their wisdom, experience,
and insight and for their dedication to the field of nutrition and dietetics.*

—The Authors, 15th Edition

To the residents and patients at Providence Mount St. Vincent who remind me every day why I chose to work in a health care field devoted to older people. To my grandparents who helped raise me and taught me the value of listening to and learning from our elders. Thank you to my husband, Greg, who has become an enthusiastic chef and did most of the cooking while I was busy editing. And to Kathy Mahan, who is the reason this book has existed for over 60 years and has always been cutting edge. Thank you for the inspiration.

—Janice

To my students at Bastyr University. You continuously inspire me with your energy and enthusiasm. To my husband Gregg, son Ian, sister Wendy, the chair of the Nutrition Department at Bastyr, Debra Boutin, and my friends and colleagues. Thank you for believing in me and providing unending support and encouragement. To Kathy Mahan: I am honored and grateful that you have entrusted us to continue your work.

—Kelly

When I was first asked to revise this text in 1975, I said no. Why would I want to take on this herculean task? Times were good. We were wearing miniskirts, bell bottoms, and platform shoes; the Vietnam war was over, and a new Environmental Protection Agency (EPA) had just been established. The Women, Infants, and Children (WIC) program for maternal and child nutrition was beginning, and total parenteral nutrition (TPN), the new “wow” therapy, had just entered the scene. TPN was a powerful tool, and nutritionists knew it. Now we had a way to feed patients with nonfunctioning guts so that they could heal and survive. Feeding a very sick person could be targeted, scientific, and aggressive. TPN enabled premature infants to survive as I would learn with my own preemie a decade later. It was an exciting time for a young dietitian. And then to be able to take over the authorship of this already reputable text—well, wow! It couldn’t have been a better entry into a career. I said yes.

Marie Krause first penned this text in 1952, revised it for several editions and then handed it over to me for the 6th edition. Since that time other co-editors (Arlin, Escott-Stump, and Raymond) and I, along with many, many contributors, now considered family, have sought to keep this text in the forefront of nutrition and dietetic education. We have navigated it through the waters of expanding nutrition science and changing clinical care, aiming to offer it as a beacon of learning for students and a reliable reference for clinicians and practitioners. Our goal has been to dispel myths and illuminate the truth. Over the 45 years that my team has been writing and editing this text, we have been honored to hear it referred to as the “nutrition bible.” Many of our contributors are nationally acclaimed specialists in their fields and have gone on to write their own books as well as lead major professional nutrition organizations. This tome has become the students’ link to these leaders in nutrition.

During its almost 70 years, this textbook has changed considerably. It has been streamlined; content that can more efficiently be found in other texts was omitted. More importantly, new content reflecting current science was added: chapters covering medical nutrition therapy (MNT) for HIV and AIDS and nutrition for sports and performance appeared with the 8th edition (1992), a chapter on nutrigenomics and integrative medicine and herbal therapy in the 10th edition (2000), a chapter on MNT in psychiatric disease in the 12th edition (2008), and one on inflammation and chronic disease in the 14th edition (2017), just to name a few.

This edition has a new name—*Krause and Mahan’s Food and the Nutrition Care Process*—and I leave as senior editor and author. My feelings are mixed. I am sad to say goodbye to such a fulfilling and

rewarding occupation after four and a half decades, and yet thrilled to leave it in the capable hands of Janice Raymond and Kelly Morrow. Janice has been co-editor and author for the previous two editions. She is experienced in ensuring the information is evidenced-based and logical, and because she continues to work as a clinical dietitian, she ensures it remains relevant. Kelly, who has been a Krause author, will now add her influence as a leader in integrative and functional nutrition in her role as editor.

Using an integrative and functional approach to nutritional care means considering nutrition status as a reflection of not only the nutrient intake of the individual but also the environmental influence on that nutrient intake. For example, what is the influence of the microbiome in the gut on nutrient absorption? Where is the individual’s food grown? How is it grown and how does this affect its nutrient content? During processing, are chemicals added to the food, either with or without intent? What is the effect of lifestyle or culture on the individual’s food choices? It is exciting and intriguing to think about adding this content to the text.

We plan that the Krause and Mahan text will continue to be the go-to resource for professors and students to learn not only the science of nutrition but also the art of nutrition care. We envision that new learners will turn to it to gain the skills of dietetic/nutrition practice—relating to the individual by asking the right questions, learning the person’s story, assessing nutritional needs, and providing nutrition care and learning in a way that the individual and the family can respond to and use.

I hope the writers of future editions will include content with a consciousness toward sustainability and planet renewal as we deal with nourishing an ever-growing population on our limited planet. How will we, the human global population, do that? How and when will we stop contaminating the water and air that provides for life? What changes will need to be made in our food systems to ensure they are sustainable? How will we continue as a species without causing the extinction of other species? Going forward I hope these questions and hopefully many of the answers will be kept in mind as Krause and Mahan is written and revised. It is important work, and I would like to see this text at the center of its progress.

It has been an honor to work with all our wonderful, committed authors and editors as well as the students and teachers who use the book. I am blessed, and it couldn’t have happened without you. Thank you from the bottom of my heart. You certainly made it a great ride!

L. Kathleen Mahan
January 6, 2020

PREFACE

Over its 15 editions, this classic text has continued to change in response to the ever-dynamic field of nutrition. And because it remains the most comprehensive nutrition textbook available, it is the reference students take into their internships and careers.

AUDIENCE

Scientific knowledge and clinical information is presented in a form that is useful to students in dietetics, nursing, and other allied health professions in an interdisciplinary setting. It is valuable as a reference for other disciplines such as medicine, dentistry, child development, physical and occupational therapy, health education, and lifestyle counseling. Nutrient and assessment appendices, tables, illustrations, and clinical insight boxes provide practical hands-on procedures and clinical tools for students and practitioners alike.

This textbook accompanies the graduating student into clinical practice as a treasured shelf reference. The popular features remain: having basic information on nutrition in the life cycle all the way through to protocols for clinical nutrition practice in one place, clinical management algorithms, focus boxes that give detailed insight on emerging topics, sample nutrition diagnoses for clinical scenarios, useful websites, and extensive appendices for patient education. All material reflects current evidence-based practice as contributed by authors who are experts in their fields. This text is the first choice in the field of dietetics for students, interns, educators, and clinicians.

ORGANIZATION

This edition follows the Conceptual Framework for Steps of the Nutrition Care Process. All nutritional care process components are addressed to enhance or improve the nutritional well-being of individuals, their families, or populations. The chapters flow according to the steps of assessment, nutrition diagnosis, intervention, monitoring, and evaluation with the separation of the pediatric medical nutrition therapy (MNT) chapters into their own section to assist with that specialty practice.

Part 1, Nutrition Assessment, organizes content for an effective assessment. Chapters here provide an overview of the digestive system, as well as calculation of energy requirements and expenditure, macronutrient and micronutrient needs, nutritional genomics, and food intake. A thorough review of biochemical tests, acid–base balance issues, and medications promote the necessary insight for provision of excellent care. A chapter titled “Inflammation and the Pathophysiology of Chronic Disease” addresses the latest knowledge about inflammation as a cause of chronic disease and the necessity of assessing for it. The final chapter in this section addresses the behavioral aspects of an individual’s food choices within the community, a safe food supply, and available resources for sufficient food access.

Part 2, Nutrition Diagnosis and Intervention, describes the critical thinking process from assessment to selection of relevant, timely, and measurable nutrition diagnoses. These nutrition diagnoses can be resolved by the registered dietitian nutritionist (RDN) or trained health professional. The process is generally used for individuals but can be applied when helping families, teaching groups, or evaluating the nutritional needs of a multicultural community or population. A nutrition diagnosis requires an intervention, and interventions relate to food and nutrient delivery (including nutrition support), use of

bioactive substances and integrative medical nutrition, education, counseling, and referral when needed.

Part 3, Nutrition in the Life Cycle, presents in-depth information on nutrition for life stages for conception, pregnancy, and lactation. Chapters on infancy, childhood, and adolescence highlight the importance of nutrition through critical periods of growth. A chapter on adult nutrition highlights risk factors for chronic diseases that usually start appearing in adulthood. Finally, nutrition for the aging adult is discussed in detail because of the growing need for nutrition services in this rapidly expanding population.

Part 4, Nutrition for Weight Management, provides a review of nutrition concepts for the achievement and maintenance of health and prevention of disease. Topics include weight management, disordered eating, dental health, bone health, and sports nutrition.

Part 5, Medical Nutrition Therapy, reflects evidence-based knowledge and current trends in nutrition therapies including integrative approaches. All of the chapters are written and reviewed by experts in their field who present MNT for conditions such as cardiovascular disorders; cancer; diabetes; liver and digestive diseases; renal disease; pulmonary disease; HIV; endocrine disorders (including thyroid disease); and rheumatologic, neurologic, and psychiatric disorders.

Part 6, Pediatric Specialties, describes the role of nutrition therapies in childhood. Chapters provide details for low-birthweight, neonatal intensive-care conditions, genetic metabolic disorders, and developmental disabilities.

NEW TO THIS EDITION

The chapter on food–drug interaction was eliminated this edition. Input from our educators and readers indicated that this chapter was not as useful as in the past due to the rapid changes that occur in the pharmaceutical industry and because computer applications are now in widespread use. We have, however, continued to include a food–drug appendix.

- New appendices on choline, biotin, the Mediterranean diet, and the International Dysphagia Diet Standardisation Initiative (IDDSI).
- Updated and expanded integrative nutrition approaches.
- Expanded section on pregnancy and lactation.
- The chapter titled “Planning the Diet with Cultural Competence” has a new co-author and expanded international nutrition guidelines.
- All chapters were updated with an emphasis on cultural diversity.
- Many new authors have provided new insights to chapters on cancer; GI; HIV; neurology; weight management; analysis of the diet; anemia; nutritional genomics; pulmonary, psychiatric, and cognitive disorders; critical care; and intellectual and developmental disabilities.
- New content highlight boxes on CRISPR, the Indigenous food movement, hearing assessment, Health At Every Size, health disparities, and a tribute to Dr. George Blackburn.

PEDAGOGY

- Unique pathophysiology algorithms and flow charts present the cause, pathophysiology, and the medical nutrition management for a variety of disorders and conditions. They equip the reader with an understanding of the illness as background for providing optimal nutritional care in a variety of healthcare settings.

- *Clinical Insight* boxes expand on clinical information in the text and highlight areas that may go unnoticed. These boxes contain information on studies and clinical resources for the student and practitioner.
- *New Directions* boxes suggest areas for further research by spotlighting emerging areas of interest within the field.
- *Focus On* boxes provide thought-provoking information on key concepts for well-rounded study and the promotion of further discussion within the classroom.
- Useful websites direct the reader to online resources that relate to the chapter topics; however, links are no longer included as they can outdate quickly.
- *Sample Nutrition Diagnosis* boxes present a problem, its etiology, and its signs and symptoms, before concluding with a sample nutrition diagnosis, providing both students and practitioners with “real-life” scenarios they may encounter in practice.
- Key terms are listed at the beginning of each chapter and bolded within the text where they are discussed in more detail.
- Chapter references are current and extensive, with the purpose of giving the student and instructor lots of opportunity for further reading and understanding.

ANCILLARIES

Accompanying this edition is the Evolve website, which includes updated and invaluable resources for instructors and students. These materials can be accessed by going to <http://evolve.elsevier.com/Mahan/nutrition/>.

INSTRUCTOR RESOURCES

- PowerPoint presentations: More than 900 slides to help guide classroom lectures.
- Image Collection: Approximately 200 images from the text are included in the PowerPoint presentations, as well as more illustrations that can be downloaded and used to develop other teaching resources.
- Audience Response System Questions (for use with iClicker and other systems): Three to five questions per chapter help aid incorporation of this new technology into the classroom.
- Test Bank: Each chapter includes NCLEX-formatted questions with page references specific to that chapter’s content to bring you more than 900 multiple-choice questions.
- Animations: Animations have been developed to visually complement the text and the processes described.
- NEW! Case Studies with Answers: Ten detailed clinical case studies using the nutrition care process.

STUDENT RESOURCES

- Study Exercises with Answers: With more than 600 questions, these exercises give instant feedback on questions related to the chapter’s content.
- NEW! Case Studies: Ten detailed clinical case studies using the nutrition care process.

Janice L. Raymond, MS, RDN, CD, CSG
Kelly Morrow, MS, RDN, FAND

ACKNOWLEDGMENTS

We sincerely thank the reviewers and especially contributors for this edition who have devoted hours and hours of time and commitment to researching the book's content for accuracy, reliability, and practicality. We are greatly in debt to them and realize that we could not continue to produce this book without them. In particular, we would like to acknowledge Ronona Crowder-Woods for her help with the Diabetes chapter, Hillary Nason on the Mediterranean Diet appendix, Amanda Fredrickson on the Diabetes Exchange List appendix, Linden Hale on the Biotin appendix and Maya DiTraglia on the Choline appendix. Thank you!

We also wish to acknowledge the hard work of Sandra Clark, Senior Content Strategist, who keeps the vision, and Danielle Frazier, Senior Content Developmental Specialist, who can get the “hot off the press” items we'd like included, and Tracey Schriefer, Senior Project Manager, who amazingly keeps the manuscript moving forward as she juggles between us and all others. Thank you!

PART I: Nutrition Assessment

1 Intake: Gastrointestinal Digestion, Absorption, and Excretion of Nutrients, 2

Kelly A. Tappenden, PhD, RDN, FASPEN

The Gastrointestinal Tract, 2

Brief Overview of Digestive and Absorptive Processes, 3

The Small Intestine: Primary Site of Nutrient Absorption, 9

The Large Intestine, 9

Summary, 15

2 Intake: Energy, 17

Carol S. Iretton-Jones, PhD, RDN, LD, CNSC, FASPEN, FAND

Energy Requirements, 17

Components of Energy Expenditure, 17

Estimating Energy Requirements, 21

Physical Activity in Children, 25

Calculating Food Energy, 25

3 Clinical: Water, Electrolytes, and Acid–Base Balance, 28

Mandy L. Corrigan, MPH, RDN, CNSC, FAND, FASPEN

Lauren Kruse, MS, RDN, CNSC

Body Water, 28

Electrolytes, 33

Acid–Base Balance, 37

Acid Generation, 38

Acid–Base Disorders, 38

4 Intake: Assessment of Food- and Nutrition-Related History, 41

Cynthia Bartok, PhD, RDN, CD

L. Kathleen Mahan, RDN, MS, CD

Nutritional Status, 41

Nutrition Screening, 41

Nutrition Assessment, 43

Nutrition Assessment

Food provides energy and building materials for countless substances that are essential for the growth and survival of every human being. This section opens with a brief overview of the digestion, absorption, transportation, and excretion of nutrients. These remarkable processes convert complex molecules in food into individual nutrients ready to be used in metabolism. Macronutrients (proteins, fats, and carbohydrates) each contribute to the total energy pool, but ultimately the energy they yield is available for the work of the muscles and organs of the body. The way nutrients become integral parts of the body and contribute to proper functioning depends heavily on the physiologic and biochemical processes that govern their actions. It is now known that these metabolic processes are altered in the presence of acute and chronic inflammation. Understanding the biomarkers and other indicators of inflammation is a critical component of nutrition assessment.

For the health provider, nutrition assessment is the first step in the nutrition care process. To implement a successful nutrition plan, the assessment must include key elements of the patient's clinical, medical, and social history, anthropometric measurements, biochemical and laboratory values, information on medication and herbal supplement use for potential food–drug interactions, plus a thorough food and nutrition intake history. Genetic research is rapidly clarifying how genes and nutrition are interrelated. Nutrigenomics is the study of the effects of foods and nutrients on gene expression and thus nutritional requirements. Thus the chapters in Part I provide an organized way to develop the skills needed to make an assessment in the nutrition care process.

Intake: Gastrointestinal Digestion, Absorption, and Excretion of Nutrients

Kelly A. Tappenden, PhD, RDN, FASPEN

KEY TERMS

amylase, pancreatic	ghrelin	pepsin
amylase, salivary	glucagon-like peptide 2 (GLP-2)	peristalsis
brush border membrane	gut–brain axis	prebiotic
chelation	isomaltase	probiotic
cholecystokinin (CCK)	lactase	proteolytic enzymes
chyme	lipase, gastric	secretin
colonic salvage	lipase, pancreatic	segmentation
crypts	lipase, salivary	somatostatin
diffusion, facilitated	lipolytic enzymes	sucrase
diffusion, passive	maltase	synbiotic
dysbiosis	micelle	transport, active
enterocytes	microbiome	transport, passive
enterohepatic circulation	microbiota	trypsin
enterokinase	microvilli	trypsinogen
enzymatic hydrolysis	motilin	unstirred water layer (UWL)
epithelial cells	mucosa	villi
gastrin	parietal cells	

One of the primary considerations for a complete nutrition assessment is to consider the three-step model of “ingestion, digestion, and utilization.” In this model, consideration is given to each step to identify all areas of inadequacy or excess. If there is any reason why a step is altered from physical, biochemical, or behavioral–environmental causes, the nutrition provider must select an appropriate nutrition diagnosis for which intervention is required. Intake and assimilation of nutrients should lead to nutritional and overall health.

THE GASTROINTESTINAL TRACT

The GIT is one of the largest organs in the body, has the greatest surface area, has the largest number of immune cells, and is one of the most metabolically active tissues in the body. The unique structure of the GIT enables ample nutrient-processing capacity in healthy humans. The human GIT is about 9 meters long, extending from the mouth to the anus and including the oropharyngeal structures, esophagus, stomach, liver and gallbladder, pancreas, and small and large intestine (Fig. 1.1).

Sections of the chapter were written by Peter L. Beyer, MS, RDN for previous editions of this text.

The GIT is designed to (1) digest the macronutrients protein, carbohydrates, and lipids from ingested foods and beverages; (2) absorb fluids, digested macronutrients, micronutrients, and trace elements; (3) provide a physical and immunologic barrier to pathogens, foreign material, and potential antigens consumed with food or formed during the passage of food through the GIT; (4) coordinate a response to microbes and antigens with the systemic immune system, resulting in controlled levels of tolerance or inflammation; and (5) provide regulatory and biochemical signaling to the nervous system, often involving the intestinal microbiota, via a pathway known as the **gut–brain axis**.

The human GIT is well suited for digesting and absorbing nutrients from a tremendous variety of foods, including meats, dairy products, fruits, vegetables, grains, complex starches, sugars, fats, and oils. Depending on the nature of the diet consumed, 90% to 97% of food is digested and absorbed; most of the unabsorbed material is of plant origin. Compared with ruminants and animals with a very large cecum, humans are considerably less efficient at extracting energy from grasses, stems, seeds, and other coarse fibrous materials. Humans lack the enzymes to hydrolyze the chemical bonds that link the molecules of sugars that make up plant fibers. However, fibrous foods and any undigested carbohydrates are fermented to varying degrees by bacteria in the human colon; this process can contribute 5% to 10% of the energy needed by humans.

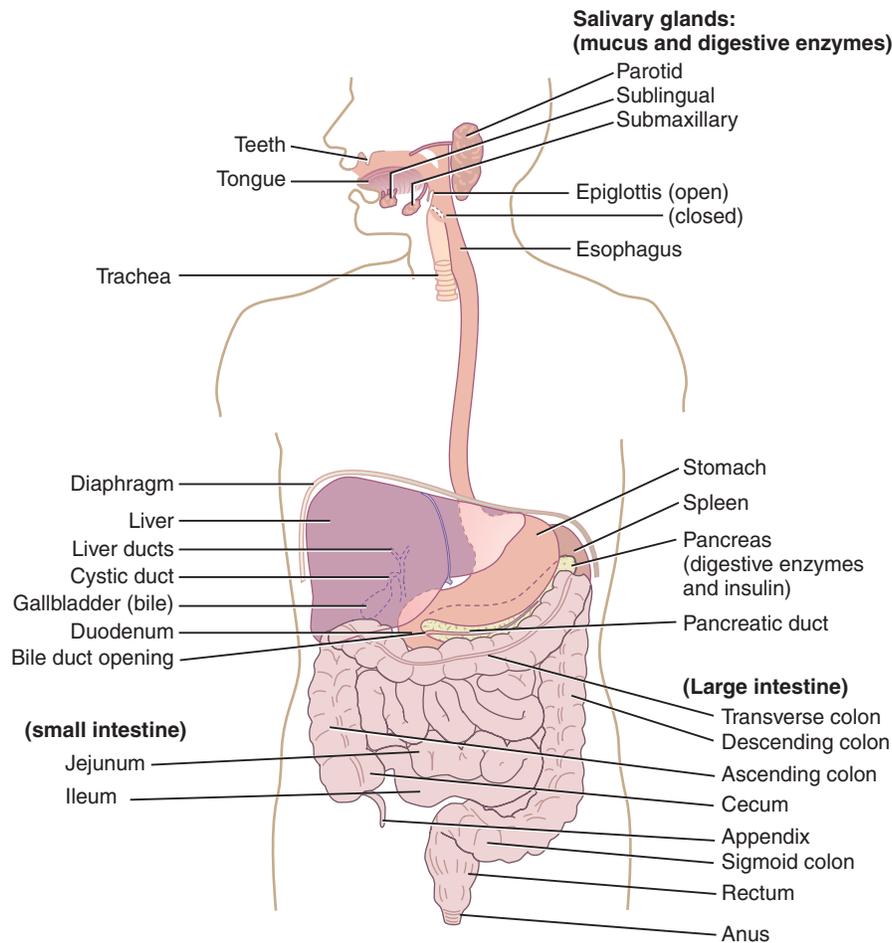

Fig. 1.1 The digestive system.

The structure of the small intestine is carefully designed to allow for a very large surface area that permits the adequate digestion and absorption of the nutrients from food. The lining of this hollow tube, called the **mucosa**, is configured in a pattern of folds that contains invaginations called **crypts** and fingerlike projections called **villi** (Fig. 1.2). These crypt-villus units are lined with a single layer of **epithelial cells**, many of which are **enterocytes** that contain even smaller cylindrical extensions called **microvilli**. The epithelial cells lining the intestinal tract have a life span of approximately 3 to 5 days, and then they are sloughed into the lumen and “recycled,” adding to the pool of available nutrients. As the cells migrate from the crypt along the villus, they mature and develop greater digestive and absorptive function.

The health of the body depends on a healthy, functional GIT. Because of the unusually high turnover rate and metabolic requirements of the epithelial cells, gastrointestinal functions are particularly susceptible to impairment due to micronutrient deficiencies, protein-energy malnutrition, and damage resulting from toxins, drugs, irradiation, food allergy reactions, or interruption of its blood supply. Approximately 45% of the energy requirement of the small intestine and 70% of the energy requirement of cells lining the colon are supplied by nutrients passing through its lumen. After only a few days of starvation or intravenous feeding (parenteral nutrition), the intestinal mucosa atrophies (i.e., the surface area decreases and secretions, synthetic functions, blood flow, and

absorptive capacity are all reduced). Resumption of food intake stimulates epithelial cell proliferation and return of normal GI function after only a few days. This knowledge justifies the clinical practice of feeding an individual orally and/or enterally (via tube), as opposed to intravenously (or parenterally), when adequate GIT function is present (see Chapter 12).

BRIEF OVERVIEW OF DIGESTIVE AND ABSORPTIVE PROCESSES

The sight, smell, taste, and even thought of food starts the secretions and movements of the GIT. In the mouth, chewing reduces the size of food particles, which are mixed with salivary secretions that prepare them for swallowing. A small amount of starch is degraded by **salivary amylase**, but digestion in the mouth is minimal. The esophagus transports food and liquid from the oral cavity and pharynx to the stomach. In the stomach, food is mixed with acidic fluid that contains **proteolytic** and **lipolytic enzymes**. Small amounts of lipid digestion take place; some proteins change in structure due to denaturation and partial digestion. When food reaches the appropriate consistency and concentration, it is now called **chyme** and passes from the stomach into the small intestine, where most digestion takes place.

The first 100 cm of the small intestine is highly active, resulting in the digestion and absorption of most ingested food (Fig. 1.3). Here the presence of food stimulates the release of hormones that stimulate the

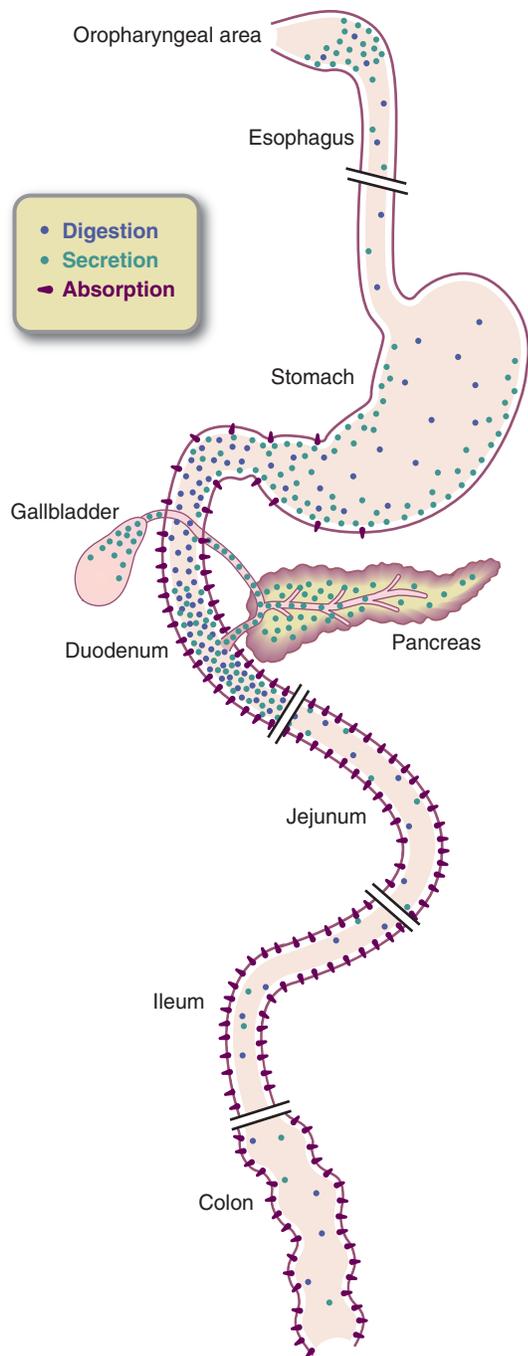

Fig. 1.2 Structure of the human intestine showing crypt-villus architecture and blood and lymph vessels.

production and release of powerful enzymes from the pancreas and bile from the gallbladder. Starches and proteins are reduced to small-molecular-weight carbohydrates and small to medium-size peptides. Dietary fats are reduced from visible globules of fat to microscopic droplets of triglycerides, then to free fatty acids and monoglycerides. Enzymes located on the brush border membrane of the enterocytes further reduce the remaining carbohydrates to monosaccharides and the remaining peptides to single amino acids, dipeptides, and tripeptides.

Large volumes of fluid are used to digest and absorb nutrients. Together with salivary and gastric secretions, secretions from the pancreas, small intestine, and gallbladder secrete 7 L of fluid into the

GIT lumen each day—far more than the 2 L ingested through dietary intake each day. All but 100 mL of the total fluid entering the lumen is reabsorbed: about 7 L in the small intestine and about 2 L in the large intestine.

Along the remaining length of the small intestine, almost all the macronutrients, minerals, vitamins, trace elements, and fluid are absorbed before reaching the colon. The colon and rectum absorb most of the remaining fluid delivered from the small intestine. The colon absorbs electrolytes and only a small amount of remaining nutrients. The movement of ingested and secreted material in the GIT is regulated primarily by hormones, nerves, and enteric muscles.

Most nutrients absorbed from the GIT enter the portal vein for transport to the liver where they may be stored, transformed into other substances, or released into circulation. However, end products of most dietary fats are transported into the bloodstream via the lymphatic circulation because they are not water soluble prior to lipoprotein metabolism in the liver (see Chapter 28).

Nutrients reaching the distal small intestine and large intestine, most notably fermentable dietary fiber and resistant starches, are fermented by the microbiota located within the lumen of these intestinal segments. Fermentation produces short-chain fatty acids (SCFAs) and gas. SCFAs provide a preferred fuel source for cells of the intestine, stimulate intestinal cell renewal and function, enhance immune function, and regulate gene expression. In addition, some carbohydrates have “prebiotic” functions that induce the growth and activity of beneficial microbes within the intestinal microbiota. The large intestine also provides temporary storage for waste products. The distal colon, rectum, and anus control defecation.

Enzymes in Digestion

Humans digest food using the chemical process called **enzymatic hydrolysis**. Cofactors such as hydrochloric acid, bile, and sodium bicarbonate facilitate these processes. Digestive enzymes synthesized in specialized cells of the mouth, stomach, and pancreas are released into the GIT lumen, whereas digestive enzymes synthesized in enterocytes of the small intestine remain embedded within the brush border membrane. Except for fiber and resistant carbohydrates, digestion and absorption of food is completed essentially in the small intestine. [Table 1.1](#) summarizes key enzymes involved in human digestion.

Regulators of Gastrointestinal Activity: Neural and Hormonal Mechanisms

Multiple layers of smooth muscle contract in coordinated patterns to optimize nutrient digestion along the GIT. These smooth muscle movements are regulated by the enteric nervous system and enteroendocrine hormones and facilitate mixing of chyme and digestive secretions (**segmentation**) or propulsion of luminal contents along the length of the GIT (**peristalsis**). To enable such coordinated actions, the enteric nervous system is integrated throughout the lining of the GIT and responds to mucosal receptors that sense the composition of chyme and distention of the lumen (i.e., fullness) and send impulses that coordinate the processes of digestion, secretion, absorption, and immunity.

Neurotransmitters from the central nervous system interface with the enteric nervous system to coordinate gastrointestinal functions such as motility, secretion, and blood flow. The GIT then largely regulates its own motility and secretory activity. However, signals from the central nervous system can override the enteric system and affect GIT function. Hormones, neuropeptides, and neurotransmitters in the GIT not only affect intestinal function but also have an effect on other nerves and tissues in many parts of the body. Some examples

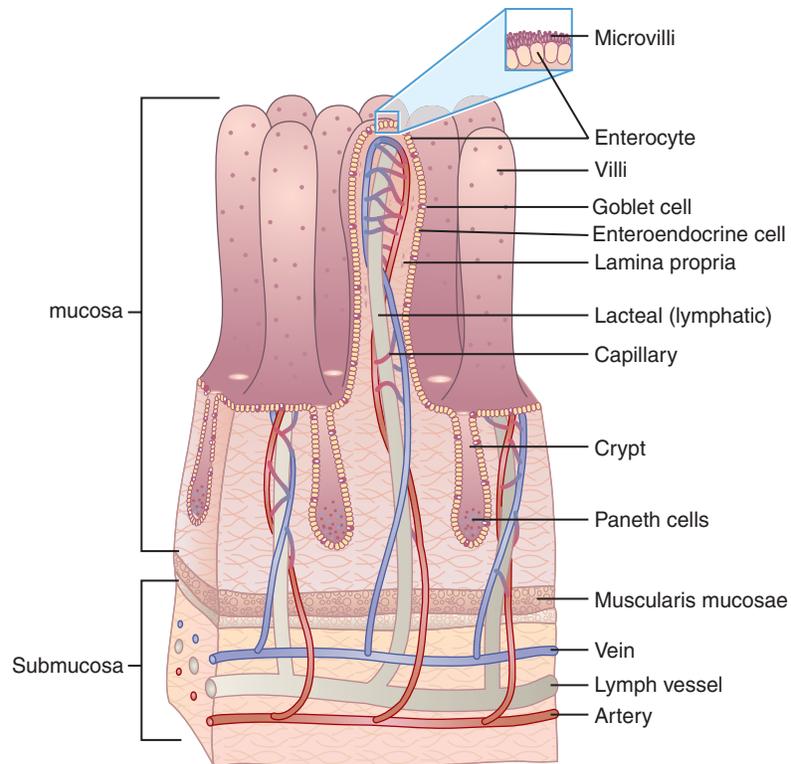

Fig. 1.3 Sites of secretion, digestion, and absorption.

of neurotransmitters released from enteric nerve endings are listed in [Table 1.2](#). In people with gastrointestinal disease (e.g., infections, inflammatory bowel disease, irritable bowel syndrome), the enteric nervous system may be overstimulated, resulting in abnormal secretion, altered blood flow, increased permeability, and altered immune function.

Autonomic innervation is supplied by the sympathetic fibers that run along blood vessels and by the parasympathetic fibers in the vagal and pelvic nerves. In general, sympathetic neurons, which are activated by fear, anger, and stress, tend to slow transit of intestinal contents by inhibiting neurons affecting muscle contraction and inhibiting secretions. The parasympathetic nerves innervate specific areas of the alimentary tract and contribute to certain functions. For example, the sight or smell of food stimulates vagal activity and subsequent secretion of acid from **parietal cells** within the stomach. The enteric nervous system also sends signals to the central nervous system that are perceived as pain, nausea, urgency or gastric fullness, or gastric emptiness by way of the vagal and spinal nerves. Inflammation, dysmotility, and various types of intestinal damage may intensify these perceptions.

Gastrointestinal Hormones

Regulation of the GIT involves numerous hormones that are secreted by enteroendocrine cells located within the epithelium lining of the GIT. These hormones can regulate function of the cell from which they were secreted (autocrine), on neighboring cells (paracrine), or distant cells by traveling through the blood to their target organs (endocrine).

More than 100 peptide hormones and hormone-like growth factors have been identified. Their actions are often complex and extend well beyond the GIT. Some of the hormones (e.g., of the **cholecystokinin [CCK]** and somatostatin family) also serve as neurotransmitters between neurons. The GIT secretes more than 30 hormone families,

making it the largest hormone-producing organ in the body ([Rehfeld, 2014](#)). Gastrointestinal hormones are involved in initiating and terminating feeding, signaling hunger and satiety, pacing movements of the GIT, governing gastric emptying, regulating blood flow and permeability, priming immune functions, and stimulating the growth of cells (within and beyond the GIT). **Ghrelin**, a neuropeptide secreted from the stomach, and motilin, a related hormone secreted from the duodenum, send a “hungry” message to the brain. Once food has been ingested, hormones PYY 3-36, CCK, glucagon-like peptide-1 (GLP-1), oxyntomodulin, pancreatic polypeptide, and gastrin-releasing polypeptide (bombesin) send signals to decrease hunger and increase satiety ([Rui, 2013](#)). Some of the GI hormones, including some of those that affect satiety, also tend to slow gastric emptying and decrease secretions (e.g., somatostatin). Other GI hormones (e.g., motilin) increase motility.

The signaling agents of the GIT also are involved in several metabolic functions. Glucose-dependent insulinotropic polypeptide (GIP) and GLP-1 are called incretin hormones because they help lower blood sugar by facilitating insulin secretion, decreasing gastric emptying, and increasing satiety. Several of these hormones and analogs are used in management of obesity, inflammatory bowel disease, diarrhea, diabetes, GI malignancies, and other conditions. This area of research is critically important.

Some functions of the hormones that affect gastrointestinal cell growth, deoxyribonucleic acid (DNA) synthesis, inflammation, proliferation, secretion, movement, or metabolism have not been fully identified. Knowledge of major hormone functions becomes especially important when the sites of their secretion or action are diseased or removed in surgical procedures, or when hormones and their analogs are used to suppress or enhance some aspect of gastrointestinal function. **Glucagon-like peptide-2 (GLP-2)** is an example of a hormone secreted from the distal GIT that increases intestinal surface area and enhances nutrient processing capacity. An analog of GLP-2, named

TABLE 1.1 Summary of Enzymatic Digestion and Absorption

Secretion and Source	Enzymes	Substrate	Action and Resulting Products	Final Products Absorbed
Saliva from salivary glands in mouth	α -amylase	Starch (α -linked polysaccharides)	Hydrolysis to form dextrins and maltose	—
	Lingual lipase	Triglyceride	Hydrolysis to form diglyceride and free fatty acids	—
Gastric secretion from gastric glands in stomach mucosa	Pepsin (activated from pepsinogen in the presence of hydrochloric acid)	Protein	Hydrolysis of peptide bonds to form peptides and amino acids	—
	Gastric lipase	Triglyceride	Hydrolysis to form diglyceride and free fatty acids	—
Exocrine secretions from pancreatic acinar cells, acting in duodenum	Lipase	Fat (in the presence of bile salts)	Hydrolysis to form monoglycerides and fatty acids; incorporated into micelles	Fatty acids into mucosal cells; reesterified as triglycerides
	Cholesterol esterase	Sterols (such as cholesterol)	Hydrolysis to form esters of cholesterol and fatty acids; incorporated into micelles	Cholesterol into mucosal cells; transferred to chylomicrons
	α -Amylase	Starch and dextrins	Hydrolysis to form dextrins and maltose	—
	Trypsin (activated trypsinogen)	Proteins and polypeptides	Hydrolysis of interior peptide bonds to form polypeptides	—
	Chymotrypsin (activated chymotrypsinogen)	Proteins and peptides	Hydrolysis of interior peptide bonds to form polypeptides	—
	Carboxypeptidase (activated procarboxypeptidase)	Polypeptides	Hydrolysis of terminal peptide bonds (carboxyl end) to form amino acids	Amino acids
	Ribonuclease and deoxyribonuclease	Ribonucleic acids (RNA) and deoxyribonucleic acids (DNA)	Hydrolysis to form mononucleotides	Mononucleotides
	Elastase	Fibrous protein (elastin)	Hydrolysis to form peptides and amino acids	—
Small intestine enzymes (embedded in the brush border membrane)	Enterokinase	Trypsinogen	Activates trypsin	Dipeptides and tripeptides
	Aminopeptidase and dipeptidase (also located within the enterocyte cytosol)	Polypeptides	Cleavage of amino acids from the amino terminus of protein (N-terminus) or peptide substrates	Amino acids
	Sucrase	Sucrose	Hydrolysis to form glucose and fructose	Glucose and fructose
	α -Dextrinase (isomaltase)	Dextrin (isomaltose)	Hydrolysis to form glucose	Glucose
	Maltase	Maltose	Hydrolysis to form glucose	Glucose
	Lactase	Lactose	Hydrolysis to form glucose and galactose	Glucose and galactose
	Nucleotidases	Nucleic acids	Hydrolysis to form nucleotides and phosphates	Nucleotides
	Nucleosidase and phosphorylase	Nucleosides	Hydrolysis to form purines, pyrimidines, and pentose phosphate	Purine and pyrimidine bases

TABLE 1.2 Examples of Neurotransmitters and Their Actions

Neurotransmitter	Site of Release	Primary Action
GABA	Central nervous system	Relaxes lower esophageal sphincter
Norepinephrine	Central nervous system, spinal cord, sympathetic nerves	Decreases motility, increases contraction of sphincters, inhibits secretions
Acetylcholine	Central nervous system, autonomic system, other tissues	Increases motility, relaxes sphincters, stimulates secretion
Neurotensin	GI tract, central nervous system	Inhibits release of gastric emptying and acid secretion
Serotonin (5-HT)	GI tract, spinal cord	Facilitates secretion and peristalsis
Nitric oxide	Central nervous system, GI tract	Regulates blood flow, maintains muscle tone, maintains gastric motor activity
Substance P	Gut, central nervous system, skin	Increases sensory awareness (mainly pain), and peristalsis

5-HT, 5-hydroxytryptamine; GABA, α -aminobutyric acid; GI, gastrointestinal.

TABLE 1.3 Functions of Major Gastrointestinal Hormones

Hormone	Site of Release	Stimulants for Release	Organ Affected	Effect on Target Organ
Gastrin	G cells of gastric mucosa and duodenum	Peptides, amino acids, caffeine Distention of the antrum Some alcoholic beverages, vagus nerve	Stomach, esophagus, GIT in general	Stimulates secretion of HCl and pepsinogen
				Increases gastric antral motility
				Increases lower esophageal sphincter tone
			Gallbladder Pancreas	Weakly stimulates contraction of gallbladder Weakly stimulates pancreatic secretion of bicarbonate
Secretin	S cells of duodenum	Acid in small intestine	Pancreas	Increases output of H ₂ O and bicarbonate; increases enzyme secretion from the pancreas and insulin release
			Duodenum	Decreases motility Increases mucus output
CCK	I cells of duodenum	Peptides, amino acids, fats, HCl	Pancreas	Stimulates secretion of pancreatic enzymes
			Gallbladder	Causes contraction of gallbladder
			Stomach	Slows gastric emptying
			Colon	Increases motility May mediate feeding behavior
GIP	K cells of duodenum and jejunum	Glucose, fat	Stomach	Reduced intestinal motility
Motilin	M cells of duodenum and jejunum	Interdigestive periods, alkaline pH in duodenum	Stomach, small bowel, colon	Promotes gastric emptying and GI motility
GLP-1	L cells of small intestine and colon (density increases in distal GIT)	Glucose, fat, short-chain fatty acids	Stomach	Prolongs gastric emptying
			Pancreas	Inhibits glucagon release; Stimulates insulin release
GLP-2	L cells of small intestine and colon (density increases in distal GIT)	Glucose, fat, short-chain fatty acids	Small intestine, colon	Stimulates intestinal growth and nutrient digestion and absorption

CCK, Cholecystokinin; GI, gastrointestinal; GIP, glucose-dependent insulinotropic polypeptide; GIT, gastrointestinal tract; GLP-1, glucagon-like peptide-1; GLP-2, glucagon-like peptide-2; H₂O, water; HCl, hydrochloric acid.

teduglutide, recently has become available for treatment of patients with short bowel syndrome who are dependent on parenteral nutrition to meet their nutrient and fluid requirements (Seidner et al, 2013; see Chapter 27). The key GIT hormones are summarized in Table 1.3.

Gastrin, a hormone that stimulates gastric secretions and motility, is secreted primarily from endocrine “G” cells in the antral mucosa of the stomach. Secretion is initiated by (1) impulses from the vagus nerve, such as those triggered by the smell or sight of food; (2) distention of the antrum after a meal; and (3) the presence of secretagogues in the antrum, such as partially digested proteins, fermented alcoholic beverages, caffeine, or food extracts (e.g., bouillon). When the lumen gets more acidic, feedback involving other hormones inhibits gastrin release (Chu and Schubert, 2013). Gastrin binds to receptors on parietal cells and histamine-releasing cells to stimulate gastric acid, to receptors on chief cells to release pepsinogen, and to receptors on smooth muscle to increase gastric motility.

Secretin, the first hormone to be named, is released from “S” cells in the wall of the proximal small intestine into the bloodstream. It is secreted in response to gastric acid and digestive end products in the duodenum, wherein it stimulates the secretion of pancreatic juice and inhibits gastric acid secretion and emptying (the opposite of gastrin). Neutralized acidity protects the duodenal mucosa from prolonged exposure to acid and provides the appropriate environment

for intestinal and pancreatic enzyme activity. The human receptor is found in the stomach and ductal and acinar cells of the pancreas. In different species, other organs may express secretin, including the liver, colon, heart, kidney, and brain (Chey and Chang, 2014).

Small bowel mucosal “I” cells secrete **CCK**, an important multifunctional hormone released in response to the presence of protein and fat. Receptors for CCK are in pancreatic acinar cells, pancreatic islet cells, gastric somatostatin-releasing D cells, smooth muscle cells of the GIT, and the central nervous system. Major functions of CCK are to (1) stimulate the pancreas to secrete enzymes, bicarbonate, and water; (2) stimulate gallbladder contraction; (3) increase colonic and rectal motility; (4) slow gastric emptying; and (5) increase satiety. CCK is also widely distributed in the brain and plays a role in neuronal functioning.

Motilin is released by endocrine cells in the duodenal mucosa during fasting to stimulate gastric emptying and intestinal migrating contractions. Erythromycin, an antibiotic, has been shown to bind to motilin receptors; thus analogs of erythromycin and motilin have been used as therapeutic agents to treat delayed gastric emptying (Wijeratne et al, 2016).

Somatostatin, released by “D” cells in the antrum and pylorus, is a hormone with far-reaching actions. Its primary roles are inhibitory and antisecretory. It decreases motility of the stomach and intestine and inhibits or regulates the release of several gastrointestinal

hormones. Somatostatin and its analog, octreotide, are being used to treat certain malignant diseases, as well as numerous gastrointestinal disorders such as diarrhea, short bowel syndrome, pancreatitis, dumping syndrome, and gastric hypersecretion (Van Op den Bosch et al, 2009; see Chapters 26 and 27).

Digestion in the Mouth

In the mouth, the teeth grind and crush food into small particles. The food mass is simultaneously moistened and lubricated by saliva. Three pairs of salivary glands—the parotid, submaxillary, and sublingual glands—produce approximately 1.5 L of saliva daily. Enzymatic digestion of starch and lipid is initiated in the mouth due to the presence of amylase and **salivary lipase**, respectively, in saliva. This digestion is minimal, and the salivary amylase becomes inactive when it reaches the acidic contents of the stomach. Saliva also contains mucus, a protein that causes particles of food to stick together and lubricates the mass for swallowing.

The masticated food mass, or bolus, is passed back to the pharynx under voluntary control, but throughout the esophagus, the process of swallowing (deglutition) is involuntary. Peristalsis then moves the food rapidly into the stomach (see Chapter 39 for a detailed discussion of swallowing).

Digestion in the Stomach

Food particles are propelled forward and mixed with gastric secretions by wavelike contractions that progress forward from the upper portion of the stomach (fundus), to the midportion (corpus), and then to the antrum and pylorus. In the stomach, gastric secretions mix with food and beverages producing a semiliquid slurry called chyme, which is 50% water. An average of 2000 to 2500 mL of fluid is secreted daily in the stomach. These gastric secretions contain hydrochloric acid (secreted by the parietal cells), pepsinogen, gastric lipase, mucus, intrinsic factor (a glycoprotein that facilitates vitamin B₁₂ absorption in the ileum), and gastrin. The protease, **pepsin**, is secreted in an inactive form, pepsinogen, which is converted by hydrochloric acid to its active form. Pepsin is active only in the acidic environment of the stomach and acts to begin the process of protein digestion.

An acid-stable lipase is secreted into the stomach by chief cells. Although this lipase is considerably less active than pancreatic lipase, it contributes to the overall processing of dietary triglycerides. Gastric lipase is more specific for triglycerides composed of medium- and short-chain fatty acids, but the usual diet contains few of these fats. Lipases secreted in the upper portions of the GIT may have a relatively important role in the liquid diet of infants; however, when pancreatic insufficiency occurs, it becomes apparent that lingual and gastric lipases are not sufficient to adequately digest fat from food and prevent lipid malabsorption.

When food is consumed, significant numbers of microorganisms are also consumed. The stomach pH is low, ranging from about 1 to 4. The combined actions of hydrochloric acid and proteolytic enzymes result in a significant reduction in the concentration of viable microorganisms. Some microbes may escape and enter the intestine if consumed in sufficient concentrations or if achlorhydria, gastrectomy, gastrointestinal dysfunction or disease, poor nutrition, or drugs that suppress acid secretions are present. This may increase the risk of pathogenic infection in the intestine.

The lower esophageal sphincter (LES), which lies above the entrance to the stomach, prevents reflux of gastric contents into the esophagus. The pyloric sphincter in the distal portion of the stomach helps regulate the exit of gastric contents, preventing backflow of chyme from the duodenum into the stomach. Obesity, certain food, gastrointestinal regulators, and irritation from nearby ulcers may alter

the performance of sphincters. Certain foods and beverages may alter LES pressure, permitting reflux of stomach contents back into the esophagus (see Chapter 26).

The stomach continuously mixes and churns food and normally releases the mixture in small quantities into the small intestine through the pyloric sphincter. The amount emptied with each contraction of the antrum and pylorus varies with the volume and type of food consumed, but only a few milliliters are released at a time. The presence of acid and nutrients in the duodenum stimulate the regulatory hormone, GIP, to slow gastric emptying.

Most of a liquid meal empties from the stomach within 1 to 2 hours, and most of a solid meal empties within 2 to 3 hours. When eaten alone, carbohydrates leave the stomach the most rapidly, followed by protein, fat, and fibrous food. In a meal with mixed types of foods, emptying of the stomach depends on the overall volume and characteristics of the foods. Liquids empty more rapidly than solids, large particles empty more slowly than small particles, and energy-dense foods empty more slowly than those containing less energy. These factors are important considerations for practitioners who counsel patients with nausea, vomiting, diabetic gastroparesis, or weight management concerns (see Chapters 26 and 20).

Digestion in the Small Intestine

The small intestine is the primary site for digestion of foods and nutrients. The small intestine is divided into the duodenum, the jejunum, and the ileum (see Fig. 1.2). The duodenum is approximately 0.5 m long, the jejunum is 2 to 3 m, and the ileum is 3 to 4 m. Most of the digestive process is completed in the duodenum and upper jejunum, and the absorption of most nutrients is largely complete by the time the material reaches the middle of the jejunum. The acidic chyme from the stomach enters the duodenum, where it is mixed with secretions from the pancreas, gallbladder, and duodenal epithelium. The sodium bicarbonate contained within these secretions neutralizes the acidic chyme and allows the digestive enzymes to work more effectively at this location.

The entry of partially digested foods, primarily fats and protein, stimulates the release of CCK, secretin, and GIP, which, in turn, stimulate the secretion of enzymes and fluids and affect gastrointestinal motility and satiety. Bile, which is predominantly a mixture of water, bile salts, and small amounts of pigments and cholesterol, is secreted from the liver and gallbladder. Through their surfactant properties, the bile salts facilitate the digestion and absorption of lipids, cholesterol, and fat-soluble vitamins. Bile acids are also regulatory molecules; they activate the vitamin D receptor and cell-signaling pathways in the liver and GIT that alter gene expression of enzymes involved in the regulation of energy metabolism (Hylemon et al, 2009). Furthermore, bile acids play an important role in hunger and satiety.

The pancreas secretes potent enzymes capable of digesting all of the major nutrients, and enzymes from the small intestine help complete the process. The primary lipid-digesting enzymes secreted by the pancreas are **pancreatic lipase** and colipase. Proteolytic enzymes include trypsin and chymotrypsin, carboxypeptidase, aminopeptidase, ribonuclease, and deoxyribonuclease. Trypsin and chymotrypsin are secreted in their inactive forms and are activated by enterokinase (also known as enteropeptidase), which is bound within the brush border membrane of enterocytes within the small intestine. **Pancreatic amylase** eventually hydrolyzes large starch molecules into units of approximately two to six sugars. Disaccharidase enzymes bound in the enterocyte brush border membrane further break down the carbohydrate molecules into monosaccharides before absorption. Varying amounts of resistant starches and most ingested dietary fiber escape digestion in the small intestine

and may add to fibrous material available for fermentation by colonic microbes.

Intestinal contents move along the small intestine at a rate of approximately 1 cm per minute, taking from 3 to 8 hours to travel through the entire intestine to the ileocecal valve; along the way, remaining substrates continue to be digested and absorbed. The ileocecal valve, like the pyloric sphincter, paces the entry of chyme into the colon and limits the amount of material passed back and forth between the small intestine and the colon. A damaged or nonfunctional ileocecal valve results in the entry of significant amounts of fluid and substrate into the colon and increases the chance for microbial overgrowth in the small intestine (see Chapter 26).

THE SMALL INTESTINE: PRIMARY SITE OF NUTRIENT ABSORPTION

The primary organ of nutrient and water absorption is the small intestine, which has an expansive absorptive area. The surface area is attributable to its extensive length, as well as to the organization of the mucosal lining, wherein there are characteristic folds in its mucosal surface that are covered with fingerlike projections called villi and invaginations called crypts (see Fig. 1.2). Enterocytes, a cell type that does much of the digestion and absorption are covered by microvilli, or the **brush border membrane**, which increases the surface area even further. The combination of folds, the crypt-villus axis, and the brush border membrane creates an enormous absorptive surface of approximately 200 to 300 m²—a surface area equivalent to a tennis court. The villi rest on a supporting structure called the lamina propria. Within the lamina propria is connective tissue, immune cells, and the blood and lymph vessels that receive the nutrients produced during digestion.

Each day, on average, the small intestine absorbs 150 to 300 g of monosaccharides, 60 to 100 g of fatty acids, 60 to 120 g of amino acids and peptides, and 50 to 100 g of ions. The capacity for absorption in the healthy individual far exceeds the normal macronutrient and energy requirements. Approximately 95% of the bile salts secreted from the liver and gallbladder are reabsorbed as bile acids in the distal ileum. Without recycling bile acids from the GIT (enterohepatic circulation), synthesis of new bile acids in the liver would not keep pace with needs for adequate digestion. Bile salt insufficiency becomes clinically important in patients who have resections of the distal small bowel and diseases affecting the small intestine, such as Crohn's disease, radiation enteritis, and cystic fibrosis. The distal ileum is also the site for vitamin B₁₂ (with intrinsic factor) absorption.

Absorptive and Transport Mechanisms

Absorption is a complex process involving many distinct pathways for specific nutrients and/or ions. However, the two basic transport mechanisms used are passive and active transport. The primary differences between the two are whether (1) the nutrient being transported is moving with a concentration gradient or (2) energy in the form of ATP is required because the nutrient being transported is moving against a concentration gradient.

Passive transport does not require energy, and nutrients move from a location of high concentration to low concentration. With passive transport a transport protein may or may not be involved. If the nutrient moves through the brush border membrane without a transport protein, this is termed **passive diffusion**, or simple passive transport. However, in cases in which a transport protein assists the passage of the nutrient across the brush border membrane, this process is termed **facilitated diffusion** (Fig. 1.4).

Active transport is the movement of molecules across cell membranes in the direction against their concentration gradient and therefore requires a transporter protein and energy in the form of ATP. Some nutrients may share the same transporter and thus compete for absorption. Transport or carrier systems also can become saturated, slowing the absorption of the nutrient. A notable example of such a carrier is intrinsic factor, which is responsible for the absorption of vitamin B₁₂ (see Chapter 26).

THE LARGE INTESTINE

The large intestine is approximately 1.5 m long and consists of the cecum, colon, rectum, and anal tract. Mucus secreted by the mucosa of the large intestine protects the intestinal wall from excoriation and bacterial activity and provides the medium for binding the feces together. Approximately 2 L of fluids are taken from food and beverages during the day, and 7 L of fluid is secreted along the GIT. Under normal circumstances, most of that fluid is absorbed in the small intestine, and approximately 2 L of fluid enters the large intestine. All but 100 to 150 mL of this fluid is absorbed; the remainder is excreted in the feces.

The large intestine is also the site of bacterial fermentation of remaining carbohydrates and amino acids, synthesis of a small amount of vitamins (particularly vitamin K), storage, and excretion of fecal residues. Colonic contents move forward slowly at a rate of 5 cm/h, and some remaining nutrients may be absorbed.

Defecation, or expulsion of feces through the rectum and anus, occurs with varying frequency, ranging from three times daily to once

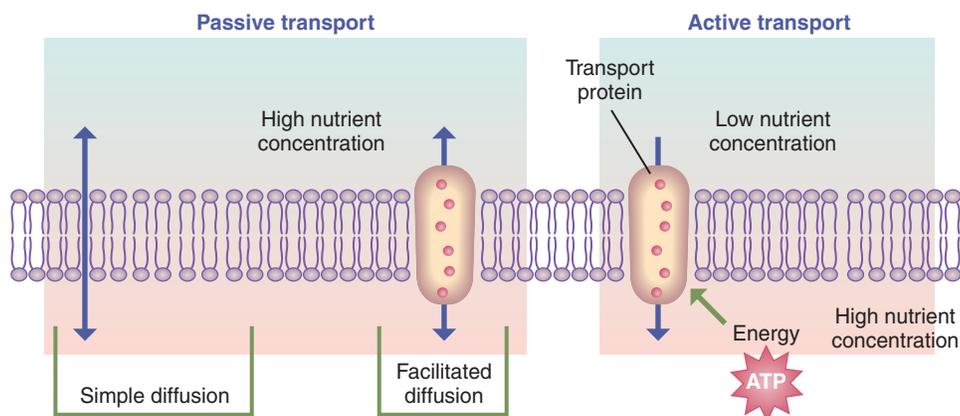

Fig. 1.4 Transport pathways through the cell membrane, as well as basic transport mechanisms. *ATP*, Adenosine triphosphate.

every 3 or more days. Average stool weight ranges from 100 to 200 g, and mouth-to-anus transit time may vary from 18 to 72 hours. The feces generally consist of 75% water and 25% solids, but the proportions vary greatly. Approximately two-thirds of the contents of the wet weight of the stool is bacteria, with the remainder coming from gastrointestinal secretions, mucus, sloughed cells, microbiota, and undigested foods. A diet that includes abundant fruits, vegetables, legumes, and whole grains typically results in a shorter overall GIT transit time, more frequent defecation, and larger and softer stools.

Intestinal Microbiota: The Microbiome

The intestinal **microbiota**, also called the **microbiome**, is a dynamic mixture of essential microbes that develops under key influences of genetics, environment, diet, and disease. Bacterial population profiles differ along the gastrointestinal tract, from the lumen to the mucosa, and among individuals. The total microbiota population outnumbers the cells in the human body by a factor of 10 and accounts for 35% to 50% of the volume of the colonic content. Key physiologic functions of the commensal microbiota include (1) protective effects exerted directly by specific bacterial species, (2) control of epithelial cell proliferation and differentiation, (3) production of essential mucosal nutrients, such as short-chain fatty acids and amino acids, (4) prevention of overgrowth of pathogenic organisms, (5) stimulation of intestinal immunity, and (6) development of the gut-brain axis (Kostic et al, 2014; see Chapter 40). Reduced abundance or changes in the relative proportions of these beneficial bacteria, a state called **dysbiosis**, is associated with various diseases in both children and adults (Buccigrossi et al, 2013; Fig. 1.5).

Normally, relatively few bacteria remain in the stomach and proximal small intestine after meals because bile, hydrochloric acid, and pepsin work as germicides. However, decreased gastric secretions can increase the risk of inflammation of the gastric mucosa (gastritis), increase the risk of bacterial overgrowth in the small intestine, or increase the numbers of microbes reaching the colon. An acid-tolerant bacterium is known to infect the stomach (*Helicobacter pylori*) and may cause gastritis and ulceration in the host (see Chapter 26).

Bacterial abundance is the greatest and action is most intense in the distal small intestine and the large intestine. After a meal, dietary

fiber, resistant starches, remaining parts of amino acids, and mucus sloughed from the intestine are fermented by the microbes present. This process of fermentation produces gases (e.g., hydrogen, carbon dioxide, nitrogen, and, in some individuals, methane) and SCFAs (e.g., acetic, propionic, butyric, and some lactic acids). During the process, several nutrients are formed by bacterial synthesis, such as vitamin K, vitamin B₁₂, thiamin, and riboflavin.

Strategies to stabilize and fortify the beneficial microbes within the microbiota in an attempt to maintain or improve health include the consumption of prebiotics, probiotics, and synbiotics.

Probiotics are live microorganisms, which, when administered in adequate amounts, provide a health benefit to the host. Probiotics can be found within fermented food products (such as yogurt, miso, or sauerkraut) or as a nutritional supplement (Hill et al, 2014). Knowledge of their role in preventing and treating a host of gastrointestinal and systemic disorders has expanded tremendously in recent years (Floch, 2018). However, when recommending a probiotic, practitioners must ensure that the specific microbial species has been shown in properly controlled studies to provide benefits to health (see Chapter 11).

Prebiotics are nondigestible food ingredients that act as a substrate that is selectively utilized by host microorganisms conferring a health benefit. Prebiotics typically require the following three attributes to benefit “beneficial” microbes, such as *Lactobacilli* and *Bifidobacteria* spp.: (1) be able to escape digestion in the upper GIT, (2) be able to be fermented by the microbiota to SCFA(s), and (3) be able to increase the abundance and/or relative proportion of bacteria known to contribute to human health. Good dietary sources of prebiotic carbohydrates include vegetables (including onions, garlic, and asparagus), fruits (especially bananas, apples, stone fruits, and mangos), grains, legumes, chicory, Jerusalem artichokes, soybeans, and wheat bran. Strong evidence exists that consumption of specific prebiotics benefits the GIT including inhibition of pathogens and immune stimulation, cardiometabolic support (e.g., reduction in blood lipid levels, effects upon insulin resistance), mental health benefits (e.g., metabolites that influence brain function, energy, and cognition) and bone health (e.g., mineral bioavailability) (Gibson et al, 2017).

Synbiotics are a synergistic combination of both probiotics and prebiotics in the same food or supplement.

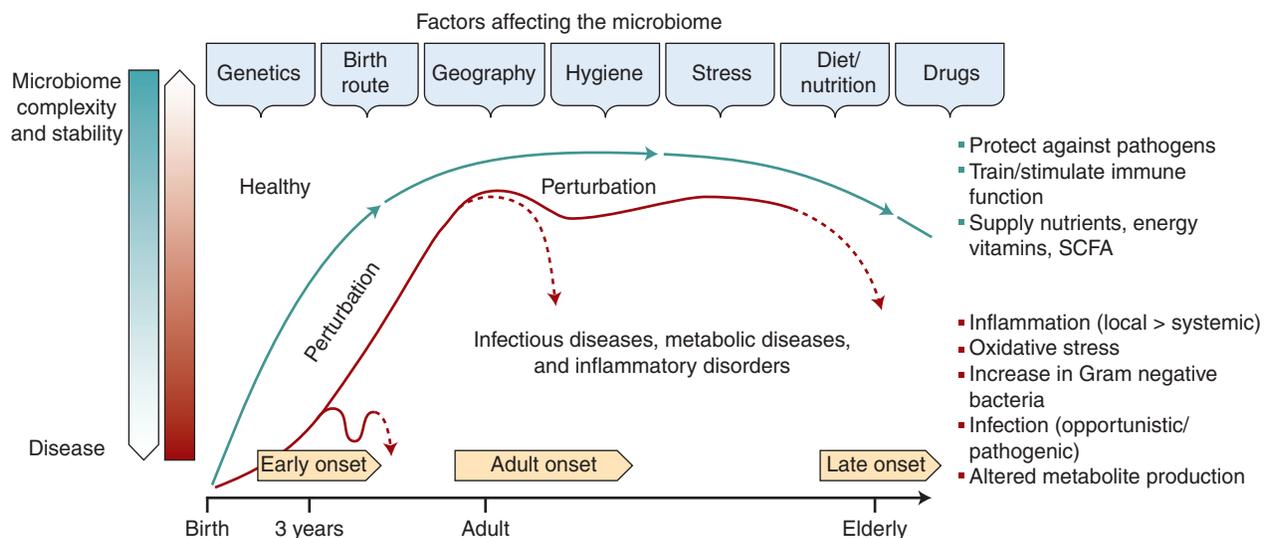

Fig. 1.5 Factors affecting stability and complexity of intestinal microbiota in health and disease. (Redrawn from Kostic AD et al: The microbiome in inflammatory bowel disease: current status and the future ahead, *Gastroenterology* 146:1489, 2014.)

Colonic Salvage of Malabsorbed Energy Sources and Short-chain Fatty Acids

Normally, varying amounts of some small-molecular-weight carbohydrates and amino acids remain in the chyme after leaving the small intestine. Accumulation of these small molecules could become osmotically important were it not for the action of bacteria in the colon. The disposal of residual substrates through production of SCFAs is called **colonic salvage**. SCFAs produced in fermentation are rapidly absorbed and take water with them. They also serve as fuel for the colonocytes and the microbiota, stimulate colonocyte proliferation and differentiation, enhance the absorption of electrolytes and water, and reduce the osmotic load of malabsorbed sugars. SCFAs also may help slow the movement of GI contents and participate in several other regulatory functions.

The ability to salvage carbohydrates is limited in humans. Colonic fermentation normally disposes of 20 to 25 g of carbohydrates over 24 hours. Excess amounts of carbohydrates and fermentable fiber in the colon can cause increased gas production, abdominal distention, bloating, pain, flatulence, decreased colonic pH, and diarrhea. Over time, adaptation occurs in individuals consuming diets high in fiber. Current recommendations are for the consumption of approximately 14 g of dietary fiber per 1000 kcal consumed each day. This recommendation can be met by consuming ample fruits, vegetables, legumes, seeds, and whole grains and is aimed to (1) support cardiovascular health, (2) maintain the health of the colonic epithelium, (3) prevent constipation, and (4) support stable, health-promoting microbiota.

Digestion and Absorption of Specific Types of Nutrients

Carbohydrates and Fiber

Most dietary carbohydrates are consumed in the form of starches, disaccharides, and monosaccharides. Starches, or polysaccharides, usually make up the greatest proportion of carbohydrates. Starches are large molecules composed of straight or branched chains of sugar molecules that are joined together, primarily in alpha 1-4 or

1-6 linkages. Most of the dietary starches are *amylopectins*, the branching polysaccharides, and amylose, the straight chain-type polymers.

Dietary fiber also is made largely of chains and branches of sugar molecules, but in this case the hydrogens are positioned on the beta (opposite) side of the oxygen in the link instead of the alpha side. Humans have significant ability to digest starch but not most fiber; this exemplifies the “stereospecificity” of enzymes.

In the mouth, the enzyme salivary amylase operates at a neutral or slightly alkaline pH and starts the digestive action by hydrolyzing a small amount of the starch molecules into smaller fragments (Fig. 1.6). Amylase deactivates after contact with hydrochloric acid. If digestible carbohydrates remained in the stomach long enough, acid hydrolysis could eventually reduce most of them into monosaccharides. However, the stomach usually empties before significant digestion can take place. By far, most carbohydrate digestion occurs in the proximal small intestine.

Pancreatic amylase breaks the large starch molecules at the 1-4 linkages to create maltose, maltotriose, and “alpha-limit” dextrins remaining from the amylopectin branches. Enzymes from the brush border of the enterocytes further break the disaccharides and oligosaccharides into monosaccharides. For example, **maltase** located at the enterocyte brush border membrane breaks down the disaccharide maltose into two molecules of glucose. The brush border membrane also contains the enzymes **sucrase**, **lactase**, and **isomaltase**, which act on sucrose, lactose, and isomaltose, respectively (Fig. 1.7).

The resultant monosaccharides (i.e., glucose, galactose, and fructose) pass through the enterocytes and into the bloodstream via the capillaries of the villi, where they are carried by the portal vein to the liver. At low concentrations, glucose and galactose are absorbed by active transport, primarily by a sodium-dependent active transporter called the sodium-glucose cotransporter (SGLT1). At higher luminal concentrations of glucose, the facilitative transporter GLUT2 becomes a primary route for transport of glucose from the lumen into the enterocyte. Fructose is absorbed from the intestinal lumen across the brush border membrane using the facilitative transporter, GLUT5. All three monosaccharides—glucose, galactose, and fructose—exit the

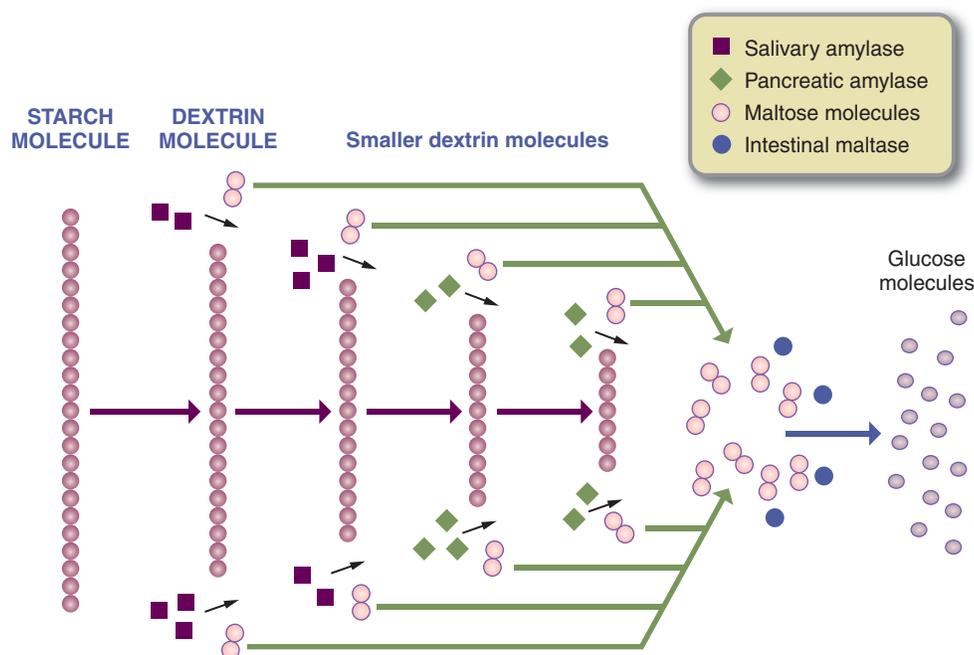

Fig. 1.6 The gradual breakdown of large starch molecules into glucose by digestion enzymes.

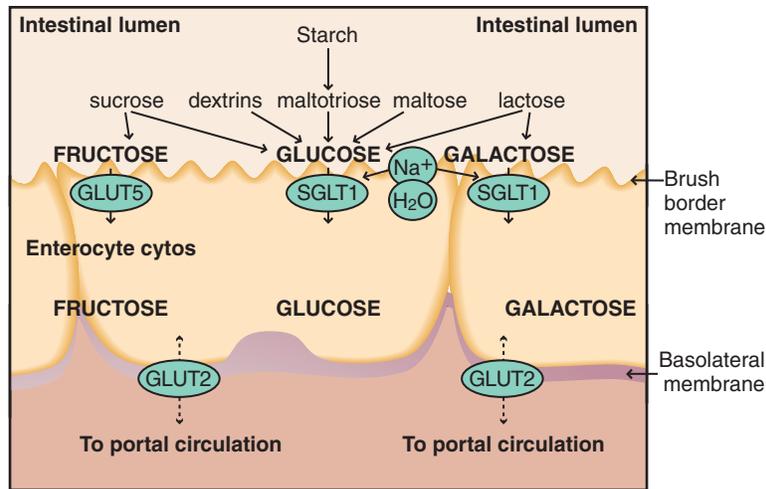

Fig. 1.7 Starch, sucrose, maltotriose, and galactose are digested to their constituent sugars. Glucose and galactose are transported through the apical brush border membrane of the enterocyte by a sodium-dependent transporter, glucose (galactose) cotransporter; fructose is transported by glucose transporter 5 (GLUT5). Glucose, fructose, and galactose are transported across the serosal membrane by the sodium-independent transporter, GLUT2.

basolateral membrane of the enterocyte into portal circulation using the facilitative transporter, GLUT2.

The active transporter, SGLT1, is key to the ability of the small intestine to absorb 7 L of fluid each day and provides the basis for why oral rehydration solutions, rather than water or sugary drinks, should be used to treat dehydration. In addition to transporting sodium and glucose, SGLT1 functions as a molecular water pump. For each molecule of glucose absorbed by SGLT1, two molecules of sodium and 210 molecules of water also are absorbed. Given that this is a major pathway for water absorption in the small intestine, to facilitate water absorption, sodium and glucose also must be present in the right amounts. This explains why the most effective oral rehydration solutions often include both sugar and salt, in addition to water.

Some forms of carbohydrates (i.e., cellulose, hemicellulose, pectin, gum, and other forms of fiber) cannot be digested by humans because neither salivary nor pancreatic amylase has the ability to split the linkages connecting the constituent sugars. These carbohydrates pass relatively unchanged into the colon, where they are partially fermented by bacteria in the colon. However, unlike humans, cows and other ruminants can subsist on high-fiber food because of the bacterial digestion of these carbohydrates that takes place in the rumen. Other resistant starches and sugars are also less well digested or absorbed by humans; thus their consumption may result in significant amounts of starch and sugar in the colon. These resistant starches and some types of dietary fiber are fermented into SCFAs and gases. Starches resistant to digestion tend to include plant foods with a high protein and fiber content such as those from legumes and whole grains.

Proteins

Protein intake in the Western world ranges from approximately 50 to 100 g daily, and a good deal of the protein consumed is from animal sources. Additional protein is added all along the GIT from gastrointestinal secretions and sloughed epithelial cells. The GIT is one of the most active synthetic tissues in the body, and the life span of enterocytes migrating from the crypts of the villi until they are shed is only 3 to 5 days. The number of cells shed daily is in the range of 10 to 20 billion. The latter accounts for an additional 50 to 60 g of protein that is digested and “recycled” and contributes to the daily

supply. In general, animal proteins are more efficiently digested than plant proteins, but human physiology allows for very effective digestion and absorption of large amounts of ingested protein sources.

Protein digestion begins in the stomach, where some of the proteins are split into proteoses, peptones, and large polypeptides. Inactive pepsinogen is converted into the enzyme pepsin when it contacts hydrochloric acid and other pepsin molecules. Unlike any of the other proteolytic enzymes, pepsin digests collagen, the major protein of connective tissue. Most protein digestion takes place in the upper portion of the small intestine, but it continues throughout the GIT. Any residual protein fractions are fermented by colonic microbes.

Contact between chyme and the intestinal mucosa allows for the action of the brush border-bound **enterokinase**, an enzyme that transforms inactive pancreatic **trypsinogen** into active **trypsin**, the major pancreatic protein-digesting enzyme. Trypsin, in turn, activates the other pancreatic proteolytic enzymes. Pancreatic trypsin, chymotrypsin, and carboxypeptidase break down intact protein and continue the breakdown started in the stomach until small polypeptides and amino acids are formed.

Proteolytic peptidases located on the brush border also act on polypeptides, breaking them down into amino acids, dipeptides, and tripeptides. The final phase of protein digestion takes place in the brush border, where some of the dipeptides and tripeptides are hydrolyzed into their constituent amino acids by peptide hydrolases.

End products of protein digestion are absorbed as both amino acids and small peptides. Several transport molecules are required for the different amino acids, probably because of the wide differences in the size, polarity, and configuration of the different amino acids. Some of the transporters are sodium or chloride dependent, and some are not. Considerable amounts of dipeptides and tripeptides also are absorbed into intestinal cells using a peptide transporter, a form of active transport (Wuensch et al, 2013). Absorbed peptides and amino acids are transported to the liver via the portal vein for metabolism by the liver and are released into the general circulation.

The presence of antibodies to many food proteins in the circulation of healthy individuals indicates that immunologically significant amounts of large intact peptides escape hydrolysis and can enter the

portal circulation. The exact mechanisms that cause a food to become an allergen are not entirely clear, but these foods tend to be high in protein, to be relatively resistant to complete digestion, and to produce an immunoglobulin response (see Chapter 25). With new technology, it is possible to map and characterize allergenic peptides; this eventually will lead to better diagnosis and development of safe immunotherapy treatments (Melioli et al, 2014).

Almost all protein is absorbed by the time it reaches the end of the jejunum, and only 1% of ingested protein is found in the feces. Small amounts of amino acids may remain in the epithelial cells and are used for synthesis of new proteins, including intestinal enzymes and new cells.

Lipids

Approximately 97% of dietary lipids are in the form of triglycerides, and the rest are found as phospholipids and cholesterol. Only small amounts of fat are digested in the mouth by lingual lipase and in the stomach from the action of gastric lipase. **Gastric lipase** hydrolyzes some triglycerides, especially short-chain triglycerides (such as those found in butter), into fatty acids and glycerol. However, most fat digestion takes place in the small intestine as a result of the emulsifying action of bile salts and hydrolysis by pancreatic lipase. As in the case of carbohydrates and protein, the capacity for digestion and absorption of dietary fat is in excess of ordinary needs.

Entrance of fat and protein into the small intestine stimulates the release of CCK, secretin, and GIP, which inhibit gastric secretions and motility, thus slowing the delivery of lipids. As a result, a portion of a large, fatty meal may remain in the stomach for 4 hours or longer. In addition to its many other functions, CCK stimulates biliary and pancreatic secretions. The combination of the peristaltic action of the small intestine and the surfactant and emulsification action of bile reduces the fat globules into tiny droplets, thus making them more accessible to digestion by the most potent lipid-digesting enzyme, pancreatic lipase.

Bile is a liver secretion composed of bile acids (primarily conjugates of cholic and chenodeoxycholic acids with glycine or taurine), bile pigments (which color the feces), inorganic salts, some protein, cholesterol, lecithin, and many compounds such as detoxified drugs that are metabolized and secreted by the liver. From its storage organ, the gallbladder, approximately 1 L of bile is secreted daily in response to the stimulus of food in the duodenum and stomach.

Emulsification of fats in the small intestine is followed by their digestion, primarily by pancreatic lipase, into free fatty acids and monoglycerides. Pancreatic lipase typically cleaves the first and third fatty acids, leaving a single fatty acid esterified to the middle glycerol carbon. When the concentration of bile salts reaches a certain level, they form **micelles** (small aggregates of fatty acids, monoglycerides, cholesterol, bile salts, and other lipids), which are organized with the polar ends of the molecules oriented toward the watery lumen of the intestine. The products of lipid digestion are solubilized rapidly in the central portion of the micelles and carried to the intestinal brush border (Fig. 1.8).

At the surface of the **unstirred water layer (UWL)**, the slightly acidic and watery plate that forms a boundary between the intestinal lumen and the brush border membranes, the lipids detach from the micelles. Remnants of the micelles return to the lumen for further transport. The monoglycerides and fatty acids thus are left to make their way across the lipophobic UWL to the more lipid-friendly membrane cells of the brush border. Upon release of the lipid components, luminal bile salts are reabsorbed actively in the terminal ileum and returned to the liver to reenter the gut in bile secretions. This efficient recycling process is known as the **enterohepatic circulation**. The pool

of bile acids may circulate from 3 to 15 times per day, depending on the amount of food ingested.

The cellular mechanism(s) whereby fatty acids traverse the brush border membrane include both passive diffusion (a form of transport that does not require energy), and active transport processes. Traditionally, the absorption of lipid was thought to be passive, wherein lipid molecules would solubilize through the brush border membrane in a manner driven by diffusion down the concentration gradient into the enterocyte. The inwardly directed concentration gradient was thought to be maintained in the fed state by the high concentration of fatty acids within the intestinal lumen and the rapid scavenging of free fatty acids for triglyceride reformation once inside the enterocyte. Current theories indicate that both passive diffusion and carrier-mediated mechanisms contribute to lipid absorption. At low fatty acid concentrations, carrier-mediated mechanisms take precedence with little passive diffusion occurring. However, when free fatty acid concentration in the intestinal lumen is high, absorption of fatty acids via passive diffusion becomes quantitatively important.

In the enterocyte, the fatty acids and monoglycerides are reassembled into new triglycerides. Others are further digested into free fatty acids and glycerol and then reassembled to form triglycerides. These triglycerides, along with cholesterol, fat-soluble vitamins, and phospholipids, are surrounded by a lipoprotein coat, forming chylomicrons (see Fig. 1.8). The lipoprotein globules pass into the lymphatic system instead of entering portal blood and are transported to the thoracic duct and emptied into the systemic circulation at the junction of the left internal jugular and left subclavian veins. The chylomicrons then are carried through the bloodstream to several tissues, including liver, adipose tissue, and muscle. In the liver, triglycerides from the chylomicrons are repackaged into very-low-density lipoproteins and transported primarily to the adipose tissue for metabolism and storage.

Under normal conditions approximately 95% to 97% of ingested fat is absorbed into lymph vessels. Because of their shorter length and thus increased solubility, fatty acids of 8 to 12 carbons (i.e., medium-chain fatty acids) can be absorbed directly into colonic mucosal cells without the presence of bile and micelle formation. After entering mucosal cells, they are able to go directly without esterification into the portal vein, which carries them to the liver.

Increased motility, intestinal mucosal changes, pancreatic insufficiency, or the absence of bile can decrease the absorption of fat. When undigested fat appears in the feces, the condition is known as steatorrhea (see Chapter 27). Medium-chain triglycerides (MCTs) have fatty acids 8 to 12 carbons long; MCTs are clinically valuable for individuals who lack necessary bile salts for long-chain fatty acid metabolism and transport. Supplements for clinical use normally are provided in the form of oil or a dietary beverage with other macronutrients and micronutrients.

Vitamins and Minerals

Vitamins and minerals from foods are made available as macronutrients and are digested and absorbed across the mucosal layer, primarily in the small intestine (Fig. 1.9). Besides adequate passive and transporter mechanisms, various factors affect the bioavailability of vitamins and minerals, including the presence or absence of other specific nutrients, acid or alkali, phytates, and oxalates. The liters of fluid that are secreted each day from the GIT serve as a solvent, a vehicle for chemical reactions, and a medium for transfer of several nutrients.

At least some vitamins and water pass unchanged from the small intestine into the blood by passive diffusion, but several different mechanisms may be used to transport individual vitamins across the

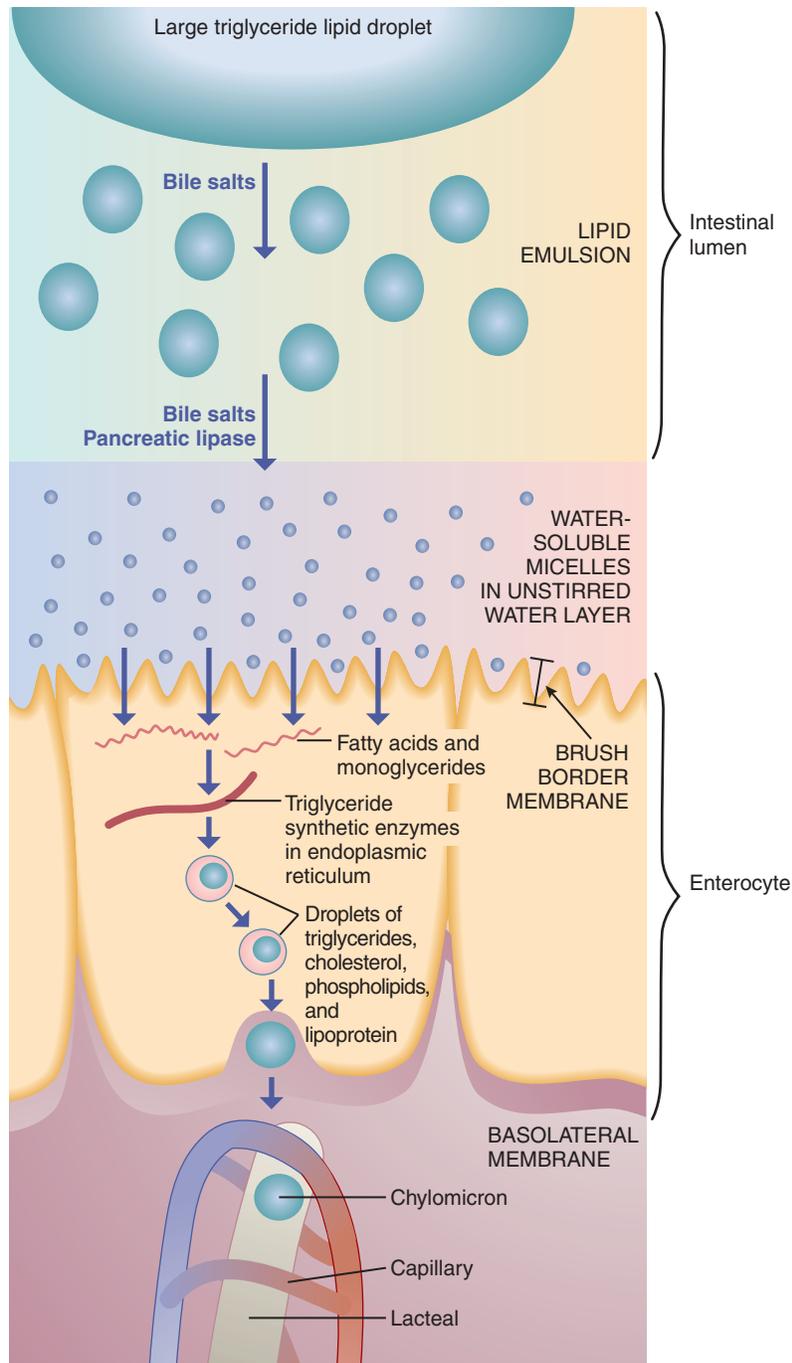

Fig. 1.8 Summary of fat absorption.

mucosa. Drugs are absorbed by a number of mechanisms but often by passive diffusion. Thus drugs may share or compete with mechanisms for the absorption nutrients into intestinal cells.

Mineral absorption is more complex, especially the absorption of the cation minerals. These cations, such as selenium, are made available for absorption by the process of **chelation**, in which a mineral is bound to a ligand—usually an acid, an organic acid, or an amino acid—so that it is in a form absorbable by intestinal cells (see Chapter 11).

Iron and zinc absorption share several characteristics in that the efficiency of absorption partly depends on the needs of the host. They also use at least one transport protein, and each has mechanisms to increase absorption when stores are inadequate. Because phytates

and oxalates from plants impair the absorption of iron and zinc, absorption is generally better when animal sources are consumed. Fermenting, soaking, sprouting and pretreatment with phytase enzymes improves the bioavailability of iron and zinc from plant based foods such as grains, legumes, nuts and seeds (Gupta et al, 2015). The absorption of zinc is impaired with disproportionately increased amounts of magnesium, calcium, and iron. Calcium absorption into the enterocyte occurs through channels in the brush border membrane, where it is bound to a specific protein carrier for transportation across the basolateral membrane. The process is regulated by the presence of vitamin D. Phosphorus is absorbed by a sodium phosphorus cotransporter, which also is regulated by vitamin D or low phosphate intake.

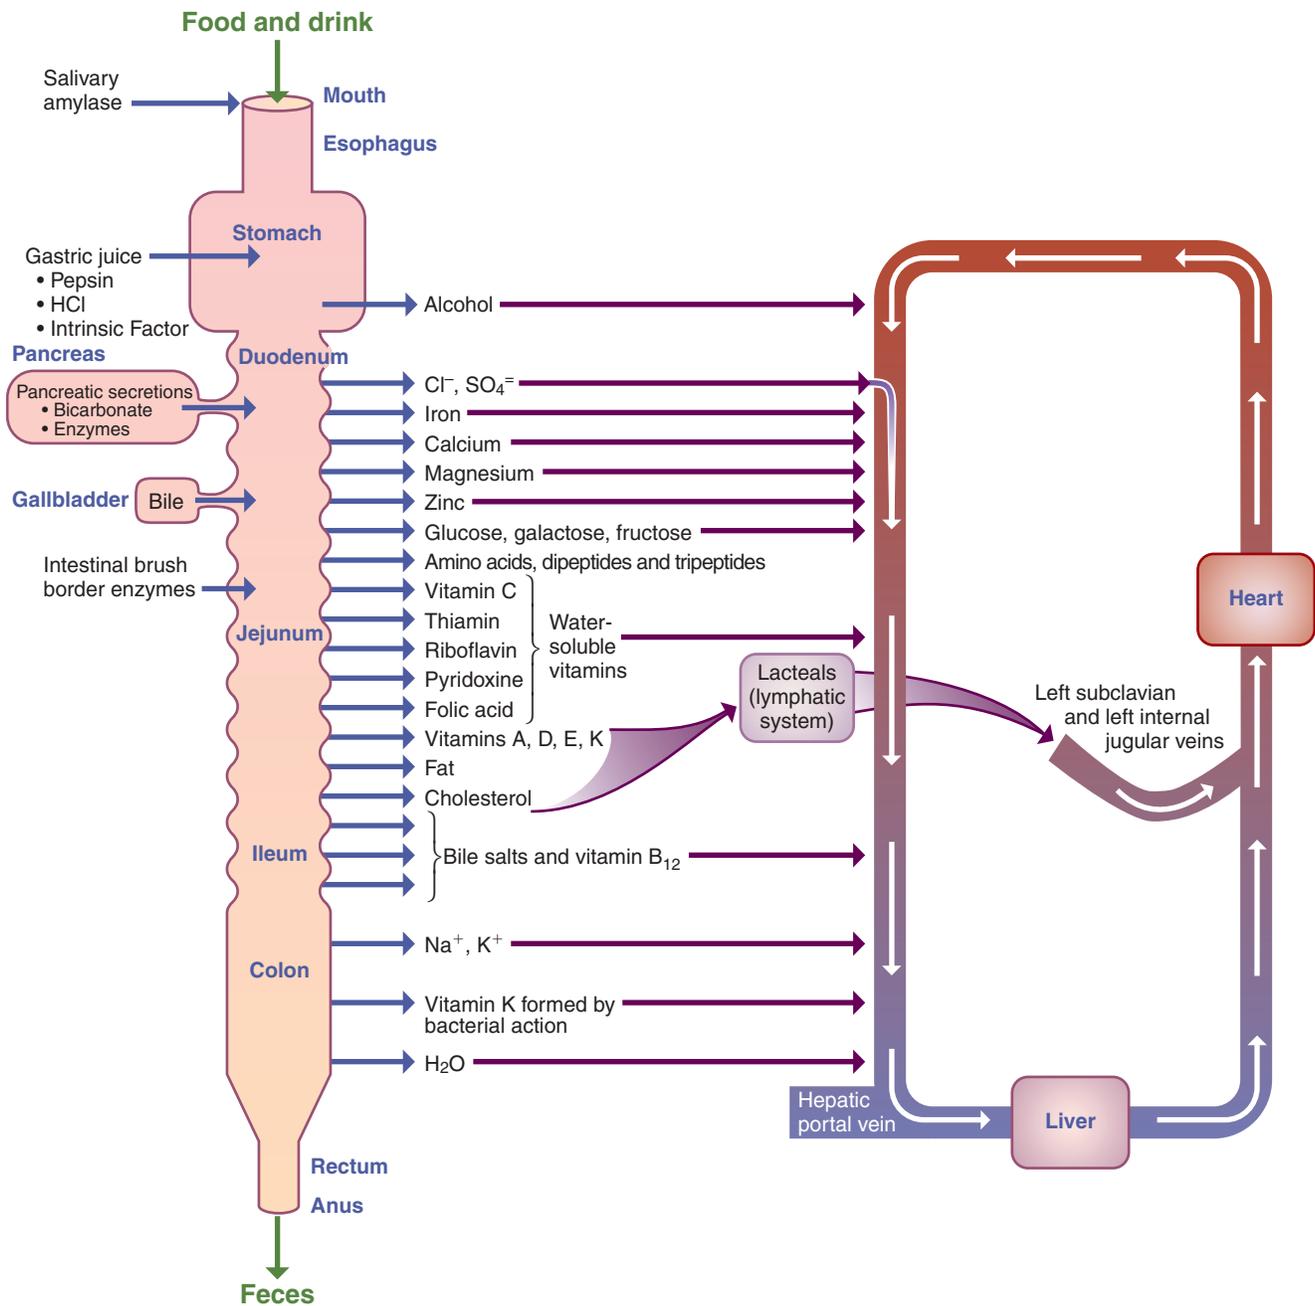

Fig. 1.9 Sites of secretion and absorption in the gastrointestinal tract.

The GIT is the site of important interactions among minerals. Supplementation with large amounts of iron or zinc may decrease the absorption of copper. In turn, the presence of copper may lower iron and molybdenum absorption. Cobalt absorption is increased in patients with iron deficiency, but cobalt and iron compete and inhibit one another's absorption. These interactions are probably the result of an overlap of mineral absorption mechanisms.

Minerals are transported in blood bound to protein carriers. The protein binding is either specific (e.g., transferrin, which binds with iron, or ceruloplasmin, which binds with copper) or general (e.g., albumin, which binds with a variety of minerals). A fraction of each mineral also is carried in the serum as amino acid or peptide complexes. Specific protein carriers are usually not completely saturated; the reserve capacity may serve as a buffer against excessive exposure.

Toxicity from minerals usually results only after this buffering capacity is exceeded.

SUMMARY

Assessment of the function of the gastrointestinal tract (GIT) is essential to the nutrition care process. Several nutrition diagnoses can be identified when assessing GIT function. Common or possible nutrition diagnoses related to digestion or metabolism include:

- Altered GI function (NC-1.4)
- Imbalance of nutrients (NI-5.4)
- Increased nutrient needs (NI-5.1)
- Altered nutrition related laboratory values (NC-2.2)
- Inadequate or excessive fluid intake (NI-3.1 and NI-3.2)
- Food–medication interaction (NC-2.3)

Intake: Energy

Carol S. Ireton-Jones, PhD, RDN, LD, CNSC, FASPEN, FAND

KEY TERMS

activity thermogenesis (AT)	facultative thermogenesis	obligatory thermogenesis
basal energy expenditure (BEE)	fat-free mass (FFM)	physical activity level (PAL)
basal metabolic rate (BMR)	high-metabolic-rate organ (HMRO)	respiratory quotient (RQ)
calorie	indirect calorimetry (IC)	resting energy expenditure (REE)
direct calorimetry	kilocalorie (kcal)	resting metabolic rate (RMR)
estimated energy requirement (EER)	lean body mass (LBM)	thermic effect of food (TEF)
excess post-exercise oxygen consumption (EPOC)	metabolic equivalents (METs)	total energy expenditure (TEE)
	nonexercise activity thermogenesis (NEAT)	

Energy may be defined as “the capacity to do work.” The ultimate source of all energy in living organisms is the sun. Through the process of photosynthesis, green plants intercept a portion of the sunlight reaching their leaves and capture it within the chemical bonds of glucose. Proteins, fats, and other carbohydrates are synthesized from this basic carbohydrate to meet the needs of the plant. Animals and humans obtain these nutrients and the energy they contain by consuming plants and the flesh of other animals.

The body makes use of the energy from dietary carbohydrates, proteins, fats, and alcohol; this energy is locked in chemical bonds within food and is released through metabolism. Energy must be supplied regularly to meet the needs for the body’s survival. Although all energy eventually takes the form of heat, which dissipates into the atmosphere, unique cellular processes first make possible its use for all the tasks required for life. These processes involve chemical reactions that maintain body tissues, electrical conduction of the nerves, mechanical work of the muscles, and heat production to maintain body temperature.

ENERGY REQUIREMENTS

Energy requirements are defined as the dietary energy intake that is required for growth or maintenance in a person of a defined age, gender, weight, height, and level of physical activity. In children and pregnant or lactating women, energy requirements include the needs associated with the deposition of tissues or the secretion of milk at rates consistent with good health. In ill or injured people, the stressors have an effect by increasing or decreasing energy expenditure.

Body weight is one indicator of energy adequacy or inadequacy. The body has the unique ability to shift the fuel mixture of carbohydrates, proteins, and fats to accommodate energy needs. However, consuming too much or too little energy over time results in body weight changes. Thus body weight reflects adequacy of energy intake,

but it is not a reliable indicator of macronutrient or micronutrient adequacy. In addition, because body weight is affected by body composition, a person with a higher lean mass to body fat mass or body fat mass to lean mass may require different energy intakes compared with the norm or “average” person. Obese individuals have higher energy needs because of an increase in body fat mass and lean body mass (Kee et al, 2012).

COMPONENTS OF ENERGY EXPENDITURE

Energy is expended by the human body in the form of **basal energy expenditure (BEE)**, thermic effect of food (TEF), and activity thermogenesis (AT). These three components make up a person’s daily **total energy expenditure (TEE)**.

Basal and Resting Energy Expenditure

BEE, or **basal metabolic rate (BMR)**, is the minimum amount of energy expended that is compatible with life. An individual’s BEE reflects the amount of energy used for 24 hours while physically and mentally at rest in a thermoneutral environment that prevents the activation of heat-generating processes, such as shivering. Measurements of BEE should be done before an individual has engaged in any physical activity (preferably on awakening from sleep) and 10 to 12 hours after the ingestion of any food, drink, or nicotine. The BEE remains remarkably constant on a daily basis.

Resting energy expenditure (REE), or **resting metabolic rate (RMR)**, is the energy expended in the activities necessary to sustain normal body functions and homeostasis. These activities include respiration and circulation, the synthesis of organic compounds, and the pumping of ions across membranes. REE, or RMR, includes the energy required by the central nervous system and for the maintenance of body temperature. It does not include thermogenesis, activity, or other energy expenditure and is higher than the BEE by 10% to 20%

(Ireton-Jones, 2010). The terms *REE* and *RMR* and *BEE* and *BMR* can be used interchangeably, but *REE* and *BEE* are used in this chapter.

Factors Affecting Resting Energy Expenditure

Numerous factors cause the REE to vary among individuals, but body size and composition have the greatest effect. See Chapter 5 for discussion of methods used to determine body composition.

Age. Because REE is highly affected by the proportion of **lean body mass (LBM)**, it is highest during periods of rapid growth, especially the first and second years of life. Growing infants may store as much as 12% to 15% of the energy value of their food in the form of new tissue. As a child becomes older, the energy requirement for growth is reduced to approximately 1% of TEE. After early adulthood there is a decline in REE of 1% to 2% per kilogram of **fat-free mass (FFM)** per decade (Keys et al, 1973). Fortunately, exercise can help maintain a higher LBM and a higher REE. Decreases in REE with increasing age may be partly related to age-associated changes in the relative size of LBM components (Cooper et al, 2013).

Body composition. FFM, or LBM, makes up most of the metabolically active tissue in the body and is the primary predictor of REE. FFM contributes to approximately 80% of the variations in REE (Wang et al, 2010). Because of their greater FFM, athletes with greater muscular development have an approximately 5% higher REE than nonathletic individuals. Organs in the body contribute to heat production (Fig. 2.1). Approximately 60% of REE can be accounted for by the heat produced by **high-metabolic-rate organs (HMROs)**: the liver, brain, heart, spleen, intestines, and kidneys). Indeed, differences in FFM between ethnic groups may be related to the total mass of these as well as musculature and presence of obesity (Wang et al, 2012). Relatively small individual variation in the mass of the liver, brain, heart, spleen, and kidneys, collectively or individually, can significantly affect REE (Javed et al, 2010). As a result, estimating the percentage of energy expenditure that appendages (arms and legs) account for in overall daily energy expenditure is difficult, although it is presumably a small amount.

Body size. Larger people generally have higher metabolic rates than smaller people, but tall, thin people have higher metabolic rates than short, stocky people. For example, if two people weigh the same but one person is taller, the taller person has a larger body surface area and a higher metabolic rate. Obesity is a major confounder in the determination of energy needs. Determination of body fat percentage may be helpful in increasing the preciseness of an equation,

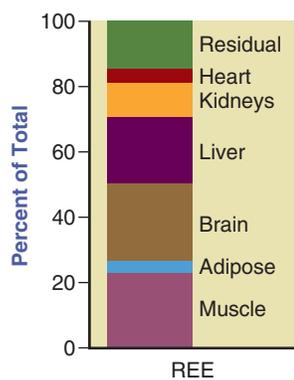

Fig. 2.1 Proportional contribution of organs and tissues to calculated resting energy expenditure. (Modified and used with permission from Gallagher D et al: Organ-tissue mass measurement allows modeling of REE and metabolically active tissue mass, *Am J Physiol Endocrinol Metab* 275:E249, 1998. Copyright American Physiological Society.)

but methodology related to measurement of body fat may cause inaccuracies in body fat and REE (Wang et al, 2012).

Climate. The REE is affected by extremes in environmental temperature. People living in tropical climates usually have REEs that are 5% to 20% higher than those living in temperate areas. Exercise in temperatures greater than 86°F imposes a small additional metabolic load of approximately 5% from increased sweat gland activity. The extent to which energy metabolism increases in extremely cold environments depends on the insulation available from body fat and protective clothing.

Gender. Gender differences in metabolic rates are attributable primarily to differences in body size and composition. Women, who generally have more fat in proportion to muscle than men, have metabolic rates that are approximately 5% to 10% lower than men of the same weight and height. However, with aging, this difference becomes less pronounced (Cooper et al, 2013).

Hormonal status. Hormones affect metabolic rate. Endocrine disorders, such as hyperthyroidism and hypothyroidism, increase or decrease energy expenditure, respectively (see Chapter 30). Stimulation of the sympathetic nervous system during periods of emotional excitement or stress causes the release of epinephrine, which promotes glycogenolysis and increased cellular activity. Ghrelin and peptide YY are gut hormones involved in appetite regulation and energy homeostasis (Larson-Meyer et al, 2010). The metabolic rate of women fluctuates with the menstrual cycle. During the luteal phase (i.e., the time between ovulation and the onset of menstruation), metabolic rate increases slightly (Ferraro et al, 1992). During pregnancy, growth in uterine, placental, and fetal tissues, along with the mother's increased cardiac workload, contributes to gradual increases in BEE of around 15% (Chapter 14).

Temperature. Fevers increase REE by approximately 7% for each degree of increase in body temperature above 98.6°F or 13% for each degree more than 37°C, as noted by classic studies (Hardy and DuBois, 1937).

Other factors. Caffeine, nicotine, and alcohol stimulate metabolic rate. Caffeine intakes of 200 to 350 mg in men or 240 mg in women may increase mean REE by 7% to 11% and 8% to 15%, respectively (Compher et al, 2006). Nicotine use increases REE by approximately 3% to 4% in men and by 6% in women; alcohol consumption increases REE in women by 9% (Compher et al, 2006). Under conditions of stress and disease, energy expenditure may increase or decrease, based on the clinical situation. Energy expenditure may be higher in people who are obese (Wang et al, 2012). Energy expenditure may be depressed during starvation and chronic dieting (Volp et al, 2011). A case study demonstrated decreased energy expenditure in people with bulimia that was improved when intake increased consistently (Sedlet and Ireton-Jones, 1989).

Thermic Effect of Food

The **thermic effect of food (TEF)** is the increase in energy expenditure associated with the consumption, digestion, and absorption of food. The TEF accounts for approximately 10% of TEE (Ireton-Jones, 2010). The TEF may also be called diet-induced thermogenesis, specific dynamic action, or the specific effect of food. TEF can be separated into obligatory and facultative (or adaptive) sub-components. **Obligatory thermogenesis** is the energy required to digest, absorb, and metabolize nutrients, including the synthesis and storage of protein, fat, and carbohydrate. Adaptive or **facultative thermogenesis** is the "excess" energy expended in addition to the obligatory thermogenesis and is thought to be attributable to the metabolic inefficiency of the system stimulated by sympathetic nervous activity.

The TEF varies with the composition of the diet, with energy expenditure increasing directly after food intake, particularly after consumption of a meal higher in protein compared with a meal higher in fat (Tentolouris et al, 2008). Fat is metabolized efficiently, with only 4% waste, compared with 25% waste when carbohydrate is converted to fat for storage. The macronutrient oxidation rate is not different in lean and obese individuals (Tentolouris et al, 2008). Although the extent of TEF depends on the size and macronutrient content of the meal, TEF decreases after ingestion over 30 to 90 minutes, so effects on TEE are small. For practical purposes, TEF is calculated as no more than an additional 10% of the REE. Spicy foods enhance and prolong the effect of the TEF. Caffeine, capsaicin, and different teas such as green, white, and oolong tea also may increase energy expenditure and fat oxidation and suppress hunger (Hursel and Westerterp-Plantenga, 2010; Reinbach et al, 2009). The role of TEF in weight management is discussed in Chapter 20.

Enteral nutrition (tube feeding) as well as parenteral nutrition exert a thermic effect on energy expenditure, which should be considered in patients receiving nutrition support. Leuck and colleagues found that energy expenditure of patients receiving enteral nutrition intermittently vs. continuously was increased at night and increased in association with each intermittent feeding (Leuck et al, 2013). A case study of a long-term home parenteral nutrition patient showed an increase in energy expenditure when the intravenous nutrition was being infused (Ireton-Jones, 2010). These are important considerations when predicting overall energy needs for patients receiving enteral or parenteral nutrition (see Chapter 12).

Activity Thermogenesis

Beyond REE and TEF, energy is expended in physical activity, either exercise-related or as part of daily work and movement. This is referred to as **activity thermogenesis**. Activity thermogenesis (AT) includes nonexercise activity thermogenesis (NEAT), the energy expended during activities of daily living, and the energy expended during sports or fitness exercise.

The contribution of physical activity is the most variable component of TEE, which may be as low as 100 kcal/day in sedentary people or as high as 3000 kcal/day in athletes. **NEAT** represents the energy expended during the workday and during leisure-type activities (e.g., shopping, fidgeting, even gum chewing), which may account for vast differences in energy costs among people (see Appendix 10). TEE reflects REE, TEF, and energy expended for exercise, as depicted in Fig. 2.2.

Individual AT varies considerably, depending on body size and the efficiency of individual habits of motion. The level of fitness also affects the energy expenditure of voluntary activity because of variations

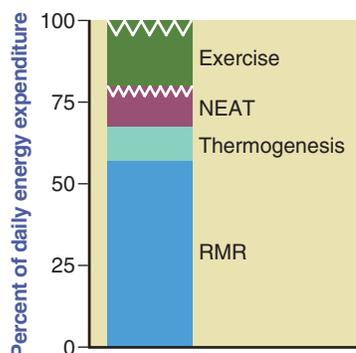

Fig. 2.2 The components of total energy expenditure: activity, thermic effect of food (TEF), and basal or resting metabolic rate.

in muscle mass. AT tends to decrease with age, a trend that is associated with a decline in FFM and an increase in fat mass. In general, men have greater skeletal muscle than women, which may account for their higher AT. The measurement of physical activity is very difficult whether related to children, adolescents, or adults (Mindell et al, 2014). However, this remains an important component of the overall energy intake recommendation suggesting that low-cost quantitative assessment methods are needed (e.g., heart rate monitoring) along with the typical questionnaire and estimate.

Additional Considerations in Energy Expenditure

Excess post-exercise oxygen consumption (EPOC) is influenced by the duration and magnitude of physical activity. In a study of high-intensity intermittent exercise, there was an increase in energy expenditure during activity, although the effect on metabolic rate post-activity was minor (Kelly et al, 2013). Habitual exercise does not cause a significantly prolonged increase in metabolic rate unless FM is decreased and FFM is increased, and then this increase in energy expenditure is mostly during the activity itself.

Amputations resulting from trauma, wounds, or disease processes affect body size; presumably then, they would affect activity energy expenditure. However, a study of energy expenditure related to level of amputation (partial foot to transfemoral) at various speeds of walking was done in unilateral amputees, and no differences in energy expenditure were found between levels of amputation or speed when walking (Göktepe et al, 2010).

Measurement of Energy Expenditure

The standard unit for measuring energy is the **calorie**, which is the amount of heat energy required to raise the temperature of 1 mL of water at 15°C by 1°C. Because the amount of energy involved in the metabolism of food is fairly large, the **kilocalorie** (kcal), 1000 calories, is used to measure it. A popular convention is to designate kilocalorie by Calorie (with a capital C). In this text, however, kilocalorie is abbreviated kcal. The **joule** (J) measures energy in terms of mechanical work and is the amount of energy required to accelerate with a force of 1 Newton (N) for a distance of 1 m; this measurement is widely used in countries other than the United States. One kcal is equivalent to 4.184 kilojoules (kJ).

Because various methods are available to measure human energy expenditure, it is important to gain an understanding of the differences in these methods and how they can be applied in practical and research settings.

Direct Calorimetry

Direct calorimetry is possible only with specialized and expensive equipment. An individual is monitored in a room-type structure (a whole-room calorimeter) that permits a moderate amount of activity. It includes equipment that monitors the amount of heat produced by the individual inside the chamber or room. Direct calorimetry provides a measure of energy expended in the form of heat but provides no information on the kind of fuel being oxidized. The method also is limited by the confined nature of the testing conditions. Therefore the measurement of TEE using this method is not representative of a free-living (i.e., engaged in normal daily activities) individual in a normal environment, because physical activity within the chamber is limited. High cost, complex engineering, and scarcity of appropriate facilities around the world also limit the use of this method.

Indirect Calorimetry

Indirect calorimetry (IC) is a more commonly used method for measuring energy expenditure. An individual's oxygen consumption and

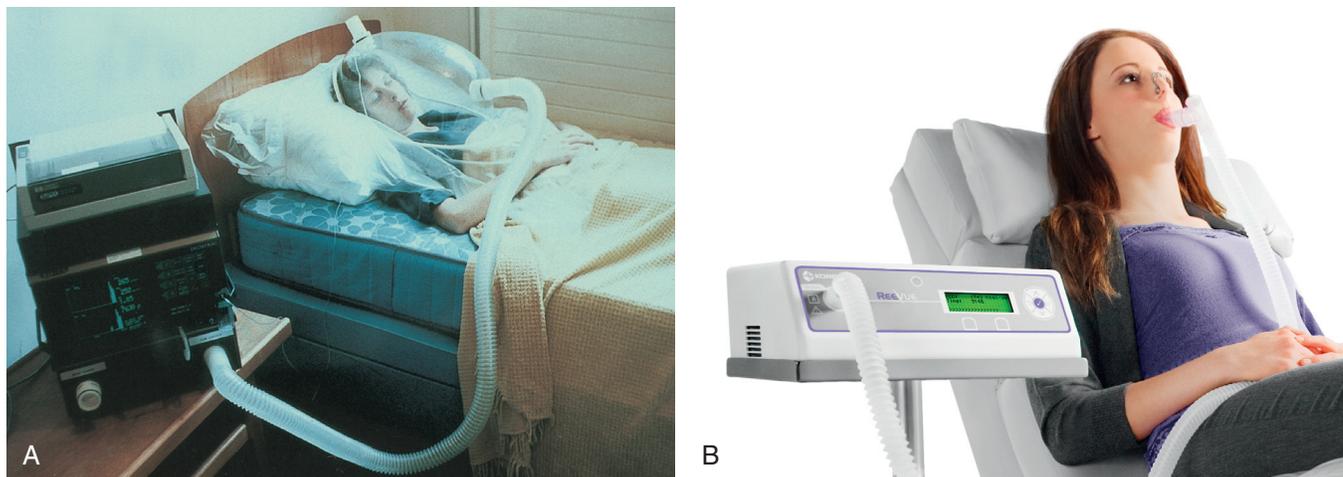

Fig. 2.3 **A**, Measuring resting energy expenditure using a ventilated hood system. (Courtesy MRC Mitochondrial Biology Unit, Cambridge, England.). **B**, Measuring resting energy expenditure using a handheld system. (Courtesy Korr.)

carbon dioxide production are quantified over a given period. The Weir equation (1949) and a constant respiratory quotient value of 0.85 are used to convert oxygen consumption to REE. The equipment varies but usually involves an individual breathing into a mouthpiece (with nose clips), a mask that covers the nose and mouth, or a ventilated hood that captures all expired carbon dioxide (Fig. 2.3). Ventilated hoods are useful for short- and long-term measurements.

IC measurements are achieved using equipment called a *metabolic measurement cart* or an *indirect calorimeter*. There are various types of metabolic measurement carts, varying from larger equipment that measures oxygen consumption and carbon dioxide production only, to equipment that also has the capability of providing pulmonary function and exercise testing parameters. These larger carts are more expensive because of the expanded capabilities, including measurement interface for IC measurements of hospitalized patients who are ventilator dependent. Metabolic carts often are used at hospitals to assess energy requirements and are found most typically in the intensive care unit (Ireton-Jones, 2010). Individuals and patients who are breathing spontaneously may have their energy expenditure measured with smaller “handheld” indirect calorimeters designed specifically for measuring oxygen consumption while using a static value for carbon dioxide production. These have easy mobility and are relatively low cost (Hipskind et al, 2011).

A strict protocol should be followed before performing IC measurement. For healthy people, a minimum of a 4-hour fast after meals and snacks is recommended. Caffeine should be avoided for at least 4 hours, and alcohol and smoking for at least 2 hours. Testing should occur no sooner than 2 hours after moderate exercise; after vigorous resistance exercise, a 14-hour period is advised (Compher et al, 2006). To achieve a steady-state measurement, there should be a rest period of 10 to 20 minutes before the measurement is taken. An IC measurement duration of 10 minutes, with the first 5 minutes deleted and the remaining 5 minutes having a coefficient of variation less than 10%, indicates a steady-state measurement (Compher et al, 2006). When the measurement conditions listed here are met and a steady state is achieved, energy expenditure can be measured at any time during the day. A suggested protocol for REE measurements is found in Table 2.1.

Energy expenditure can be measured for ill or injured individuals as well (Cooney and Frankenfield, 2012). Equipment used for the patient who is ventilator dependent may be different from that used for the ambulatory individual; however, a protocol specifying the

TABLE 2.1 REE Measurement Protocol (Adults)

REE Measurement Preparation

- Food – fast for 7 hours or 4 hours if < 300 kcal intake
- Caffeine – none for 4 hours
- Nicotine – none for 2.5 hours
- Exercise – none for 4 hours

Simplify: Rule of 4’s – no food, caffeine, nicotine, exercise for 4 hours before the REE measurement

REE Measurement Conditions

- Rest period pre-REE: healthy adult 20-30 mins
- Gas collection device:
 - Ventilated hood/canopy, mouthpiece & nose clip, facemask
- Ambient room temp 72-77°F
- Quiet and dim light
- Continue for 10 mins or as per individual protocol

Used with Permission: Ireton-Jones, C. Good Nutrition Good Living (Adapted)

conditions of measurement should be used for these patients as well (Ireton-Jones, 2010). When these conditions are met, IC can be applied for measuring the energy expenditure of acute or critically ill inpatients, outpatients, or healthy individuals.

Respiratory Quotient

When oxygen consumption and carbon dioxide production are measured, the **respiratory quotient (RQ)** may be calculated as noted in the following equation. The RQ indicates the fuel mixture being metabolized. The RQ for carbohydrate is 1 because the number of carbon dioxide molecules produced is equal to the number of oxygen molecules consumed.

$RQ = \text{volume of CO}_2 \text{ expired} / \text{volume of O}_2 \text{ consumed (VCO}_2 / \text{VO}_2)$

RQ values:

- 1 = carbohydrate
- 0.85 = mixed diet
- 0.82 = protein
- 0.7 = fat
- ≤0.65 = ketone production

RQs greater than 1 are associated with net fat synthesis, carbohydrate (glucose) intake, or total caloric intake that is excessive, whereas a very low RQ may be seen under conditions of inadequate nutrient intake (McClave et al, 2003). Although RQ has been used to determine the efficacy of nutrition support regimens for hospitalized patients, McClave found that changes in RQ failed to correlate to percent calories provided or required, indicating low sensitivity and specificity that limits the efficacy of RQ as an indicator of overfeeding or underfeeding. However, use of RQ is appropriate as a marker of test validity (to confirm measured RQ values are in physiologic range) and a marker for respiratory tolerance of the nutrition support regimen.

Other Methods of Measuring Energy Expenditure

Alternative methods of measuring energy expenditure remain in the research setting because of the need for specialized equipment and expertise.

Doubly labeled water. The doubly labeled water (DLW) technique for measuring TEE is considered the gold standard for determining energy requirements and energy balance in humans. The DLW method is based on the principle that carbon dioxide production can be estimated from the difference in the elimination rates of body hydrogen and oxygen. After an oral loading dose of water labeled with deuterium oxide ($^2\text{H}_2\text{O}$) and oxygen-18 (H_2^{18}O)—hence the term *doubly labeled water*—is administered, the $^2\text{H}_2\text{O}$ is eliminated from the body as water, and the H_2^{18}O is eliminated as water and carbon dioxide. The elimination rates of the two isotopes are measured for 10 to 14 days by periodic sampling of body water from urine, saliva, or plasma. The difference between the two elimination rates is a measure of carbon dioxide production. Carbon dioxide production then can be equated to TEE using standard IC techniques for the calculation of energy expenditure.

The caloric value of AT can be estimated by using the DLW method in conjunction with IC and can be used to determine adherence to recommended intake and body composition longitudinally (Wong et al, 2014). The DLW technique is most applicable as a research tool; the stable isotopes are expensive, and expertise is required to operate the highly sophisticated and costly mass spectrometer for the analysis of the isotope enrichments. These disadvantages make the DLW technique impractical for daily use by clinicians.

Measuring Activity-Related Energy Expenditure

Triaxial monitors. A triaxial monitor has also been used to measure energy related to activity. It more efficiently measures multidirectional movement by employing three uniaxial monitors. In a review of numerous articles, Plasqui and Westerterp (2007) found that a triaxial monitor correlated with energy expenditure measured using DLW technique. Application of an easily accessible and useable monitor allows determination of real activity levels, thereby reducing errors related to overreporting or underreporting of actual energy expenditure for weight management.

Physical Activity Questionnaire

Physical activity questionnaires (PAQs) are the simplest and least expensive tools for gaining information about an individual's activity level. Reporting errors are common among PAQs, which can lead to discrepancies between calculated energy expenditure and that determined by DLW (Neilson et al, 2008). For healthy individuals, this may account for slowed weight loss or gain and, as such, a need to modify caloric intake.

ESTIMATING ENERGY REQUIREMENTS

Equations for Estimating Resting Energy Expenditure

Over the years several equations have been developed to estimate the REE. Equations are available that allow the estimation of REE as derived from measurement using IC in adults. Until recently, the Harris-Benedict equations were some of the most widely used equations to estimate REE in normal and ill or injured individuals (Harris and Benedict, 1919). The Harris-Benedict equations have been found to overestimate REE in normal-weight and obese individuals by 7% to 27% (Frankenfield et al, 2003). A study comparing measured REE with estimated REE using the Mifflin-St. Jeor equations, Owen equations, and Harris-Benedict equations for males and females found that the Mifflin-St. Jeor equations were most accurate in estimating REE in both normal weight and obese people (Frankenfield et al, 2003). The Mifflin-St Jeor equations were developed from measured REE using IC in 251 males and 247 females; 47% of these individuals had a body mass index (BMI) between 30 and 42 kg/m² (Mifflin et al, 1990). Mifflin-St. Jeor equations are used today to estimate energy expenditure of healthy individuals and in some patients and are as follows:

$$\begin{aligned} \text{Males kcal/day} &= 10(\text{wt}) + 6.25(\text{ht}) - 5(\text{age}) + 5 \\ \text{Females kcal/day} &= 10(\text{wt}) + 6.25(\text{ht}) - 5(\text{age}) - 161 \\ \text{Weight} &= \text{actual body weight in kilograms} \\ \text{Height} &= \text{centimeters; age} = \text{years} \end{aligned}$$

Although the Harris-Benedict equations have been applied to ill and injured people, these equations, as well as those of Mifflin, were developed for use in healthy individuals, and their application to any other population is questionable. In addition, the database from which the Harris-Benedict equations were developed no longer reflects the population, and therefore use of these equations is not recommended.

Magnetic resonance imaging (MRI), computer tomography (CT), and dual-energy x-ray absorptiometry (DEXA) have been investigated as methods to evaluate REE from determination of LBM and fat mass in humans (Gallagher et al, 1998). While body weight, age, height, and gender may be similar among individuals or groups, body cell mass differs, and this creates the variations in REE that may confound weight loss, gain, or maintenance when predicting REE. Although REE is usually estimated from statistical equations, using imaging techniques to estimate the REE from organ-tissue mass components allows for distinct individuality of REE (Heymsfield et al, 2018). This will provide greater accuracy in determining REE by assessing energy expenditure in relation to body cell mass and body composition.

Energy expenditure of ill or injured patients also can be estimated or measured using IC. Energy expenditure may be affected by illness or injury; however, several studies have shown this increase to be variable from a significant increase to little to none over “normal” energy expenditure. Stable dialysis patients have not been shown to have an increase in REE compared with healthy adults (Dombrowski and Heuberger, 2018). In patients receiving home parenteral nutrition, measured REEs were related to energy expenditures predicted using 20 kcal/kg or the Ireton-Jones equations (Ławiński et al, 2015). Therefore assumptions of REE are often inaccurate—measurement of REE is best even in nonacute patient care. For energy requirements for critically ill patients, see Chapter 37.

Determining TEE

The equations for estimating or measuring energy expenditure begin with REE. Additional factors for TEF and activity must be added. As

stated previously, the TEF may be considered as an overall additive factor within activity thermogenesis in calculations of TEE. A simplified way of predicting physical activity additions to REE is through the use of estimates of the level of physical activity, which are then multiplied by the measured or predicted REE. To estimate TEE for minimal activity, increase REE by 10% to 20%; for moderate activity, increase REE by 25% to 40%; for strenuous activity, increase REE by 45% to 60%. These levels are ranges used in practice and can be considered “expert opinion” rather than evidence based at this time.

Estimating Energy Requirements From Energy Intake

Traditionally, recommendations for energy requirements were based on self-recorded estimates (e.g., diet records) or self-reported estimates (e.g., 24-hour recalls) of food intake. However, these methods do not provide accurate or unbiased estimates of an individual’s energy intake. The percentage of people who underestimate or underreport their food intake ranges from 10% to 45%, depending on the person’s age, gender, and body composition. This occurs in the compromised patient population as well (Ribeiro et al, 2014) (see Chapter 4).

Many online programs are available in which an individual can enter the food and quantity consumed into a program that estimates the macronutrient and micronutrient content. These programs allow users to enter data and receive a summary report, often with a detailed report provided to the health professional as well. Widely available programs include Food Prodigy and the MyPlate Tracker from the U.S. Department of Agriculture (see Chapter 4).

Other Prediction Equations

The National Academy of Sciences, Institute of Medicine (IOM), and Food and Nutrition Board, in partnership with Health Canada, developed the estimated energy requirements for men, women, children, and infants and for pregnant and lactating women (IOM, 2005). The **estimated energy requirement (EER)** is the average dietary energy intake predicted to maintain energy balance in a healthy adult of a defined age, gender, weight, height, and level of physical activity consistent with good health. In children and pregnant and lactating women, the EER is taken to include the energy needs associated with the deposition of tissues or the secretion of milk at rates consistent with good health. Table 2.2 lists average dietary reference intake (DRI) values for energy in healthy, active people of reference height, weight, and age for each life-stage group (IOM, 2002; 2005).

Supported by DLW studies, prediction equations have been developed to estimate energy requirements for people according to their life-stage group. Box 2.1 lists the EER prediction equations for people of normal weight. TEE prediction equations also are listed for various overweight and obese groups, as well as for weight maintenance in obese girls and boys. All equations have been developed to maintain current body weight (and promote growth when appropriate) and current levels of physical activity for all subsets of the population; they are not intended to promote weight loss (IOM, 2002; 2005).

The EER incorporates age, weight, height, gender, and level of physical activity for people ages 3 years and older. Although variables such as age, gender, and feeding type (i.e., breast milk, formula) can affect TEE among infants and young children, weight has been determined as the sole predictor of TEE needs (IOM, 2002; 2005). Beyond TEE requirements, additional calories are required for infants, young children, and children ages 3 through 18 to support the deposition of tissues needed for growth, and for pregnant and lactating women. Thus the EER among these subsets of the population is the sum of TEE plus the caloric requirements for energy deposition.

TABLE 2.2 Dietary Reference Intake Values for Energy for Active Individuals*

Life-Stage Group	Criterion	ACTIVE PAL EER (kcal/day)	
		Male	Female
Infants			
0-6 mo	Energy expenditure + Energy deposition	570	520 (3 mo)
7-12 mo	Energy expenditure + Energy deposition	743	676 (9 mo)
Children			
1-2 yr	Energy expenditure + Energy deposition	1046	992 (24 mo)
3-8 yr	Energy expenditure + Energy deposition	1742	1642 (6 yr)
9-13 yr	Energy expenditure + Energy deposition	2279	2071 (11 yr)
14-18 yr	Energy expenditure + Energy deposition	3152	2368 (16 yr)
Adults			
>18 yr	Energy expenditure	3067†	2403† (19 yr)
Pregnant Women

BOX 2.1 Estimated Energy Expenditure Prediction Equations at Four Physical Activity Levels**EER for Infants and Young Children 0-2 Years****(Within the 3rd to 97th Percentile for Weight-for-Height)**

EER = TEE + Energy deposition

0-3 months $(89 \times \text{Weight of infant [kg]} - 100) + 175$ (kcal for energy deposition)

4-6 months $(89 \times \text{Weight of infant [kg]} - 100) + 56$ (kcal for energy deposition)

7-12 months $(89 \times \text{Weight of infant [kg]} - 100) + 22$ (kcal for energy deposition)

13-35 months $(89 \times \text{Weight of child [kg]} - 100) + 20$ (kcal for energy deposition)

EER for Boys 3-8 Years (Within the 5th to 85th Percentile for BMI)§

EER = TEE Energy deposition

$EER = 88.5 - 61.9 \times \text{Age (yr)} + PA \times (26.7 \times \text{Weight [kg]} + 903 \times \text{Height [m]}) + 20$ (kcal for energy deposition)

EER for Boys 9-18 Years (Within the 5th to 85th Percentile for BMI)

EER = TEE + Energy deposition

$EER = 88.5 - 61.9 \times \text{Age (yr)} + PA \times (26.7 \times \text{Weight [kg]} + 903 \times \text{Height [m]}) + 25$ (kcal for energy deposition)

in which

PA = Physical activity coefficient for boys 3-18 years:

PA = 1 if PAL is estimated to be $\geq 1 < 1.4$ (Sedentary)

PA = 1.13 if PAL is estimated to be $\geq 1.4 < 1.6$ (Low active)

PA = 1.26 if PAL is estimated to be $\geq 1.6 < 1.9$ (Active)

PA = 1.42 if PAL is estimated to be $\geq 1.9 < 2.5$ (Very active)

EER for Girls 3-8 Years (Within the 5th to 85th Percentile for BMI)

EER = TEE + Energy deposition

$EER = 135.3 - 30.8 \times \text{Age (yr)} + PA \times (10 \times \text{Weight [kg]} + 934 \times \text{Height [m]}) + 20$ (kcal for energy deposition)

EER for Girls 9-18 Years (Within the 5th to 85th Percentile for BMI)

EER = TEE + Energy deposition

$EER = 135.3 - 30.8 \times \text{Age (yr)} + PA \times (10 \times \text{Weight [kg]} + 934 \times \text{Height [m]}) + 25$ (kcal for energy deposition)

in which

PA = Physical activity coefficient for girls 3-18 years:

PA = 1 (Sedentary)

PA = 1.16 (Low active)

PA = 1.31 (Active)

PA = 1.56 (Very active)

EER for Men 19 Years and Older (BMI 18.5-25 kg/m²)

EER = TEE

$EER = 662 - 9.53 \times \text{Age (yr)} + PA \times (15.91 \times \text{Weight [kg]} + 539.6 \times \text{Height [m]})$

in which

PA = Physical activity coefficient:

PA = 1 (Sedentary)

PA = 1.11 (Low active)

PA = 1.25 (Active)

PA = 1.48 (Very active)

EER for Women 19 Years and Older (BMI 18.5-25 kg/m²)

EER = TEE

$EER = 354 - 6.91 \times \text{Age (yr)} + PA \times (9.36 \times \text{Weight [kg]} + 726 \times \text{Height [m]})$

in which

PA = Physical activity coefficient:

PA = 1 (Sedentary)

PA = 1.12 (Low active)

PA = 1.27 (Active)

PA = 1.45 (Very active)

EER for Pregnant Women

14-18 years: EER = Adolescent EER + Pregnancy energy deposition

First trimester = Adolescent EER + 0 (Pregnancy energy deposition)

Second trimester = Adolescent EER + 160 kcal (8 kcal/wk \times 20 wk) + 180 kcal

Third trimester = Adolescent EER + 272 kcal (8 kcal/wk \times 34 wk) + 180 kcal

19-50 years: = Adult EER + Pregnancy energy deposition

First trimester = Adult EER + 0 (Pregnancy energy deposition)

Second trimester = Adult EER + 160 kcal (8 kcal/wk \times 20 wk) + 180 kcal

Third trimester = Adult EER + 272 kcal (8 kcal/wk \times 34 wk) + 180 kcal

EER for Lactating Women

14-18 years: EER = Adolescent EER + Milk energy output - Weight loss

First 6 months = Adolescent EER + 500 - 170 (Milk energy output - Weight loss)

Second 6 months = Adolescent EER + 400 - 0 (Milk energy output - Weight loss)

19-50 years: EAR = Adult EER + Milk energy output - Weight loss

First 6 months = Adult EER + 500 - 70 (Milk energy output - Weight loss)

Second 6 months = Adult EER + 400 - 0 (Milk energy output - Weight loss)

Weight Maintenance TEE for Overweight and At-Risk for Overweight Boys 3-18 Years (BMI >85th Percentile for Overweight)

$TEE = 114 - 50.9 \times \text{Age (yr)} + PA \times (19.5 \times \text{Weight [kg]} + 1161.4 \times \text{Height [m]})$

in which

PA = Physical activity coefficient:

PA = 1 if PAL is estimated to be $\geq 1.0 < 1.4$ (Sedentary)

PA = 1.12 if PAL is estimated to be $\geq 1.4 < 1.6$ (Low active)

PA = 1.24 if PAL is estimated to be $\geq 1.6 < 1.9$ (Active)

PA = 1.45 if PAL is estimated to be $\geq 1.9 < 2.5$ (Very active)

Weight Maintenance TEE for Overweight and At-Risk for Overweight Girls 3-18 Years (BMI >85th Percentile for Overweight)

$TEE = 389 - 41.2 \times \text{Age (yr)} + PA \times (15 \times \text{Weight [kg]} + 701.6 \times \text{Height [m]})$

in which

PA = Physical activity coefficient:

PA = 1 if PAL is estimated to be $\geq 1 < 1.4$ (Sedentary)

PA = 1.18 if PAL is estimated to be $\geq 1.4 < 1.6$ (Low active)

PA = 1.35 if PAL is estimated to be $\geq 1.6 < 1.9$ (Active)

PA = 1.60 if PAL is estimated to be $\geq 1.9 < 2.5$ (Very active)

Overweight and Obese Men 19 Years and Older (BMI ≥ 25 kg/m²)

$TEE = 1086 - 10.1 \times \text{Age (yr)} + PA \times (13.7 \times \text{Weight [kg]} + 416 \times \text{Height [m]})$

in which

 PA = 1.45 if PAL is estimated to be $\geq 1.9 < 2.5$ (Very active)

*EER is the average dietary energy intake that is predicted to maintain energy balance in a healthy adult of a defined age, gender, weight, height, and level of physical activity consistent with good health. In children and pregnant and lactating women, the EER includes the needs associated with the deposition of tissues or the secretion of milk at rates consistent with good health.

†PAL is the physical activity level that is the ratio of the total energy expenditure to the basal energy expenditure.

‡TEE is the sum of the resting energy expenditure, energy expended in physical activity, and the thermic effect of food.

§BMI is determined by dividing the weight (in kilograms) by the square of the height (in meters).

BMI, Body mass index; EER, estimated energy requirement; PA, physical activity; PAL, physical activity level; TEE, total energy expenditure. From Institute of Medicine, Food and Nutrition Board: *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids*, Washington, DC, 2002, The National Academies Press, www.nap.edu.

The prediction equations include a physical activity (PA) coefficient for all groups except infants and young children (see [Box 2-1](#)). PA coefficients correspond to four **physical activity level (PAL)** lifestyle categories: sedentary, low active, active, and very active. Because PAL is the ratio of TEE to BEE, the energy spent during activities of daily living, the sedentary lifestyle category has a PAL range of 1 to 1.39. PAL categories beyond sedentary are determined according to the energy spent by an adult walking at a set pace ([Table 2.3](#)). The walking equivalents that correspond to each PAL category for an average-weight adult walking at 3 to 4 mph are 2, 7, and 17 miles per day, for low active, active, and very active (IOM, 2002; 2005). All equations are only estimates and individual variations may be wide and unexpected (O’Riordan et al, 2010).

TABLE 2.3 Physical Activity Level Categories and Walking Equivalence*

PAL Category	PAL Values	Walking Equivalence (Miles/Day at 3-4 mph)
Sedentary	1-1.39	
Low active	1.4-1.59	1.5, 2.2, 2.9 for PAL = 1.5
Active	1.6-1.89	3, 4.4, 5.8 for PAL = 1.6 5.3, 7.3, 9.9 for PAL = 1.75
Very active	1.9-2.5	7.5, 10.3, 14 for PAL = 1.9 12.3, 16.7, 22.5 for PAL = 2.2 17, 23, 31 for PAL = 2.5

*In addition to energy spent for the generally unscheduled activities that are part of a normal daily life. The low, middle, and high miles/day values apply to relatively heavyweight (120-kg), midweight (70-kg), and lightweight (44-kg) individuals, respectively.

PAL, Physical activity level.

From Institute of Medicine, The National Academies: *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids*, Washington, DC, 2002/2005, The National Academies Press.

Estimated Energy Expended in Physical Activity

Energy expenditure in physical activity can be estimated using either the method shown in Appendix 10, which represents energy spent during common activities and incorporates body weight and the duration of time for each activity as variables, or using information in [Fig. 2.3](#), which represents energy spent by adults during various intensities of physical activity—energy that is expressed as metabolic equivalents (METs) (IOM, 2002; 2005).

Estimating Energy Expenditure of Selected Activities Using Metabolic Equivalents

METs are units of measure that correspond with a person’s metabolic rate during selected physical activities of varying intensities and are expressed as multiples of REE. A MET value of 1 is the oxygen metabolized at rest (3.5 mL of oxygen per kilogram of body weight per minute in adults) and can be expressed as 1 kcal/kg of body weight per hour. Thus the energy expenditure of adults can be estimated using MET values (1 MET = 1 kcal/kg/hr). For example, an adult who weighs 65 kg and is walking moderately at a pace of 4 mph (which is a MET value of 4.5) would expend 293 calories in 1 hour ($4.5 \text{ kcal} \times 65 \text{ kg} \times 1 = 293$) ([Table 2.4](#)).

Estimating a person’s energy requirements using the IOM’s EER equations requires identifying a PAL value for that person. A person’s PAL value can be affected by various activities performed throughout the day and is referred to as the change in physical activity level (Δ PAL). To determine Δ PAL, take the sum of the Δ PALs for each activity performed for 1 day from the DRI tables (IOM, 2002; 2005). To calculate the PAL value for 1 day, take the sum of activities and add the BEE (1) plus 10% to account for the TEF ($1 + 0.1 = 1.1$). For example, to calculate an adult woman’s PAL value, take the sum of the Δ PAL values for activities of daily living, such as walking the dog (0.11) and vacuuming (0.14) for 1 hour each, sitting for 4 hours doing light activity (0.12), and then performing moderate to vigorous activities such as walking for 1 hour at 4 mph (0.20) and ice skating for 30 minutes (0.13) for a total of 0.7. To that value add the BEE adjusted for the 10% TEF (1.1) for the final calculation:

$$0.7 + 1.1 = 1.8$$

TABLE 2.4 Intensity and Effect of Various Activities on Physical Activity Level in Adults*

Physical Activity	METs†	Δ PAL/10 min‡	Δ PAL/hr‡
Daily Activities			
Lying quietly	1	0	0
Riding in a car	1	0	0
Light activity while sitting	1.5	0.005	0.03
Vacuuming	3.5	0.024	0.14
Doing household tasks (moderate effort)	3.5	0.024	0.14
Gardening (no lifting)	4.4	0.032	0.19
Mowing lawn (power mower)	4.5	0.033	0.20
Leisure Activities: Mild			
Walking (2 mph)	2.5	0.014	0.09
Paddling (leisurely)	2.5	0.014	0.09
Golfing (with cart)	2.5	0.014	0.09
Dancing	2.9	0.018	0.11
Leisure Activities: Moderate			
Walking (3 mph)	3.3	0.022	0.13
Cycling (leisurely)	3.5	0.024	0.14
Walking (4 mph)	4.5	0.033	0.20
Leisure Activities: Vigorous			
Chopping wood	4.9	0.037	0.22
Playing tennis (doubles)	5	0.038	0.23
Ice skating	5.5	0.043	0.26
Cycling (moderate)	5.7	0.045	0.27
Skiing (downhill or water)	6.8	0.055	0.33
Swimming	7	0.057	0.34
Climbing hills (5-kg load)	7.4	0.061	0.37
Walking (5 mph)	8	0.067	0.40
Jogging (10-min mile)	10.2	0.088	0.53
Skipping rope	12	0.105	0.63

*PAL is the physical activity level that is the ratio of the total energy expenditure to the basal energy expenditure.

†METs are multiples of an individual's resting oxygen uptakes, defined as the rate of oxygen (O₂) consumption of 3.5 mL of O₂/min/kg body weight in adults.

‡The Δ PAL is the allowance made to include the delayed effect of physical activity in causing excess post exercise oxygen consumption and the dissipation of some of the food energy consumed through the thermic effect of food.

MET, Metabolic equivalent; PAL, physical activity level.

Modified from Institute of Medicine of The National Academies: *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, protein, and amino acids*, Washington, DC, 2002, The National Academies Press.

For this woman, the PAL value (1.8) falls within an active range. The PA coefficient that correlates with an active lifestyle for this woman is 1.27.

To calculate the EER for this adult woman, age 30, use the EER equation for women 19 years and older (BMI 18.5–25 kg/m²); see Box 2.1. The following calculation estimates the EER for a

30-year-old active woman who weighs 65 kg, is 1.77 m tall, with a PA coefficient (1.27):

$$\text{EER} = 354 - 6.91 \times \text{Age (yr)} + \text{PA} \times (9.36 \times \text{Weight [kg]} + 726 \times \text{Height [m]})$$

$$\text{EER} = 354 - (6.91 \times 30) + 1.27 \times [(9.36 \times 65) + (726 \times 1.77)]$$

$$\text{EER} = 2551 \text{ kcal}$$

PHYSICAL ACTIVITY IN CHILDREN

Energy spent during various activities and the intensity and impact of selected activities also can be determined for children and teens (see Box 2.1).

CALCULATING FOOD ENERGY

The total energy available from a food is measured with a bomb calorimeter. This device consists of a closed container in which a weighed food sample, ignited with an electric spark, is burned in an oxygenated atmosphere. The container is immersed in a known volume of water, and the rise in the temperature of the water after igniting the food is used to calculate the heat energy generated.

Not all of the energy in foods and alcohol is available to the body's cells, because the processes of digestion and absorption are not completely efficient. In addition, the nitrogenous portion of amino acids is not oxidized but is excreted in the form of urea. Therefore the biologically available energy from foods and alcohol is expressed in values rounded off slightly below those obtained using the calorimeter. These values for protein, fat, carbohydrate, and alcohol (Fig. 2.4) are 4, 9, 4, and 7 kcal/g, respectively. Fiber is an “unavailable carbohydrate” that resists digestion and absorption; its energy contribution is minimal.

Although the energy value of each nutrient is known precisely, only a few foods, such as oils and sugars, are made up of a single nutrient. More commonly, foods contain a mixture of protein, fat, and carbohydrate. For example, the energy value of one medium (50 g) egg calculated in terms of weight is derived from protein (13%), fat (12%), and carbohydrate (1%) as follows:

$$\text{Protein} : 13\% \times 50 \text{ g} = 6.5 \text{ g} \times 4 \text{ kcal/g} = 26 \text{ kcal}$$

$$\text{Fat} : 12\% \times 50 \text{ g} = 6 \text{ g} \times 9 \text{ kcal/g} = 54 \text{ kcal}$$

$$\text{Carbohydrate} : 1\% \times 50 \text{ g} = 0.05 \text{ g} \times 4 \text{ kcal/g} = 2 \text{ kcal}$$

$$\text{Total} = 82 \text{ kcal}$$

The energy value of alcoholic beverages can be determined using the following equation:

$$\text{Alcohol kcal} = \text{amount of beverage (oz)} \times \text{proof} \times 0.8 \text{ kcal/proof/oz.}$$

Proof is a description used for alcoholic beverages. It is the proportion of alcohol to water or other liquids in an alcoholic beverage. The standard in the United States defines 100-proof as equal to 50% of ethyl alcohol by volume. To determine the percentage of ethyl alcohol in a beverage, divide the proof value by 2. For example, 86-proof whiskey contains 43% ethyl alcohol. The latter part of the equation—0.8 kcal/proof/1 oz—is the factor that accounts for the caloric density of alcohol (7 kcal/g) and the fact that not all of the alcohol in liquor is available for energy. For example, the number of kilocalories in 1½ oz of 86-proof whiskey would be determined as follows:

$$1\frac{1}{2} \text{ oz} \times 86\% \text{ proof} \times 0.8 \text{ kcal/proof/1 oz} = 103 \text{ kcal}$$

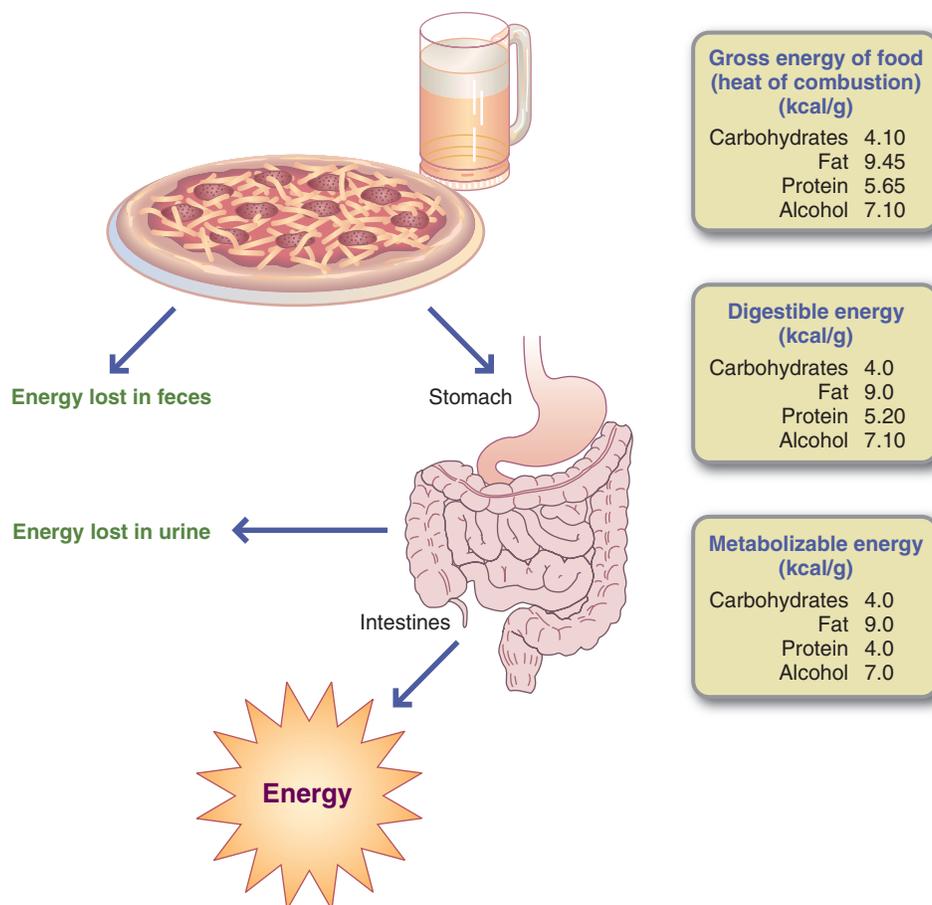

Fig. 2.4 Energy value of food.

See Appendix 24 for the caloric content of alcoholic beverages.

Energy values of foods based on chemical analyses may be obtained from the U.S. Department of Agriculture (USDA) Nutrient Data Laboratory website or from *Bowes and Church's Food Values of Portions Commonly Used* (Pennington and Spungen, 2009).

Many computer software programs that use the USDA nutrient database as the standard reference are also available and many online websites can be used (see Chapter 4).

Recommendations for macronutrient percentages vary based on the goal of the client and any underlying or overriding disease process. This is discussed in other chapters.

Clinical: Water, Electrolytes, and Acid–Base Balance

Mandy L. Corrigan, MPH, RDN, CNSC, FAND, FASPEN
Lauren Kruse, MS, RDN, CNSC

KEY TERMS

acid–base balance	hydrostatic pressure	osmolality
acidemia	hypervolemia	osmolarity
alkalemia	hyponatremia	osmotic pressure
anion gap	insensible water loss	renin-angiotensin system
antidiuretic hormone	interstitial fluid	respiratory acidosis
buffer	intracellular fluid (ICF)	respiratory alkalosis
contraction alkalosis	lymph edema	sensible water loss
corrected calcium	metabolic acidosis	“third space” fluid
dehydration	metabolic alkalosis	Total Body Water (TBW)
edema	metabolic water	vasopressin
electrolytes	Na/K-ATPase pump	
extracellular fluid (ECF)	oncotic pressure (colloidal osmotic pressure)	

Fluid, electrolyte, and acid–base management is complex and requires an understanding of the functions and homeostatic mechanisms the body uses to maintain an optimal environment for cell function. Alterations in fluid, electrolyte, and acid–base balance are commonly seen in hospitalized patients and can affect homeostasis both acutely and chronically. Understanding the function and regulation of fluid and electrolytes lends the ability to prevent and treat these imbalances in patients across any disease state.

The volume, composition, and distribution of body fluids have profound effects on cell function. A stable internal environment is maintained through a sophisticated network of homeostatic mechanisms, which are focused on ensuring that water intake and water loss are balanced. Disease, trauma, and surgery can disrupt fluid, electrolyte, and acid–base balance and alter the composition, distribution, or amount of body fluids. Even small changes in pH, electrolyte concentrations, and fluid status can adversely impact cell function. If these alterations are not corrected, severe consequences or death can ensue.

BODY WATER

Water is the largest single component of the body. At birth, water is at the highest proportion that it will be throughout the entire human life span and accounts for 75% to 85% of total body weight; this proportion decreases with age and adiposity. Water accounts for 60% to 70% of total body weight in the lean adult but only 45% to 55% in the obese adult. Metabolically active cells of the muscle and viscera have the highest concentration of water; calcified tissue cells have the lowest. Total body water is higher in athletes than in nonathletes, decreases with age, and decreases with diminished muscle mass. Although the

proportion of body weight accounted for by water varies with gender, age, and body fat, there is little day-to-day variation in an individual.

Functions

Water makes solutes available for cellular reactions, regulates body temperature, maintains blood volume, transports nutrients, and is involved with digestion, absorption, and excretion. Loss of 20% of body water (**dehydration**) may cause death; loss of only 10% may lead to damage to essential body systems. Even mild dehydration (loss of 1% to 2%) can lead to loss of cognitive function and alertness, an increase in heart rate, and a decrease in exercise performance (Murray, 2007). Healthy adults can live up to 10 days without water, and children can live up to 5 days, whereas a person can survive for several weeks without food.

Distribution

Total body water (TBW) is mainly distributed in the **intracellular fluid (ICF)** and **extracellular fluid (ECF)**. The transcellular fluid is comprised of 3% of TBW and is the small amount of fluid making up cerebral spinal, pericardial, and pleural fluids as well as fluid surrounding the eye. **ICF** is contained within cells and accounts for two-thirds of total body water. **ECF** accounts for the remaining one-third of total body water. **ECF** is the water and dissolved substances in the plasma and lymph, and also includes **interstitial fluid** (the fluid around the cells in tissues). While the distribution of body water varies under different circumstances, the total amount in the body remains relatively constant. Water intake of foods and beverages is balanced by water lost through urination, perspiration, feces, and respiration. Edema is the abnormal accumulation of fluid in the “**third space**,” including intercellular tissue spaces or body cavities. Fluid in the “third space” is isolated and therefore does not contribute to the functional duties of body water within the body.

CLINICAL INSIGHT

Edema

Edema is the abnormal accumulation of interstitial fluid volume in the “third space,” including intercellular tissue spaces or body cavities, that leads to a palpable and/or visible swelling. Fluid in the “third space” is isolated and therefore does not contribute to the functional duties of body water within the body.

The causes of edema can be multifactorial and have four main causes that impact fluid balance (Fig. 3.1).

1. Decrease in **oncotic pressure** (the pressure at the capillary membrane): Circulating plasma proteins decrease in states like protein losing enteropathy, nephrotic syndrome, or liver disease. Circulating proteins normally draw water into the vascular space, but with less circulating proteins there is a decrease in colloid pressure (albumin is the largest contributor to oncotic pressure).
2. Increase in the permeability of the capillaries: Allows protein leaks into the interstitial space, thereby attracting more water out of the vascular space. This can be seen in acute respiratory distress syndrome, trauma, burns, or inflammation.
3. Increase in **hydrostatic pressure**: The force from the increased pressure or blood volume pushes fluid into the interstitial space as seen in disease states such as cirrhosis, congestive heart failure, renal failure, or venous thrombosis.
4. Lymphatic dysfunction: **Lymph edema** is usually localized to specific areas of the body when there is an obstruction of the lymphatic vessels. It occurs

when fluid and protein cannot return to circulation, and the trapped protein-rich lymph fluid attracts water. Lymph edema can be seen in cancer patients who have had surgery for lymph node dissection.

Edema is graded based on severity (grades 1, 2, 3, 4+) and can be classified as pitting or nonpitting. If pressure is applied by a finger or thumb to an area with edema, it is classified as pitting edema when an impression or “pit” remains after the finger is removed (Fig. 3.2).

Edema is typically referred to by the location it is present (e.g., pedal edema when present in the feet or peripheral edema when found in the extremities). Edema can also be further categorized as dependent, independent, or generalized. Dependent edema is characterized by the accumulation of fluid in inferior areas. For example, a patient on bed rest with peripheral edema and elevated legs/feet may experience dependent edema in the sacrum and hips with the fluid shifting to an inferior area of the body. Generalized edema is not confined to one area rather fluid accumulates all throughout the body. In contrast, independent edema is isolated to one area of the body (Ratliff, 2015).

When conducting nutrition focused physical examination as part of the nutrition assessment, it's important to evaluate both sides of the body, left and right, for the presence or absence of edema since edema can be unilateral or bilateral.

Water Balance

Water movement is dictated by hydrostatic pressure, diffusion, osmosis, and active transport. Water moves in and out of the ICF and ECF based on the **osmolarity** (ability for osmotic pressure to move fluid between compartments) to obtain equilibrium. Osmotic pressure is directly proportional to the number of particles in the

solution and usually refers to the pressure at the cell membrane. The sodium-potassium adenosine triphosphatase pump (**Na/K-ATPase pump**) plays a key role in regulating water balance. In simple terms, osmotic pressure of the ICF is a function of its potassium content because potassium is the predominant intracellular cation. The osmotic pressure of ECF is relative to the sodium content because

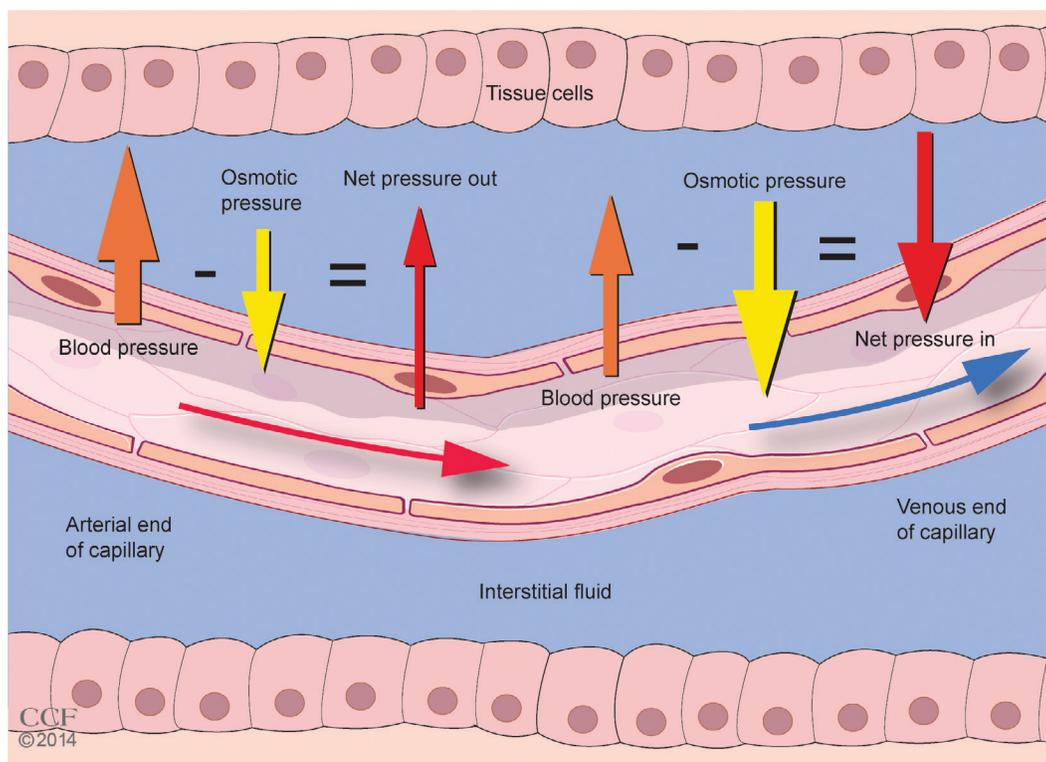

Fig. 3.1 Effects of Intravascular and Interstitial Pressure on Fluid Movement

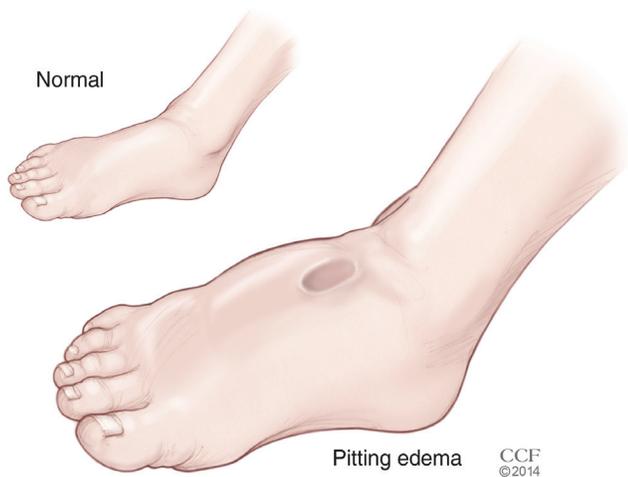

Fig. 3.2 Pitting Edema

sodium is the major extracellular cation. Although variations in the distribution of sodium and potassium ions are the principal causes of water shifts between the various fluid compartments, chloride and phosphate also are involved with water balance (see the electrolyte section later in this chapter).

Osmolality is a measure of the osmotically active particles per kilogram of the solvent in which the particles are dispersed. The average sum of the concentration of all the cations in serum is approximately 150 mEq/L. The cation concentration is balanced by 150 mEq/L of anions, yielding a total serum osmolality of approximately 300 mOsm/L. Osmolality or tonicity are words used interchangeably in clinical practice. Normal osmolality or tonicity is 280 to 300 mOsm and values above or below this range are termed hypotonic (typically a sign of water excess) or hypertonic (often a sign of water deficit).

Shifts in water balance can have adverse consequences. Body water is regulated by the gastrointestinal (GI) tract, kidneys, and brain, which keeps body water content fairly constant. Skin, the body's largest organ, also plays a role in regulating temperature and body water. In general, the amount of water intake is approximately equivalent to output each day.

Mechanisms to maintain water equilibrium come from a number of hormones including **antidiuretic hormone** (aka **vasopressin**), aldosterone, angiotensin II, cortisone, norepinephrine, and epinephrine (Canada et al, 2015). Increased serum osmolality or decreased blood volume leads to the release of antidiuretic hormone which signals the kidneys to conserve water. In the presence of low ECF volume, the kidneys release renin to produce angiotensin II (the **renin-angiotensin system**). Angiotensin II has several functions, including stimulation of vasoconstriction and the thirst centers.

Water Intake

Thirst is regulated by the hypothalamus and controls water intake in healthy individuals. Sensitivity to thirst is decreased in older individuals, chronically or acutely ill patients, infants, and athletes leading to a higher potential for water deficits. Sources of water include fluids (oral, enteral tube feeding, parenteral fluids), food, and oxidative metabolism (Tables 3.1, 3.2, and 3.3). The oxidation of foods in the body produces **metabolic water** as an end product. The oxidation of 100 g of fat, carbohydrate, or protein yields 107, 55, or 41 g of water, respectively,

TABLE 3.1 Content of Common Intravenous Fluids

Fluid	Dextrose (g/L)	Sodium (mEq/L)	Chloride (mEq/L)	Additional Components (mEq/L)
0.45% NaCl	0	77	77	n/a
0.9% NaCl	0	154	154	n/a

for a total of approximately 200 to 300 mL/day (Whitmire, 2008; Canada, 2015).

Tonicity of body fluids can be measured (serum osmolality) or estimated from the following formula:

$$\text{Osmolality (mOsm)} = (2 \times \text{Serum sodium mEq/L}) + (\text{BUN mg/dL}) + (\text{Blood glucose mg/dL})$$

TABLE 3.3 Water Content of Enteral Nutrition Formulations

Enteral Formula Concentration	Percentage of Free Water

1.2 kcal/mL	81%
1.5 kcal/mL	76%
2.0 kcal/mL	69%

CLINICAL INSIGHT**Osmotic Forces**

Osmotic pressure is directly proportional to the number of particles in solution and usually refers to the pressure at the cell membrane. Osmotic pressure of intracellular fluid is a function of its potassium content because potassium is the predominant cation there. In contrast, the osmotic pressure of extracellular fluid (ECF) may be considered relative to its sodium content because sodium is the major cation present in ECF. Although variations in the distribution of sodium and potassium ions are the principal causes of water shifts between the various fluid compartments, chloride and phosphate also influence water balance. Proteins cannot diffuse because of their size and thus also play a key role in maintaining osmotic equilibrium. **Oncotic pressure**, or **colloidal osmotic pressure**, is the pressure at the capillary membrane. It is maintained by dissolved proteins in the plasma and interstitial fluids. Oncotic pressure helps retain water within blood vessels, preventing its leakage from plasma into the interstitial spaces. In patients with an exceptionally low plasma protein content, such as those who are under physiologic stress or have certain diseases, water leaks into the interstitial spaces, causing edema or third spacing; thus the fluid is called **“third space” fluid**.

Osmoles and Milliosmoles

Concentrations of individual ionic constituents of extracellular or intracellular fluids are expressed in terms of milliosmoles per liter (mOsm/L). One mole equals the gram molecular weight of a substance; when dissolved in 1 L of water, it becomes 1 osmole (Osm). One milliosmole (mOsm) equals 1/1000th of an osmole.

Osmolality is a measure of the osmotically active particles per kilogram of the solvent in which the particles are dispersed. It is expressed as milliosmoles of solute per kilogram of solvent (mOsm/kg). **Osmolarity** is the term formerly used to describe concentration—milliosmoles per liter of the entire solution—but osmolality is now the measurement for most clinical work. However, in reference to certain conditions such as hyperlipidemia, it makes a difference whether osmolality is stated as milliosmoles per kilogram of solvent or per liter of solution.

The average sum of the concentration of all the cations in serum is about 150 mEq/L. The cation concentration is balanced by 150 mEq/L of anions, yielding a total serum osmolality of about 300 mOsm/L. An osmolar imbalance is caused by a gain or loss of water relative to a solute. An osmolality of less than 285 mOsm/L generally indicates a water excess; an osmolality of greater than 300 mOsm/L indicates a water deficit.

Water Intoxication and Fluid Overload

Water intoxication occurs as a result of water intake in excess of the body’s ability to excrete water. The increased **ICF** volume is accompanied by osmolar dilution. The increased volume of ICF causes the cells, particularly the brain cells, to swell, leading to headache, nausea, vomiting, muscle twitching, blindness, and convulsions with impending stupor. If left untreated, water intoxication can be fatal. Water

intoxication is not commonly seen in normal, healthy individuals. It may be seen in endurance athletes who consume large amounts of electrolyte-free beverages during events, individuals with psychiatric illness, or as a result of water drinking contests (Adetoki et al, 2013).

Fluid overload, or **hypervolemia**, occurs when excess fluid accumulation is present within the body, leading to excess in circulating blood volume. This may occur as a result of excess fluid intake (via oral, enteral, or parenteral route), injury or illness causing stress to the body, or diagnoses such as kidney, heart, or liver disease. Symptoms of fluid overload may often include generalized or localized swelling, sudden weight gain, dyspnea, orthopnea, pulmonary congestion, or modifications in arterial pressures. Treatment for fluid overload is often dictated by the inherent cause; options may include reduction in fluid intake, diuretic therapy, and sodium restriction.

Water Elimination

Water loss normally occurs through the kidneys as urine and through the GI tract in the feces (measurable, **sensible water loss**), as well as through air expired from the lungs and water vapor lost through the skin (nonmeasurable, **insensible water loss**). The kidney is the primary regulator of sensible water loss. Under normal conditions the kidneys have the ability to adjust to changes in body water composition by either decreasing or increasing water loss in the urine. Natural diuretics are substances in the diet that increase urinary excretion, such as alcohol and caffeine.

Insensible water loss is continuous and usually unconscious. High altitude, low humidity, and high temperatures can increase insensible fluid loss through the lungs and through sweat. Athletes can lose 6% to 10% of body weight in sweat loss and fluids need to be replaced. Dehydration leads to an increase in core body temperature, which rises 0.15 to 0.20° C for every 1% of body weight lost due to sweating (Casa et al, 2000). In high-risk conditions, it is suggested athletes evaluate pre- and post-activity fluid loss and consume 1 to 1.25 L of fluid for each 1 kg of body water lost during exercise (Binkley, 2002).

The GI tract can be a major source of water loss (Fig. 3.3). Under normal conditions the water contained in the 7 to 9 L of digestive juices and other ECFs secreted daily into the GI tract is reabsorbed almost entirely in the ileum and colon, except for about 100 mL that is excreted in the feces. Because this volume of reabsorbed fluid is about twice that of the blood plasma, excessive GI fluid losses through diarrhea may have serious consequences, particularly for very young and very old individuals.

Choleric diarrhea, acute diarrhea caused by contaminated food or water containing the bacteria *vibrio cholera*, is responsible for the loss of many lives in developing countries and hydration can be corrected without intravenous fluids. Oral rehydration solution, an isotonic fluid, is a simple mixture of water, sugar, and salt and is highly effective in improving hydration status (Parrish and DiBaise, 2015). Other abnormal fluid losses may occur as a result of emesis, hemorrhage, fistula drainage, burn and wound exudates, gastric and surgical tube drainage, and the use of diuretics.

When water intake is insufficient or water loss is excessive, healthy kidneys compensate by conserving water and excreting more concentrated urine. The renal tubules increase water reabsorption in response to the hormonal action of vasopressin. However, the concentration of the urine made by the kidneys has a limit: approximately 1400 mOsm/L. Once this limit has been reached, the body loses its ability to excrete solutes. The ability of the kidneys to concentrate urine may be compromised in older individuals or in young infants, resulting in increased risk of developing dehydration or hypernatremia, especially during illness.

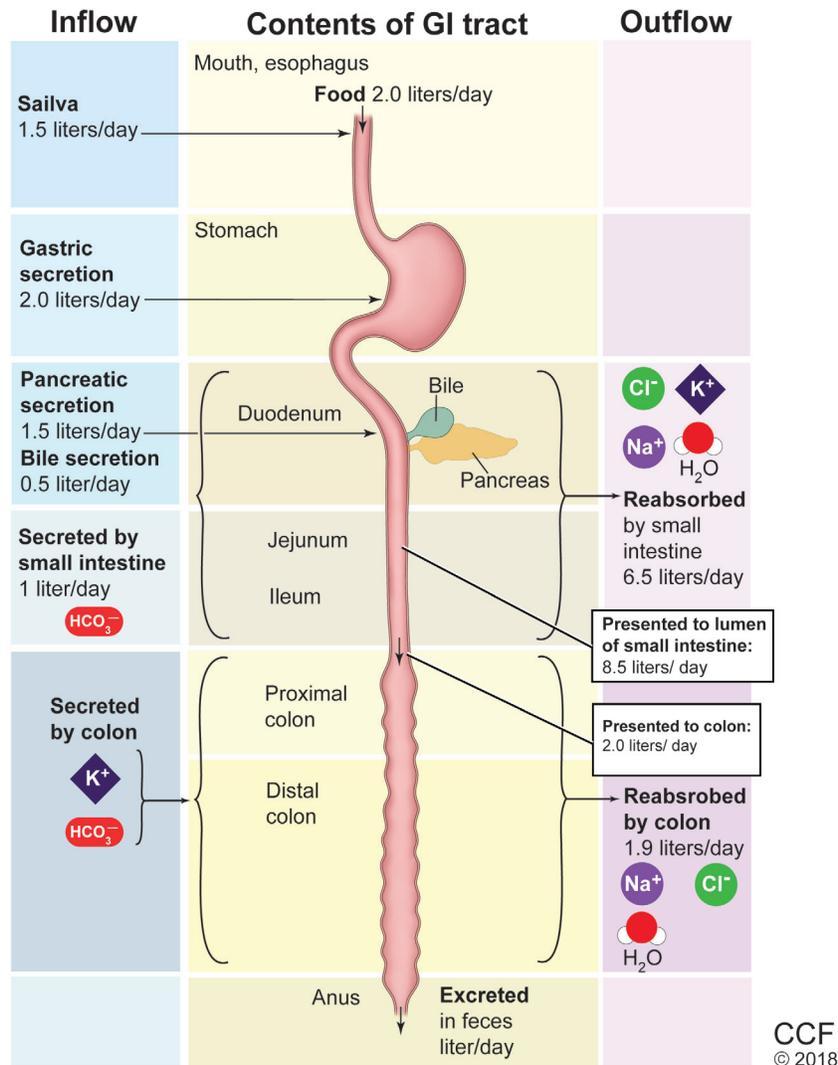

Fig. 3.3 Content of Gastrointestinal Secretions

Signs of dehydration include headache, fatigue, decreased appetite, lightheadedness, poor skin turgor (although this may be present in well-hydrated older persons), skin tenting on the forearm, concentrated urine, decreased urine output, sunken eyes, dry mucous membranes of the mouth and nose, orthostatic blood pressure changes, and tachycardia. In a dehydrated person the specific gravity, a measure of the dissolved solutes in urine, increases above the normal levels, and the urine becomes remarkably darker.

High ambient temperature and dehydration adversely affect exercise performance. Fluids of appropriate composition in appropriate amounts are essential (see *Clinical Insight: Water Requirements: When Eight Is Not Enough*).

Clinical Assessment of Fluid Status

A variety of methods to estimate fluid requirements are based on age, caloric intake, and weight. Obesity has led to challenges with using weight-based calculations for fluid requirements, as water accounts for only 45% to 55% of body weight for patients with lower proportions of lean body mass. In clinical practice, fluid estimations should be individualized to each patient, especially those with cardiac, liver, or renal failure, and in the presence of ongoing high-volume GI losses.

In most cases a suitable daily water intake (fluids and including foods) is approximately 3.7 L (15.5 cups) for adult males and 2.7 L (11+ cups) for adult females, depending on body size (*Institute of Medicine of the National Academies, 2005*). Because solid food provides 19% of total daily fluid intake, this equals 750 mL of water or approximately 3 cups daily. When this is added to the 200 to 300 mL (about 1 cup) of water contributed by oxidative metabolism, men should consume about 11.5 cups and women need 7 cups of fluids daily. Total fluid intake comes from drinking water, other liquids, and food; the adequate intake (AI) for water is for total daily water intake and includes all dietary water sources.

Unfortunately there is no gold standard to assess hydration status. Clinicians must carefully assess data from a variety of sources, including physical examination by the medical team, nutrition-focused physical examinations, imaging reports (e.g., identifying abnormal fluid collections within the lungs, ascites), laboratory studies (i.e., serum sodium), subjective report of symptoms from patients, sudden weight changes, medications, and vital signs. In clinical settings it is important to acknowledge all sources of fluid delivery (oral, enteral feeding tube, intravenous fluids, parenteral nutrition, and intravenous fluids given with medications) and all sources of fluid losses including

CLINICAL INSIGHT**Water Requirements: When Eight Is Not Enough**

There is no storage form of water, and therefore fluid requirements and fluid losses must be maintained at equilibrium. Often clinicians quickly estimate fluid requirements based on energy requirements (1 mL/kcal for adults and 1.5 mL/kcal for infants) or approximately 35 mL/kg of usual body weight in nonobese adults, 50 to 60 mL/kg in children, and 150 mL/kg in infants.

At certain points within the lifecycle, the body will naturally require more fluid. Infants need more water because of the limited capacity of the kidneys to handle a large renal solute load, higher percentage of body water, and large surface area per unit of body weight. A lactating woman's need for water also increases, approximately 2 ½ to 3 cups per day for milk production.

Knowledge of disease states also helps in determining when higher fluid requirements may occur. Fluid intake should exceed the excretion of sensible and insensible losses in order to prevent dehydration. In patients with Short Bowel Syndrome (SBS), inadequate absorption of fluid can lead to dehydration. SBS patients with an enterostomy (or colon not connected to the small bowel) often have increased fluid requirements and are at an increased risk of dehydration if too much stool is lost due to malabsorption. Like children with infectious diarrhea in developing countries, SBS patients benefit from the use of oral rehydration solutions by mouth, in order to utilize the active co-transport of sodium and glucose molecules at the intestinal brush border, which helps maintain hydration (Matarese, 2005). Use of oral rehydration solution sipped throughout the day and separating fluids from meals can be helpful strategies for helping SBS patients maintain their hydration status. When oral intake alone is not sufficient to prevent dehydration, parenteral fluids may be needed. Use of parental fluids can be temporary (e.g., due to an acute event such as a urinary tract infection in an elderly adult) or chronic for certain disease states (e.g., SBS or gastrointestinal fistula).

Fluid needs of hospitalized patients should be individualized and adequacy of fluid intake assessed from physical examination by the medical team, nutrition-focused physical examinations, imaging reports, laboratory studies (Na, BUN, Cr, Hgb/Hct, albumin, etc.), subjective report of symptoms from patients, sudden weight changes, medications, and vital signs.

urine, diuretic medications, and GI secretions (e.g., emesis, gastric secretions, surgical drains, stool, fistulas) (Popkin et al, 2010).

Of note, thirst is not an effective signal to consume fluids in infants, heavily exercising athletes (Casa, 2015), individuals in extreme heat, sick individuals, and older adults who may have a diminished thirst sensation. Hospitalized patients, regardless of the diagnosis, are at risk for water and electrolyte imbalance. Older adults are particularly susceptible because of factors such as impaired renal concentrating ability, fever, diarrhea, vomiting, and a decreased ability to care for themselves.

ELECTROLYTES

Electrolytes are minerals with electric charges that dissociate in a solution into positive or negatively charged ions. Electrolytes can be simple inorganic salts of sodium, potassium, or magnesium, or complex organic molecules; they play a key role in a host of normal metabolic functions (Table 3.4). One milliequivalent (mEq) of any substance has the capacity to combine chemically with 1 mEq of a substance with an opposite charge. For univalent ions (e.g., Na⁺), 1 millimole (mmol) equals 1 mEq; for divalent ions (e.g., Ca⁺⁺), 1 mmol equals 2 mEq (see Appendix 1 for conversion guidelines).

The major **extracellular** electrolytes are sodium, calcium, chloride, and bicarbonate. Potassium, magnesium, and phosphate are the major **intracellular** electrolytes. These elements, which exist as ions in body

TABLE 3.4 Electrolyte Classification

Electrolyte	Location
Cations	
Sodium	Extracellular cation
Potassium	Intracellular cation
Calcium	Extracellular cation
Magnesium	Intracellular cation
Anions	
Chloride	Extracellular Anion
CO ₂	Extracellular Anion
Phosphorus (inorganic)	Intracellular Anion

fluids, are distributed throughout all body fluids. Electrolytes are responsible for maintenance of physiologic body functions, cellular metabolism, neuromuscular function, and osmotic equilibrium. Although oral intake varies, homeostatic mechanisms regulate the concentrations of electrolytes throughout the body.

Changes in either intracellular or extracellular electrolyte concentrations can have a major impact on bodily functions. The **Na/K-ATPase pump** closely regulates cellular electrolyte contents by actively pumping sodium out of cells in exchange for potassium. Other electrolytes follow ion gradients (gradient of electrical potential for movement across a membrane).

Calcium

Although approximately 99% of the body's calcium (Ca⁺⁺) is stored in the skeleton (bones and teeth), the remaining 1% has important physiologic functions. Ionized Ca⁺⁺ within the vascular compartment is a cation with a positive charge. Approximately half of the Ca⁺⁺ found in the intravascular compartment is bound to the serum protein albumin. Thus, when serum albumin levels are low, total Ca⁺⁺ levels decrease because of hypoalbuminemia.

The binding ability of Ca⁺⁺ and its ionized content in blood have implications for normal homeostatic mechanisms. Blood tests for Ca⁺⁺ levels often measure total and ionized Ca⁺⁺ levels. Ionized (or free, unbound) Ca⁺⁺ is the active form of Ca⁺⁺ and is not impacted by hypoalbuminemia. In healthy adults, normal levels for serum total Ca⁺⁺ are about 8.5 to 10.5 mg/dL, whereas normal levels for ionized Ca⁺⁺ are 4.5 to 5.5 mEq/L (refer to the reference ranges for each reporting laboratory).

Functions

Ca⁺⁺ is an extracellular cation necessary for blood clotting; Ca⁺⁺ regulates nerve transmission, muscle contraction, bone metabolism, and blood pressure regulation. Ca⁺⁺ is regulated by parathyroid hormone (PTH), calcitonin, vitamin D, and phosphorus. Through a complex system of regulation among multiple organs, including the kidney, GI tract, and bone, Ca⁺⁺ absorption can be enhanced to increase Ca⁺⁺ reabsorption to maintain homeostasis. When serum Ca⁺⁺ levels are low, PTH causes release of Ca⁺⁺ from the bones and stimulates increased absorption from the GI tract. Calcitonin works in the opposite direction, shutting off the release of Ca⁺⁺ from the bone and decreasing GI absorption. Vitamin D stimulates while phosphorus inhibits Ca⁺⁺ absorption in the GI tract.

In the setting of hypoalbuminemia, serum Ca⁺⁺ levels are not accurate because nearly 50% of Ca⁺⁺ is protein bound. An ionized Ca⁺⁺ level is the most accurate assay for Ca⁺⁺ because it is the active form and is not affected by protein levels. In healthy adults, normal levels for serum total Ca⁺⁺ are approximately 8.5 to 10.5 mg/dL, whereas normal

levels for ionized Ca^{++} are 4.5 to 5.5 mEq/L (refer to the reference ranges for each reporting laboratory). When ionized Ca^{++} levels are not available, a simple formula may be used. The **corrected calcium** formula accounts for a 0.8 mg/dL decrease in Ca^{++} for each 1 g/dL decrease in serum albumin below 4 g/dL. The corrected calcium formula is

$$([4 - \text{Serum albumin (g/dL)}] \times 0.8) + \text{Measured calcium (mg/dL)}$$

Ionized Ca^{++} levels are altered inversely by changes in acid–base balance; as serum pH rises, Ca^{++} binds with protein, leading to decreased ionized Ca^{++} levels. As pH is lowered, the opposite occurs. Because Ca^{++} has an important role in cardiac, nervous system, and skeletal muscle function, hypocalcemia and hypercalcemia can become life threatening.

Common causes of hypercalcemia are cancer with the presence of bone metastases or hyperparathyroidism, when there is a large amount of Ca^{++} moved into the ECF. Symptoms of hypercalcemia include lethargy, nausea, vomiting, muscle weakness, and depression. Treatment usually is directed at treating the underlying cause of the problem, discontinuing Ca^{++} -containing medications, and increasing the excretion of Ca^{++} through the kidneys (by delivery of intravenous fluids followed by diuretic medications).

Hypocalcemia often is marked with numbness or tingling, hyperactive reflexes, tetany, lethargy, muscle weakness, confusion, and seizures. Causes of hypocalcemia include low serum phosphorus or magnesium levels, medications that cause Ca^{++} losses, hypoalbuminemia, vitamin D deficiency, or hypoparathyroidism. Oral Ca^{++} supplements are most often the first-line therapy in the absence of symptoms. Because other hormones, electrolytes, and vitamins are involved in Ca^{++} regulation, these are assessed in the setting of true hypocalcemia. Low phosphorus and magnesium levels must be replete before Ca^{++} levels can be corrected (Rhoda et al, 2011).

Absorption and Excretion

Approximately 20% to 60% of dietary Ca^{++} is absorbed and is tightly regulated because of the need to maintain steady serum Ca^{++} levels in the face of fluctuating intake. The ileum is the most important site of Ca^{++} absorption. Ca^{++} is absorbed via passive transport and through a vitamin D–regulated transport system.

The kidney is the main site of Ca^{++} excretion. The majority of serum Ca^{++} is bound to proteins and not filtered by the kidneys; only about 100 to 200 mg/day is excreted in the urine in normal adults. Ca^{++} is also excreted through sweat and feces.

Sources

Dairy products are the main source of Ca^{++} in the American diet, with some green vegetables, nuts, legumes, canned fish including bones, and Ca^{++} -enriched tofu having moderate amounts of Ca^{++} . Food manufacturers fortify many foods with additional Ca^{++} , such as orange juice that may have some bioavailability (see Appendix 39).

Recommended Intakes

In adults, recommended intakes of Ca^{++} range from 1000 to 1300 mg/day, depending on age and gender. An upper limit for Ca^{++} intake has been estimated to be approximately 2500 to 3000 mg/day (see inside cover). Excessive intake of Ca^{++} may lead to kidney stones and gastrointestinal side effects like constipation.

Sodium

Sodium (Na^+) is the major cation of ECF with a normal range of 135 to 145 mEq/L (refer to the reference ranges for each reporting laboratory). Secretions such as bile and pancreatic juice contain substantial amounts of Na^+ . Gastric secretions and diarrhea also contain Na^+ , but contrary to common belief, sweat is hypotonic and contains

a relatively small amount of Na^+ . Approximately 35% to 40% of the total body Na^+ is in the skeleton and the remainder is in body fluids.

Functions

As the predominant ion of the ECF, Na^+ thus regulates extracellular and plasma volume. Na^+ is also important in neuromuscular function and maintenance of acid–base balance. Maintenance of serum Na^+ levels is vital, because severe **hyponatremia** can lead to seizures, coma, and death.

Extracellular Na^+ concentrations are much higher than intracellular levels (normal serum Na^+ is around 135 mEq/L, whereas intracellular levels are around 10 mEq/L). The sodium–potassium ATP pump is an active transport system that works to keep Na^+ outside the cell through exchange with potassium. The Na/K-ATPase pump requires carriers for Na^+ and potassium along with energy for proper function. Exportation of Na^+ from the cell is the driving force for facilitated transporters, which import glucose, amino acids, and other nutrients into the cells.

Hyponatremia. Assessing hyponatremia or hypernatremia takes into consideration the role of Na^+ in regulating fluid balance and requires evaluation of overall hydration status. Hyponatremia is one of the most common electrolyte disorders among hospitalized patients and occurs in 25% of inpatients. When hyponatremia is below 125 mEq/L, symptoms generally become apparent. Patients may display signs of headache, lethargy, restlessness, decreased reflexes, seizures, or coma in extreme cases. There are three basic causes for hyponatremia. Hypertonic hyponatremia is due to excess delivery of mannitol or hyperglycemia, which causes serum Na^+ to increase by 1.6 mEq for every 100 mg/dL rise in serum glucose. Mannitol is sometimes used for the treatment of cerebral edema or kidney failure. It increases serum osmolality, which leads to dilutional hyponatremia from water movement out of the cells. Isotonic hyponatremia occurs in the presence of hyperlipidemia or hyperproteinemia, because the aqueous component that Na^+ is dissolved and results in a falsely low value (this is mainly a laboratory artifact and is not often seen in clinical practice). The final type is hypotonic hyponatremia. Evaluation depends on fluid status to evaluate the three subtypes.

Isovolemic hyponatremia can be caused by malignancies, adrenal insufficiency, or the syndrome of inappropriate antidiuretic hormone secretion (SIADH). SIADH (see Chapter 30) can result from central nervous system disorders, pulmonary disorders, tumors, and certain medications. The treatment is usually water restriction. Hypervolemic hypotonic hyponatremia is characterized by excess TBW and Na^+ (overall higher excess water than Na^+) because of reduced excretion of water or excess free water administration. Cardiac, renal, or hepatic failure are the most common causes, and patients have edema or ascites on physical examination. The treatment is fluid restriction or diuretics to aid in decreasing TBW, and oral Na^+ restriction also may be beneficial. The final type is hypovolemic hypotonic hyponatremia, characterized by a deficit in TBW and Na^+ that requires treatment with fluid replacement. Often fluid losses leading to hypovolemic hyponatremia include excessive vomiting, excessive sweating (marathon athletes), diarrhea, wound drainage/burns, high-volume gastrointestinal secretions, or excessive diuretic use. Equations to calculate fluid deficits can be used to replace half of the fluid deficit in the first 24 hours. Correcting Na^+ levels must be done slowly (max of 8 to 12 mEq in 24 hours) to prevent osmotic demyelinating syndrome that is seen with rapid correction (Rhoda et al, 2011).

Hypernatremia. A serum Na^+ level greater than 145 mEq/L is classified as hypernatremia, and there are various types. Hypovolemic hypernatremia is caused by a loss of Na^+ and TBW when water losses exceed Na^+ losses. It is important to identify the cause of the fluid losses so that they can be corrected and prevented in the future. The treatment is to slowly replace fluid volume with a hypotonic fluid solution. Hypervolemic hypernatremia is caused by excessive intake of Na^+

resulting in higher Na^+ gain than water gains. The treatment is to restrict Na^+ (especially in intravenous fluids) and possibly the use of diuretics. Isovolemic hyponatremia is seen with disease states such as diabetes insipidus. Signs of hyponatremia include lethargy, thirst, hyperreflexia, seizures, coma, or death. Formulas for calculating a water deficit are helpful to guide fluid replacement. Free water deficit is calculated as follows (Kingley, 2005):

$$[0.6 \times \text{Weight (kg)}] \times 1 - [140 / \text{Na (mEq/L)}]$$

Absorption and Excretion

Na^+ is absorbed readily from the intestine and carried to the kidneys, where it is filtered and returned to the blood to maintain appropriate levels. The amount absorbed is proportional to the intake in healthy adults.

About 90% to 95% of normal body Na^+ loss is through the urine; the rest is lost in feces and sweat. Normally the quantity of Na^+ excreted daily is equal to the amount ingested. Na^+ excretion is maintained by a mechanism involving the glomerular filtration rate, the cells of the juxtaglomerular apparatus of the kidneys, the renin-angiotensin-aldosterone system, the sympathetic nervous system, circulating catecholamines, and blood pressure.

Na^+ balance is regulated in part by aldosterone, a mineralocorticoid secreted by the adrenal cortex. When blood Na^+ levels rise, the thirst receptors in the hypothalamus stimulate the thirst sensation. Ingestion of fluids returns Na^+ levels to normal. Under certain circumstances Na^+ and fluid regulation can be disrupted, resulting in abnormal blood Na^+ levels. SIADH is characterized by concentrated, low-volume urine and dilutional hyponatremia as water is retained. SIADH can result from central nervous system disorders, pulmonary disorders, tumors, and certain medications. Common drug classes/medications include antidepressants, anticonvulsants, antipsychotic agents, cytotoxic agents, and pain medication are the common medications (Shepselovich et al, 2017).

Estrogen, which is slightly similar to aldosterone, also causes Na^+ and water retention. Changes in water and Na^+ balance during the menstrual cycle, during pregnancy, and while taking oral contraceptives are attributable partially to changes in progesterone and estrogen levels.

Dietary Reference Intake

The dietary reference intakes (DRIs) give an upper limit of 2.3 g of Na^+ per day (or 5.8 g sodium chloride per day). The mean daily salt intake in the United States is approximately 6 to 12 g/day (Institute of Medicine of the National Academies, 2005), which exceeds the adequate intake (AI) for Na^+ of 1.2 to 1.3 g per day for adult males and females (see Table 3.4).

Healthy kidneys are usually able to excrete excess Na^+ intake; however, persistent excessive Na^+ intake has been implicated in development of hypertension. In addition to its role in hypertension, excessive salt intake has been associated with increased urinary Ca^{++} excretion, kidney stones, and some cases of osteoporosis. Higher Na^+ consumption has been associated with higher weight status, and a positive relationship has been observed between Na^+ intake and obesity independent of energy intake (Song et al, 2013; Yoon, 2013; Zhu et al, 2014). In addition, a positive association has been identified between Na^+ intake and increased circulation of leptin (secreted by fat cells and influences inflammatory response and Na^+ excretion) and tumor necrosis factor alpha (plays a role in inflammation) (Zhu et al, 2014).

Sources

The major source of Na^+ is sodium chloride, or common table salt, of which Na^+ constitutes 40% by weight. Protein foods generally contain more naturally existing Na^+ than do vegetables and grains, whereas fruits contain little or none. The addition of table salt, flavored salts,

flavor enhancers, and preservatives during food processing accounts for the high Na^+ content of most convenience and fast-food products.

Magnesium

Magnesium is the second most prevalent intracellular cation. Approximately half of the body's magnesium is located in bone, whereas another 45% resides in soft tissue; only 1% of the body's magnesium content is in the ECF. Normal serum magnesium levels are about 1.6 to 2.5 mEq/L; however, about 70% of serum magnesium is free or ionized. The remainder is bound to proteins and is not active.

Function

Magnesium (Mg^{2+}) is an important cofactor in many enzymatic reactions in the body, bone metabolism, central nervous system, and cardiovascular function. Many of the enzyme systems regulated by Mg^{2+} are involved in nutrient metabolism and nucleic acid synthesis, leading to the body's need to carefully regulate Mg^{2+} status.

As with Ca^{++} , severe hypo- or hypermagnesemia can have life-threatening consequences. Physical symptoms of Mg^{2+} abnormalities are similar to those observed with other electrolyte deficiencies, and the challenges with serum measurements discussed earlier make assessment of Mg^{2+} status difficult. Symptoms of hypomagnesemia include muscle weakness, tetany, ataxia, nystagmus, and, in severe cases, ventricular arrhythmia. Frequent causes of hypomagnesemia include excessive stool losses (as seen in short bowel syndrome or malabsorption), inadequate Mg^{2+} in the diet (oral, enteral, or parenteral nutrition), intracellular shifts during refeeding syndrome (Box 3.1; see Chapter 12), acute pancreatitis, burns, alcoholism, diabetic ketoacidosis, and medications causing increased Mg^{2+} losses via the urine. Long-term use of proton pump inhibitors also may be a rare cause (Toh et al, 2015).

Often hypomagnesemia is treated with oral supplementation if no physical symptoms are noted. However, dietitians should monitor cautiously for diarrhea with oral Mg^{2+} supplements if they are not given in divided doses (such as magnesium oxide), which often can increase

BOX 3.1 Refeeding Syndrome

Refeeding syndrome is a metabolic response that can be seen upon reintroduction of nutrients to the body in patients that have been without adequate nutrition. Refeeding syndrome can impact patients with malnutrition or those previously well nourished with metabolic stress in the presence of significant illness.

During starvation, the body's metabolism shifts from using glucose to using fat as the main fuel source. When nutrients are provided to the body, there is a metabolic shift. An increase of insulin leads to this intracellular shift, and thus concentrations of electrolytes in the serum fall. Low levels of phosphorus, magnesium, and potassium can be seen, and there are significant risks of cardiac arrhythmia, neurological consequences (seizures, delirium, neuropathy), and respiratory failure. Fluid retention and thiamin deficiency can also occur.

Prevention of Refeeding Syndrome:

1. Patient screening for risk of refeeding syndrome
2. Slow reintroduction and advancement of calories provided from enteral or parenteral nutrition to patients
3. Clinical monitoring (for cardiac, neuro, respiratory, fluid status, etc.)
4. Laboratory monitoring of serum electrolytes and treatment of abnormalities

From Canada T, Tajchman SK, Tucker AM, et al, editors: *ASPEN Fluids, electrolytes and acid base disorders handbook*, Silver Spring, MD, 2015, ASPEN, pp 1–397; Skipper A: Refeeding syndrome or refeeding hypophosphatemia: a systematic review of cases, *Nutr Clin Pract* 27:34–40, 2012; Rhoda KM, Porter MJ, Quintini C: Fluid and electrolyte management: putting a plan in motion, *JPEN J Parenter Enteral Nutr* 35: 675–685, 2011; Kraft MD, Btaiche IF, Sacks GS: Review of the refeeding syndrome, *Nutr Clin Pract* 20:625–633, 2005.

Mg²⁺ losses through the stool. Increased losses through the stool is avoided with supplementation from salts such as magnesium gluconate, magnesium citrate, or magnesium lactate. Intravenous repletion with Mg²⁺ is required with symptomatic signs of deficiency or if serum levels are below 1 mg/dL.

Hypermagnesemia, a serum value greater than 2.5 mg/dL, can be due to excess supplementation or Mg²⁺-containing medications, severe acidosis, or dehydration. Treatment options include omission of Mg²⁺-containing medications and correction of the fluid imbalance.

Absorption/Excretion

Approximately 30% to 50% of Mg²⁺ ingested from the diet is absorbed (within the jejunum and ileum through passive and active transport mechanisms). Mg²⁺ is regulated by the intestine, kidney, and bone. Mg²⁺ absorption is regulated to maintain serum levels; if levels drop, more is absorbed and if levels increase, less is absorbed. The kidney is the major regulator of Mg²⁺ excretion, but some Mg²⁺ is also lost via the stool. As magnesium is a cofactor for the Na-K ATPase pump, low magnesium levels should be evaluated and corrected especially when hypokalemia is refractory to repletion (unable to regain a normal level despite delivery of appropriate repletion doses). The kidneys increase potassium excretion in response to hypomagnesemia.

Sources

Mg²⁺ is found in a variety of foods, making an isolated Mg²⁺ deficiency unlikely in otherwise healthy individuals. Highly processed foods tend to have lower Mg²⁺ content, whereas green leafy vegetables, nuts, seeds, legumes, and whole grains are good sources (see Appendix 43).

Dietary Reference Intakes

The recommended intake of Mg²⁺ in adults ranges from 310 to 420 mg/day, depending on age and gender (see inside cover).

Phosphorus

Phosphorus is the primary intracellular anion, and its role in adenosine triphosphate (ATP) is vital in energy metabolism. In addition, phosphorus is important in bone metabolism. About 80% of the body's phosphorus is found in bones. Normal levels for serum phosphorus are between 2.4 and 4.6 mg/dL (refer to the reference ranges for each reporting laboratory).

Functions

Large amounts of free energy are released when the phosphate bonds in ATP are split. In addition to this role, phosphorus is vital for cellular function in phosphorylation and dephosphorylation reactions, as a buffer in acid–base balance, and in cellular structure as part of the phospholipid membrane. Because of the vital role that phosphorus plays in energy production, severe hypophosphatemia can be a life-threatening event. This is seen most often clinically in refeeding syndrome and occurs with the increased use of phosphorus for the phosphorylation of glucose (Skipper, 2012; Rhoda et al, 2011; Kraft et al, 2005). In addition to intracellular shifts, hypophosphatemia can be medication related (insulin, epinephrine, dopamine, erythropoietin, phosphorus-binding medications). Severe and symptomatic hypophosphatemia (<1 mg/dL) can be critical and includes impaired cardiac function, reduced contractions of the diaphragm leading to a weakened respiratory state, confusion, reduced oxygen delivery to tissues, coma, and even death.

Absorption and Excretion

Phosphorus absorption is dependent on serum levels and vitamin D status. Around 80% of phosphorus intake is absorbed in the small

bowel when hypophosphatemia is present. The kidney is the major site of phosphorus excretion and regulates phosphorus absorption based on PTH and acid–base status. Phosphorus absorption decreases when vitamin D deficiency occurs or with certain medications that bind phosphorus (e.g., antacids or phosphate binders used in patients with chronic kidney disease).

Sources

Phosphorus is found mainly in animal products, including meats and milk; dried beans, soda, processed foods, baked goods, and seafood or meats soaked in phosphate solutions are common dietary sources in the American diet.

Dietary Reference Intakes

The recommended intake of phosphorus is approximately 700 mg/day, depending on age and gender, with an upper limit of 3500 to 4000 mg (see inside cover).

Potassium

With approximately 98% of potassium (K⁺) in the intracellular space, K⁺ is the major cation of ICF. The normal serum K⁺ concentration is typically 3.5 to 5 mEq/L (refer to the reference ranges for each reporting laboratory).

Functions

With Na⁺, K⁺ is involved in maintaining a normal water balance, osmotic equilibrium, and acid–base balance. In addition to Ca⁺⁺, K⁺ is important in the regulation of neuromuscular activity. Concentrations of Na⁺ and K⁺ determine membrane potentials in nerves and muscle. K⁺ also promotes cellular growth. The K⁺ content of muscle is related to muscle mass and glycogen storage; therefore if muscle is being formed, an adequate supply of K⁺ is essential. K⁺ has an integral role in the Na/K-ATPase pump.

Hypokalemia and hyperkalemia can have devastating cardiac implications. When hypokalemia is less than 3 mEq/L, symptoms are more apparent and critical. Symptoms of hypokalemia include muscle weakness, cramping in the extremities, vomiting, and weakness. Clinically, hypokalemia occurs with large volume losses of gastrointestinal fluids that contain K⁺, insulin delivery, excessive losses through the urine caused by certain medications (diuretics), and diabetic ketoacidosis. Guidelines exist for the treatment of hypokalemia (oral or intravenous medications) and are adjusted in renal impairment because K⁺ is excreted by the kidneys.

Hyperkalemia can be critical, especially when levels exceed 6.5 mEq/L and are accompanied by symptoms of muscle weakness, paralysis, respiratory failure, and arrhythmias/ECG changes. Causes of hyperkalemia in a clinical setting include hemolysis causing falsely elevated laboratory results, kidney disease impairing K⁺ excretion, medications such as K⁺-sparing diuretics, gastrointestinal hemorrhage, rhabdomyolysis, catabolism, metabolic acidosis, or overzealous K⁺ supplementation.

Absorption and Excretion

K⁺ is absorbed readily from the small intestine. Approximately 80% to 90% of ingested K⁺ is excreted in the urine; the remainder is lost in the feces. The kidneys maintain normal serum levels through their ability to filter, reabsorb, and excrete K⁺ under the influence of aldosterone. In the setting of hypokalemia, aldosterone secretions are lower, and the kidneys shift to reabsorb K⁺ and excrete Na⁺.

Sources

K⁺-rich food sources include fruits, vegetables, legumes, fresh meat, and dairy products. Salt substitutes commonly contain K⁺. **Box 3.2**

BOX 3.2 Classification of Select Foods by Potassium Content

Low (0-100 mg/serving)*	Medium (100-200 mg/serving)*	High (200-300 mg/serving)*	Very High (>300 mg/serving)*
Fruits	Fruits	Fruits	Fruits
Applesauce	Apple, 1 small	Apricots, canned	Avocados, ¼ small
Blueberries	Apple juice	Grapefruit juice	Banana, 1 small
Cranberries	Apricot nectar	Kiwi, ½ medium	Cantaloupe, ¼ small
Lemon, ½ medium	Blackberries	Nectarine, 1 small	Dried fruit, ¼ cup
Lime, ½ medium	Cherries, 12 small	Orange, 1 small	Honeydew melon, ⅛ small
Pears, canned	Fruit cocktail	Orange juice	Mango, 1 medium
Pear nectar	Grape juice	Peach, fresh, 1 medium	Papaya, ½ medium
Peach nectar	Grapefruit, ½ small	Pear, fresh, 1 medium	Prune juice
Vegetables	Grapes, 12 small	Vegetables	Vegetables
Cabbage, raw	Mandarin oranges	Asparagus, fresh, cooked, 4 spears	Artichoke, 1 medium
Cucumber slices	Peaches, canned	Beets, fresh, cooked	Bamboo shoots, fresh
Green beans, frozen	Pineapple, canned	Brussels sprouts	Beet greens, ¼ cup
Leeks	Plum, 1 small	Kohlrabi	Corn on the cob, 1 ear
Lettuce, iceberg, 1 cup	Raspberries	Mushrooms, cooked	Chinese cabbage, cooked
Water chestnuts, canned	Rhubarb	Okra	Dried beans
Bamboo shoots, canned	Strawberries	Parsnips	Potatoes, baked, ½ medium
	Tangerine, 1 small	Potatoes, boiled or mashed	Potatoes, French fries, 1 oz
	Watermelon, 1 cup	Pumpkin	Spinach
	Vegetables	Rutabagas	Sweet potatoes, yams
	Asparagus, frozen	Miscellaneous	Swiss chard, ¼ cup
	Beets, canned	Granola	Tomato, fresh, sauce, or juice; tomato paste, 2 tbsp
	Broccoli, frozen	Nuts and seeds, 1 oz	Winter squash
	Cabbage, cooked	Peanut butter, 2 tbsp	Miscellaneous
	Carrots	Chocolate, 1.5-oz bar	Bouillon, low sodium, 1 cup
	Cauliflower, frozen		Cappuccino, 1 cup
	Celery, 1 stalk		Chili, 4 oz
	Corn, frozen		Coconut, 1 cup
	Eggplant		Lasagna, 8 oz
	Green beans, fresh, raw		Milk, chocolate milk, 1 cup
	Mushrooms, fresh, raw		Milkshakes, 1 cup
	Onions		Molasses, 1 tbsp
	Peas		Pizza, 2 slices
	Radishes		Salt substitutes, ¼ tsp
	Turnips		Soy milk, 1 cup
	Zucchini, summer squash		Spaghetti, 1 cup
			Yogurt, 6 oz

*One serving equals ½ cup unless otherwise specified

categorizes select foods according to their K^+ content. When evaluating K^+ sources and losses, clinicians must consider other nonfood sources of K^+ , such as intravenous fluids with added K^+ , certain medications containing K^+ , and medications that may cause the body to excrete K^+ .

Dietary Reference Intakes

The adequate intake level for K^+ for adults is 4700 mg/day. No upper limit has been set. K^+ intake is inadequate in a large number of Americans, as many as 50% of adults. The reason for the poor K^+ intake is simply inadequate consumption of fruits and vegetables. Insufficient K^+ intake has been linked to hypertension and cardiac arrhythmia.

ACID–BASE BALANCE

An acid is any substance that tends to release hydrogen ions in solution, whereas a base is any substance that tends to accept hydrogen ions in solution. The hydrogen ion concentration (H^+) determines acidity.

Because the magnitude of H^+ is small compared with that of other serum electrolytes, acidity is expressed more readily in terms of pH units. A low blood pH indicates a higher H^+ and greater acidity, whereas a high pH value indicates a lower H^+ and greater alkalinity.

Acid–base balance is the dynamic equilibrium state of H^+ . Maintaining the arterial blood pH level within the normal range of 7.35 to 7.45 is crucial for many physiologic functions and biochemical reactions. Regulatory mechanisms of the kidneys, lungs, and buffering systems enable the body to maintain the blood pH level despite the enormous acid load from food consumption and tissue metabolism. A disruption of the acid–base balance occurs when acid or base losses or gains exceed the body's regulatory capabilities or when normal regulatory mechanisms become ineffective. These regulatory disturbances may develop in association with certain diseases, toxin ingestion, shifts in fluid status, and certain medical and surgical treatments (Table 3.5). If a disrupted acid–base balance is left untreated, multiple detrimental effects ranging from electrolyte abnormalities to death can ensue.

TABLE 3.5 Four Major Acid–Base Imbalances

Acid-base Imbalance	pH	Primary Disturbance	Compensation	Possible Causes
Respiratory				
Respiratory acidosis	Low	Increased pCO ₂	Increased renal net acid excretion with resulting increase in serum bicarbonate	Emphysema; COPD; neuromuscular disease where respiratory function is impaired; excessive retention of CO ₂
Respiratory alkalosis	High	Decreased pCO ₂	Decreased renal net acid excretion with resulting decrease in serum bicarbonate	Heart failure, pregnancy, sepsis, meningitis, anxiety, pain, excessive expiration of CO ₂
Metabolic				
Metabolic acidosis	Low	Decreased HCO ₃ ⁻	Hyperventilation with resulting low pCO ₂	Diarrhea; uremia; ketoacidosis from uncontrolled diabetes mellitus; starvation; high-fat, low-carbohydrate diet; drugs, alcoholism, kidney disease
Metabolic alkalosis	High	Increased HCO ₃ ⁻	Hypoventilation with resulting increase in pCO ₂	Diuretics use; increased ingestion of alkali; loss of chloride; vomiting/nasogastric tube suction

ACID GENERATION

The body produces a large amount of acids daily through routine processes such as metabolism and oxidation of food, endogenous production of acid from tissue metabolism, and ingestion of acid precursors. The main acid is carbon dioxide (CO₂), termed a volatile acid, which is produced from the oxidation of carbohydrates, amino acids, and fat. Nonvolatile or fixed acids, including phosphoric and sulfuric acids, are produced from the metabolism of phosphate-containing compounds to form phosphates and phosphoric acid and sulfur-containing amino acids (such as the metabolism of methionine and cysteine). Organic acids, such as lactic, uric, and keto acids, come from the incomplete metabolism of carbohydrates and fats. These organic acids typically accumulate only during exercise, acute illness, or fasting. Under normal conditions, the body is able to maintain normal acid–base status through a wide range of acid intake from foods.

Regulation

Various regulatory mechanisms maintain the pH level within very narrow physiologic limits. At the cellular level, **buffer** systems composed of weak acids or bases and their corresponding salts minimize the effect on pH of the addition of a strong acid or base. The buffering effect involves formation of a weaker acid or base in an amount equivalent to the strong acid or base that has been added to the system (see Fig. 3.3).

Proteins and phosphates are the primary intracellular buffers, whereas the bicarbonate and H₂CO₃ system is the primary extracellular buffer. The acid–base balance also is maintained by the kidneys and lungs. The kidneys regulate hydrogen ion (H⁺) secretion and bicarbonate resorption. The kidneys regulate the pH of the urine by excreting H⁺ or HCO₃⁻ and can make bicarbonate. The kidneys are the slowest-responding mechanism to maintain acid–base balance. The lungs control H⁺ through the amount of CO₂ that is exhaled. When more CO₂ is exhaled, it reduces the H⁺ concentration in the body. The respiratory system responds quickly to alter either the depth or rate of air movement in the lungs.

ACID–BASE DISORDERS

Acid–base disorders can be differentiated based on whether they have metabolic or respiratory causes. The evaluation of acid–base status requires analysis of serum electrolytes and arterial blood gas (ABG) values (Table 3.6). There are four main acid–base

TABLE 3.6 Common Arterial Blood Gas Values*

Clinical Test	ABG Value
pH	7.35–7.45
pCO ₂	35–45 mm Hg
pO ₂	80–100 mm Hg
HCO ₃ ⁻ (bicarbonate)	22–26 mEq/L
O ₂ saturation	>95%

*Check exact reference range at laboratory when interpreting patient results

ABG, Arterial blood gas.

abnormalities: metabolic acidosis, metabolic alkalosis, respiratory acidosis, and respiratory alkalosis. It is important to characterize the type of acid–base disorder because this will dictate the treatment and response or “compensation” mechanism enacted by the body. Metabolic acid–base imbalances result in changes in bicarbonate (i.e., base) levels, which are reflected in the total carbon dioxide (TCO₂) portion of the electrolyte profile. TCO₂ includes bicarbonate (HCO₃⁻), carbonic acid (H₂CO₃) and dissolved carbon dioxide; however, all but 1 to 3 mEq/L are in the form of HCO₃⁻. Thus, for ease of interpretation, TCO₂ should be equated with HCO₃⁻. Respiratory acid–base imbalances result in changes in the partial pressure of dissolved carbon dioxide (pCO₂). This is reported in the ABG values in addition to the pH, which reflect the overall acid–base status.

Metabolic Acidosis

Metabolic acidosis results from increased production or accumulation of acids or loss of base (i.e., HCO₃⁻) in the extracellular fluids. Simple, acute metabolic acidosis results in a low blood pH (or **acidemia**), low HCO₃⁻, and normal pCO₂. Examples of metabolic acidosis include diabetic ketoacidosis, lactic acidosis, toxin ingestion, uremia, and excessive HCO₃⁻ loss via the kidneys or intestinal tract. Multiple deaths previously have been attributed to lactic acidosis caused by administration of parenteral nutrition devoid of thiamin. In patients with metabolic acidosis, the anion gap is calculated to help determine cause and appropriate treatment. An **anion gap** is the measurement of the interval between the sum of “routinely

measured” cations minus the sum of the “routinely measured” anions in the blood. The anion gap is

$$(\text{Na}^+ + \text{K}^+) - (\text{Cl}^- + \text{HCO}_3^-)$$

where Na^+ is sodium, K^+ is potassium, Cl^- is chloride, and HCO_3^- is bicarbonate. Normal is 12 to 14 mEq/L (refer to the reference ranges for each reporting laboratory).

Anion gap metabolic acidosis occurs when a decrease in HCO_3^- concentration is balanced by increased acid anions other than chloride. This causes the calculated anion gap to exceed the normal range of 12 to 14 mEq/L. This normochloremic metabolic acidosis may develop in association with diabetic ketoacidosis, lactic acidosis, uremia, ingestion (e.g., methanol, paraldehyde, ethylene glycol, alcohol), or be iatrogenic (Wilson, 2003). Nongap metabolic acidosis occurs when a decrease in HCO_3^- concentration is balanced by an increase in chloride concentration, resulting in a normal anion gap. This hyperchloremic metabolic acidosis may develop in association with small bowel fistulae, excess chloride ingestion (from medications or parenteral sources), diarrhea, pancreatic fistulae, renal tubular acidosis, ureterosigmoidostomy, or adrenal insufficiency (Canada et al, 2015).

Metabolic Alkalosis

Metabolic alkalosis results from the administration or accumulation of HCO_3^- (i.e., base) or its precursors, excessive loss of acid (e.g., during gastric suctioning), or loss of ECF containing more chloride than HCO_3^- (e.g., from villous adenoma or diuretic use). Simple, acute metabolic alkalosis results in a high blood pH, or **alkalemia**. Metabolic alkalosis also may result from volume depletion; decreased blood flow to the kidneys stimulates reabsorption of Na^+ and water, increasing HCO_3^- reabsorption. This condition is known as **contraction alkalosis**. Alkalosis also can result from severe hypokalemia (serum K^+ concentration <2 mEq/L). As K^+ moves from the intracellular to the extracellular fluid, hydrogen ions move from the extracellular to the intracellular fluid to maintain electroneutrality. This process produces intracellular acidosis, which increases hydrogen ion excretion and HCO_3^- reabsorption by the kidneys.

Respiratory Acidosis

Respiratory acidosis is caused by decreased ventilation and consequent CO_2 retention. Simple, acute respiratory acidosis results in a low pH, normal HCO_3^- and elevated pCO_2 . Acute respiratory acidosis can occur as a result of sleep apnea, asthma, aspiration of a foreign object, or acute respiratory distress syndrome (ARDS). Chronic respiratory acidosis is associated with obesity hypoventilation syndrome, chronic obstructive pulmonary disease (COPD) or emphysema, certain neuromuscular diseases, and starvation cachexia. Prevention of overfeeding is prudent as it can worsen acidosis (Ayers and Dixon, 2012).

Respiratory Alkalosis

Respiratory alkalosis results from increased ventilation and elimination of CO_2 . The condition may be mediated centrally (e.g., from head injury, pain, anxiety, cerebrovascular accident, or tumors) or by peripheral stimulation (e.g., from pneumonia, hypoxemia, high altitudes, pulmonary embolism, congestive heart failure, or interstitial lung disease). Simple, acute respiratory alkalosis results in a high pH, (or alkalemia), normal HCO_3^- , and decreased pCO_2 .

Compensation

When an acid–base imbalance occurs, the body attempts to restore the normal pH by developing an opposite acid–base imbalance to offset the effects of the primary disorder, a response known as

compensation. For example, the kidneys of a patient with a primary respiratory acidosis (decreased pH) compensate by increasing HCO_3^- reabsorption, thereby creating a metabolic alkalosis. This response helps increase the pH. Similarly, in response to a primary metabolic acidosis (decreased pH), the lungs compensate by increasing ventilation and CO_2 elimination, thereby creating a respiratory alkalosis. This compensatory respiratory alkalosis helps increase pH.

Respiratory compensation for metabolic acid–base disturbances occurs quickly—within minutes. In contrast, renal compensation for respiratory acid–base imbalances may take 3 to 5 days to be maximally effective (Ayers et al, 2015). Compensation does not always occur, and when it does, it is not completely successful (i.e., does not result in a pH of 7.4). The pH level still reflects the underlying primary disorder. Clinicians must distinguish between primary disturbances and compensatory responses because treatment always is directed toward the primary acid–base disturbance and its underlying cause. As the primary disturbance is treated, the compensatory response corrects itself. Predictive values for compensatory responses are available to differentiate between primary acid–base imbalances and compensatory responses. Clinicians also may use tools such as clinical algorithms.

Acid–Base Balance: Guidelines and Applications to Dietetics Practice

Acid–base balance is a complicated topic that requires a high-level understanding of many complex processes. Table 3.5 displays the anticipated ABG alterations and compensation mechanisms. A few rules of thumb may be helpful to understanding this topic. In uncompensated and simple acid–base disorders, pH and pCO_2 move in opposite directions in respiratory disorders. In uncompensated and simple acid–base disorders, pH and HCO_3^- move in the same direction. When mixed acid–base disorders occur, pCO_2 and HCO_3^- generally move in opposite directions. Regardless of the disorder, the medical team directs the treatment at the underlying cause and uses supporting information from the medical history, current clinical condition, medications, laboratory values, intake and output records, and physical examination to determine the cause. Dietetics professionals play an important role in understanding the physiologic process and how it relates to regulation of electrolyte and fluid balance. Adjustments to the nutrition care plan related to acid–base balance can include shifting chloride and acetate salts in parenteral nutrition, manipulating macronutrients to prevent overfeeding, or adjusting fluid and electrolytes.

acceptable macronutrient distribution range (AMDR)	food record	recommended dietary allowance (RDA)
bioactive compound	nutrition assessment	tolerable upper level (UL)
calorie count	nutrition care indicators	
dietary intake data	nutrition care process (NCP)	
dietary reference intakes (DRIs)	nutrition screening	
	nutritional status	

NUTRITIONAL STATUS

Nutritional status is the physiologic state or condition of an individual based on the balance between the individual's intake and unique requirement for nutrients (Fig. 4.1). Nutrient intake represents the amount of a nutrient that is absorbed into the body from foods, beverages, medications, and supplements consumed. Thus nutrient intake depends on:

- the amount of a nutrient contained in the diet,
- the bioavailability of a nutrient based on its source, and
- the body's capacity to digest and absorb nutrients within the gastrointestinal system.

Nutrition professionals such as registered dietitian nutritionists (RDNs) and nutrition and dietetic technicians, registered (NDTRs) serve as food and nutrition experts on health care teams. They are in a key position to evaluate the nutrient quantity, quality, and bioavailability of a client's diet. In addition, because many acute and chronic medical conditions impact the body's ability to digest and absorb nutrients from dietary sources, nutrition professionals often evaluate gastrointestinal function when assessing nutritional status.

A nutrient requirement represents the need for a nutrient based on an individual's unique physiologic profile. Adjunctive data such as age, gender, physical activity level, and life cycle stage assist in estimating an individual's nutrient needs in relation to known standards such as the **dietary reference intakes (DRIs)**. In addition, disease status (e.g., nutrient deficiencies), genetics, and medical conditions (e.g., liver disease, inborn errors of metabolism) that further impact nutrient requirements must be carefully considered when estimating nutritional requirements.

Assessment of nutritional status is the foundation of nutrition care and the primary role of the nutrition professional on the research or health care team. Nutritional status assessment can detect a nutrient insufficiency or excess in the early stages, allowing dietary intake and lifestyle to be improved through nutrition intervention before a more significant deficiency or toxicity develops. In the management of acute and chronic diseases, nutritional status assessment provides an important opportunity for the nutrition professional to identify patients who

need medical nutrition therapy (MNT), which ultimately links clients to interventions that support improved health and well-being, and reduce medical care costs (Parkhurst et al, 2013).

As illustrated in Fig. 4.2, imbalances in nutritional status develop over time when intake is higher or lower than an individual can physiologically adapt to. In minor or early nutritional deficits such as stage 1 iron deficiency, the body adapts by increasing absorption of dietary iron to regain balance (see Chapter 31). If the iron deficiency is detected in the early stages through detailed assessment of a food and nutrition history and a ferritin test, the impact may be limited to depletion of stores. If the deficit is substantial or if the requirement for iron is substantially higher than normal, the body's ability to adapt can be exceeded, and a deficiency will ensue. Over time, the imbalance will lead to changes in the biochemistry, anatomy, and physiology of the body, such as overt anemia and chronic fatigue.

While it is theoretically possible to obtain a reasonable estimate of an individual's intake of calories, micronutrients, and macronutrients, nutrition professionals are unlikely to be able to estimate an individual's actual nutrient requirements under most conditions. Thus to accurately assess nutritional status (i.e., a deficiency or excess), the assessment of nutrient intake is combined with additional data in order to support a conclusion that a client's estimated intake is too high or too low to support optimal health (see Fig. 4.2). In a "prototypical" nutritional deficiency, the five domains of assessment data in the **nutrition care process (NCP)** shown in Box 4.1 can provide the supportive data needed to establish and reveal the severity of a nutritional imbalance. Box 4.2 shows examples of **problem, etiology, signs and symptoms (PES) statements** created during the NCP that demonstrate how different assessment domain data can be used to describe different types of nutritional status concerns.

NUTRITION SCREENING

Only a portion of individuals or groups ("clients") that present in health care, community, or research settings requires the attention and

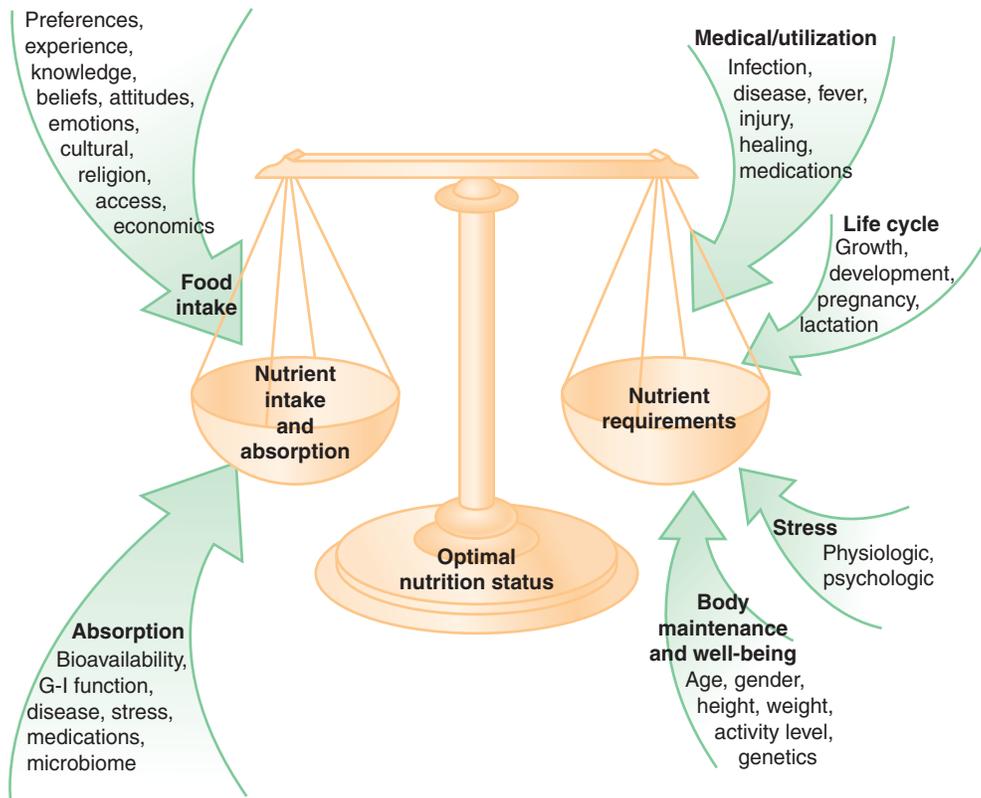

Fig. 4.1 Optimal nutrition status: a balance between nutrient intake and nutrient requirements.

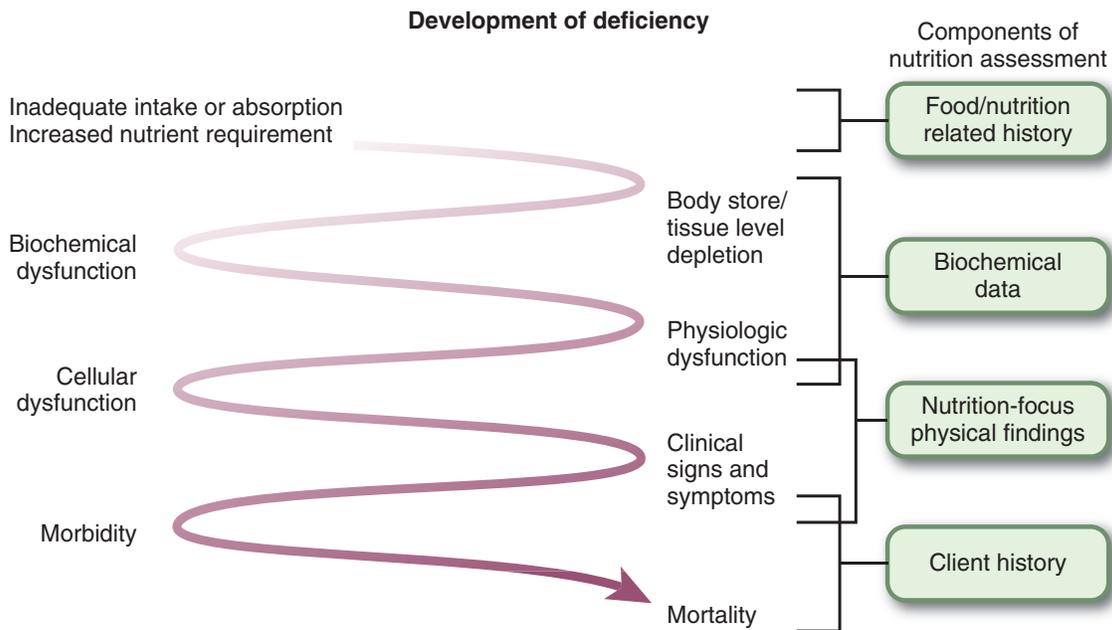

Fig. 4.2 Development of clinical nutritional deficiency and detection by nutrition assessment data.

BOX 4.1 Nutrition Care Process: Nutrition Assessment (Step One)

Data Sources

- Screening or referral form
- Interview of patient or key social support
- Medical or health records
- Community- or organization-based surveys and focus groups
- Health surveillance data, reports, research studies

Domains (Categories) of Data Collected

- Food/nutrition-related history
- Anthropometric measurements
- Biochemical data, medical tests, and procedures
- Nutrition-focus physical examination findings
- Client history

Activities

- Review or collect assessment data that are vital, important, and relevant
- Using appropriate standards or criteria, interpret the data to identify discrepancies that affect nutrition and health status
- Determine whether the data patterns match the defining characteristics of particular nutrition diagnoses

Critical Thinking

- Which data are vital, important, and relevant?
- Are more data points needed to complete the assessment?
- Which assessment methods are valid and reliable?
- Which discrepancies matter?

Adapted from Academy of Nutrition and Dietetics. Nutrition Terminology Reference Manual (eNCPT): Dietetics Language for Nutrition Care. <https://www.ncpro.org/pubs/idnt-en/>.

BOX 4.2 Example Nutrition Diagnosis (PES) Statements for Nutritional Status Problems

Concept: Nutrient Deficiencies Can Be Due to Low Dietary Intake

Inadequate mineral intake (Iron, NI-5.10.1.3) related to knowledge deficit regarding foods high in iron as evidenced by consumption of 30% of the RDA for iron and low ferritin, Hct, and MCHC values.

Concept: Nutrient Deficiencies Can Be Due to Poor Absorption of Nutrients

Altered gastrointestinal (GI) function (NC-1.4) related to *Helicobacter pylori* infection-induced gastritis as evidenced by refractory iron deficiency anemia despite 6 weeks of oral iron therapy.

Concept: Nutrient Deficiencies Can Be Due to High Nutrient Requirements

Increased nutrient needs (Iron, NI-5.1) related to heavy menstrual blood losses as evidenced by iron deficiency anemia (low ferritin, Hct, and MCHC values) despite adequate intake of highly bioavailable heme iron (120% RDA).

services of nutrition professionals. To provide cost-effective nutrition services, the first step is to complete a **nutrition screening** test or examination to identify clients who currently have or are at risk for nutrition problems. During screening, clients who are determined to be at risk enter into the NCP (Fig. 4.3), and then receive services and care from nutrition professionals. More specifically, clients are screened

into the NCP when they have an identifiable nutrition problem (diagnosis) that can be addressed or ameliorated with nutrition intervention(s) delivered by a nutrition professional (AND, 2018a). Thus screening is technically considered to be outside of the NCP.

An ethical aspect of screening is that it connects clients who need specialized care with the services of a nutrition professional, allowing that patient to receive the medical care that is needed to regain health and wellness. A legal aspect of screening is that it legally transfers a portion of the care to the nutrition professional. Medical care facilities identify the timeframe in which every client should be screened and, if needed, the timeframe in which the client should be assessed by an RDN.

Box 4.3 shows the characteristics of optimal screening tools. When available, health care practitioners should utilize population-specific, validated screening tools such as the Nutritional Risk Screening (NRS 2002), the Simple Two-Part Tool, the Malnutrition Screening Tool (MST), the Mini Nutritional Assessment (MNA), and the Malnutrition Universal Screening Tool (MUST). The most recent Evidence Analysis Library (EAL) review from the Academy of Nutrition and Dietetics regarding the performance of screening tools for adults hospitalized in acute care and ambulatory settings suggests that the screening tools listed above have high sensitivity (>90%) and specificity (>90%); but only the MST had both the validity and reliability data to earn a Grade I (good evidence) rating (AND, 2018b). An example screening form developed for subacute and ambulatory elderly populations, the MNA Short Form is shown in Fig. 4.4.

For many settings and patient populations, there are no published screening tools or, if tools do exist, the research supporting their validity and reliability is lacking. In these situations, RDNs often develop a custom-made screening tool for each location (e.g., hospital unit, clinic) or patient population under their care. Examples of potential screening data that could be incorporated into a custom-made screening tool for either pediatric or adult patient groups are shown in Box 4.4.

NUTRITION ASSESSMENT

As shown in Fig. 4.3, clients who are identified as at risk for nutritional problems during the nutritional screening stage formally enter step one of the NCP, nutrition assessment. **Nutrition assessment** is a “systematic method for obtaining, verifying, and interpreting data needed to identify nutrition-related problems, their causes, and significance” (AND, 2018a). The purpose of completing a nutrition assessment is to determine whether a client has one or more nutrition-related problems (diagnoses). In the NCP, the nutrition diagnoses are documented in step two of the NCP in PES statement format (see Box 4.2 and Chapter 9). After identification of the nutrition diagnoses, the RDN can intervene (NCP step three) to address the nutrition problem and then evaluate and monitor progress (NCP step four) to determine whether the interventions have been effective in achieving key outcomes for the client (see Chapter 9).

Nutrition assessment is a comprehensive evaluation that often includes data from the five NCP domains and a variety of sources (see Box 4.1). On an initial assessment (first visit), the nutrition professional collects data within these five domains in an “ongoing, dynamic process” to determine whether the patterns of the data match the defining characteristics of particular nutrition diagnoses (AND, 2018a). On subsequent visits, the nutrition professional may limit assessment data to **nutrition care indicators**, which are specific assessment data points that quantify changes associated with the interventions, the nutrition diagnosis, the cause and etiology of the diagnosis, and other health care outcomes defined by evidence-based medicine or regulatory

THE NUTRITION CARE PROCESS MODEL

BOX 4.3 Characteristics of an Ideal Nutrition Screening Tool

Simple, quick, and easy to use by a variety of health care providers
Utilizes data that are readily available (medical chart, patient report, survey data)
Cost-effective to administer

Reliability:

- Interrater: produces the same screening result when administered by different users
- Intrarater: produces the same screening result when administered by the same user on different occasions

Validity:

- Sensitivity: percentage of clients with nutrition diagnoses identified as "at risk"
- Specificity: percentage of clients without nutrition diagnoses identified as not at risk

Adapted from NSCR: Definitions and Criteria (2009). Academy of Nutrition and Dietetics (AND). <https://www.andeal.org/topic.cfm?menu=3584&cat=3958>.

bodies. Or, the nutrition professional may assess a broader spectrum of data to determine whether other nutrition diagnoses may apply to the client. Critical thinking is important in the process of gathering existing data, using valid and reliable methods to generate new data, interpreting discrepancies in the data, and finding patterns in the data that are consistent with nutritional diagnoses. Any novel data generated by the nutrition professional should be collected, interpreted, and entered into the medical record with integrity, expertise, and validity (AND, 2018a).

NUTRITION-RELATED HISTORY

Part 1 of this text, including Chapters 1 through 10, focuses on the knowledge and skills needed to complete a comprehensive nutrition assessment involving the five domains of assessment data. This chapter will focus on assessment of the domain Food- and Nutrition-Related History, a broad and varied category of data that includes the subdomains and data scope shown in Table 4.1 (AND, 2018a). In brief, Food- and Nutrition-Related History includes assessments of the type

Mini Nutritional Assessment MNA[®]

Last name:		First name:		
Sex:	Age:	Weight, kg:	Height, cm:	Date:

Complete the screen by filling in the boxes with the appropriate numbers. Total the numbers for the final screening score.

Screening	
A Has food intake declined over the past 3 months due to loss of appetite, digestive problems, chewing or swallowing difficulties? 0 = severe decrease in food intake 1 = moderate decrease in food intake 2 = no decrease in food intake	<input type="checkbox"/>
B Weight loss during the last 3 months 0 = weight loss greater than 3 kg (6.6 lbs) 1 = does not know 2 = weight loss between 1 and 3 kg (2.2 and 6.6 lbs) 3 = no weight loss	<input type="checkbox"/>
C Mobility 0 = bed or chair bound 1 = able to get out of bed / chair but does not go out 2 = goes out	<input type="checkbox"/>
D Has suffered psychological stress or acute disease in the past 3 months? 0 = yes 2 = no	<input type="checkbox"/>
E Neuropsychological problems 0 = severe dementia or depression 1 = mild dementia 2 = no psychological problems	<input type="checkbox"/>
F1 Body Mass Index (BMI) (weight in kg) / (height in m²) 0 = BMI less than 19 1 = BMI 19 to less than 21 2 = BMI 21 to less than 23 3 = BMI 23 or greater	<input type="checkbox"/>
IF BMI IS NOT AVAILABLE, REPLACE QUESTION F1 WITH QUESTION F2. DO NOT ANSWER QUESTION F2 IF QUESTION F1 IS ALREADY COMPLETED.	
F2 Calf circumference (CC) in cm 0 = CC less than 31 3 = CC 31 or greater	<input type="checkbox"/>
Screening score (max. 14 points)	<input type="checkbox"/> <input type="checkbox"/>
12-14 points: Normal nutritional status 8-11 points: At risk of malnutrition 0-7 points: Malnourished

BOX 4.4 Nutritional Risk Factors

Food- and Nutrition-Related History

- Calorie, food group, breastmilk, formula, enteral, or parenteral intake below estimated needs
- Macro- or micronutrient intake below estimated needs
- Diet quality or variety below standards
- Excessive alcohol or drug use
- Poor eating environment
- Medications: polypharmacy, food-drug interactions
- Supplements: excessive intake, food-supplement interactions
- Food beliefs, attitudes, behaviors, knowledge: pica, disordered eating, restrictive eating, picky eating, inability or unwillingness to consume food, knowledge deficit
- Access: limited availability of safe and nutritious foods/beverages, limited access to food preparation facilities or supplies, limited access to resources and programs
- Cognitive or physical impairment that affects eating and food preparation
- Excessive or inadequate physical activity

Anthropometric Measurements

- Weight status: significant weight loss or gain, low or high BMI, inadequate or excessive growth measures
- Body composition: fat or muscle wasting, high waist circumference or waist-to-hip ratio

Biochemical Data, Medical Tests and Procedures

- Abnormal laboratory values: anemia, lipid profile, liver profile, GI profile, kidney function, circulating proteins
- Medical tests: GI function, swallow study, biopsies, ultrasound, endoscopy results

Nutrition-Focus Physical Findings

- Global: muscle or fat wasting, underweight, overweight, edema
- Digestive: poor appetite, nausea, vomiting, diarrhea, constipation, poor dentition, denture problems
- Skin: pressure ulcers, poor wound healing, signs of deficiency/excess
- Other: visual impairment, immobility, cognitive or neurologic impairment

Client History

- Personal: high-risk age (infancy, elderly), literacy, education, tobacco use
- Medical: diagnosis of chronic disease (renal, liver, cardiac, diabetes, gastrointestinal, cancer, AIDS), acute injury (trauma, sepsis, burn), or life cycle stage with high requirements (infancy, childhood, adolescence, pregnancy, lactation)
- Social: socioeconomic limitations, unstable housing, lack of social support, crisis, high stress levels

of diet currently and historically consumed by the client, how the diet is consumed, client characteristics that affect dietary needs, and important factors that determine underlying dietary choices and potential responses to future dietary changes.

FOOD AND NUTRIENT INTAKE

The Food and Nutrient Intake subdomain of Food- and Nutrition-Related History includes both assessment of the quantity and quality of foods and beverages in the diet as well as the timing and patterns of food and beverage intake (see Table 4.1). **Dietary intake data** may be assessed either by asking clients what they have consumed in the past (retrospective intake data) or by having clients record what they are consuming in real time (prospective intake data). Once information

TABLE 4.1 Nutrition Care Process: Food- and Nutrition-Related History Data

Subdomain	Scope
Food and Nutrient Intake	Total amount, timing, and patterns of intake of foods, beverages, nutrients, and food components
Food and Nutrient Administration	Overall dietary practices, food restrictions, fasting, or food modifications; eating environment; route of administration (oral, enteral, parenteral)
Medication and Complementary/Alternative Medicine Use	Current and historical use of prescription drugs, over-the-counter drugs, herbs, and other complementary/alternative medicine products
Knowledge/Beliefs/Attitudes	Knowledge, skills, beliefs, emotions, and attitudes related to food, nutrition, dietary practices, or behavior change
Behavior	Behaviors that impact ability to achieve nutrition-related goals
Factors Affecting Access to Food and Food/Nutrition-Related Supplies	Factors that limit or assist client in obtaining adequate amounts of safe and healthful foods, beverages, and nutrients
Physical Activity and Function	Physical activity level and indicators of physical functioning of the body related to nutritional status
Nutrition-Related Patient/Client-Centered Measures	Client's perception of the nutrition intervention and its impact on quality of life

Adapted from Academy of Nutrition and Dietetics. Nutrition Terminology Reference Manual (eNCPT): Dietetics Language for Nutrition Care. <https://www.ncpro.org/pubs/idnt-en/>.

is gathered about the client's diet, the nutrition professional can evaluate whether calorie, macronutrient, micronutrient, and other components of the diet are within health-promoting ranges and patterns.

A **food record**, or **food diary**, is the most comprehensive dietary intake tool available for assessing the quantity, quality, and timing of foods and beverages consumed by a client. After the provision of detailed instructions in its use by the nutrition professional, the client (or a trusted support person) prospectively records the foods and beverages consumed over a period of several days or weeks. A food diary form is shown in Fig. 4.5. Analysis of the food diary (discussed below) can provide detailed information on the quantity and quality of foods, beverages, nutrients, and food components consumed, timing and patterns of intake, and bioavailability of nutrients based on food sources (Table 4.2). In addition, the food diary form can be customized to include information that is most needed for client and clinician feedback, such as hunger and fullness scales, emotional responses to eating, location of eating, or physical symptoms (e.g., nausea or diarrhea) that occur after eating. Given that the forms are time consuming to fill out and that they must be filled out during (not after) each eating occasion for optimal validity, the nutrition professional can reduce the client burden by requiring the minimum number of days of records and the minimum data points or details needed to monitor key nutritional outcomes. Studies show that to characterize typical intake patterns, the optimal balance of client burden and data accuracy is obtained with 3 to 4 complete days of data collection with

TABLE 4.2 Comparison of Food and Nutrient Intake Assessment Methods—cont'd

Method	Advantages	Disadvantages	Best Uses
Calorie Count	<ul style="list-style-type: none"> • Actual observation of food intake • Quick (20 minutes) and easy to complete in office setting • Low time and effort for nutrition professional to review • Low client reactivity and burden 	<ul style="list-style-type: none"> • May not represent typical intake patterns or food preferences • Time consuming for nutrition professional to analyze with software 	<ul style="list-style-type: none"> • Short-term view of the current diet • Analysis calorie and macronutrient intake in relation to patient health status • Client with limited motivation, skills, or literacy

Adapted from Thompson FE, Byers T. Dietary Assessment Resource Manual. *J Nutr.* 1994 Nov;124(11 Suppl):2245S-2317S. doi: 10.1093/jn/124.suppl_11.2245s and Dietary Assessment Primer. National Institutes of Health, National Cancer Institute. <https://dietassessmentprimer.cancer.gov>.

at least 2 weekdays and 1 weekend day (Thompson and Byers, 1994; National Institutes of Health [NIH], 2018a). For some purposes, such as monitoring of food allergy or intolerance symptoms in response to food intake, clients may need to record data for several weeks (see Chapter 25 and Fig. 25.5).

A **food frequency questionnaire (FFQ)** is a survey completed by the client to retrospectively assess the types of foods and beverages consumed over a specified interval of time (e.g., past 1 month, 6 months, 12 months). In a traditional FFQ, clients indicate the frequency with which they consume various food items of interest—ranging from “never” to multiple times per day (Fig. 4.6). This method is ideal for providing information on typical foods consumed, quality of foods consumed, and diet variety over a prior period of time (see Table 4.2). Semiquantitative FFQs also include assessments of portion sizes or amounts consumed (Fig. 4.7), but questions remain about the validity of quantitative dietary intake data resulting from FFQs (Thompson and Byers, 1994; NIH, 2018a).

Nutrition professionals can select from a wide variety of validated FFQs that are broad or narrow in scope, or potentially adapt an existing FFQ to collect information on just the foods, beverages, or nutrients that are most relevant, important, and vital to the client’s clinical situation. For optimal validity, the foods that are listed and the literacy and numeracy skills required to complete the tool should match the client or group that is being assessed.

In a **24-hour recall**, the nutrition professional leads the client through a structured interview process to capture information on the quantity and quality of foods and beverages consumed in the previous 24 hours, including details on the timing, amounts, preparation methods, and brands (Thompson and Byers, 1994; NIH, 2018a). In a multiple pass-style of 24-hour recall, the nutrition professional first generates a basic outline of the foods and beverages consumed during the previous 24 hours divided into the meals and snacks the client has defined. On a second pass, the nutrition professional gathers details about foods and beverages consumed, including preparation method, brand name, portion size, key food attributes (whole grain, fortified, enriched, low sodium, etc.), and anchoring activities (while driving, at work, watching TV, etc.).

To improve validity, the nutrition professional can use prompts to help the client remember all foods consumed and ask questions in a neutral and unbiased way (“What was the first time you ate or drank anything after you woke up?” versus “What did you eat for breakfast?”). Carefully collected 24-hour recalls can yield dietary intake data similar to a food record but may miss data on diet variability unless multiple 24-hour recalls are taken over a period of time (see Table 4.2). Advances in technology now include software-directed structured interview formats and automated self-administered tools, such as the National Cancer Institute’s Automated Self-Administered 24-Hour

Dietary Assessment Tool (ASA24) for both adults and children (NIH, 2018a; NIH, 2018b).

A **calorie count** is a method primarily used in inpatient settings such as hospitals and nursing homes (see Table 4.2). Over the course of several weekdays and weekend days, a health care practitioner reviews the client’s food trays before and after each eating occasion and estimates the percentage of each food and beverage consumed. Using facility software, which includes information on the portion size and nutritional content of all foods and beverages served in the facility, and the percentage of each item consumed, the nutrition professional can estimate the food and nutrient intake of the client. Often the goal is to determine whether low food and beverage intakes are contributing to an emerging pattern of weight loss and malnutrition so early intervention can occur.

Each of the traditional retrospective and prospective methods currently used in clinical and research settings has specific purposes, strengths, and weaknesses (see Table 4.2). In all methods except the calorie count, intentional under- and overreporting of foods and beverages so the diet appears “healthier” is a concern (Thompson and Byers, 1994; NIH, 2018a). Through setting a comfortable environment with patients, asking neutral questions, and refraining from comments that may be perceived by the client as “judgmental,” the nutrition professional may reduce the likelihood of clients consciously or unconsciously altering their intake or misreporting intake data to impress the nutrition professional. The ultimate goal is to select a method that leads to accurate diagnosis of nutrition problems or monitoring of key nutrition care criteria related to interventions.

As these traditional dietary assessment methods are often time and labor-intensive and subject to a variety of sources of error, there has been increasing interest in the use of technology to provide information about dietary intake. New methods include photographic or video imaging of both the preparation and consumption of foods and beverages. In active capture methods an individual takes images of food before and after eating and can supplement the photos with text or voice recordings. In passive capture methods, images or recordings are made continuously throughout the day. Both types of technologies can be used to capture a primary record of the foods and beverages consumed or to enhance other dietary assessment methods such as 24-hour recall or food record.

A review of published studies suggests that photographic or video methods for dietary assessment are effective as a supplement to other self-report measures by revealing unreported and misreported food items (Gemming et al, 2015). When used as the sole method for dietary assessment, if images are of a sufficient quality, reasonable estimates of nutrient intake are possible. These methods often utilize nutrition professionals to evaluate the images of food consumed, but several utilize software to automate this step of the analysis. In addition to

estimating dietary intake, photography and videography can be used to evaluate other aspects of a nutrition assessment including the eating environment, mealtime interactions between caregivers and children, the ability to use eating utensils, feeding difficulties, and methods of food preparation.

Some of these technological advances have trickled down to clients in the form of cellular phone applications (apps), creating an opportunity

to collect and analyze food intake and physical activity information for both client and clinician use (Moore, 2018). Originally created for the public to use in self-monitoring health behaviors, several apps also provide options to share tracking data with nutrition professionals and generate useful reports of food and nutrient intake as well as physical activity behaviors (Box 4.5). These apps share many of the same benefits and drawbacks as typical food and physical activity diaries.

Beverage Questionnaire (BEVQ-15)

Instructions:

In the past month, please indicate your response for each beverage type by marking an "X" in the bubble for "how often" and "how much each time".

1. Indicate how often you drink the following beverages, for example, if you drank 5 glasses of water per week, mark 4-6 times per week.
2. Indicate the approximate amount of beverage you drank each time, for example, if you drank 1 cup of water each time, mark 1 cup under "how much each time".
3. Do not count beverages used in cooking or other preparations, such as milk in cereal.
4. Count milk added to tea and coffee in the *tea/coffee with cream beverage category* NOT in the milk categories.

Development of a Brief Questionnaire to Assess Habitual Beverage Intake (BEVQ-15): Sugar-Sweetened Beverages and Total Beverage Energy Intake. *J Acad Nutr Diet.* 2012 Jun;112(6):840-9. doi: 10.1016/j.jand.2012.01.023.

However, as the app completes the analysis for the clinician, these tools can potentially save clinicians time. The clinician should investigate the app fully before its use to ensure that the data for nutrition and physical activity are accurate and to understand the limits on the app's reliability and validity (Moore, 2018).

Assessment and Interpretation of Energy Intake

A starting point for nearly all dietary analysis work is to assess and evaluate the energy balance of the diet. Adequate calories are needed to sustain the body's structure and function as well as to support health and well-being (physical activity, healing). In addition, the needs for many nutrients (e.g., macronutrients) and food group allowances are established based on calorie intake or needs. Assessment and evaluation of calorie balance requires a thorough and complete dietary assessment tool that captures both the quantity and quality of foods and beverages consumed. Typically, this includes either a multi-day food record or multiple 24-hour recalls. Information on foods consumed can then be entered into dietary analysis programs to obtain an estimate of caloric intake (Moore, 2018; Fig. 4.8). The caloric intake value can then be compared with measurements of energy expenditure such as by direct calorimetry, or to estimates of energy requirements from indirect calorimetry or equations based on client characteristics such as age, height, weight, activity level, and injuries (see Chapter 2).

BOX 4.5 Apps for Tracking Nutritional Intake and Physical Activity

YouFood Photo Food Journal	Clients can photograph food and beverages consumed, journal about and rate intake, and obtain advice and ideas from community members Best for: people who desire nondieting approach, easy ways to monitor intake, and peer support
Recovery Record	Clients record meals and behaviors for eating disorder treatment, clinicians can review results and send feedback Best for: people who want to use technology to record data and interact with health care team
Calio	Voice technology allows people to speak data input for food, nutrition, and activity tracker and make requests for analysis of data and advice Best for: individuals who desire voice-interface
MyFitnessPal	Food and nutrition tracker with large food database and ability to scan bar codes of processed food items to speed up data entry Best for: individuals who desire calorie and weight-loss approach
Calorie Mama & Bitesnap	Provides dietary analysis based only on photos of foods and beverages Best for: rough estimates of intake, photo journaling intake
eaTracker	Food and Physical Activity tracker from Dietitians of Canada Best for: Canadian foods, research-based foods database
MakeMe	Track and share health goals and data within a team of individuals Best for: health challenges at work, fitness centers, and group classes

Assessment and Interpretation of Food Group Quantity and Balance

As foods and beverages typically provide the foundation of the diet, analysis of the balance of the foods consumed in the diet is an important role of the nutrition professional. In facilities that have access to software to analyze food records or 24-hour recalls, the software often can provide analysis of the food balance of the diet (Fig. 4.9). In facilities and settings that lack the software, the nutrition professional can develop the skill and experience to quickly translate foods and beverages consumed into standard food group portions or equivalents, adding little time to a 24-hour recall or review of food records, making this an efficient and effective start to nutrition assessment. In settings where clinicians are provided very limited time for dietary analysis, quick estimates of food group quantity and balance may be the only realistic dietary assessment method available.

Quantitative food patterns can also be used as standards by which to evaluate the balance of foods and beverages consumed. Quantitative food patterns show the average amount of food from each food group that should be consumed to meet both calorie and nutrient targets at a variety of calorie levels. Examples of quantitative food patterns that can be used as standards for food group quantity and balance analysis include:

- USDA Food Pattern
- USDA Vegetarian Food Pattern
- USDA Mediterranean Food Pattern
- DASH Diet Pattern
- Diabetes Exchange Meal Pattern

Fig. 4.8 Nutrient analysis report. (Nutritional analysis from The Food Processor® Nutrition and Fitness Software by ESHA Research, Inc., version 11.0.124, ©2015.)

Strict observance of the defined methods is very important—foods and beverages must be correctly classified into groups, quality standards for food should be met (e.g., caloric and nutrient density), and portion sizes must be correctly converted to obtain accurate food group quantity and balance information in relation to a standard.

Assessment and Interpretation of Food Quality

Research continues to highlight the importance of food and dietary quality in the prevention of chronic disease, which has led to an increased interest in measurement of dietary quality in both research and clinical settings (Gil et al, 2015). After collection of dietary intake data from food diaries, multiple 24-hour recalls, or an FFQ, a clinician can utilize dietary assessment software or other computer analysis programs to evaluate dietary quality using tools such as the Health Eating Index (HEI), the Diet Quality Index (DQI), the Healthy Diet

Indicator (HDI), or the Mediterranean Diet Score (MDS) (Gil et al, 2015). These diet quality methods often not only assess whether a diet achieves sufficient intake of food groups such as fruit, vegetables, beans or pulses, whole grains, and dairy foods but also whether the diet is consistent with nutrient and component standards such as sodium, added sugars, alcohol, and saturated fat. As most clinicians will not have the time or resources to analyze dietary intake data using these methods, an alternative approach is to review food diaries and 24-hour recalls with specific food quality standards in mind, such as the 2015–2020 Dietary Guidelines for Americans.

Assessment and Interpretation of Beverages (Water, Alcohol, and Caffeine)

Assessment of beverage intake can include examination of typical intake patterns of water, milk, fruit juice, fruit drinks, soft drinks, sports

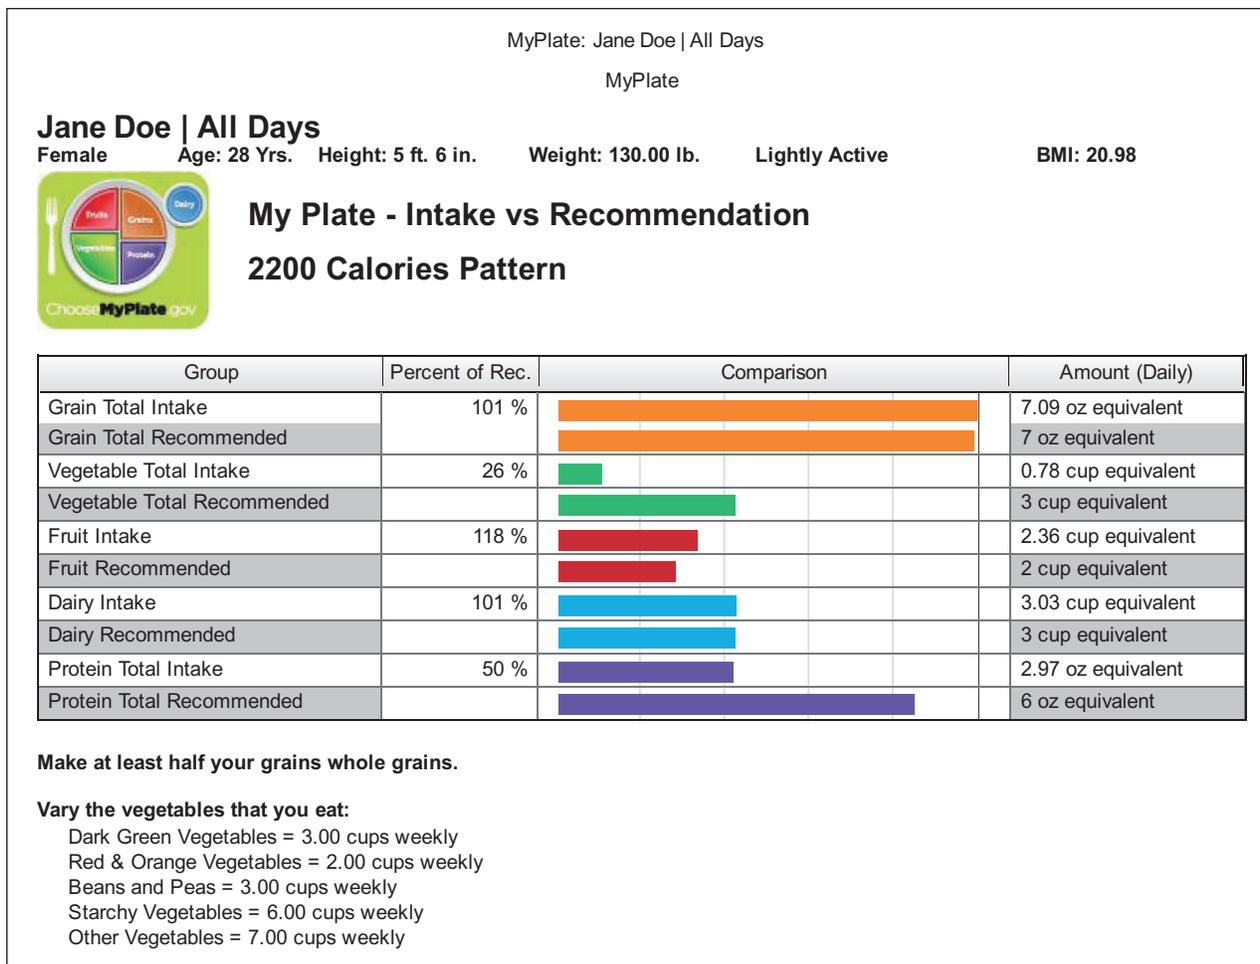

Fig. 4.9 Food analysis report. (Nutritional analysis from The Food Processor® Nutrition and Fitness Software by ESHA Research, Inc., version 11.0.124, ©2015.)

or energy drinks, coffee, tea, and alcoholic beverages. Information from beverage intake, either with or without additional food data, can be used to estimate intake of water, alcohol, and caffeine. In addition, because beverages contain food components with health implications (e.g., calories, water, sugar, alcohol, caffeine, calcium, vitamin D, potassium,) the type and amount of beverages that a person consumes can have health implications for conditions such as obesity and weight gain, bone health, kidney disease, and cardiovascular disease. In a recent nationally representative sample of adults, researchers found that:

- Beverages constitute about 75% to 85% of total daily water intake
- Water (tap and bottled) is the main contributor (30% to 37%) to total dietary water intake
- Beverages contribute 14% to 22% of total energy intake
- Alcohol, soda, and soft drinks are substantial contributors (2% to 6%) to total energy intake, but have little nutritional value (Drewnowski et al, 2013).

If the nutrition professional needs information about total intake of water, alcohol, and caffeine from both foods and beverages, multiple days of food diaries or 24-hour recalls analyzed with commercial dietary assessment software is necessary (see Fig. 4.8). If the nutrition professional simply wants to assess the quantity or quality of beverages in the diet, a simplified FFQ such as the Beverage Intake Questionnaire (BEVQ-15) may be sufficient (Hedrick et al, 2018; see Fig. 4.7). Total water intake can be compared with a variety of methods of

estimating water needs to evaluate adequacy (see Chapter 3 and Appendix 14). Caffeine and alcohol intake can be compared with suggested limits in the US Dietary Guidelines or other medical condition-specific guidelines (see Chapter 10).

Assessment and Interpretation of Macronutrients

The fat, protein, carbohydrate, fiber, and water content of the diet can be assessed by analyzing multiple days of food records or 24-hour recalls with commercially available dietary assessment software (see Fig. 4.8). This software also may provide information about specific types of macronutrients such as sugar, soluble fiber, saturated fats, and trans fatty acids. Alternatively, the skilled nutrition professional can assess the calorie containing macronutrients (fat, protein, carbohydrate) in the diet using the diabetic exchange system (Appendix 18).

The DRIs can serve as standards for evaluating the intake of macronutrients in most healthy individuals across the life cycle (see inside cover). **Acceptable intake (AI)** values are set when the research basis for a particular nutrient is limited. The AI represents the daily average intake of a nutrient that appears to be consistent with overall health and nutrient balance in observational studies. AI values for total fiber, linoleic acid, linolenic acid, and water exist and, given the limited research base, they should be used with caution. **Recommended dietary allowance (RDA)** values are set for nutrients with a research base substantial enough to characterize the distribution of nutrient needs of a population subgroup. The RDA represents the daily average intake

of a nutrient that would meet the needs of 97% to 98% of a specific population subgroup. RDA values exist for carbohydrates and protein. These RDA values are considered the lower boundary of intake needed to meet needs (i.e., prevent deficiency), rather than the amount needed to promote optimal health and wellness. **Acceptable macronutrient distribution ranges (AMDRs)** are ranges of intake (expressed as a percentage of total calories) for carbohydrates, proteins, and fats that not only meet the needs for essential nutrients but also minimize the risk of chronic diseases. AMDR values exist for carbohydrates, fat, linoleic acid, linolenic acid, and protein. AMDR ranges were developed with intended uses for nutrition assessment and prescription.

Critical thinking of the nutrition professional involves careful consideration of the strengths and weaknesses of the DRIs. Each person's requirements for nutrients is unique; thus, comparison of an individual's intake to a reference such as the RDA should be viewed as an attempt to establish a "likelihood" or "probability" that a particular level of intake is inadequate, adequate, or excessive. In addition, the research base for the DRIs includes only studies of presumably healthy adults. The DRI values are not intended to represent the needs of individuals with known health conditions, trauma, surgery, malnutrition, or any condition that alters nutrient needs. Whenever possible, the nutrition professional should search for standards that are specific to the client's health status or write a nutrition prescription in the chart to specify customized ideal levels of macronutrient intake and timing using evidence-informed practice that will be used as the standard for assessment and intervention.

Particular recommendations exist for added sugars, solid fats, and trans fatty acids from a variety of government and health associations. For example, the following limits have been proposed:

- Saturated fat: <10% of total calories (U.S. Dietary Guidelines); <5-6% total calories (American Heart Association)
- Trans fatty acids: "as low as possible" (American Heart Association, DRIs)
- Sugars: <25 g/d females, <38 g/d males (American Heart Association) or <10% of kcal (U.S. Dietary Guidelines)
- Total solid fats and added sugars (SOFAS): Based on calorie level of the diet, but typically ranges from 160 to 330 kcal/day for most adults (USDA Food Patterns)

Beyond these general recommendations for healthy individuals, standard therapeutic diets such as the Dietary Approaches to Stop Hypertension (DASH) diet include specific recommendations for a variety of dietary components such as saturated fat, cholesterol, and fiber (see Chapter 32 and Appendix 17).

Assessment and Interpretation of Micronutrients

The micronutrient content of the diet can be assessed by analyzing multiple days of food records or 24-hour recalls with the assistance of commercially available dietary assessment software (see Fig. 4.8). If the nutrition professional is interested in micronutrients, careful assessment of foods and beverages that are enriched, fortified, or contain added vitamins and minerals is vital. The dietary assessment software may provide information about specific forms of vitamins in the diet, such as folate versus folic acid, if the foods in the database include such distinctions. However, as the software database is largely from chemical analysis of foods, the nutrition professional will need to consider the food sources of the nutrients in order to factor in the bioavailability of the nutrient levels listed in the report.

As described above, the RDA and AI values provided by the Institute of Medicine can serve as a starting point for establishing a "likelihood" or "probability" that a particular level of intake is inadequate, adequate, or excessive. However, the intake of many micronutrients varies on a day-to-day basis much more than macronutrients. Thus the uncertainty around judgments of intake adequacy involve uncertainty

around a person's actual requirement and uncertainty around the typical intake of a micronutrient. For healthy individuals, intake above the RDA is likely adequate but intake below the RDA is not necessarily inadequate. If intake is below the RDA, more data will be needed to interpret nutritional status, such as laboratory values or nutrition-focused physical examination findings (see Appendices 12 and 13). As discussed above, for patients with medical conditions, it is ideal to identify micronutrient recommendations particularly related to that condition (e.g., DASH diet) or write a nutrition prescription in the chart to specify customized ideal levels of specific micronutrients that are evidence-informed and therapeutic for the client.

The **tolerable upper level (UL)** is a DRI value that identifies the highest average daily intake that does not cause adverse effects. In combination with dietary assessment software analysis, the UL value can assist with determining the safety of consuming foods that are enriched, fortified, or otherwise supplemented with nutrients. In addition, the UL value can provide information about the potential risks of nutrient supplementation in healthy individuals. The UL is not intended to apply to individuals who are consuming micronutrient supplements to address nutrient deficiencies, or other medical conditions that have specific micronutrient needs; these situations also require research-based or individual recommendations specific to the client.

Assessment and Interpretation of Other Bioactive Dietary Components

Bioactive compounds include compounds that have "the capability and the ability to interact with one or more component(s) of the living tissue by presenting a wide range of probable effects" (Guaadaoui et al, 2014). According to this framework, natural or synthetic, potentially helpful or harmful, food or nonfood sourced compounds of plant or animal origin would qualify as potentially biologically active in the human body. In this rapidly developing field of study, nutrition professionals are likely to see an ever-expanding list of possible bioactive components and their role in human health and disease. Table 4.3 presents the more common dietary components that nutrition professionals may attempt to assess, interpret, or intervene related to clients.

Assessment of the diet is likely to be limited to qualitative evaluation of the frequency of foods consumed that contain the component of interest. Limited data exist for beneficial bioactive components outside of the typical micronutrients found in foods (e.g. carotenoids). About 800 harmful and beneficial dietary components are monitored in the Total Diet Study, but only in a few hundred foods in the food supply (Total Diet Study, 2019). Few standards exist for interpreting whether intake is within safe, optimal, or health-promoting levels. Nutrition professionals can consult evidence-based MNT guidelines to generate a specific nutrition prescription for a client or refer the client for evaluation by a nutrition professional trained in integrative and functional medicine (refer online to the Academy of Nutrition and Dietetics Practice Group Dietitians in Integrative and Functional Medicine / Find a Practitioner).

FOOD AND NUTRIENT ADMINISTRATION

The subdomain "Food and Nutrient Administration" of Food- and Nutrition-Related History includes details about the client's current and historical approaches to eating, including the current diet order, diets selected or followed in the past, food restrictions and fasting, prior education regarding therapeutic diets, and the eating environment (see Table 4.1). Often this information is obtained through chart review (diet order, prior nutrition education), patient interview, and intake forms. Examples of data points from this section of the Food- and Nutrition-Related History include therapeutic diets implemented on past hospitalizations, prior education on a therapeutic diet, the

TABLE 4.3 Dietary Components and Bioactive Compounds of Interest

Beneficial Component	Potential Food Sources	Potential Implications
Curcumin	Turmeric	Antioxidant, antiinflammatory, anticancer, and neuroprotective properties
Flavonoids	Fruit, vegetables, chocolate, wine, tea	Antiinflammatory, antithrombogenic, antidiabetic, anticancer, and neuroprotective properties
Isothiocyanates	Cruciferous vegetables	Metabolism and elimination of xenobiotics (e.g., carcinogens) from the body, antioxidant and antiinflammatory properties
Phytosterols	Legumes, unrefined vegetable oils, whole grains, nuts, seeds, enriched foods	Reduction in LDL cholesterol
Soy Isoflavones	Soy beans/products	Reduction in breast cancer, improved vascular function
Viscous (soluble) Fiber	Legumes, whole grains and cereals, vegetables, fruits, nuts, and seeds	Reduction in total and LDL cholesterol, lower postprandial insulin and blood glucose levels
Harmful Component	Potential Food Sources	Potential Implications
Lead	Tap water—leaches in from metal pipes	Neurotoxin, widespread organ damage
Mercury	Seafood, including canned albacore tuna, swordfish	Damage to brain, kidneys, liver, heart, nervous system, developing fetus
Arsenic	Water, rice (whole grain, refined, milks, syrups), fruit juices	Skin, bladder, and lung cancers
Bisphenol A (BPA)	Packaged foods—leaches in from food and beverage containers, linings of food and beverage cans	Organ damage, lowered IQ, miscarriage, hormone disruption

Adapted from Phytochemicals. Linus Pauling Institute, Micronutrient Information Center: <https://lpi.oregonstate.edu/mic/dietary-factors/phytochemicals>; and Metals. U.S. Food and Drug Administration: <https://www.fda.gov/food/chemicals-metals-pesticides-food/metals>.

types of weight loss diets attempted in the past and their benefits and drawbacks, foods that should not be served or recommended to the patient with food allergies, access points for enteral or parenteral nutrition, frequency and duration of fasts for religious or health reasons, or whether the client needs or has access to assistance when eating meals. This data is crucial when working with a variety of patients across the life cycle, whether in a facility or home-based setting.

NUTRITION KNOWLEDGE, BELIEFS, AND ATTITUDES

This subdomain includes assessment of the nutrition knowledge and skills as well as important beliefs and attitudes that can enhance or detract from adoption of current or future nutrition interventions (see Table 4.1). This information can be obtained through chart review, patient interview, or intake forms. For example, this type of information can contribute value to the nutrition assessment by showing whether a patient:

- is familiar with foods that contain key therapeutic nutrients
- has the cooking skills needed to implement a therapeutic dietary change
- is likely or unlikely to follow through with a particular nutrition intervention due to religious, cultural, or personal values
- is struggling with emotional eating, negative self-talk, or disordered eating
- is willing to make a dietary change and feels confident in the ability to do so

Clients who have the ability (knowledge and skills) to implement a nutrition intervention are more likely to be successful (see Chapter 13). Similarly, clients whose beliefs and attitudes are consistent with a nutrition intervention are more likely to be willing to implement the intervention. Conversely, nutrition interventions are unlikely to be successful if the client lacks skills or knowledge to implement them, if they

conflict with prior nutrition education, or if the client is opposed to carrying out the intervention due to religious, personal, cultural, moral, or ethical values and beliefs.

NUTRITION BEHAVIORS

The Nutrition Behaviors subdomain includes the patient's behaviors, activities, and actions that impact the success of prior, current, and future nutrition interventions (see Table 4.1). For new clients, the RDN can assess behaviors that are likely to be significant barriers to achievement of future dietary change such as restrictive eating, bingeing, purging, refusal to eat, and unwillingness to try new foods or alter the diet. For returning clients, additional assessments of adherence to the overall nutrition plan can include attendance at scheduled visits and adherence to interventions or self-monitoring activities that were collaboratively developed at previous visits. Clients that present with significant barriers to dietary change or who return multiple times with low adherence may benefit from additional social support, referral to outside agencies, or referral to counselors or psychologists for evaluation.

MEDICATION AND COMPLEMENTARY OR ALTERNATIVE MEDICINES

As foods, beverages, medications, and dietary supplements can interact with each other, careful assessment of these possible interactions is part of the Food- and Nutrition-Related History domain (see Table 4.1). A list of prescription medications, over-the-counter medications, complementary medications, and therapeutic nutritional supplements can be generated from a combination of chart review, patient interview, and intake forms. Based on current scientific knowledge of food–drug interactions, the RDN can assess whether supplements, foods, or beverages (types, patterns, timing) may alter the

bioavailability or biological action of drugs, or whether the types of drugs or supplements taken by the patient could alter nutrient absorption, metabolism, excretion, or gastrointestinal (GI) function (taste, smell, appetite) enough to compromise nutritional status (see Appendix 13).

NUTRITION ACCESS

The Nutrition Access subdomain includes assessment of factors that impact the ability to obtain a safe and nutritious diet (see Table 4.1). Some examples include:

- Access to safe and nutritious foods and beverages
- Availability of grocery shopping facilities
- Availability of meal preparation supplies and facilities
- Presence of assistive food preparation and eating devices
- Eligibility for and participation in government and community programs related to food and nutrition

Research has consistently shown that health disparities and health inequities are a result of the social determinants of health or the social and economic conditions under which people live (Centers for Disease Control [CDC], 2018). Addressing these major health inequities is not about providing more health care, but rather about ensuring equal access to the resources needed to make healthier choices and avoid exposures that are harmful to health (CDC, 2018). Successful strategies include linking clients and communities to community and government programs that improve access to safe and nutritious food, clean air and water, recreation opportunities, and preventive health care as well as engaging in public policy and advocacy work (see Chapter 8).

PHYSICAL ACTIVITY AND PHYSICAL FUNCTION

This subdomain includes assessment of indicators of the body's functioning in relation to nutritional status (see Table 4.1). The most common variable assessed is physical activity patterns, which are a key determinant of overall health and energy expenditure and needs. Detailed assessment and interpretation of the dimensions of fitness, such as muscle strength, muscle endurance, cardiovascular endurance, flexibility, and coordination, require additional training or referral to an exercise physiologist. RDNs can complete training for the *Physical Activity Toolkit for Registered Dietitians: Utilizing Resources of Exercise is Medicine*, developed by the Weight Management and Sports, Cardiovascular, and Wellness Nutrition dietetic practice groups in collaboration with the American College of Sports Medicine. This toolkit contains information and resources needed to assess and evaluate the frequency and duration of basic cardiovascular and strength activities (Raynor and Champagne, 2016).

Other indicators of physical functioning in this subdomain include the ability to eat independently or feed others (breastfeed). Information on how to evaluate a child's or adult's physical or cognitive abilities to prepare food or eat independently can be found in Chapters 43 and 19, respectively. Chapter 14 provides a review of potential goals for breastfeeding initiation, duration, and exclusivity as well as methods to assess basic breastfeeding behaviors. Assessment and interpretation of adequacy of breastmilk production (parental) or intake (child) often requires the expertise of an International Board-Certified Lactation Consultant (IBCLC) and access to professional grade breast pumps and infant scales.

NUTRITION QUALITY OF LIFE

The Nutrition Quality of Life subdomain relates to the client's sense of well-being in response to the health challenges that they are

experiencing and the nutrition interventions recommended by the nutrition professional (see Table 4.1). Nearly all interventions proposed by the health care team will require resources of the client, which could include money, time, effort, and loss of freedom of choices in health behaviors. Sensitivity toward the impact of an intervention on the client's lifestyle can help establish rapport with the client and create a safe space for the client to discuss real and perceived barriers to implementation of nutrition recommendations. After assessment of the potential impact of nutrition interventions on quality of life, the clinician can make recommendations that are more likely to be adopted by the client.

CLINICAL CASE STUDY

Jessup identifies as a 75-year-old white male of English and French ancestry. He is referred to your private practice for assessment of potential malnutrition. The referral letter from the doctor's visit 2 weeks ago provides you with these pieces of assessment data:

Food- and Nutrition-Related History: Client reported a "moderate" decrease in food intake over the past 2 months.

Anthropometric Data: Current height = 68 inches, current weight = 145 lb, prior weight (3 months ago) = 149 lb.

Biochemical Data, Medical Tests, and Procedures: Low hemoglobin, hematocrit.

Nutrition-Focus Physical Findings: Client reports poor appetite, constipation, and loosening of the dentures.

Client History: Depression and iron deficiency anemia (diagnosed in past 2 weeks), history of hypertension (controlled by medications), loss of wife 7 weeks ago after a prolonged illness, still socially connected (family, friends, church, volunteering).

Nutrition Care Questions

1. A complete the Mini Nutritional Assessment Form (see Fig. 4.4) for Jessup. What is his numerical score? What is the interpretation of that score?
2. Which nutritional diagnoses may apply to his situation?
3. During his visit, which key nutritional risk factors (see Box 4.4) and Food- and Nutrition-Related History (see Table 4.1) will you prioritize in your assessment? Which data points will support your ability to narrow down the list of potential nutrition diagnoses you listed in Question 2?
4. Which type of dietary assessment tool found in Table 4.2 do you think is best suited for this client and this situation? Which tool is most likely to give you the dietary intake data you listed in Question 3?
5. What novel data can you provide to the medical team through your assessment? Which methods for collecting food and nutrient intake data could provide the necessary data? Which are most reliable and valid for this client and this setting?

Clinical: Biochemical, Physical, and Functional Assessment

Mary Demarest Litchford, PhD, RDN, LDN

KEY TERMS

25 hydroxy vitamin D (25[OH]D ₃)	erythrocyte sedimentation rate (ESR)	osteocalcin
air displacement plethysmogram (ADP)	ferritin	positive acute-phase reactants
albumin	functional medicine	prealbumin (PAB)
analyte	Functional Nutrition Assessment	Quetelet index (W/H ²)
anemia of chronic and inflammatory disease (ACD)	head circumference	retinol
anthropometry	height-for-age	retinol-binding protein (RBP)
basic metabolic panel (BMP)	hematocrit (Hct)	serum iron
bioelectrical impedance analysis (BIA)	hemoglobin (Hgb)	stadiometer
body composition	hemoglobin A1C (Hgb A1C)	total iron-binding capacity (TIBC)
body mass index (BMI)	high-sensitivity CRP (hs-CRP)	transferrin
complete blood count (CBC)	homocysteine	transthyretin (TTHY)
comprehensive metabolic panel (CMP)	ideal body weight (IBW)	triceps skin fold (TSF)
C-reactive protein (CRP)	inflammation	urinalysis
creatinine	length-for-age	usual body weight (UBW)
dehydration	macrocytic anemia	waist circumference (WC)
differential count	methylmalonic acid (MMA)	waist-to-height ratio (WHtR)
dual-energy x-ray absorptiometry (DXA)	microcytic anemia	waist-to-hip ratio (WHR)
edema	midarm circumference (MAC)	weight-for-age
	negative acute-phase reactants	weight-for-length

Nutrition assessment may be completed within the context of a traditional medical model or a functional integrative medical model. Clinicians must demonstrate critical thinking skills to observe, interpret, analyze, and infer data to detect new nutrition diagnoses or determine that nutrition-related issues have resolved (Charney and Peterson, 2013). The three sources of information—biochemical data, physical attributes, and functional changes—are viewed in the context of each other, and the trends of data over time are useful to identify patterns consistent with nutrition and medical diagnoses (Fig. 5.1).

Health care reforms are changing the practice of dietetics specific to nutrition assessment in several ways. First, the practice of ordering diets is changing to allow registered dietitian nutritionists (RDNs) the privilege of writing diet orders within the parameters set by the governing body of the health care organization. Second, the practice of ordering routine laboratory tests has changed, and health care providers must justify the need for each laboratory test ordered. Many RDNs have the authority to order laboratory tests with a clinical indicator or International Classification of Diseases (ICD) code to justify the request. RDNs must be proactive to request the authority to write diet orders and order laboratory tests and embrace the responsibilities associated with these privileges. Third, the use of evidence-based

medical guidelines is reshaping the types and frequency of biochemical testing, physical assessments, and functional tests ordered. These changes augment the value of physical and functional assessment as pivotal components of nutrition assessment. Practitioners should assess patients from a global perspective, requesting necessary tests, and not be limited by the history of reimbursement for testing. Also, many consumers are seeking health care services that are not covered currently by traditional insurance and government-funded health care programs. The nutrition professional can determine the validity and usefulness of these requests for testing. Before recommending a biochemical test to be performed, the dietitian should consider: “How will the test results change my intervention?”

BIOCHEMICAL ASSESSMENT OF NUTRITION STATUS

Laboratory tests are ordered to diagnose diseases, support nutrition diagnoses, monitor effectiveness of nutrition preventions, evaluate medication effectiveness, and evaluate nutrition care process (NCP) interventions or medical nutrition therapy (MNT). Acute illness, surgery, or injury can trigger dramatic changes in laboratory test results,

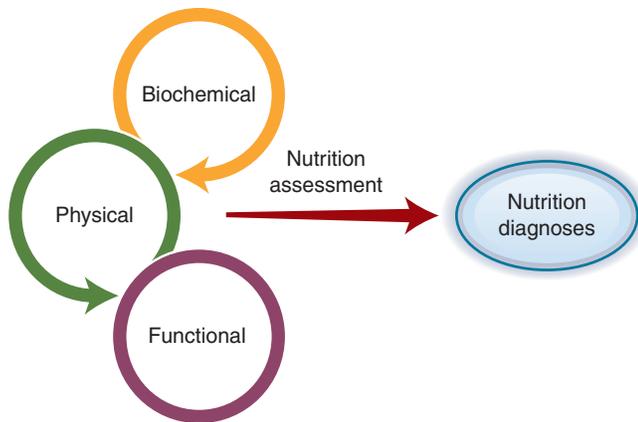

Fig. 5.1 Interrelationship of biochemical data, physical attributes, and functional status.

including rapidly deteriorating nutrition status. However, chronic diseases that develop slowly over time also influence these results, making them useful in preventive care.

Definitions and Applications of Laboratory Test Results

Laboratory assessment is a stringently controlled process. It involves comparing control samples with predetermined substance or chemical constituent (**analyte**) concentrations with every patient specimen. The results obtained must compare favorably with predetermined acceptable values before the patient data can be considered valid. Laboratory data are the only *objective data* used in nutrition assessment that are “controlled”—that is, the validity of the method of its measurement is checked each time a specimen is assayed by also assaying a sample with a known value.

Laboratory-based nutrition testing, used to estimate nutrient concentration in biologic fluids and tissues, is critical for assessment of clinical and subclinical nutrient deficiencies. As shown in [Fig. 5.2](#), the size of a nutrient pool can vary continuously from a frank deficit to insufficiency to adequate to toxic. Most of these states can be assessed in the laboratory so that nutritional intervention can occur before a clinical or anthropometric change or a frank deficiency occurs ([Litchford, 2017](#)). Single test results must be evaluated in light of the patient’s current medical condition, nutrition-focused physical examination findings, medications, lifestyle choices, age, hydration status, fasting status at the time of specimen collection, and reference

standards used by the clinical laboratory. Single test results may be useful for screening or to confirm an assessment based on changing clinical, anthropometric, and dietary status. Comparison of current test results to historic baseline test results from the same laboratory is desirable when available. It is vital to monitor trends in test results and patterns of results in the context of genetic and environmental factors. Changes in laboratory test results that occur over time are often an objective measure of nutrition or pharmacologic interventions and modified lifestyle choices.

Specimen Types

Ideally, the specimen to be tested reflects the total body content of the nutrient to be assessed. However, the best specimen may not be readily available. The most common specimens for analysis of nutrients and nutrient-related substances include the following:

- Whole blood: Collected with an anticoagulant if entire content of the blood is to be evaluated; none of the elements are removed; contains red blood cells (RBCs), white blood cells (WBCs), and platelets suspended in plasma
- Serum: The fluid obtained from blood after the blood has been clotted and then centrifuged to remove the clot and blood cells
- Plasma: The transparent (slightly straw-colored) liquid component of blood, composed of water, blood proteins, inorganic electrolytes, and clotting factors
- Blood cells: Separated from anticoagulated whole blood for measurement of cellular analyte content
- Erythrocytes: RBCs
- Leukocytes: WBCs and leukocyte fractions
- Blood spots: Dried whole blood from finger or heel prick that is placed on paper and can be used for selected hormone tests and other tests such as infant phenylketonuria screening
- Other tissues: Obtained from scrapings (i.e., buccal swabs, or biopsy samples)
- Urine (from random samples or timed collections): Contains a concentrate of excreted metabolites
- Feces (from random samples or timed collections): Important in nutritional analyses when nutrients are not absorbed and therefore are present in fecal material or to determine composition of gut flora or microbiota

Less commonly used specimens include the following:

- Breath tests: Noninvasive tool to evaluate nutrient metabolism and malabsorption, particularly of sugars. Emerging breath test technologies are being used to evaluate protein requirements,

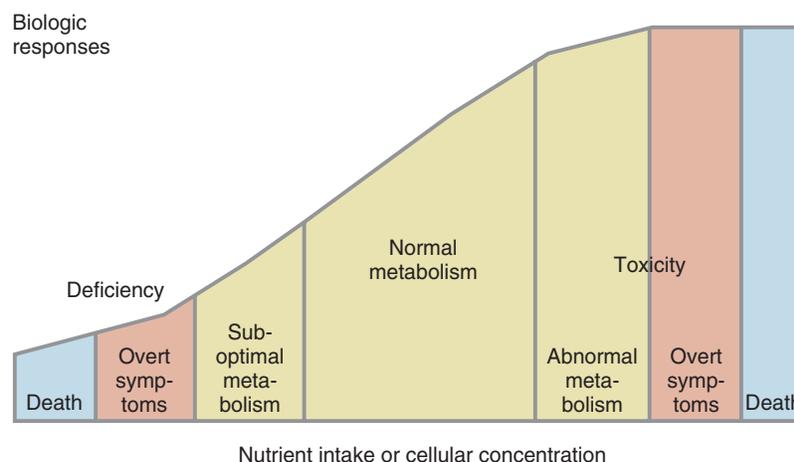

Fig. 5.2 The size of a nutrient pool can vary continuously from frankly deficient, to adequate, to toxic.

inflammatory stress, fructose malabsorption, and bacterial overgrowth in the intestine

- Hair and nails: Easy-to-collect tissue for determining exposure to selected toxic metals
- Saliva: Noninvasive medium with a fast turnover; currently is used to evaluate functional adrenal and other hormone levels
- Sweat: Electrolyte test used to detect sweat chloride levels to determine presence of cystic fibrosis
- Hair and nails specimens have significant drawbacks, including lack of standardized procedures for processing, assay, and quality control and there is potential environmental contamination. Nutrient levels or indices may be less than the amounts that can be measured accurately. Hair can be used for deoxyribonucleic acid (DNA) testing and may be useful in the future as a noninvasive methodology to predict genetic predisposition to disease and effectiveness of MNT (see Chapter 6). Considerable research is being done to improve the usefulness of noninvasive and easy-to-collect specimens that are not routinely ordered.

NUTRITION INTERPRETATION OF ROUTINE MEDICAL LABORATORY TESTS

Clinical Chemistry Panels

Historically the majority of laboratory tests were ordered as panels or groupings; however, the current practice is that the professional ordering of the test must justify the medical need for each test ordered. The

bundling or grouping of laboratory tests is changing as health care reforms reshape medical practices to be more cost effective. The most commonly ordered groups of tests are the **basic metabolic panel (BMP)** and the **comprehensive metabolic panel (CMP)** that include groups of laboratory tests defined by the Centers for Medicare and Medicaid Services for reimbursement purposes. The BMP and CMP require the patient to fast for 10 to 12 hours before testing. The BMP includes eight tests used for screening blood glucose level, electrolyte and fluid balance, and kidney function. The CMP includes all the tests in the BMP and six additional tests to evaluate liver function. **Table 5.1** explains these tests (see Appendix 12).

Complete Blood Count

The **complete blood count (CBC)** provides a count of the cells in the blood and description of the RBCs. A hemogram is a CBC with a white blood cell **differential count** (often called a *differential* or *diff*). **Table 5.2** provides a list of the basic elements of the CBC and differential, with reference ranges and explanatory comments.

Stool Testing

Mucosal changes in the gastrointestinal (GI) tract are indicated by problems such as diarrhea and bloody or black stool. Tests may be done on a stool sample and can reveal excessive amounts of fat (an indication of malabsorption), the status of the GI flora, and the amounts and types of bacteria present in the gut. Fecal samples may be tested for the presence of blood, pathogens, and gut flora. The fecal occult blood test is ordered routinely for adults older than

TABLE 5.1 Constituents of the Basic Metabolic Panel and Comprehensive Metabolic Panel

Analytes	Reference Range*	Purpose	Significance
Basic Metabolic Panel (BMP) (All Tests Reflect Fasting State)			
Glucose	70-99 mg/dL; 3.9-5.5 mmol/L (fasting)	Used to screen for diabetes and to monitor patients with diabetes. Individuals experiencing severe stress from injuries or surgery have hyperglycemia related to catecholamine release	Fasting glucose >125 mg/dL indicates DM (oral glucose tolerance tests are not needed for diagnosis); fasting glucose >100 mg/dL is indicator of insulin resistance Monitor levels along with triglycerides in those receiving parenteral nutrition for glucose intolerance
Total calcium	8.5-10.5 mg/dL; 2.15-2.57 mmol/L Normal dependent on albumin level	Reflects the calcium levels in the body that are not stored in bones. Used to evaluate parathyroid hormone function, calcium metabolism and monitor patients with renal failure, renal transplant, and some cancers	Hypercalcemia associated with endocrine disorders, malignancy, and hypervitaminosis D Hypocalcemia associated with vitamin D deficiency and inadequate hepatic or renal activation of vitamin D, hypoparathyroidism, magnesium deficiency, renal failure, and nephrotic syndrome When serum albumin is low, ionized calcium is measured
Na ⁺	135-145 mEq/L; 135-145 mm/L	Reflects the relationship between total body sodium and extracellular fluid volume as well as the balance between dietary intake and renal excretory function	Used in monitoring various patients, such as those receiving parenteral nutrition or who have renal conditions, uncontrolled DM, various endocrine disorders, ascitic and edematous symptoms, or acidotic or alkalotic conditions; water dysregulation, and diuretics. Increased with dehydration and decreased with overhydration
K ⁺	3.6-5 mEq/L; 3.6-5 mmol/L	Levels often change with sodium levels. As sodium increases, potassium decreases and vice versa. Reflects kidney function, changes in blood pH, and adrenal gland function	Used in monitoring various patients, such as those receiving parenteral nutrition or who have renal conditions, uncontrolled DM, various endocrine disorders, ascitic and edematous symptoms, or acidotic or alkalotic conditions; decreased K ⁺ associated with diarrhea, vomiting, or nasogastric aspiration, water dysregulation, some drugs, licorice ingestion, and diuretics; increased K ⁺ associated with renal diseases, crush injuries, infection, and hemolyzed blood specimens.

Continued

TABLE 5.1 Constituents of the Basic Metabolic Panel and Comprehensive Metabolic Panel—cont'd

Analytes	Reference Range*	Purpose	Significance
Basic Metabolic Panel (BMP) (All Tests Reflect Fasting State)			
Cl ⁻	101-111 mEq/L; 101-111 mmol/L	Reflects acid–base balance, water balance, and osmolality	Used in monitoring various patients, such as those receiving parenteral nutrition or who have renal conditions, chronic obstructive pulmonary disease, diabetes insipidus, acidotic or alkalotic conditions; increased with dehydration and decreased with overhydration
HCO ₃ ⁻ (or total CO ₂)	21-31 mEq/L; 21-31 mmol/L	Used to assess acid–base balance and electrolyte status	Used in monitoring various patients, such as those receiving parenteral nutrition or who have renal conditions, chronic obstructive pulmonary disease, uncontrolled DM, various endocrine disorders, ascitic and edematous symptoms, or acidotic or alkalotic conditions
BUN or urea	5-20 mg urea nitrogen/dL; 1.8-7 mmol/L	Used to assess excretory function of kidney and metabolic function of liver	Increased in those with renal disease and excessive protein catabolism and overhydration; decreased in those with liver failure and negative nitrogen balance and in females who are pregnant
Creatinine	0.6-1.2 mg/dL; 53-106 μmol/L (males) 0.5-1.1 mg/dL; 44-97 μmol/L (females)	Used to assess excretory function of kidney	Increased in those with renal disease and after trauma or surgery; and decreased in those with malnutrition (i.e., BUN/creatinine ratio >15:1)
Comprehensive Metabolic Panel (CMP) (All Tests Reflect Fasting State and Includes All of the Tests in the BMP and Six Additional Tests)			
Albumin	3.5-5 mg/dL; 30-50 g/L	Reflects severity of illness, inflammatory stress and serves as marker for mortality	Decreased in those with liver disease or acute inflammatory disease and overhydration. Increases with dehydration. It is not a biomarker of protein status
Total protein	6.4-8.3 g/dL; 64-83 g/L	Reflects albumin and globulin in blood	Not a useful measure of nutrition or protein status
ALP	30-120 units/L; 0.5-2 μKat/L	Reflects function of liver; may be used to screen for bone abnormalities	Increased in those with any of a variety of malignant, muscle, bone, intestinal, and liver diseases or injuries
ALT	4-36 units/L at 37° C; 4-36 units/L	Reflects function of liver	Used in monitoring liver function in those receiving parenteral nutrition
AST	0-35 IU/L; 0-0.58 μKat/L	Reflects function of liver; may be used to screen for cardiac abnormalities	Used in monitoring liver function in those receiving parenteral nutrition
Bilirubin	Total bilirubin 0.3-1 mg/dL; 5.1-17 μmol/L Indirect bilirubin 0.2-0.8 mg/dL; 3.4-12 μmol/L Direct bilirubin 0.1-0.3 mg/dL; 1.7-5.1 μmol/L	Reflects function of liver; also used to evaluate blood disorders, and biliary tract blockage	Increased in association with drugs, gallstones, and other biliary duct diseases; intravascular hemolysis and hepatic immaturity; decreased with some anemias
Phosphorous (phosphate)	3-4.5 mg/dL; 0.97-1.45 mmol/L		Hyperphosphatemia associated with hypoparathyroidism and hypocalcemia; hypophosphatemia associated with hyperparathyroidism, chronic antacid ingestion, and renal failure
Total cholesterol	<200 mg/dL; 5.20 mmol/L		Decreased in those with malnutrition, malabsorption, liver diseases, and hyperthyroidism
Triglycerides	<100 mg/dL; <1.13 mmol/L (age and gender dependent)		Increased in those with glucose intolerance (e.g., in those receiving parenteral nutrition who have combined hyperlipidemia) or in those who are not fasting

*Reference ranges may vary slightly among laboratories.

ALP, Alkaline phosphate; ALT, alanine aminotransferase; AST, aspartate aminotransferase; BUN, blood urea nitrogen; Cl⁻, chlorine; CO₂, carbon dioxide; DM, diabetes mellitus; HCO₃⁻, bicarbonate; K⁺, potassium; Na⁺, sodium; PEM, protein-energy malnutrition.

age 50 and younger adults with unexplained anemia. Stool culture testing may be ordered in patients with prolonged diarrhea, especially if foodborne illness is suspected. If pathogenic bacteria are isolated in stool culture, appropriate pharmacologic interventions are initiated. Patients with chronic GI symptoms such as

maldigestion or unexplained weight loss or gain may benefit from gut flora testing to identify pathologic flora or an imbalance of physiologic flora. In addition, stool tests may be helpful to evaluate the gut microbiota and the effectiveness of probiotic, prebiotic, and synbiotic use.

TABLE 5.2 Constituents of the Hemogram: Complete Blood Count and Differential

Analytes	Reference Range*	Significance
Red blood cells	4.7-6.1 × 10 ⁶ /μl (males); 4.7-6.1 10 ¹² /L 4.2-5.4 × 10 ⁶ /μl (females); 4.2-5.4 10 ¹² /L	In addition to nutritional deficits, may be decreased in those with hemorrhage, hemolysis, genetic aberrations, marrow failure, or renal disease or who are taking certain drugs; not sensitive for iron, vitamin B ₁₂ , or folate deficiencies
Hemoglobin concentration	14-18 g/dL; 8.7-11.2 mmol/L (males) 12-16 g/dL; 7.4-9.9 mmol/L (females) >11 g/dL; >6.8 mmol/L (pregnant females) 14-24 g/dL; 8.7-14.9 mmol/L (newborns)	In addition to nutritional deficits, may be decreased in those with hemorrhage, hemolysis, genetic aberrations, marrow failure, or renal disease or who are taking certain drugs
Hematocrit	42%-52% (males) 35%-47% (females) 33% (pregnant females) 44%-64% (newborns)	In addition to nutritional deficits, may be decreased in those with hemorrhage, hemolysis, genetic aberrations, marrow failure, or renal disease or who are taking certain drugs Somewhat affected by hydration status
MCV	80-99 fl 96-108 fl (newborns)	Decreased (microcytic) in presence of iron deficiency, thalassemia trait and chronic renal failure; normal or decreased in anemia of chronic disease; increased (macrocytic) in presence of vitamin B ₁₂ or folate deficiency and genetic defects in DNA synthesis; neither microcytosis nor macrocytosis sensitive to marginal nutrient deficiencies
MCH	27-31 pg/cell 23-34 pg/cell (newborns)	Causes of abnormal values similar to those for MCV
MCHC	32-36 g/dL; 32-36% 32-33 g/dL; 32-33% (newborns)	Decreased in those with iron deficiency and thalassemia trait; not sensitive to marginal nutrient deficiencies
WBC	5-10 × 10 ⁹ /L; 5,000-10,000/mm ³ (2 yr-adult) 6-17 × 10 ⁹ /L; 6,000-17,000/mm ³ (<2 yr) 9-30 × 10 ⁹ ; 9,000-30,000/mm ³ (newborns)	Increased (leukocytosis) in those with infection, neoplasia; stress decreased (leucopenia) in those with malnutrition, autoimmune diseases, or overwhelming infections or who are receiving chemotherapy or radiation therapy
Differential	55%-70% neutrophils 20-40% lymphocytes 2-8% monocytes 1%-4% eosinophils 0.5%-1% basophils	<i>Neutrophilia</i> : Ketoacidosis, trauma, stress, pus-forming infections, leukemia <i>Neutropenia</i> : malnutrition, aplastic anemia, chemotherapy, overwhelming infection <i>Lymphocytosis</i> : Infection, leukemia, myeloma, mononucleosis <i>Lymphocytopenia</i> : Leukemia, chemotherapy, sepsis, AIDS <i>Eosinophilia</i> : Parasitic infestation, allergy, eczema, leukemia, autoimmune disease <i>Eosinopenia</i> : Increased steroid production <i>Basophilia</i> : Leukemia <i>Basopenia</i> : Allergy

*Reference ranges may vary slightly among laboratories.

AIDS, Acquired immune deficiency syndrome; DNA, deoxyribonucleic acid; MCH, mean corpuscular hemoglobin; MCHC, mean corpuscular hemoglobin concentration; MCV, mean corpuscular volume.

Urinalysis

The **urinalysis** test is used as a screening or diagnostic tool to detect substances or cellular material in the urine associated with different metabolic and kidney disorders. Some urinalysis data have broader medical and nutritional significance (e.g., glycosuria suggests abnormal carbohydrate metabolism and possibly diabetes). The full urinalysis includes a record of (1) the appearance of the urine, (2) the results of basic tests done with chemically impregnated reagent strips (often called dipsticks) that can be read visually or by an automated reader, and (3) the microscopic examination of urine sediment. **Table 5.3** provides a list of the chemical tests performed in a urinalysis and their significance.

ASSESSMENT OF HYDRATION STATUS

Assessment of hydration status is vital because water dysregulation can be associated with other imbalances such as electrolyte imbalance. Types of water dysregulation include volume depletion or extracellular fluid contraction, dehydration or sodium intoxication, and overhydration or excessive fluid shift into interstitial-lymph fluid compartment. **Dehydration** often is due to excessive loss of water and electrolytes from vomiting; diarrhea; excessive laxative

abuse; diuretics; fistulas; GI suction; polyuria; fever; excessive sweating; or decreased intake caused by anorexia, nausea, depression, or limited access to fluids. Characteristics include rapid weight loss, decreased skin turgor, dry mucous membranes, dry and furrowed tongue, postural hypotension, a weak and rapid pulse, slow capillary refill, a decrease in body temperature (95° to 98° F), decreased urine output, cold extremities, or disorientation (see Chapter 3).

Volume depletion is a state of vascular instability resulting from blood loss, GI bleeding, burns, vomiting, and diarrhea. Volume depletion may occur with low serum sodium (hyponatremia), high blood sodium (hypernatremia), or normal serum sodium levels.

Edema (overhydration), occurs when there is an increase in the extracellular fluid volume. The fluid shifts from the extracellular compartment to the interstitial fluid compartment (see Fig. 3.2 in Chapter 3). Overhydration is caused by an increase in capillary hydrostatic pressure or capillary permeability, or a decrease in colloid osmotic pressure. It often is associated with renal failure, chronic heart failure, cirrhosis of the liver, Cushing's syndrome, excess use of sodium-containing intravenous fluids, and excessive intake of sodium-containing food or medications. Characteristics include rapid weight gain, peripheral edema, distended neck veins, slow emptying of peripheral veins, a bounding and full pulse, rales in the

TABLE 5.3 Chemical Tests in a Urinalysis

Analyte	Expected Value	Significance
Specific gravity	1.010-1.025	Can be used to test and monitor the concentrating and diluting abilities of the kidney and hydration status; low in those with diabetes insipidus, glomerulonephritis, or pyelonephritis; high in those with vomiting, diarrhea, sweating, fever, adrenal insufficiency, hepatic diseases, or heart failure
pH	4.6-8 (normal diet)	Acidic in those with a high-protein diet or acidosis (e.g., uncontrolled DM or starvation), during administration of some drugs, and in association with uric acid, cystine, and calcium oxalate kidney stones; alkaline in individuals consuming diets rich in vegetables or dairy products and in those with a urinary tract infection, immediately after meals, with some drugs, and in those with phosphate and calcium carbonate kidney stones
Protein	2-8 mg/dL	Marked proteinuria in those with nephrotic syndrome, severe glomerulonephritis, or congestive heart failure; moderate in those with most renal diseases, preeclampsia, or urinary tract inflammation; minimal in those with certain renal diseases or lower urinary tract disorders
Glucose	Not detected (2-10 g/dL in DM)	Positive in those with DM; rarely in benign conditions
Ketones	Negative	Positive in those with uncontrolled DM (usually type 1); also positive in those with a fever, anorexia, certain GI disturbances, persistent vomiting, or cachexia or who are fasting or starving
Blood	Negative	Indicates urinary tract infection, neoplasm, or trauma; also positive in those with traumatic muscle injuries or hemolytic anemia
Bilirubin	Not detected	Index of unconjugated bilirubin; increase in those with certain liver diseases (e.g., gallstones)
Urobilinogen	0.1-1 units/dL	Index of conjugated bilirubin; increased in those with hemolytic conditions; used to distinguish among hepatic diseases
Nitrite	Negative	Index of bacteriuria
Leukocyte esterase	Negative	Indirect test of bacteriuria; detects leukocytes

DM, Diabetes mellitus; GI, gastrointestinal.

lungs, polyuria, ascites, and pleural effusion. Pulmonary edema may occur in severe cases.

Laboratory measures of hydration status include serum sodium, blood urea nitrogen (elevated out of proportion to serum creatinine), serum osmolality, and urine-specific gravity. Although the laboratory tests are important, decisions regarding hydration should only be made only in conjunction with other information from physical examination, nutrition-focused physical examination, and the clinical condition of the patient. In addition, many other laboratories may be affected by overhydration or dehydration, and accurate interpretation of laboratory results is critical in assessing patients (see Table 5.1).

Inflammation and Biochemical Assessment

Inflammation is a protective response by the immune system to infection, acute illness, trauma, toxins, many chronic diseases, and physical stress. Biochemical indices are affected by inflammation primarily by redirection to synthesis of acute phase reactants. Inflammatory conditions trigger the immune response to release eicosanoids and cytokines, which mobilize nutrients required to synthesize **positive acute-phase reactants** (which increase in response to inflammation) and leukocytes. Cytokines (interleukin-1beta [IL-1 β], tumor necrosis factor alpha [TNF- α], interleukin-6 [IL-6]), and eicosanoids (prostaglandin E2 [PGE2]) influence whole-body metabolism, body composition, and nutritional status. Cytokines reorient hepatic synthesis of plasma proteins and increase the breakdown of muscle protein to meet the demand for protein and energy during the inflammatory response. Moreover, there is a redistribution of albumin to the interstitial compartment, resulting in edema. Declining values of the **negative acute-phase reactants** (i.e., serum albumin, prealbumin, and transferrin) also reflect the inflammatory processes and severity of tissue injury. In the acute inflammatory state, negative acute phase

reactant values do not reflect current dietary intake or protein status (White et al, 2012).

Cytokines impair the production of erythrocytes and reorient iron stores from hemoglobin and serum iron to ferritin. During infection IL-1 β inhibits the production and release of transferrin while stimulating the synthesis of ferritin. Therefore laboratory test results used to predict the risk of nutritional anemias (see Chapter 31) are not useful in assessing the patient with an inflammatory response. Refer to Chapter 7 for more information on the effects of cytokines on organ systems.

As the body responds to acute inflammation, TNF- α , IL-1 β , IL-6, and PGE2 increase to a set threshold, then IL-6 and PGE2 inhibit TNF- α synthesis and IL-1 β secretion, creating a negative feedback cycle. Hepatic synthesis of positive acute-phase reactants diminishes, and synthesis of negative acute-phase reactants increases. Albumin shifts from the interstitial compartment to the extravascular space where it can be measured as serum albumin. Albumin in the interstitial space cannot be measured, therefore albumin is not a reliable marker for protein status. Iron stores shift from ferritin to transferrin and hemoglobin.

Markers of Inflammation

Biochemical markers of inflammation include positive acute phase reactants and negative acute phase reactants. In the presence of inflammation, the hepatic synthesis of positive acute-phase reactants is *increased* while the synthesis of the negative acute-phase reactants is *depressed*. See Table 5.4 for acute phase reactants. Additional markers of oxidative stress and inflammation can be found in Table 5.5.

Positive Acute Phase Reactants

C-Reactive Protein

C-reactive protein (CRP) is a nonspecific marker of inflammation that may help estimate and monitor the severity of illness.

TABLE 5.4 Acute Phase Reactants

Positive Acute-Phase Reactants	Negative Acute-Phase Proteins
C-reactive protein	Albumin
α_1 antichymotrypsin	Transferrin
α_1 -antitrypsin	Prealbumin (transthyretin)
Haptoglobins	Retinol-binding protein
Ceruloplasmin	
Serum amyloid A	
Fibrinogen	
Ferritin	
Complement and components C3 and C4	
Orosomuroid	

High-sensitivity CRP (hs-CRP) is a more sensitive measure of chronic inflammation seen in patients with atherosclerosis and other chronic diseases (Wang et al, 2017). Although the exact function of CRP is unclear, it increases in the initial stages of acute stress—usually within 4 to 6 hours of surgery or other trauma. Furthermore, its level can increase as much as 1000-fold, depending on the intensity of the stress response. When the CRP level begins to decrease, the patient has entered the anabolic period of the inflammatory response and the beginning of recovery when more intensive nutrition therapy may be beneficial. Ongoing assessment and follow-up are required to address changes in nutrition status.

Ferritin

Ferritin is a positive acute-phase protein, meaning that synthesis of ferritin increases in the presence of inflammation. Ferritin is not a reliable indicator of iron stores in patients with acute inflammation, uremia, metastatic cancer, or alcoholic-related liver diseases. Cytokines

TABLE 5.5 Advantages and Disadvantages of Various Biomarkers of Oxidative Stress

Biomarker	Advantages	Disadvantages	Comments
IsoPs (isoprostanes)	Can be detected in various samples (serum, urine) and has been shown to be elevated in the presence of a range of CV risk factors	Current methods of quantification are impractical for large-scale screening.	No evidence linking this biomarker to clinical outcomes yet. F ₂ -IsoPs show most potential
MDA (malondialdehyde)	Technically easy to quantify spectrophotometrically using the TBARS assay ELISA kits to detect MDA also have good performance Studies show MDA can predict progression of CAD and carotid atherosclerosis at 3 years	TBARS assay is nonspecific (can detect aldehydes other than MDA) and sample preparation can influence results.	Shows promise as a clinical biomarker; however, does not have a functional impact on the pathophysiology of CVD
Nitrotyrosine (3-NO ₂ -tyr)	Human studies have demonstrated association with CAD independent of traditional risk factors	Circulating levels are not equivalent to tissue levels. Current detection methods are expensive and impractical.	Nitrotyrosine formation on particular cardiovascular proteins has direct effect on function
S-glutathionylation	S-glutathionylation of SERCA, eNOS and Na ⁺ -K ⁺ pump demonstrated as biomarkers as well as role in pathogenesis	Detection of S-glutathionylation prone to methodological artifact Access to tissue (myocardium, vasculature), where modification occurs presents a clinical obstacle	Modified hemoglobin currently being investigated as biomarker
Myeloperoxidase (MPO)	Commercial assays available. An enzyme abundant in granules in inflammatory cells. Strong evidence that MPO correlates with CVD risk	Influenced by sample storage and time to analysis	MPO is a promising biomarker for CVD risk prediction
Oxidized LDL cholesterol (OxLDL)	Forms and occurs in vascular walls as foam cells and stimulates production of proinflammatory cytokines by endothelial cells. Elevated in CAD, increasing OxLDL correlates with increasing clinical severity. Also is predictive of future CAD in healthy population. Good reproducibility from frozen samples	Reduction in OxLDL by antioxidant pharmacotherapy has not been matched by reduction in CVD severity.	ELISAs for OxLDL detection readily available
ROS-induced changes to gene expression	The expression of several genes involved in regulating oxidative stress may be measured simultaneously using microarray technology, potentially increasing the power of this biomarker	Microarray technology can be manually and computationally expensive	It is unclear if expression profiles of cells in biologic samples reflect that in cardiovascular tissues
Serum antioxidant capacity	Activity of antioxidant enzymes such as glutathione peroxidase 1 (GPX-1) and superoxide dismutase (SOD) are demonstrated to be inversely proportional to CAD. Commercial kits available to measure antioxidant capacity. Reproducibly quantified despite frozen sample storage	Antioxidant activity in serum may not reflect that of the cells that are important to the pathogenesis of CVD	Clinical relevance of antioxidant quantification to CVD risk needs further investigation

CAD, Coronary artery disease; CV, cardiovascular; CVD, cardiovascular disease; ELISA, enzyme-linked immunosorbent assay; TBARS, thiobarbituric acid (TBA) reacting substances; eNOS, endothelial nitric oxide synthase; GPX-1, glutathione peroxidase-1, ROS, reactive oxygen species; SERCA, sarcoplasmic reticulum Ca²⁺-ATPase, SOD, superoxide dismutase.

and other inflammatory mediators can increase ferritin synthesis, ferritin leakage from cells, or both. Elevations in ferritin occur 1 to 2 days after the onset of the acute illness and peak at 3 to 5 days. If iron deficiency also exists, it may not be diagnosed because the level of ferritin would be falsely elevated.

Erythrocyte Sedimentation Rate

Erythrocyte sedimentation rate (ESR) reflects the rate at which RBCs settle into columns or stacks in a saline or plasma within a given time period. Inflammatory processes lead to increased weight of the RBC and more likely to settle rapidly unlike normal erythrocytes. ESR is useful in differentiating disease entities and is also used to monitor disease therapy (i.e., as ESR increases, the disease state worsens) (Litchford, 2017).

Negative Acute Phase Reactants

Albumin

Albumin is responsible for the transport of major blood constituents, hormones, enzymes, medications, minerals, ions, fatty acids, amino acids, and metabolites. A major role of albumin is to maintain colloidal osmotic pressure, providing approximately 80% of colloidal osmotic pressure of the plasma. When serum albumin levels decrease, the water in the plasma moves into the interstitial compartment and edema results. This loss of plasma fluid results in hypovolemia, which triggers renal retention of water and sodium.

Albumin has a half-life of 18 to 21 days. Levels of albumin remain nearly normal during uncomplicated starvation as redistribution from the interstitium to the plasma occurs. Levels of albumin fall precipitously in inflammatory stress and often do not improve with aggressive nutrition support. Serum levels reflect the severity of illness but do not reflect current protein status or the effects of nutrient-dense supplemental nutrition. For these reasons, a well-nourished but stressed patient may have low levels of albumin and the hepatic transport proteins, whereas a patient who has had significant weight loss and undernutrition may have normal or close to normal levels. Albumin is very sensitive to hydration status, and the practitioner must be aware and document the true cause of an elevated or depressed albumin level.

Albumin is synthesized in the liver and is a measure of liver function. When disease affects the liver, the synthesis of albumin, by the hepatocytes, is impaired. Because of the half-life of albumin, significant changes in liver function are not immediately apparent.

Prealbumin (Transthyretin)

Prealbumin (PAB), officially **transthyretin (TTHY)**, is a hepatic protein transported in the serum as a complex of retinol-binding protein and vitamin A. It transports the thyroid hormones triiodothyronine and thyroxine (T_4), along with T_4 -binding globulin. It has a short half-life ($t_{1/2} = 2$ days), and currently it is considered a marker of inflammation. Levels of PAB plummet in inflammatory stress and are not sensitive measures to evaluate the effectiveness of aggressive nutrition support. Moreover, serum levels decrease with malignancy and protein-wasting diseases of the intestines or kidneys. Serum levels do not reflect protein status or the effects of refeeding in the individual with depleted protein reserves. Serum levels also decrease in the presence of a zinc deficiency because zinc is required for hepatic synthesis and secretion of PAB. Consider zinc status from dietary intake and medical history, in addition to inflammation, when interpreting low plasma PAB levels.

PAB levels are often normal in starvation-related malnutrition but decreased in well-nourished individuals who have undergone

recent stress or trauma. During pregnancy, the changed estrogen levels stimulate PAB synthesis and serum levels may increase. In nephrotic syndrome, PAB levels also may be increased. Proteinuria and hypoproteinemia are common in nephrotic syndrome, and because PAB is synthesized rapidly, a disproportionate percentage of PAB can exist in the blood, whereas other proteins take longer to produce (Litchford, 2017).

Retinol-Binding Protein

The hepatic protein with the shortest half-life ($t_{1/2} = 12$ hr) is **retinol-binding protein (RBP)**, a small plasma protein that does not pass through the renal glomerulus because it circulates in a complex with PAB. As implied by its name, RBP binds **retinol**, and transport of this vitamin A metabolite seems to be its exclusive function. RBP is synthesized in the liver and released with retinol. After RBP releases retinol in peripheral tissue, its affinity for PAB decreases, leading to dissociation of the PAB-RBP complex and filtration of apoprotein (apo)-RBP by the glomerulus.

The plasma RBP concentration has been shown to decrease in starvation-related malnutrition. However, RBP levels also fall in the presence of inflammatory stress and may not improve with refeeding. RBP may not reflect protein status in acutely stressed patients. It may even be elevated with renal failure because the RBP is not being catabolized by the renal tubule.

RBP4 is an adipocyte-derived peptide of RBP that influences glucose homeostasis and lipoprotein metabolism. Human clinical trials have demonstrated increased RBP4 levels in obesity, insulin resistance, gestational diabetes, proliferative diabetic retinopathy, and nondiabetic stage 5 chronic kidney disease, ischemic stroke, suggesting a possible relationship between these conditions. Larger clinical trials are needed to define this relationship (Xun et al, 2018; Perduca et al, 2018; Klisić et al, 2017; Zhou et al, 2017).

Transferrin

Transferrin is a globulin protein that transports iron to the bone marrow for production of **hemoglobin (Hgb)**. The plasma transferrin level is controlled by the size of the iron storage pool. When iron stores are depleted, transferrin synthesis increases. It has a shorter half-life ($t_{1/2} = 8$ days) than albumin. Levels diminish with acute inflammatory reactions, malignancies, collagen vascular diseases, and liver diseases. Transferrin levels reflect inflammation and are not useful as a measure of protein status.

Immunocompetence

Inflammation-related malnutrition is associated with impaired immunocompetence, including depressed cell-mediated immunity, phagocyte dysfunction, decreased levels of complement components, reduced mucosal secretory antibody responses, and lower antibody affinity. Assessing immunocompetence (i.e., eosinophils) is also useful in the patient who is being treated for allergies (see Chapter 25).

There is no single marker for immunocompetence except for the clinical outcome of infection or allergic response. Laboratory markers with a high degree of sensitivity include vaccine-specific serum antibody production, delayed-type hypersensitivity response, vaccine-specific or total secretory immunoglobulin A in saliva, and the response to attenuated pathogens. Less sensitive markers include natural killer cell cytotoxicity, oxidative burst of phagocytes, lymphocyte proliferation, and the cytokine pattern produced by activated immune cells. Using a combination of markers is currently the best approach to measuring immunocompetence.

ASSESSMENT FOR NUTRITIONAL ANEMIAS

Anemia is a condition characterized by a reduction in the number of erythrocytes per unit of blood volume or a decrease in the Hgb of the blood to below the level of usual physiologic need. By convention, anemia is defined as Hgb concentration below the 95th percentile for healthy reference populations of men, women, or age-grouped children. Anemia is not a disease but a symptom of various conditions, including extensive blood loss, excessive blood cell destruction, or decreased blood cell formation. It is observed in many hospitalized patients and is often a symptom of a disease process; its cause should be investigated. Clinical nutritionists must distinguish between anemia caused by nutritional inadequacies and that caused by other factors (i.e., dehydration masking falsely low blood values). See Chapter 31 for discussion of the management of anemias.

Classification of Anemia

Nutritional deficits are a major cause of decreased Hgb and erythrocyte production. The initial descriptive classification of anemia is derived from the **hematocrit (Hct)** value or CBC as explained in Table 5.2. Anemias associated with a mean RBC volume of less than 80 fl (femtoliters) are microcytic; those with values of 80 to 99 fl are normocytic; those associated with values of 100 fl or more are macrocytic (see Chapter 32). Data from the CBC are helpful in identifying nutritional causes of anemia. **Microcytic anemia** is associated most often with iron deficiency, whereas **macrocytic anemia** generally is caused by either folate- or vitamin B₁₂-deficient erythropoiesis. However, because of the low specificity of these indexes, additional data are needed to distinguish between the various nutritional causes and nonnutritional causes, such as thalassemia trait and chronic renal insufficiency. Normocytic anemia is associated with the **anemia of chronic and inflammatory disease (ACD)**. This type of anemia is associated with autoimmune diseases, rheumatic diseases, chronic heart failure, chronic infection, Hodgkin's disease and other types of cancer, inflammatory bowel disease, kidney disease and other chronic inflammatory conditions, severe tissue injury, and multiple fractures. ACD does not respond to iron supplementation.

Other information from the CBC that helps differentiate the nonnutritional causes of anemia includes leukocyte, reticulocyte, and platelet counts. When level of leukocytes, reticulocytes, and platelet counts are low, the pattern of results suggests marrow failure. Elevated levels of leukocytes, reticulocytes, and platelet counts are associated with anemia and likely caused by leukemia or infection. ESR testing is ordered when symptoms are nonspecific and if inflammatory autoimmune diseases are suspected. Reticulocytes are large, nucleated, immature RBCs that are released in small numbers with mature cells. When RBC production rates increase, reticulocyte counts also increase. Any time anemia is accompanied by a high reticulocyte count, elevated erythropoietic activity in response to bleeding should be considered. In such cases, stool specimens can be tested for occult blood to rule out chronic GI blood loss. Other causes of a high reticulocyte count include intravascular hemolysis syndromes and an erythropoietic response to therapy for iron, vitamin B₁₂, or folate deficiencies.

Normocytic or microcytic anemia may be caused by chronic or acute blood loss, such as from recent surgery, injury, or from the GI tract as indicated by a positive occult stool test. Note that in those with hemolytic anemias and early iron deficiency anemia, the RBC size may still be normal. Macrocytic anemias include folate deficiency and vitamin B₁₂ deficiency. The presence of macrocytic RBCs requires evaluation of folate and vitamin B₁₂ status. DNA synthesis is affected negatively by deficiencies of folic acid and vitamin B₁₂, resulting in

impaired RBC synthesis and maturation of RBCs. These changes cause large, nucleated cells to be released into the circulation. Although vitamin B₁₂-related anemia is categorized as a macrocytic normochromic anemia, approximately 40% of the cases are normocytic.

Markers of Iron Deficiency Anemias

Hematocrit or Packed Cell Volume and Hemoglobin

Hct and Hgb are part of a routine CBC and are used together to evaluate iron status. Hct is the measure of the percentage of RBCs in total blood volume. Usually the Hct percentage is three times the Hgb concentration in grams per deciliter. The Hct value is affected by an extremely high WBC count and hydration status. Individuals living in high altitudes often have increased values. It is common for individuals older than age 50 to have slightly lower levels than younger adults.

The Hgb concentration is a measure of the total amount of Hgb in the peripheral blood. It is a more direct measure of iron deficiency than Hct because it quantifies total Hgb in RBCs rather than a percentage of total blood volume. Hgb and Hct are below normal in the four types of nutritional anemias and always should be evaluated in light of other laboratory values and recent medical history (see Chapter 31).

Serum Ferritin

Ferritin is the storage protein that sequesters the iron normally gathered in the liver (reticuloendothelial system), spleen, and marrow. As the iron supply increases, the intracellular level of ferritin increases to accommodate iron storage. A small amount of this ferritin leaks into the circulation. This ferritin can be measured by assays that are available in most clinical laboratories. In individuals with normal iron storage, 1 ng/mL of serum ferritin is about 8 mg of stored iron. In healthy adults, the measurement of ferritin that has leaked into the serum is an excellent indicator of the size of the body's iron storage pool.

ACD is the primary condition in which ferritin fails to correlate with iron stores. ACD, a common form of anemia in hospitalized patients, occurs in those with cancer or inflammatory or infectious disorders. It occurs during inflammation because red cell production decreases as the result of inadequate mobilization of iron from its storage sites. In those with chronic inflammatory conditions (i.e., arthritis) depletion of stored iron develops partly because of reduced absorption of iron from the gut due to release of hepcidin. Also the regular use of nonsteroidal antiinflammatory drugs can cause occult GI blood loss. ACD has many forms and must be distinguished from iron deficiency anemia so that inappropriate iron supplementation is not initiated.

Serum Iron

Serum iron measures the amount of circulating iron that is bound to transferrin. However, it is a relatively poor index of iron status because of large day-to-day changes, even in healthy individuals. Diurnal variations also occur, with the highest concentrations occurring midmorning (from 6 am to 10 am), and a nadir, averaging 30% less than the morning level, occurring midafternoon. Serum iron should be evaluated in light of other laboratory values and recent medical history to assess iron status.

Total Iron-Binding Capacity and Transferrin Saturation

Total iron-binding capacity (TIBC) is a direct measure of all proteins available to bind mobile iron and depends on the number of free binding sites on the plasma iron-transport protein transferrin. Intracellular iron availability regulates the synthesis and secretion of transferrin (i.e., transferrin concentration increases in those with iron deficiency).

Transferrin saturation reflects iron availability to tissues (bone marrow erythropoiesis). It is determined by the following equation:

$$\% \text{ Transferrin saturation} = (\text{Serum Fe} / \text{TIBC}) \times 100$$

In addition, when the amount of stored iron available for release to transferrin decreases and dietary iron intake is low, saturation of transferrin decreases.

There are exceptions to the general rule that transferrin saturation decreases and TIBC increases in patients with iron deficiency. For example, TIBC increases in those with hepatitis. It also increases in people with hypoxia, women who are pregnant, or those taking oral contraceptives or receiving estrogen replacement therapy. On the other hand, TIBC decreases in those with malignant disease, nephritis, and hemolytic anemias. Furthermore, the plasma level of transferrin may be decreased in those with malnutrition, fluid overload, and liver disease. Thus although TIBC and transferrin saturation are more specific than Hct or Hgb values, they are not perfect indicators of iron status.

An additional concern about the use of serum iron, TIBC, and transferrin saturation values is that normal values persist until frank deficiency actually develops. Thus these tests cannot detect decreasing iron stores and iron insufficiencies.

Tests for Macrocytic Anemias From B Vitamin Deficiencies

Macrocytic anemias include folate deficiency and vitamin B₁₂ deficiency. The nutritional causes of macrocytic anemia are related to the availability of folate and vitamin B₁₂ in the bone marrow and require evaluation of both nutrient levels and methyl malonic acid, an intermediate metabolite of vitamin B₁₂ metabolism. Both nutrients decrease DNA synthesis by preventing the formation of thymidine monophosphate. Folate and vitamin B₁₂ are used at different steps of the synthetic pathway. Impaired RBC synthesis occurs and large, nucleated RBCs then are released into the circulation (see Chapter 31).

Assessing Folate and Vitamin B₁₂ Status

Evaluation for macrocytic anemia includes static measurement of folate and vitamin B₁₂ deficiency in blood. They can be assayed using tests of the ability of the patient's blood specimen to support the growth of microbes that require either folate or vitamin B₁₂, or radiobinding assays, or immunoassays.

Serum homocysteine. Folate and vitamin B₁₂ are required for the synthesis of S-adenosylmethionine (SAM), the biochemical precursor involved in the transfer of one-carbon (methyl) groups during many biochemical syntheses. SAM is synthesized from the amino acid methionine by a reaction that includes the addition of a methyl group and the purine base adenine (from adenosine triphosphate, or ATP). For example, when SAM donates a methyl group for the synthesis of thymidine, choline, creatine, epinephrine, and protein and DNA methylation, it is converted to S-adenosylhomocysteine. After losing the adenosyl group, the remaining **homocysteine** can be converted either to cysteine by the vitamin B₆-dependent transsulfuration pathway or back to methionine in a reaction that depends on adequate folate and vitamin B₁₂.

When either folate or vitamin B₁₂ is lacking, the homocysteine-to-methionine reaction is blocked, causing homocysteine to build up in the affected tissue and spill into the circulation. The vitamin B₆-dependent transsulfuration pathway can metabolize excess homocysteine. Homocysteine has been shown to be sensitive to folate and vitamin B₁₂ deficiency.

Therefore an elevated homocysteine level indicates either genetic defects involved in the enzymes that catalyze these reactions, or a

deficiency in folate, vitamin B₁₂, or vitamin B₆. Research indicates that several folate gene polymorphisms affecting the methylation of folate and B₁₂ contribute risk for several chronic cardiovascular and neurologic disorders (Kagawa et al, 2017; see Chapters 6 and 42).

Folate assessment. Folate most often is measured simultaneously in whole blood with its combined amount from plasma and blood cells, and in the serum alone. The difference between whole-blood folate and serum folate levels then is used to calculate total RBC folate concentration. RBC folate concentration is a better indicator of folate status than serum folate, because folate is much more concentrated in RBCs than in the serum. RBC folate measurement more closely reflects tissue stores and is considered the most reliable indicator of folate status. Folate is absorbed in the jejunum, and its malabsorption has several causes, but a specific test for folate absorption is not available. The presence and extent of deficiency should be assessed in patients with celiac disease, those who have had malabsorptive bariatric surgery, those with a history of long-term use of medications such as anticonvulsants and sulfasalazine, those with chronic alcohol consumption, those with methyltetrahydrofolate reductase (MTHFR) genetic polymorphisms, and those with rheumatoid arthritis taking methotrexate (see Chapters 5 and 8).

Vitamin B₁₂ assessment. Vitamin B₁₂ is measured in the serum, and all indications are that the serum level gives as much information about vitamin B₁₂ status as does the RBC level. If vitamin B₁₂ status is compromised, intrinsic factor antibodies (IFAB) and parietal cell antibodies are measured; the presence of antibodies suggests the main cause of macrocytic anemia. Historically the Schilling test was used to detect defects in vitamin B₁₂ absorption; it rarely is used today because the test requires that the patient be given radioactive vitamin B₁₂ (see Chapter 32). **Methylmalonic acid (MMA)** levels in serum or urine are more useful to assess B₁₂ status.

Vitamin B₁₂ and methylmalonic acid. Once a genetic or autoimmune cause is ruled out, the most straightforward biochemical method for differentiating between folate and vitamin B₁₂ deficiencies is by measuring the serum or urinary MMA level. MMA is formed during the degradation of the amino acid valine and odd-chain fatty acids. MMA is the side product in this metabolic pathway that increases when the conversion of methylmalonic coenzyme A (CoA) to succinyl CoA is blocked by lack of vitamin B₁₂, a coenzyme for this reaction. Therefore deficiency leads to an increase in the MMA pool, which is reflected by the serum or urinary MMA level. The urinary MMA test is more sensitive than the serum B₁₂ test because it indicates true tissue B₁₂ deficiency. The serum MMA test may give falsely high values in renal insufficiency and intravascular volume depletion. The urinary MMA test is the only B₁₂ deficiency assay that has been validated as a screening tool. Homocysteine and MMA tend to detect impending vitamin deficiencies better than the static assays. This is especially important when assessing the status of certain patients such as vegans or older adults, who could have vitamin B₁₂ deficiency associated with central nervous system impairment.

FAT-SOLUBLE VITAMINS

Fat malabsorption often results in impaired absorption of vitamins A, E, D, and K. Factors including low luminal pH, bile salts below the critical micellar concentration, and inadequate triglyceride hydrolysis can interfere with normal bile salt micelle formation, causing impaired absorption of fat-soluble vitamins. Individuals with fat malabsorptive disorders, including those who have had bariatric surgery, are at greatest risk of deficiencies of fat-soluble vitamins. See Appendix 12 for further discussion of tests for assessing specific vitamin adequacy.

Vitamin A

Vitamin A status can be estimated using serum retinol, and the normal level in adults is 30 to 80 mcg/dL. A primary deficiency of vitamin A can result from inadequate intake, fat malabsorption, or liver disorders. A secondary deficiency of vitamin A may be due to decreased bioavailability of provitamin A carotenoids or interference with vitamin A absorption, storage, or transport (e.g., celiac disease, cystic fibrosis, pancreatic insufficiency, malabsorptive weight loss surgery, or bile duct obstruction). Vitamin A deficiency is common in prolonged malnutrition and reported a year or longer after gastric bypass surgery and biliopancreatic weight loss surgery (Parrott et al, 2017). The oxidative stress associated with major surgeries, including gastric bypass surgery, also may interfere with vitamin A absorption and use. Because of shared absorptive mechanisms with vitamin D, serum retinol always should be assessed in the presence of vitamin D supplementation.

Acute or chronic vitamin A toxicity is defined as retinol levels greater than 100 mcg/dL. Hypervitaminosis A has been reported in almost 50% of patients taking 150% of the RDA for vitamin A, in the form of retinol, between 6 to 12 months after laparoscopic sleeve gastrectomy (Aarts et al, 2011). Chronic vitamin A toxicities are associated with loss of hair; dry mucous membranes; dry, rough skin; and even cortical bone loss and fractures (see Appendix 12).

Vitamin D

Individual vitamin D status can be estimated by measuring plasma **25 hydroxy vitamin D (25[OH]D₃)** levels. Current clinical practice reference ranges have been updated by the Institute of Medicine (IOM, 2011). Traditional levels defining vitamin D sufficiency have been based on the lowest threshold value for plasma 25(OH)D₃ (approximately 80 nmol/L or 32 ng/mL) that prevents secondary hyperparathyroidism, increased bone turnover, bone mineral loss, or seasonal variations in plasma parathyroid hormone. The IOM review concluded that individuals are at risk of deficiency at serum 25(OH)D₃ levels below 30 nmol or 12 ng/mL and that practically all persons have sufficient serum levels at 50 nmol or 20 ng/mL. The American Geriatric Society (AGS) published a new consensus statement on vitamin D and calcium supplementation for reduction of falls and fractures in adults 65 years and older and for high-risk populations with malabsorption syndromes, those using medications that accelerate vitamin D metabolism, the obese, and those with minimal sun exposure (AGS, 2014).

Vitamin D sufficiency is defined as 25(OH)D₃ at 75 nmol/L, or 30 ng/mL (AGS, 2014). Serum levels even higher at 90 to 100 nmol/L (36 to 40 ng/mL) are recommended by some (Bischoff-Ferrari, 2014). The U.S. Preventive Services Task Force (USPSTF) found adequate evidence that daily supplementation with 400 IU or less of vitamin D and 1000 mg or less of calcium—or greater than 400 IU vitamin D or greater than 1000 mg calcium—had no benefit for the primary prevention of fractures in community-dwelling, postmenopausal women without a history of osteoporotic fractures, increased risk for falls, or a diagnosis of osteoporosis (USPSTF, 2018). Optimal levels of 25(OH)D₃ have not been defined, and the measurement of serum levels lacks standardization and calibration.

A vitamin D deficiency may be due to inadequate dietary intake, inadequate exposure to sunlight, or malabsorption. Deficiency of vitamin D also can lead to secondary malabsorption of calcium. Calcium malabsorption occurs in chronic renal failure because renal hydroxylation is required to activate vitamin D, which promotes synthesis of a calcium-binding protein in intestinal absorptive cells (see Chapter 34). Vitamin D toxicity is rare, but it has been reported in a few patients taking megadoses of vitamin D. Reported adverse effects include hypercalcemia, hyperphosphatemia, suppressed parathyroid-hormone levels, and hypercalciuria (Taylor and Davies, 2018).

Vitamin E

Vitamin E status can be estimated by measuring serum alpha-tocopherol or the ratio of serum alpha-tocopherol to total serum lipids. A low ratio suggests vitamin E deficiency. Deficiencies are uncommon in the developed world except in individuals with fat malabsorption syndromes. The main symptoms of a vitamin E deficiency include mild hemolytic anemia and nonspecific neurologic effects. In adults, alpha-tocopherol levels less than 5 µg/mL (<11.6 µmol/L) are associated with a deficiency. In adults with hyperlipidemia, a low ratio of serum alpha-tocopherol to lipids (<0.8 mg/g total lipid) is the most accurate indicator.

Vitamin E toxicity is uncommon, but intakes of vitamin E greater than 1000 mg/d may result in a significant bleeding risk, especially if the individual is taking anticoagulation medications. A meta-analysis of the relationship between supplemental vitamin E and all-cause mortality demonstrated that supplementation with vitamin E appears to have no effect on all-cause mortality at doses up to 5500 IU/d (Abner et al, 2011).

Vitamin K

Vitamin K status can be estimated using prothrombin time (PT). PT is used to evaluate the common pathway of blood clotting. The synthesis of clotting factors II, VII, IX, and X are vitamin K dependent. **Osteocalcin** or bone Gla protein (BGP), a bone turnover marker, may also be used to assess vitamin K status. The production of BGP is stimulated by 1,25 dihydroxy vitamin D (1,25[OH]₂D₃) and depends on vitamin K. Vitamin K increases the carboxylation of osteocalcin or BGP, but it does not increase its overall rate of synthesis. A reduced vitamin K status is associated with reduced BGP or serum osteocalcin levels. This relationship may explain the pathophysiologic findings of vitamin K–deficiency osteoporosis. The function of osteocalcin is unclear; however, it may exist as a deposition site for hydroxyapatite crystals or it also may affect energy metabolism via the production and action of insulin (Hammami, 2014).

WATER-SOLUBLE VITAMINS AND TRACE MINERALS

Ascorbic Acid

Ascorbic acid or vitamin C is a water-soluble vitamin and also an antioxidant. Vitamin C status can be determined by measuring blood ascorbic acid levels. Values less than 6 mg/dL (<34 micromol/L) suggest insufficiency and values less than 2 mg/dL (<11 micromol/L) suggest a deficiency. Deficiencies are rare in developed countries unless self-imposed dietary intake is highly restrictive. Symptoms of a deficiency include bleeding gums, loose teeth, poor wound healing, and perifollicular hemorrhages. Toxicities have been reported in individuals taking more than 2 g/d for an extended period of time. Individuals consuming more than 1000 mg of ascorbic acid daily may increase their risk of kidney stones. Rebound scurvy may occur in individuals who abruptly stop taking megadoses of ascorbic acid (Ferraro et al, 2016).

B-Vitamins

Vitamin B₁₂ and folate are the most common water-soluble vitamin deficiencies reported in adults. Frank deficiencies of other water-soluble vitamins and trace minerals are uncommon in populations that consume a variety of whole foods and fortified foods. Thiamin deficiency has been reported in individuals who chronically consume high levels of alcohol with inadequate thiamin intake, in those with persistent vomiting, in those on high doses of diuretics

with poor intake, in those with impaired absorption because of disease or surgery, as well as individuals on long-term parenteral nutrition (PN) without adequate vitamin added. To assess thiamin status, thiamin diphosphate in whole blood is measured because plasma and serum levels reflect recent dietary changes and may be misleading. A deficiency of thiamin results in either wet beriberi, dry beriberi, or Wernicke encephalopathy (WE). Symptoms of wet beriberi include heart failure, tachycardia, and lactic acidosis. Symptoms of dry beriberi are primarily neurologic findings (i.e. peripheral neuropathy, impairment of sensory, motor, and reflex functions). Symptoms of WE include abnormal eye movement, cerebellar dysfunction, and confusion.

Subclinical deficiencies of water-soluble vitamins and other trace minerals may be present in some individuals. However, the current methodologies for evaluating nutritional status of these components are expensive and controversial. See Appendix 12 for further discussion of tests for assessing specific vitamin and trace mineral adequacy.

Markers of Body Composition

Creatinine

Creatinine is formed from creatine, found almost exclusively in muscle tissue. Serum creatinine is used along with blood urea nitrogen (BUN) to assess kidney function (see Chapter 34). Urinary creatinine has been used to assess somatic (muscle) protein status. Creatine is synthesized from the amino acids glycine and arginine with addition of a methyl group from the folate- and cobalamin-dependent methionine–SAM–homocysteine cycle. Creatine phosphate is a high-energy phosphate buffer that provides a constant supply of ATP for muscle contraction. When creatine is dephosphorylated, some of it is converted spontaneously to creatinine by an irreversible, nonenzymatic reaction. Creatinine has no specific biologic function; it is released continuously from the muscle cells and excreted by the kidneys with little reabsorption.

The use of urinary creatinine to assess somatic protein status is confounded by omnivorous diets. Because creatine is stored in muscle, muscle meats are rich sources. The creatinine formed from dietary creatine cannot be distinguished from endogenously produced creatinine. When a person follows a meat-restricted diet, the size of the somatic (muscle) protein pool is directly proportional to the amount of creatinine excreted. Therefore men generally have higher serum levels and excrete larger amounts of creatinine than women, and individuals with greater muscular development have higher serum levels and excrete larger amounts than those who are less muscular. Total body weight is not proportional to creatinine excretion, but muscle mass is. Creatinine excretion rate is related to muscle mass and is expressed as a percentage of a standard value as shown by the following equation for creatinine-height index (CHI):

$$\text{CHI} = \frac{24\text{-hr urine creatinine (mg)} \times 100}{\text{Expected 24-hr urine creatinine/cm height}}$$

Calculated CHI greater than 80% is normal, 60% to 80% suggests mild skeletal muscle depletion, 40% to 60% suggests moderate depletion, and less than 40% suggests severe depletion (Blackburn et al, 1977).

Daily creatinine excretion varies significantly within individuals, probably because of losses in sweat. In addition, the test is based on 24-hour urine collections, which are difficult to obtain. Because of these limitations, urinary creatinine concentration as a marker of muscle mass has limited use in health care settings and is used typically only in research (Table 5.6).

TABLE 5.6 Expected Urinary Creatinine Excretions for Adults Based on Height

ADULT MALES*		ADULT FEMALES†	
Height (cm)	Creatinine (mg)	Height (cm)	Creatinine (mg)
157.5	1288	147.3	830

*Creatinine coefficient males 23 mg/kg “ideal” body weight.

†Creatinine coefficient females 18 mg/kg “ideal” body weight.

Nitrogen Balance

Nitrogen balance studies are used primarily in research studies to estimate the balance between exogenous nitrogen intake (orally, enterally, or parenterally) and removal of nitrogen-containing compounds (urinary, fecal, wound), and other nitrogen sources. These studies are not a measure of protein anabolism and catabolism because true protein turnover studies require consumption of labeled (stable isotope) protein to track protein use. Even if useful, nitrogen balance studies are difficult because valid 24-hour urine collections are tedious unless the patient has a catheter. In addition, changes in renal function are common in patients with inflammatory metabolism, making standard nitrogen balance calculations inaccurate without calculation of nitrogen retention (Dickerson, 2016). Clinicians using nitrogen balance to estimate protein flux in critically ill patients must remember the limitations of these studies and that positive nitrogen balance may not mean that protein catabolism has decreased, particularly in inflammatory (disease and trauma) conditions.

CHRONIC DISEASE RISK ASSESSMENT

Lipid Indices of Cardiovascular Risk

The American College of Cardiology (ACC) and American Heart Association (AHA) released practice guidelines for the assessment of cardiovascular risk (Stone et al, 2014). These guidelines are referred to as the Adult Treatment Panel 4 (ATP 4) and replace the Adult Treatment Panel 3 (ATP 3). Four high-risk groups are identified:

- Adults with atherosclerotic cardiovascular disease (ASCVD)
- Adults with diabetes, aged 40 to 75 years, with low-density lipoprotein (LDL) levels 70 to 189 mg/dL
- Adults with LDL cholesterol levels of at least 190 mg/dL
- Adults aged 40 to 75 years who have LDL levels 70 to 189 mg/dL and at least 7.5% 10-year risk of atherosclerotic cardiovascular disease

Ten-year risk of atherosclerotic cardiovascular disease is determined using the Framingham 10-year general cardiovascular disease risk equations. Risk factors include age, gender, total cholesterol, high-density lipoprotein (HDL) cholesterol, smoking status, systolic blood pressure, and current treatment for high blood pressure (Box 5.1). The ACC/AHA Guidelines deemphasize use of any markers other than LDL cholesterol and HDL cholesterol. Emerging risk markers for atherosclerotic cardiovascular disease (ACVD) that are not recommended in ATP 4 include differentiating subparticles of LDL by size and grouping by pattern, apolipoprotein B (apoB), and apolipoprotein E (apoE) phenotype. The Cholesterol Expert Panel determined that these markers are not independent markers for risk and do not add to prediction equations. Other researchers propose mathematical models that predict the risk of plaque formation for combined levels of LDL and HDL (Hao and Friedman, 2014). However, the Systematic Review for the 2018 AHA, ACC, and numerous professional organizations and societies published *Guideline on the Management of Blood Cholesterol*. These Guidelines proposed the use of nonstatin lipid modifying medications to reduce the risk of ASCVD. PCSK9 inhibitors and ezetimibe were identified as beneficial, but niacin and cholesterol-ester protein inhibitors were not effective in reducing ASCVD risk (Grundy et al, 2018).

See Chapter 32 for further discussion of the lipid profile and cardiovascular risk.

BOX 5.1 Lipid And Lipoprotein Atherosclerotic Cardiovascular Risk Factors

Laboratory test cutpoints used to calculate 10-year risk of ACVD

Total cholesterol: >200 mg/dL

HDL: <40 mg/dL

LDL: >131 mg/dL

In selected high-risk individuals, these laboratory test cutpoints may be considered:

hs-CRP cutpoints used to assign risk

- <1.0 mg/L = low risk
- 1.1-3.0 mg/L = average risk
- 3.1-9.9 mg/L = high risk
- ≥10 mg/L = very high risk
- If initial value is >3.0 but <10 mg/L, repeat in 2 weeks

Lipoprotein-associated phospholipase A₂ (Lp-PLA₂): used in conjunction with hs-CRP with intermediate or high risk

Apolipoprotein A-1: May be used in addition to LDL-C monitoring as a non-HDL-C marker in patients with serum triglycerides ≥200 mg/dL; decreased level is atherogenic

Apolipoprotein B/A ratio: May be used in addition to LDL-C monitoring as a non-HDL-C marker in patients with serum triglycerides ≥200 mg/dL

Other laboratory test results associated with cardiovascular risk, but not recommended in ATP 4

VLDL density: Remnants are atherogenic

Lp(a): Elevated levels are atherogenic

Serum homocysteine: Increased = greater risk

RBP4: Elevated levels may identify early insulin resistance and associated cardiovascular risk factors

HDL, High-density lipoprotein; hs-CRP, high-sensitivity C-reactive protein; LDL, low-density lipoprotein; Lp(a), lipoprotein little a; RBP4, retinol-binding protein 4; VLDL, very low-density lipoprotein. Adapted from Stone NJ et al: 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on practice guidelines, *Circulation* 129(25 Suppl 2):S1, 2014.

The National Lipid Association (NLA) Expert Panel presents somewhat different treatment goals from the ATP 4. The NLA includes treatment goals for non-HDL cholesterol, LDL cholesterol, and apoB (Jacobson et al, 2014; see Chapter 32).

Patients undergoing lipid assessments should be fasting for 12 hours at the time of blood sampling. Fasting is necessary primarily because triglyceride levels rise and fall dramatically in the postprandial state, and LDL cholesterol values are calculated from measured total serum cholesterol and HDL cholesterol concentrations. This calculation, based on the Friedewald equation, is most accurate when triglyceride concentrations are less than 400 mg/dL.

$$\text{LDL} = \text{Total Cholesterol} - (\text{Triglyceride}/5) - \text{HDL}$$

The Friedewald equation gives an estimate of fasting LDL cholesterol levels that is generally within 4 mg/dL of the true value when triglyceride concentrations are less than 400 mg/dL (Friedewald, 1972).

Diabetes

In adults with normal glucose control, approximately 4% to 6% of the total Hgb is glycosylated. The percent of this glycohemoglobin or **hemoglobin A1C (Hgb A1C)** in the blood is related directly to the average blood glucose levels for the preceding 2 to 3 months and does not reflect more recent changes in glucose levels. It is useful in differentiating between short-term hyperglycemia in individuals under stress or who have had an acute myocardial infarction and those with diabetes. Hgb A1C has been added as a diagnostic criterion for diagnosis of diabetes mellitus once the initial value is confirmed by a repeat Hgb A1C above 6.5%, or plasma glucose above 200 mg/dL (11 mmol/L). Historically, Hgb A1C was not used as a diagnostic criterion for gestational diabetes because of changes in red cell turnover (American Diabetes Association [ADA], 2018). Other researchers suggest that combined Hgb A1C and oral glucose tolerance test (OGTT) may be useful in diagnosing gestational diabetes (Renz et al, 2015).

Hgb A1C can be correlated with daily mean plasma glucose (Box 5.2). Each 1% change in Hgb A1C represents approximately 35 mg/dL change in mean plasma glucose. Test results are useful to provide feedback to patients about changes they have made in their nutritional intakes (ADA, 2011). See Chapter 29 for further discussion of Hgb A1C and diabetes management.

Insulin test results reflect both endogenous and exogenous insulin. It may also be used to differentiate type 1 and type 2 diabetes, to diagnose type 2 diabetes in which there is an increased production of insulin with a concurrent increase in blood glucose. Insulin testing is used to identify the etiology of hypoglycemia (plasma glucose < 55 mg/dL) especially if there is a shortage of glucose to the brain due to hypoglycemia and the patient is unconscious due to hypoglycemia. Conditions associated with elevated insulin levels are metabolic syndrome (cluster of conditions associated with the development of type 2 diabetes and cardiovascular disease), obesity, steroid use, acromegaly (abnormal

BOX 5.2 Correlation Between A1C and Mean Plasma Glucose (MPG)

A1C	Approximate MPG (mg/dL)
4	65
5	100
6	135
7	170
8	205

growth of hand hands, feet, and face caused by overproduction of growth hormone by the pituitary gland), Cushing's syndrome (complex hormonal condition manifest with thinning skin, weakness, weight gain, bruising, hypertension, diabetes, osteopetrosis, facial puffiness), type 2 diabetes, insulinoma (tumor of pancreas that produces an excess amount of insulin). Conditions associated with decreased insulin excretion include severe liver disease, type 1 diabetes, and severe heart failure (Buppajarntham, 2014).

C-Peptide

C-peptide is an insulin precursor that is released from the pancreatic beta-cells during cleavage of insulin from proinsulin. It is excreted by the kidney and has a half-life 3 to 4 times longer than that of insulin. C-peptide levels are elevated with insulinomas, sulfonylurea intoxication, insulin resistance, and chronic kidney disease. It is suppressed in type 1 diabetes, and insulin-independent hypoglycemia. C-peptide should be measured in combination with insulin and proinsulin to differentiate between insulin-dependent hypoglycemia and insulin-independent hypoglycemia.

PHYSICAL ASSESSMENTS

Anthropometry

Anthropometry involves obtaining physical measurements of an individual, comparing them to standards that reflect the growth and development of that individual, and using them for evaluating overnutrition, undernutrition, or the effects of nutrition preventions over a period of time. Accurate and consistent measurements require training in the proper techniques using calibrated instruments. Measurements of accuracy can be established by several clinicians taking the same measurement and comparing results. Valuable anthropometric measurements include height, weight, and girth measurements. Skinfold thicknesses and circumference measurements are used in some settings but are associated with a higher rate of inconsistency. Head circumference and length are used in pediatric populations. Birth weight and ethnic, familial, and environmental factors affect these parameters and should be considered when anthropometric measures are evaluated.

Interpretation of Height and Weight in Children and Teens

Currently, reference standards are based on a statistical sample of the U.S. population. The World Health Organization (WHO) international growth standards are based on data from multiple countries and ethnic populations and have been adopted for use in numerous countries. In the United States the expert review panel of WHO and Centers for Disease Control and Prevention (CDC) growth charts recommend the WHO growth standards for children aged less than 24 months and the CDC growth charts for children aged 24 months to 18 years.

Height and weight measurements of children are recorded as percentiles, which reflect the percentage of the total population of children of the same sex who are at or below the same height or weight at a certain age. Children's growth at every age can be monitored by mapping data on growth curves, known as **height-for-age**, **length-for-age**, **weight-for-age**, and **weight-for-length** curves. Appendix 4 provides pediatric growth charts and percentile interpretations.

Length and Height

The methodology used for determining the length or height of children is determined by the age of the child. Recumbent length measurements are used for infants and children younger than 2 or 3 years of age. Ideally these young children should be measured using a length board as shown in Fig. 5.3. Recumbent lengths in children ages 2 and younger

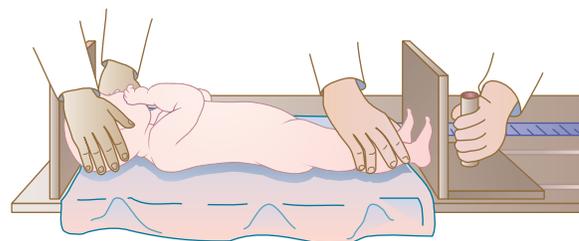

Fig. 5.3 Measurement of the length of an infant.

should be recorded on the birth to 24-month growth grids. Standing height is determined in children using a measuring rod, or **stadiometer**, and should be recorded on the 2- to 20-year growth grids, as in Appendix 4. Sitting heights may be measured in children who cannot stand (see Fig. 43.1). Recording on the proper growth grids provides a record of a child's gain in height over time and compares the child's height with that of other children of the same age. The rate of length or height gain reflects long-term nutritional adequacy.

Weight

Weight in children and teens is a more sensitive measure of nutritional adequacy than height, because it reflects more recent nutritional intake and provides a rough estimate of overall fat and muscle reserves. For children with larger bodies or in those with edema, weight alone makes it difficult to assess overall nutritional status. Weight should be recorded on the age- and gender-appropriate growth grid.

Body weight is interpreted using various methods, including **body mass index (BMI)**, usual weight, and actual weight. BMI is used as a screening tool to identify children and teens who are at risk for overweight or underweight. BMI does not distinguish between excess fat, muscle, and bone mass or fat distribution and should be considered in the context of other growth assessment measurements. Although the calculation of BMI is the same for adults and children, the interpretation of BMI is different in children and teens. BMI is plotted on the CDC BMI-for-age growth charts from which a percentile ranking can be determined. These percentiles are the most commonly used indicator to assess the size and growth patterns of children and teens aged 2 to 20 years in the United States (see Appendix 4). Consistent plotting within a growth channel between the 5% to 85% is considered normal growth although healthy outliers do exist. BMI-for-age weight status categories are noted in Box 5.3.

Interpretation of Height and Weight in Adults

In adults, height and weight measurements are also useful for evaluating nutrition status. Both should be measured because the tendency is to overestimate height and underestimate weight, resulting in an underestimation of the relative weight or BMI. In addition, many adults are losing height as a result of osteoporosis, joint deterioration, and poor posture, and this should be documented.

Measurements of height can be obtained using a direct or an indirect approach. The direct method involves a stadiometer, and the

BOX 5.3 Interpretation of BMI-for-Age Percentiles in Children and Teens

Percentile Range	Interpretation
Less than 5th percentile	Underweight
5th percentile to less than 85th percentile	Healthy weight
85th percentile to less than the 95th percentile	Overweight
Equal to or greater than the 95th percentile	Obese

adult must be able to stand straight or recline flat. Indirect methods, including knee-height measurements, arm span, or recumbent length using a tape measure, may be options for those who cannot stand or stand straight, such as individuals with scoliosis, kyphosis (curvature of the spine), cerebral palsy, muscular dystrophy, contractures, paralysis, or those who are bedridden (see Appendix 6). Recumbent height measurements made with a tape measure while the person is in bed may be appropriate for individuals in institutions who are comatose, critically ill, or unable to be moved. However, this method can be used only with patients who do not have musculoskeletal deformities or contractures (see Box 5.4).

Ideal weight for height reference standards such as the Metropolitan Life Insurance Tables from 1959 and 1983 or the National Health and Nutrition Examination Survey percentiles are no longer used. A commonly used method of determining ideal body weight is the Hamwi Equation (Hamwi et al, 1964). It does not adjust for age, race, or frame size and its validity is questionable. Nonetheless, it is in widespread use by clinicians as a quick method for estimation of ideal weight:

Men: 106 lb for first 5 feet of height and 6 lb per inch over 5 feet; or 6 lb subtracted for each inch under 5 feet

Women: 100 lb for first 5 feet of height and 5 lb per inch over 5 feet; or 5 lb subtracted for each inch under 5 feet

Using the Hamwi method a female who is 5 feet 5 inches tall would have an ideal weight of 125 lb.

Actual body weight is the weight measurement obtained at the time of examination. This measurement may be influenced by changes in the individual's fluid status. Weight loss can reflect dehydration but also can reflect a pattern of suboptimal food intake. The percentage of weight loss is highly indicative of the extent and severity of an individual's illness. The Characteristics of Malnutrition defined by the Academy of Nutrition and Dietetics (AND) and the American Society for Parenteral and Enteral Nutrition (ASPEN) serve as a benchmark for evaluating weight loss (White et al, 2012):

- Significant weight loss: 5% loss in a month, 7.5% loss in 3 months, 10% loss in 6 months
- Severe weight loss: >5% weight loss in a month, >7.5% weight loss in 3 months, >10% weight loss in 6 months

Percentage weight loss = $\frac{\text{Usual wt} - \text{Actual wt}}{\text{Usual wt}} \times 100$

- For example, if a person's usual weight is 200 lb and he now weighs 180 lb, that is a weight loss of 20 lb.

$$200 \text{ to } 180 = \frac{20\text{lb}}{200\text{lb}} = 0.10 \text{ or } 10\%$$

- If this person has lost this 10% in 2 months, that would be more than 7.5% in 3 months and considered SEVERE weight loss.

Another method for evaluating the percentage of weight loss is to calculate an individual's current weight as a percentage of usual weight. **Usual body weight (UBW)** is a more useful parameter than **ideal body weight (IBW)** for those who are experiencing involuntary weight loss. However, one problem with using UBW is that it may depend on the patient's memory.

BOX 5.4 Using Height and Weight to Assess a Hospitalized Patient's Nutritional Status

- Measure. Do not just ask a person's height.
- Measure weight (at admission at admission and current).
- Determine percentage of weight change over time (weight pattern).
- Determine percentage above or below usual or ideal body weight.

Body Mass Index

The **Quetelet index (W/H²)** or the **body mass index (BMI)** is used to determine whether an adult's weight is appropriate for height and can indicate overnutrition or undernutrition. BMI accounts for differences in body composition by defining the level of adiposity and relating it to height, thus eliminating dependence on frame size (Stensland and Margolis, 1990). Numerous research studies have demonstrated that individuals with a higher BMI are more likely to experience obesity-related health issues (Flegal et al, 2013), however there is no single body fat measure that clearly differentiates between health from disease or risk of disease. BMI is calculated as follows:

$$\text{Metric: BMI} = \text{Weight (kg)} \div \text{Height (m)}^2$$

$$\text{English: BMI} = \text{Weight (lb)} \div \text{Height (in)}^2 \times 703$$

Nomograms are also available to calculate BMI, as are various charts (see Appendix 8). The Clinical Insight box: *Calculating BMI and Determining Appropriate Body Weight* gives an example of the BMI calculation.

CLINICAL INSIGHT

Calculating BMI and Determining Appropriate Body Weight

Example: Woman who is 5'8" (68 in) tall and weighs 185 pounds (lb)

Step 1: Calculate current BMI:

$$\text{Formula: (Metric) Weight (kg) } 84 \text{ kg} \div \text{Height (m)}^2 (1.72 \text{ m}) \times (1.72 \text{ m}) \\ = 84 \div 2.96 \text{ m}^2 = \text{BMI} = 28.4 = \text{overweight}$$

Step 2: Appropriate weight range to have a BMI that falls between 18.5 and 24.9

$$18.5 \quad (18.5) \times (2.96) = 54.8 \text{ kg} = 121 \text{ lb}$$

$$24.9 \quad (24.9) \times (2.96) = 73.8 \text{ kg} = 162 \text{ lb}$$

$$\text{Appropriate weight range} = 121 - 162 \text{ lb or } 54.8 - 73.8 \text{ kg}$$

Formula (English) $\text{Weight (lb)} \div (\text{Height (in)} \times \text{Height (in)}) \times 703 = \text{BMI}$
BMI, Body mass index.

Standards classify a BMI of less than 18.5 for an adult as underweight, a BMI between 25 and 29.9 as overweight, and a BMI greater than 30 as obese. A healthy BMI for adults is considered between 18.5 and 24.9 (CDC, 2018). There are some clinical limitations to the use of BMI as a measure of body fatness. Age, sex, ethnicity, and muscle mass can influence the relationship between BMI and body fat. BMI does not distinguish between excess fat, muscle, and bone mass or fat distribution. BMI is correlated with weight more than fat (CDC, 2018). BMI values tend to increase with age and thereby increasing risk for obesity-related health issues. However, for older adults with chronic conditions, there is increasing evidence that an obesity paradox exists in which an elevated BMI is associated with lower all-cause and cardiovascular mortality compared with patients with lower weight (Winter et al, 2014; Hainer and Aldhoon-Hainerová, 2013; see Chapter 19).

Body Composition

Body composition is a critical component of nutrition assessment and medical status. It is used concurrently with other assessment factors to differentiate the estimated proportions of fat mass, soft tissue body mass, and bone mass. For example, muscular people and athletes may be wrongly classified as overweight because of excess muscle mass contributing to increased weight rather than excessive adipose tissue. Older adults tend to have lower bone density and reduced lean body mass and therefore may weigh less than younger adults of the same height and yet have greater adiposity. Variation in

body composition exists among different population groups as well as within the same group. The majority of body composition studies that were performed on whites may not be valid for other ethnic groups. There are differences and similarities between blacks and whites relative to fat-free body mass, fat patterning, and body dimensions and proportions; blacks have greater bone mineral density and body protein compared with whites (Wagner and Heyward, 2000). In addition, optimal BMIs for Asian populations must be in the lower ranges of “normal” for optimal health to reflect their higher risk for cardiovascular disease and diabetes (Araneta et al, 2015). These factors must be considered to avoid inaccurate estimation of body fat and interpretation of risk.

Imaging techniques such as dual-energy x-ray absorptiometry (DXA) and magnetic resonance imaging (MRI) are used in research and clinical settings to assess body composition. The focus of the research on different imaging methodologies is to quantify characteristics of lean soft tissue (LST) that predicts clinical risk and nutrition status. Areas of greatest research are to assess for sarcopenia, sarcopenic obesity (individuals with obesity, low muscle mass, low muscle strength, and low physical performance), and osteosarcopenic obesity (individuals with obesity, bone loss, low muscle mass, low muscle strength, and low physical performance) (Prado and Heymsfield, 2014).

Subcutaneous Fat in Skinfold Thickness

In research studies and selected health care settings, fat-fold or skinfold thickness measurements may be used to estimate body fat in an individual. Skinfold measurement assumes that 50% of body fat is subcutaneous. Because of limitations with accuracy and reproducibility, these measurements are not used routinely in clinical settings.

Circumference Measurements

Circumference measurements may be useful in health care settings in which these measurements are recorded periodically (e.g., monthly or quarterly) and tracked over time to identify trends and potential risk factors for chronic conditions. However, in acutely ill individuals with daily fluid shifts measures of arm circumference and triceps skinfold (TSF) measurements usually are not performed. Use of neck circumference (NC) has been proposed as a marker of overweight, obesity, and associated disease risk in children and adults. Its measurement is a novel, noninvasive screening tool that is easy to do without the privacy concerns associated with waist and hip circumference measurements. NC is measured on bare skin between the midcervical spine and midanterior neck just below the laryngeal prominence (the Adam’s apple) with the head in the Frankfurt plane (looking straight ahead). The tape should be as close to horizontal as anatomically feasible (i.e., the tape line in the front of the neck will be at the same height as the tape line in the back of the neck) (Coelho et al, 2016).

Studies of adults and elderly report that NC is associated highly with waist circumference, weight, BMI, and percent body fat. Large NC (> 40.5 cm in males; > 35.7 cm in females) was associated with hypertension and type 2 diabetes (Coelho et al, 2016). Findings from study of a predominantly African American cohort include significant correlations between serum insulin, triglycerides, LDL cholesterol levels, and NC (Arnold et al, 2014).

NC can be used as a reliable tool to identify adolescents with high BMIs (Kelishadi et al, 2016; Androustos, 2012). The Canadian Health Measures Survey has published reference data for interpretation of NC measurements in Canadian children (Katz et al, 2014).

Bioelectrical Impedance Analysis (BIA)

Bioelectrical Impedance Analysis (BIA) estimates body composition and cellular activity by measuring the bulk of the electrical

impedance in the body. The body composition analysis technique is based on the principle that, relative to water, lean tissue has a higher electrical conductivity and lower impedance than fatty tissue because of its electrolyte content. The testing involves application of electrical conductors to the patient’s hand and foot, sending a low voltage electrical current through the body. Each body tissue type has a different electrical conductivity property. An algorithm derived from statistical analysis of BIA measurements is used to calculate the parameters measured by this technology. Parameters include total body water, intracellular and extracellular body water (i.e., third spacing of body fluids), fat-free mass, percent body fat, phase angle, and cellular metabolism. The evaluation of cellular metabolism is based on the phase angle. The phase angle measures the relationship between reactance, resistance, and impedance to predict the integrity of cell membranes. High phase angles show that a cell is strong enough to hold water and is a good marker for overall health. Low phase angle show that the cell membrane is weak and may not be able to hold water. BIA can be used to assess for third spacing of fluids even on a subclinical basis.

The BIA method is safe, noninvasive, portable, and rapid. For accurate results the patient should be well hydrated; have not exercised in the previous 4 to 6 hours; and have not consumed alcohol, caffeine, or diuretics in the previous 24 hours. If the person is dehydrated, a higher percentage of body fat than really exists is measured. Fever, electrolyte imbalance, and extreme obesity also may affect the reliability of measurements (Sergi et al, 2017). Presently there are no universally accepted reference norms for interpretation of data. There is limited research using BIA in critical care patients. Monitoring trends in data may be helpful. BIA is contraindicated for individuals who are pregnant, due to ethical concerns, or who have an implanted pacemaker or defibrillator (Buch et al, 2012; Lee and Gallagher, 2008). Fig. 5.4 illustrates a BIA test.

Circumference Measurements in Children

Head circumference measurements are useful in children younger than 3 years of age, primarily as an indicator of nonnutritional abnormalities (i.e., congenital microcephaly, hydrocephalus). Undernutrition must be very severe to affect head circumference; see Box 5.5 and Chapter 15.

Measuring Circumference

Midarm circumference (MAC) is measured in centimeters halfway between the acromion process of the scapula and the olecranon process at the tip of the elbow. MAC should be measured when assessing for nutritional status of children and compared with the standards

Fig. 5.4 Bioelectrical impedance analysis. (Image reproduced with permission of ImpediMed Limited.)

BOX 5.5 Measuring Head Circumference**Indications**

- Head circumference is a standard measurement for serial assessment of growth in children from birth to 36 months and in any child whose head size is in question.

Equipment

- Paper or metal tape measure (cloth can stretch) marked in tenths of a centimeter because growth charts are listed in 0.5-cm increments

Technique

- The head is measured at its greatest circumference.
- The greatest circumference is usually above the eyebrows and pinna of the ears and around the occipital prominence at the back of the skull.
- More than one measurement may be necessary because the shape of the head can affect the location of the maximum circumference.
- Compare the measurement with the National Center for Health Statistics standard curves for head circumference (see Appendices 5 and 9).

Data from Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children*, ed 9, St Louis, 2015, Mosby.

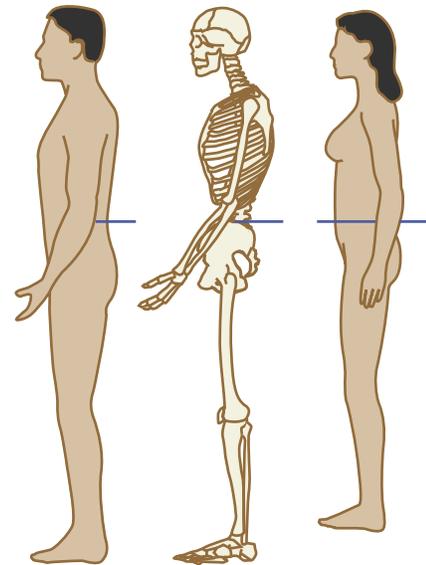

Fig. 5.5 Measuring tape position for waist circumference.

developed by WHO for children aged 6 to 59 months of age (de Onis et al, 1997). It is an independent anthropometric assessment tool in determining malnutrition in children.

Circumference Measurements in Adults

MAC is measured the same way in adults as in children. Combining MAC with **triceps skin fold (TSF)** measurements allows indirect determination of the arm muscle area (AMA) and arm fat area which can be tracked against a standard and used as an assessment of malnutrition. Because of limitations with accuracy and reproducibility, these measurements are rarely used to assess adult nutrition status.

Waist and Hip Circumference, Waist-to-Hip Ratio, and Waist-to-Height Ratio

Selected circumference measurements may be useful in determining estimated risk for chronic diseases and assessing changes in body composition. **Waist circumference (WC)** is obtained by measuring the distance around the narrowest area of the waist between the lowest rib and iliac crest and above the umbilicus using a nonstretchable tape measure (Fig. 5.5). Hip circumference is measured at the widest area of the hips at the greatest protuberance of the buttocks. Because fat distribution is an indicator of risk, circumferential or girth measurements may be used. The presence of excess body fat around the abdomen out of proportion to total body fat is a risk factor for chronic diseases associated with obesity and the metabolic syndrome. A WC of greater than 40 inches (102 cm) for men and greater than 35 inches (88 cm) for women is an independent risk factor for metabolic disease (CDC, 2014; Stone et al, 2013). These measurements may not be as useful for those less than 60 inches tall or with a BMI of 35 or greater (CDC, 2014). WC is considered to be a more valid predictor of metabolic risk than BMI, except when BMI is greater than or equal to 35 (CDC, 2018).

To determine the **waist-to-hip ratio (WHR)**, divide the waist measurement by the hip measurement. The WHO defines the ratios of greater than 9.0 in men and greater than 8.5 in women as one of the decisive benchmarks for metabolic syndrome and is consistent with findings of research predicting all cause and cardiovascular disease mortality (Srikanthan et al, 2009; Welborn and Dhaliwal, 2007).

Fig. 5.5 shows the proper location to measure waist (abdominal) circumference.

The waist-to-height ratio (WHtR) is defined as the waist circumference divided by the measured height. WHtR is a measure of the distribution of adipose tissue. Generally speaking, the higher the values of WHtR, the greater the risk of metabolic syndrome and obesity-related atherosclerotic cardiovascular diseases (Schneider et al, 2010). Desirable ratios are less than 0.5 in adults 40 years and younger, between 0.5 and 0.6 in adults aged 40 to 50 years, and 0.6 or less in adults over 50. These targets apply to both males and females and a variety of ethnic groups. For example, a BMI of 25 is equivalent to a WHtR of 0.51. **Table 5.7** provides a guide to interpreting WHtR by gender.

A systematic review of evidence on use of WHtR on elderly populations showed evidence that WHtR is associated with obesity and is a predictor of risk factors associated with cardiovascular disease, metabolic syndrome, and diabetes (Corrêa et al, 2016; Ashwell and Gibson, 2016). However, WHtR is not identified as a risk marker in the ACC/AHA ATP 4.

TABLE 5.7 Interpretation of Waist-to-Height Ratio by Gender

Females	Males	Interpretation
WHtR	WHtR	
< 0.35	< 0.35	Underweight; no increased risk
0.35-0.42	0.35-0.43	Slim; no increase risk
0.42-0.49	0.43-0.53	Healthy; no increased risk
0.49-0.54	0.53-0.58	Overweight; increased/high risk
0.54-0.58	0.58-0.63	Obese; increased/high risk
> 0.58	> 0.63	Very obese; very high risk

WHtR, Weight-to-height ratio.

Adapted from Ashwell, M & Gibson, S. Waist-to-height ratio as an indicator of 'early health risk': simpler and more predictive than using a 'matrix' based on BMI and waist circumference. *BMJ Open* 2016; 6:e010159. doi: 10.1136/bmjopen-2015-010159.

Other Methods of Measuring Body Composition

Dual-Energy X-Ray Absorptiometry

Dual-energy x-ray absorptiometry (DXA) measures fat, bone mineral, and fat-free soft tissue. The energy source in DXA is an x-ray tube that contains an energy beam. The amount of energy loss depends on the type of tissue through which the beam passes; the result can be used to measure mineral, fat, and lean tissue compartments. DXA is easy to use, emits low levels of radiation, and is available in the hospital setting, making it a useful tool. Generally, it is found to be a reliable measurement of percentage body fat; however, the patient must remain still for more than a few minutes, which may be difficult for older adults and those in chronic pain. Measurements are influenced by the thickness of tissues and hydration status (Prado and Heymsfield, 2014). Fig. 5.6 illustrates a DXA scan.

Air Displacement Plethysmogram

Air displacement plethysmogram (ADP) relies on measurements of body density to estimate body fat and fat-free masses. Performing an ADP with the BOD-POD device is a densitometry technique found to be an accurate method to measure body composition. ADP appears to be a reliable instrument in body composition assessment for athletes and obese individuals. ADP does not rely on body water content to determine body density and body composition, which makes it potentially useful in those adults with end-stage renal disease (Flakoll et al, 2004; Fig. 5.7).

Indirect calorimetry

Indirect calorimetry is the most accurate method for estimating energy expenditure by measuring inspired and expired oxygen and carbon dioxide. Total energy requirements (TEE) are calculated from the resting energy expenditure (REE) measured for a short period of time using metabolic carts or handheld devices. Studies in healthy populations comparing the data generated from the handheld devices to the data from the traditional indirect calorimetry are both accurate and reliable. However, in studies validating the handheld device in patients with disease or injury the results have not yielded a high degree of clinical accuracy (Zhao et al, 2014). More research is needed to fine-tune the accuracy and reliability of the handheld devices.

NUTRITION-FOCUSED PHYSICAL EXAMINATION

Nutrition-focused physical examination (NFPE) is one of the components of nutrition assessment in the NCP model. Data gathered in the NFPE are used in conjunction with food and nutrition history, laboratory and diagnostic test results, physical measurements, and client history to accurately make one or more nutrition diagnoses. The *International Dietetics & Nutrition Terminology Reference Manual* (IDNT) (AND, 2018) defines nutrition-focused physical examination as “findings from an evaluation of body systems, muscle and subcutaneous fat wasting, oral health, suck, swallow/breathe ability, appetite and affect.” Unlike a comprehensive clinical examination that reviews all body systems, NFPE is a focused assessment that addresses specific signs and symptoms by reviewing selected body systems.

Approach

A systems approach is used when performing the NFPE, which should be conducted in an organized, logical way to ensure efficiency and thoroughness (Litchford, 2013). Body systems include the following:

- General appearance
- Vital signs
- Skin
- Nails
- Hair
- Head
- Eyes
- Nose
- Mouth
- Neck/chest
- Abdomen
- Musculoskeletal

Equipment

The extent of the NFPE dictates the necessary equipment. Any or all of the following may be used: examination gloves, a stethoscope, a pen-light or flashlight, a tongue depressor, scales, calipers, a tape measure, a blood pressure cuff, a watch with a second hand, and dynamometer to measure hand grip strength.

TABLE 5.8 Physical Examination Techniques

Technique	Description
Inspection	General observation that progresses to a more focused observation using the senses of sight, smell, and hearing; note appearance, mood, behavior, movement, facial expressions; most frequently used technique
Palpation	Gentle tactile examination to feel pulsations and vibrations; assessment of body structures, including texture, size, temperature, tenderness, and mobility
Percussion	Assessment of sounds to determine body organ borders, shape, and position; not always used in a NFPE
Auscultation	Use of the naked ear or bell or diaphragm of stethoscope to listen to body sounds (e.g., heart and lung sounds, bowel sounds, blood vessels); not always used in NFPE

Adapted from Litchford MD: *Nutrition focused physical assessment: making clinical connections*, Greensboro, NC, 2013, CASE Software & Books.

Examination Techniques and Findings

Four basic physical examination techniques are used during the NFPE. These techniques include inspection, palpation, percussion, and auscultation (Table 5.8). Appendix 11 discusses NFPE in more detail.

Interpretation of data collected in each component of an NFPE requires critical thinking skills and the following steps in clinical reasoning:

- Identify abnormal findings or symptoms.
- Localize the findings anatomically.
- Interpret findings in terms of probable process.
- Make a hypothesis about the nature of the patient's problem.
- Test the hypothesis by collaborating with other medical professionals and establish a working nutrition diagnosis.
- Develop a plan agreeable to the patient following all the steps of the NCP model (Bickley, 2017) (see Chapter 9).

Guidelines for Assessing Malnutrition in Children

Definitions and guidelines to identify malnutrition in children are evolving. Pediatric malnutrition is defined as an imbalance between nutrient requirements and dietary intake that results in deficits of energy, protein, and micronutrients stores, resulting in impaired growth and development. Pediatric malnutrition is either related to an illness or injury or caused by an environmental circumstance or

behavioral factor (Mehta et al, 2013). Specific parameters for determining pediatric undernutrition and malnutrition are being standardized (Becker et al, 2015).

Guidelines for Assessing Malnutrition in Adults

The Academy and the ASPEN Consensus Statement: Characteristics Recommended for the Identification and Documentation of Adult Malnutrition provides a standardized and measurable set of criteria for all health professionals to use to identify malnutrition (White et al, 2012). It uses a cause-based nomenclature that reflects the current understanding of the role of inflammatory response on the incidence, progression, and resolution of adult malnutrition. Moreover, malnutrition syndromes are defined by patient settings, including acute illness or surgery, chronic disease, and environmental or social circumstances. In addition, the presence and degree of inflammation further differentiates types of malnutrition as non-severe and severe. Nonsevere does not mean not urgent; it means mild to moderate malnutrition or undernutrition (Fig. 5.8).

No single parameter defines malnutrition. The Consensus guidelines identify six characteristics of malnutrition. From these, the clinician must identify a minimum of two characteristics that relate to the context of the concurrent medical condition for a nutrition diagnosis of malnutrition. The characteristics of nonsevere and severe malnutrition are noted in Table 5.9.

Measures of Functionality

Loss of functionality and mobility has a ripple effect on achieving activities of daily living (ADLs) and nutrition-related ADLs. An emerging component of nutrition-focused examination is assessment for muscle strength and functionality. Clinicians may work collaboratively with rehabilitation therapists to assess this and identify strategies to improve physical strength and mobility using diet and exercise.

Physical Activity Assessment

Inclusion of a physical activity assessment is part of a comprehensive nutrition assessment because lifestyle and behavioral factors play a role in the cause and prevention of chronic diseases. Electronic tracking of physical activity through smartphones and other wearable fitness and health tracking devices are useful in collecting, compiling, and preparing summary reports useful to clinicians and patients. Box 5.6 provides a series of questions that can be asked to identify the current levels and interest in future activity levels for ambulatory patients and clients.

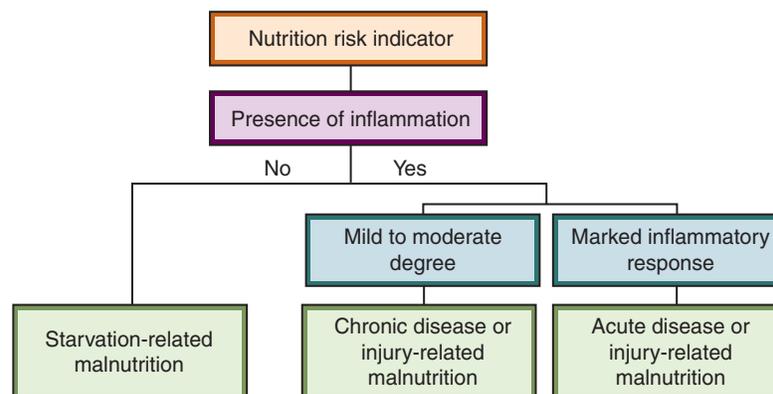

Fig. 5.8 Cause-based malnutrition. (Adapted from White JV et al: Consensus statement of the Academy of Nutrition and Dietetics/American Society for Parenteral and Enteral Nutrition: characteristics recommended for the identification and documentation of adult malnutrition (undernutrition), *J Acad Nutr Diet* 112(5):730, 2012.)

TABLE 5.9 Characteristics of Adult Malnutrition

ACUTE ILLNESS OR INJURY		CHRONIC ILLNESS		SOCIAL OR ENVIRONMENTAL CIRCUMSTANCES	
Nonsevere	Severe	Nonsevere	Severe	Nonsevere	Severe
Interpretation of Weight Loss for Malnutrition by Cause					
1-2% in 1 wk	>2% in 1 wk	5% in 1 wk	>5% in 1 wk	>5% in 1 wk	>5% in 1 wk
5% in 1 mo	>5% in 1 mo	7.5% in 3 mo	>7.5% in 3 mo	>7.5% in 3 mo	>7.5% in 3 mo
7.5% in 3 mo	>7.5% in 3 mo	10% in 6 mo	>10% in 6 mo	>10% in 6 mo	>10% in 6 mo
		20% in 1 yr	>20% in 1 yr	>20% in 1 yr	>20% in 1 yr
Interpretation of Reduced Energy Intake for Malnutrition by Cause					
For >7 days	For > or = to 5 days	For > or = to 1 mo	For > or = to 1 mo	For > or = to 3 mo	For > or = to 1 mo
< 75% of estimated energy needs	< or = to 50% of estimated energy needs	<75% of estimated energy needs	< or = to 75% of estimated energy needs	<75% of estimated energy needs	< or = to 50% of estimated energy needs
Loss of Body Fat					
Mild	Moderate	Mild	Severe	Mild	Severe
Loss of Muscle					
Mild	Moderate	Mild	Severe	Mild	Severe
Fluid Accumulation					
Mild	Moderate to severe	Mild	Severe	Mild	Severe
Reduced Grip Strength					
N/A	Measurably reduced	N/A	Measurably reduced	N/A	Measurably reduced

Adapted from White JV et al: Consensus statement of the Academy of Nutrition and Dietetics/American Society for Parenteral and Enteral Nutrition: characteristics recommended for the identification and documentation of adult malnutrition (undernutrition), *J Acad Nutr Diet* 112(5):730, 2012.

BOX 5.6 Physical Activity Assessment Questionnaire

To be considered physically active, you must get at least:

- 30 minutes of moderate physical activity on 5 or more days a week, OR
- 20 minutes of vigorous physical activity on 3 or more days a week

How physically active do you plan to be over the next 6 months? (*Choose the best answer.*)

____ I am not currently active and do not plan to become physically active in the next 6 months.

____ I am thinking about becoming more physically active.

____ I intend to become more physically active in the next 6 months.

____ I have been trying to get more physical activity.

____ I am currently physically active and have been for the last 1-5 months.

____ I have been regularly physically active for the past 6 months or more.

Compared with how physically active you have been over the last 3 months, how would you describe the last 7 days? (*Check one*)

____ More active ____ Less active ____ About the same

Recall your participation in activities or in sedentary behaviors, over the past 24 hours:

- Reading, watching TV, or computer time ____ minutes/day
- Fast walking ____ minutes/day
- Physical activity (swimming, tennis, racquetball, similar) ____ minutes/day
- Other physical activity (describe _____) ____ minutes/day

What are the 3 most important reasons why you would consider increasing your physical activity?

- Improve my health Control my weight Lower my stress

Measures of Strength

With aging, the balanced cycle of muscle synthesis and degradation shifts toward more breakdown than synthesis of muscle tissue (see Chapter 19). The consequence is atrophy of muscle mass and loss of strength and power. Handgrip dynamometry can provide a baseline nutritional assessment of muscle function by measuring grip strength and endurance and is useful in serial measurements. Measurements of handgrip dynamometry are compared with reference standards provided by the manufacturer. Decreased grip strength is an important sign of frailty and is one of the characteristics of severe malnutrition (White et al, 2012). Low grip strength is associated consistently with a greater likelihood of premature mortality, the development of disability, and an increased risk of complications or prolonged length of stay after hospitalization or surgery in middle-aged and older adults (McLean et al, 2014).

Rehabilitation therapists use a number of evidence-based measures of upper and lower extremity physical function and performance that include muscle resistance testing, walking tests, stair climbing, rising from a chair, and balance. A score is determined for each test and summed for interpretation. Working collaboratively with rehabilitation therapists allows for a better understanding of functional measures of performance and how they relate to nutritional status.

Functional Medicine

Functional medicine is an evolving, evidence-based discipline that sees the body with its mutually interactive systems as a whole, rather than as a set of isolated signs and symptoms. The Institute of Functional Medicine (IFM) promotes an evaluation process that recognizes the biochemical, genetic, and environmental individuality of each person. The focus is patient centered, not just disease centered.

TABLE 5.10 Selected Components of Functional Nutrition Assessment

Ingestion	Digestion	Utilization—Cellular and Molecular Functional Relationships
Food, fiber, water, supplements, medication	Adequate microflora	Antioxidants: water-soluble vitamin C, phytonutrients
Intake patterns affected by emotional or disordered eating	Allergies	Methylation and acetylation: dependence on adequate B complex vitamins and minerals
Toxins entering the body via food, skin, inhalants, water, environment (including pesticides and chemicals)	Genetic enzyme deficits	Oils and fatty acids: prostaglandin balance, cell membrane function, vitamin E function
	Hydration	Protein metabolism: connective tissue, enzymes, immune function, etc.
	Infection/inflammatory response	Vitamin D in concert with functional metabolic partner nutrients vitamins A and K
	Lifestyle: sleep, exercise, stressors	

Lifestyle and health-promoting factors include nutrition, exercise, adequate sleep, healthy relationships, and a positive sense of self.

The **Functional Nutrition Assessment** acknowledges the web-like interconnectedness of internal physiologic factors and identifies root causes of chronic disease by integrating traditional dietetic practice with nutritional genomics (see Chapter 6), the restoration of gastrointestinal function, the quelling of chronic inflammation (see Chapter 7),

and the interpretation of nutritional biomarkers. The functional nutrition practitioner organizes the data collected from a detailed intake that includes exploration of core areas of imbalance: dietary, hormonal, oxidative stress, environmental exposures, immune function, and psychological and spiritual health. This leads a unique and personalized assessment of disease for each individual within the framework of the NCP (see Table 5.10, Fig. 5.9, and Chapter 11).

CLINICAL CASE STUDY

Gia, a 58-year-old F, is admitted to City Hospital following a work-related accident. She has a history of hypertension, obesity, and unsuccessful weight loss attempts using restrictive diets. She loves fried foods, soft drinks, and sweets. Her medical profile today is:

	Normal Value	Gia's Values
Age	58 years old	
Height	59 in	
Weight	200 lb	
Glucose	70-99 mg/dL; 4.1-5.9 mmol/L	142 mg/dL; 7.8 mmol/L
Calcium	9.0-10.5 mg/dL; 2.25-2.62 mmol/L	9.1 mg/dL; 2.27 mmol/L
Sodium	136-145 mEq/L; 136-145 mmol/L	145 mEq/L; 145 mmol/L
Potassium	3.5-5.0 mEq/L; 3.5-5.0 mmol/L	3.6 mEq/L; 3.6 mmol/L
CO ₂	23-30 mEq/L; 23-30 mmol/L	25 mEq/L; 25 mmol/L
Chloride	98-106 mEq/L; 98-106 mmol/L	98 mEq/L; 98 mmol/L
BUN	10-20 mg/dL; 3.6-7.1 mmol/L	30 mg/dL; 10.7 mmol/L
Creatinine	F 0.5-1.1 mg/dL; 44-97 μmol/L M 0.6-1.2 mg/dL; 53-106 μmol/L	0.9 mg/dL; 79.6 μmol/L
Albumin	3.5-5.0 g/dL; 35-50 g/L	3.8 g/dL; 38 g/L
Total protein	6.4-8.3 g/dL; 64-83 g/L	8.0 g/dL; 80 g/L
ALP	30-120 U/L; 0.5-2.0 μkat/L	35 U/L; 0.5 μkat/L
ALT	4-36 units/L; 4-36 units/L	28 units/L; 28 units/L
AST	0-35 units/L; 0-0.58 μkat/L	23 units/L; 0.38 μkat/L
Bilirubin, total	0.3-1.0 mg/dL; 5.1-17 μmol/L	1.5 mg/dL; 25.65 μmol/L
RBC	F 4.2-5.4 × 10 ⁶ mL; 4.2-5.4 × 10 ¹² L M 4.7-6.1 × 10 ⁶ mL; 4.7-6.1 × 10 ¹² L	5.1 × 10 ⁶ mL; 5.1 × 10 ¹² L
Hgb	F 12-16 g/dL; 7.4-9.9 mmol/L M 14-18 g/dL; 8.7-11.2 mmol/L	11 g/dL; 7 mmol/L
Hct	F 37-47%; 0.37-0.47 M 42-52%; 0.42-0.52	30%; 0.30

MCV	80-95 mm ³ ; 80-95 fL	108 mm ³ ; 108 fL
MCH	27-31 pg	33 pg
MCHC	32-36 g/dL; 32%-36%	40 g/dL; 40%
WBC	5000-10000/mm ³ ; 5-10 × 10 ⁹	8 × 10 ⁹
Total cholesterol	< 200 mg/dL; <5.2 mmol/L	245 mg/dL
LDL	<130 mg/dL	145 mg/dL
HDL	F > 55 mg/dL M > 45 mg/dL	30 mg/dL
Triglycerides	F 35-135 mg/dL; 0.4-1.52 mmol/L F 40-160 mg/dL; 0.45-1.81 mmol/L	210 mg/dL

Gia is referred for medical nutrition therapy. NFPE indicates a prefrail female, with excessive abdominal fat stores, low muscular development, and no fluid accumulation. Assess her nutrition status using the data provided.

Nutrition Diagnostic Statement

- Altered laboratory values related to chronic restrictive dieting as well as overeating highly processed foods as evidenced by signs of nutritional anemia and dyslipidemia.

Nutrition Care Questions

- Considering Gia's medical history, what does her laboratory report for hemoglobin, hematocrit, and mean corpuscular volume suggest?
- What does her laboratory report for total cholesterol, LDL, HDL, and triglycerides values suggest?
- What does her laboratory report for sodium, blood urea nitrogen suggest?
- What additional laboratory tests would be helpful for a comprehensive nutrition assessment?

ALP, Alkaline phosphate; ALT, alanine aminotransferase; AST, aspartate aminotransferase; BUN, blood urea nitrogen; CO₂, carbon dioxide; Hct, hematocrit; Hgb, hemoglobin; MCH, mean corpuscular hemoglobin; MCHC, mean corpuscular hemoglobin concentration; MCV, mean corpuscular volume; RBC, red blood cell; WBC, white blood cell.

KEY TERMS

autosome	genome-wide association study (GWAS)	obesogen
bioactive food components	genomic imprinting	penetrance
candidate gene approach	genotype	pharmacogenomics
chromosome	heterozygous	phenotype
coding region	histone	polymorphism
codon	homozygous	posttranslational modification
deoxyribonucleic acid (DNA)	intervening sequences	precision (personalized) health
dominant	intron	promoter region
ELSI	karyotype	proteomics
epigenetics	ligand	recessive
epigenetic inheritance	mendelian inheritance	regulatory region
epigenetic marks/tags	messenger RNA (mRNA)	response elements
epigenome, epigenomics	metabolome, metabolomics	rs number
expression genome-wide association studies (eGWAS)	microbiome, microbiomics	sex chromosome
exon	mitochondrial DNA (mtDNA)	signal transduction
gene, genetics	mitochondrial (maternal) inheritance	single nucleotide polymorphism (SNP)
gene variant/genetic variation	mutation	somatic
Genetic Information Nondiscrimination Act (GINA)	nucleotide	transcription
genome, genomics	nutrigenetics	transcription factors
	nutrigenomics	transcriptomics
	nutritional genomics	translation

Imagine meeting with clients and having an assessment of their genetic capabilities and disease susceptibilities. Add to that information their laboratory reports as well as insight into their lifestyle choices: the foods they eat, their exercise habits, how well they manage their thoughts and emotions, how supportive their relationships are, the quantity and quality of their sleep, and their degree of toxic exposures. Further, as a well-trained nutrition professional, you understand the complex interconnections among their genetic profile, lifestyle choices, and chronic disease. It's routine for you to assess the molecular, biochemical, and physiologic mechanisms contributing to the client's current health status and to translate this information into effective therapeutic interventions that can restore health or prevent disease, as needed. Such a scenario is what's envisioned for the era of **precision (personalized) health** where therapy is tailored to each individual so that nutrition professionals can help clients optimize their health and describe the promise that nutritional genomics brings to the field of nutrition and dietetics.

Nutrition research is focused increasingly on the mechanisms that underlie these interactions and on projecting how this understanding can be translated into clinical interventions for more effective chronic disease management and prevention. Health is a continuum that spans

wellness at one end and illness at the other. Genes are an important component in determining at which end of this continuum we find ourselves; they determine our unique signature of susceptibility to being well or ill. However, research into chronic disease is teaching us that environmental factors such as diet and other lifestyle choices made on a daily basis strongly influence who among the susceptible will actually develop dysfunction and disease. Food choices, physical activity habits, sleep patterns, thoughts and emotions, and systems of meaning—relationships with self and others and one's sense of purpose in life—affect cellular function at the molecular, biochemical, and physiologic levels. The influence of these environmental factors is modifiable through daily choices and, when appropriate to the genetic makeup, has the potential for changing the health trajectory from a poor quality of life filled with disease and disability to one of thriving and flourishing.

This understanding of the key role of choices regarding these modifiable lifestyle factors is enabling clinicians to assess to the root cause of chronic disease, to identify the molecular and biochemical mechanisms that underlie symptoms, and to tailor therapy to the individual's uniqueness. As a result, the promise of the molecular era is not only to manage chronic disease more effectively but also to

restore health and, ultimately, to prevent chronic disease from developing. The interactions among genes, diet and other lifestyle factors, and their influence on health and disease are the focus of nutritional genomics.

GENETIC AND GENOMIC FUNDAMENTALS

Genetics is the science of heredity. It is the study of individual genes and their variations, how they give rise to measurable traits and the mechanisms by which traits (genes) are inherited from one generation to the next. **Genomics** focuses on the full set of an organism's genes, its **genome**, and how genes interact with each other and with the environment. Genetic research focuses on identifying genes in an organism, their location, the function of the proteins they encode, and how genes are associated with various traits, some health-promoting, some disease-promoting. Genomic research looks at the structure and functions of the whole genome, including interactions between different groups of genes or other elements. Whereas genetics was initially concerned with diseases that arise from a change in a single gene, genomics has broadened the focus to include the complex interaction of multiple genes, variations in these genes, and environmental factors that influence their expression. This focus positions genomic-related research and clinical applications primarily on addressing chronic disease, which involves the interaction among genes and environmental factors. The Human Genome Project was a multinational collaboration formed to identify each of the approximately 3 billion nucleotide building blocks of the human genome. See [Box 6.1](#) for background information on the importance of this project to the progress of understanding the interconnections among genes, environment, and health.

The basic unit of heredity is the **gene**, which is made up of **DNA** (**deoxyribonucleic acid**). The nucleotide sequence of a gene encodes the instructions for making a protein or a peptide component of a protein. Changes in the nucleotide sequence of the DNA are translated

into the amino acid sequence of the protein and can potentially change the ability of that protein to perform its role. These changes are passed from parent to child and are the basis for inheritance of traits. In higher organisms the DNA is housed within the nucleus of cells ([Fig. 6.1](#)). The DNA molecule is a double helix consisting of two strands of **nucleotide** subunits held together by hydrogen bonds. Each nucleotide contains the sugar deoxyribose, the mineral phosphorus, and one of four nitrogen-containing bases: adenine (A), thymine (T), guanine (G), or cytosine (C). Any base can sit next to one another, but across strands of the helix, these bases pair specifically: A pairs with T, G pairs with C ([Fig. 6.2](#)). The nucleotides are arranged in a linear order, and this order determines the particular information encoded in a stretch of DNA that results in the synthesis of a protein. The nucleotide sequence of DNA is unique to the individual and is called its **genotype**.

To be useful to the cells, information in the DNA first must be decoded and translated into proteins, which perform the work of the organism's "operating system." A sequence of DNA nucleotides that encodes the information for synthesizing a protein is called a gene. Human DNA contains approximately 20,000 genes. Each gene has a location or "address" at a specific site on a particular chromosome. Long stretches of nucleotides often are found between genes along the chromosome. Such sequences are called **intervening sequences** and compose the majority of the DNA in humans. These sequences do not code for proteins, but they are not "junk DNA" as originally thought. Instead, they perform structural and regulatory functions, such as controlling when, where, and how much of a protein is produced.

The large amount of genetic material in the nucleus is distributed among multiple **chromosomes**, which are formed by wrapping DNA tightly around specific proteins called **histones**. Human beings have 23 pairs of chromosomes, 22 **autosomes**, and 2 **sex chromosomes**. One copy of each member of a pair comes from the mother and the other from the father. Females have two X chromosomes; males have one X and one Y chromosome. The nucleus of each human cell contains all 46 chromosomes.

BOX 6.1 The Human Genome Project

The Human Genome Project (HGP) has been the impetus for a fundamental shift to integrating genetic principles into health care. This ambitious project was a \$15 billion international effort that began in 1990, headquartered within the U.S. by the Department of Energy and the National Institutes of Health. The initial goal was to identify each of the 3 billion nucleotides in human DNA, the genetic material (genome). Subsequent goals would include (1) cataloging each gene in the human genome, (2) identifying each gene and its protein product, (3) detecting changes in genes and their association with disease susceptibility, and (4) shedding light on how environmental triggers influence genes and disease susceptibility. Additionally, the genomes of other organisms would be sequenced to enable their use as model systems in the laboratory in order to explore key mechanisms, from retrieving encoded information from DNA to understanding gene-environment interactions.

The HGP completed the sequencing phase in 2003, much earlier than expected. However, identifying the human sequence did not automatically provide answers to all the key questions that were needed to develop clinical applications that could be used to restore health and prevent disease, particularly for the chronic diseases whose prevalence was significant worldwide. A number of disciplines emerged corresponding to the various steps in the processes, from retrieving information to translating that information into proteins to regulating gene expression. This latter process includes epigenetics, which has been a bit of a "missing link" in understanding how genes give rise to chronic diseases, which is essential for developing effective clinical applications and for disease

prevention. See [Box 6.2](#) for information about the primary "omic" disciplines that have emerged. Each of these disciplines has continued developing as a primary research focus and is contributing valuable insight into the gene/environment/health and disease connections.

Another major accomplishment of the initial HGP work has been the advances that have occurred in genetic technologies, without which this work would not have been able to move forward so quickly. Advances include the ability to move from studying single genes and their variations to high-throughput whole genome sequencing that has greatly increased the speed with which the work can be conducted and decreased the cost of sequencing. Additionally, the genomes of numerous other organisms have been sequenced. Some of these organisms, such as the laboratory mouse, have served a valuable role as model systems for understanding human processes. The genetics and environmental conditions of model systems can be manipulated and the molecular, biochemical, and physiologic outcomes studied as well as the heritability of any changes noted. The HGP also emphasized educating genetic scientists and clinicians, integrating the results of genetic research into clinical practice, and developing sophisticated computer technology (bioinformatics) in order to make sense of the large volume of data that would be generated. As a result of this collaborative effort on a global scale, the era of precision health, only dreamed about in 1990, is now a viable goal for health care. For a history of the Human Genome Project, see the National Human Genome Research Institute's website.

DNA, The Molecule of Life

Trillions of cells

Each cell:

- 46 human chromosomes
- 2 meters of DNA
- 3 billion DNA subunits (the bases A, T, C, G)
- Approximately 25,000 genes code for proteins that perform most life functions

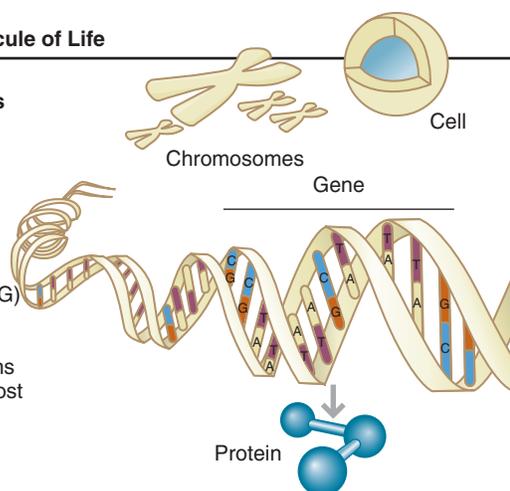

Fig. 6.1 DNA, the Molecule of Life. Cells are the fundamental working units of every living system. All the instructions needed to direct their activities are contained within the chemical deoxyribonucleic acid. (From U.S. Department of Energy, Human Genome Program: www.ornl.gov/hgmis.)

DNA Replication Prior to Cell Division

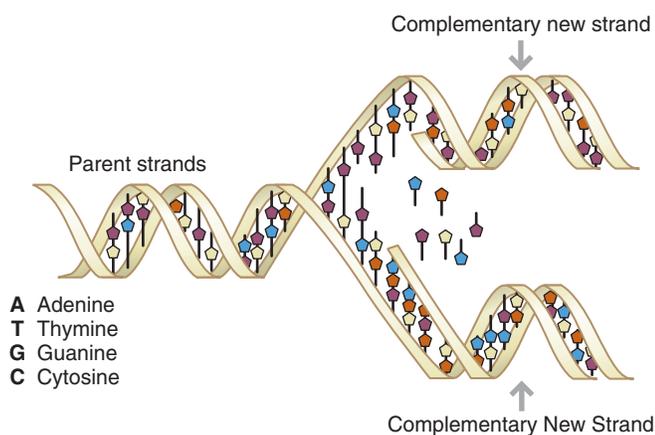

Fig. 6.2 DNA Replication Prior to Cell Division. Each time a cell divides into two daughter cells, its full genome is duplicated; for humans and other complex organisms, this duplication occurs in the nucleus. During cell division the deoxyribonucleic acid (DNA) molecule unwinds, and the weak bonds between the base pairs break, allowing the strands to separate. Each strand directs the synthesis of a complementary new strand, with free nucleotides matching up with their complementary bases on each of the separated strands. Strict base-pairing rules are adhered to (i.e., adenine pairs only with thymine [an A-T pair] and cytosine with guanine [a C-G pair]). Each daughter cell receives one old and one new DNA strand. The cells' adherence to these base-pairing rules ensures that the new strand is an exact copy of the old one. This minimizes the incidence of errors (mutations) that may greatly affect the resulting organism or its offspring. (From U.S. Department of Energy, Human Genome Program: www.ornl.gov/hgmis.)

Gene Expression: Transcription and Translation

To initiate the process of decoding the DNA, the condensed chromosomes housing the genes first must open (decondense) to allow access to the information in the DNA nucleotide sequence. A common mechanism employed is the covalent attachment of acetyl groups to the histone proteins associated with the chromosomes. This action

relaxes the DNA and makes it accessible to the enzymes involved in **transcription** (the decoding process). Information decoding involves transcription by ribonucleic acid (RNA) polymerase into pre-messenger RNA (pre-mRNA) and subsequent translation of mRNA into the amino acid sequence of the protein according to a universal genetic code. The architecture of a gene typically includes a promoter region, where the RNA polymerase attaches and a **coding region** (also called a “structural region”) that contains the encoded information for synthesizing that gene’s protein. Within the coding region are sequences of nucleotides called **exons** that correspond to the order of the amino acids in the gene’s protein product. The coding region also contains **introns** (sequences that are interspersed between exons and do not code for amino acids needed for synthesizing proteins).

Upstream from the promoter region is the **regulatory region** that controls the ability of the polymerase to attach to the promoter, thereby influencing whether transcription occurs. Within this region are **response elements**, DNA sequences that serve as binding sites for regulatory proteins such as **transcription factors** and their bound **ligands**. The binding of transcription factors triggers the recruitment of additional proteins to form a protein complex that in turn changes the expression of that gene by changing the conformation of the promoter region, increasing or decreasing the ability of RNA polymerase to attach and transcribe (express) the gene. The array of response elements within the promoter region can be complex, allowing for the binding of multiple transcription factors that in turn fine-tune the control of gene expression. It is through the binding of transcription factors to response elements that environmental factors such as the bioactive components in food essentially “talk” to a gene, conveying information that more or less of its protein product is needed.

Once transcribed, the pre-mRNA must be processed (posttranscriptional processing) to form mature **messenger RNA (mRNA)** from which the introns have been removed and the nucleotide sequence of the mRNA is ready to be translated into the amino acid sequence of the encoded protein. The protein synthesis process is called **translation**. Each set of three nucleotides makes up a **codon**, which in turn specifies a particular amino acid and its position within the protein (Figs. 6.3 and 6.4).

DNA Genetic Code Dictates Amino Acid Identity and Order

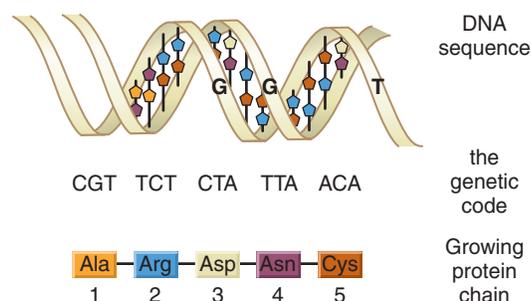

Fig. 6.3 DNA Genetic Code Dictates Amino Acid Identity and Order. All living organisms are composed largely of proteins. Proteins are large, complex molecules made up of long chains of subunits called amino acids. Twenty different kinds of amino acids are usually found in proteins. Within the gene, each specific sequence of three deoxyribonucleic acid bases (codons) directs the cells protein-synthesizing machinery to add specific amino acids. For example, the base sequence ATG codes for the amino acid methionine. Because three bases code for one amino acid, the protein coded by an average-sized gene (3000 bp) contains 1000 amino acids. The genetic code is thus a series of codons that specify which amino acids are required to make up specific proteins. A, adenine; bp, base pairs; C, cytosine; G, guanine; T, thymine. (From U.S. Department of Energy, Human Genome Program: www.ornl.gov/hgmis.)

BOX 6.2 Genomics and Other “Omic” Disciplines

Several new disciplines, technologies, and tools applicable to health care have developed from the Human Genome Project. The major disciplines have been genomics, proteomics, metabolomics, and microbiomics. **Genomics** is the study of organisms and their genetic material (the genome): composition, organization, and function.

The genome (total DNA sequence) is transcribed into coding and noncoding RNA transcripts. **Transcriptomics** is the study of the transcripts produced: the types of transcripts genome-wide and the amount produced. The coding RNA contains information needed to synthesize proteins and was originally thought to be the only functional type of RNA. Transcriptomics research has revealed that the majority of the genome is transcribed but that noncoding RNA comprises most of the transcripts produced. Although their physiologic roles are only beginning to be understood, some of these transcripts are being found to be associated with disease.

Proteomics focuses in part on identifying the protein encoded by each gene, the protein's function, and the effect of a mutation in a gene on the structure and function of the encoded protein. Research in proteomics also includes identifying the posttranslational modifications of proteins, such as enzymatic cleavage to generate an active protein or the addition of chemical groups such as in glycosylation and phosphorylation.

Metabolomics is the study of the substrates and products of metabolism (the metabolites). The goal is to identify each metabolite and its role in the metabolic processes carried out in cells, biofluids, tissues, and organs.

Microbiomics concerns the microbial ecology of body cavities, such as the digestive tract and the oral cavity, another important body cavity in nutrition

practice. Beneficial and pathogenic microbes colonize these cavities and influence health. The Human Microbiome Project (<https://hmpdacc.org>) has been instrumental in identifying which microbes are present in health and disease and sequencing the genomes of each.

Pharmacogenomics, which is conceptually similar to nutritional genomics, involves using genomics to analyze the genetic variations in the genes that encode the drug-metabolizing enzymes and using this information to predict a patient's response to a drug. Genetic variability can lead to differing function in these enzymes, which explains why a drug may have the intended effects for one person, be ineffective for another, and be harmful to a third. In addition to identifying individuals for whom the drug therapy will be beneficial, it's possible to calculate the appropriate starting dosage and minimize adverse events. The common blood-thinning medication warfarin provides an example of pharmacogenomics and its clinical applications (see Box 6.14).

Many genetic technologies and tools have been developed for the various “omics” disciplines. Basic DNA sequencing technology applied to microbiomics has significantly shortened the time needed to identify pathogenic microorganisms, which allows antimicrobial therapy to be initiated much sooner than previously possible. Next-generation sequencing technology enables research and clinical laboratories to generate complete genomic profiles in a fraction of the time and cost of earlier technology. The vast amount of data generated by these disciplines has led to rapid growth in the field of bioinformatics. The ability of sophisticated computers to organize, store, and retrieve massive amounts of data has been integral to the rapid advances of the genomics era.

Following translation, most proteins need further processing (**post-translational modification**) before they are active. This occurs with proenzyme and prohormones that must be enzymatically processed before becoming active or other proteins that are phosphorylated or glycosylated prior to being functional.

Investigation of these downstream steps in the gene expression process has created new fields, often called the “omics” (Hasin et al, 2017). These disciplines correlate with the major steps in the process of genetic information retrieval and translation: transcriptomics, post-transcriptional and posttranslational processing, proteomics, metabolomics, and epigenomics (see Box 6.2).

Genomic Regulation of Gene Expression

In higher organisms such as human beings, the expression of the information encoded within the genes is regulated at the chromosome level and at the DNA level. In both cases the strategy is the same: physically block or allow access to the genes in order to prevent or allow the expression of genes. As described earlier, the large amount of DNA in the genome is condensed and not available for transcription. The region of the chromosome to be transcribed must first be opened (relaxed) before RNA polymerase can access the promoter of the gene of interest. The attachment of acetyl or other chemical groups to the histone proteins relaxes the chromosome and permits access to the DNA. In the absence of the attachment of these chemical groups, the chromosome stays condensed, the promoter is not accessible, and the gene is not expressed (Fig. 6.5).

A similar process is used at the DNA level for promoting or inhibiting transcription once the chromosome has relaxed except that the chemical group is frequently a methyl group. Recall the architecture of a typical gene as having a regulatory region, a promoter region, and a coding region. When methyl groups are attached to the DNA in the promoter region, the RNA polymerase is physically blocked from attaching and initiating transcription. For transcription to occur in higher organisms, methyl groups must be removed, and specialized proteins called transcription factors must bind to the DNA in the regulatory region.

Health or Disease?

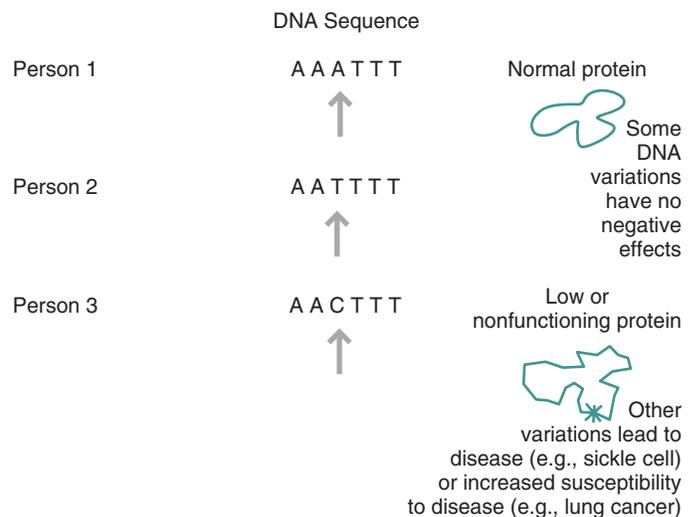

Fig. 6.4 DNA Sequence Variation in Genes Can Change the Protein Produced. Human beings differ from each other in only an estimated 0.1% of the total sequence of nucleotides that compose deoxyribonucleic acid. These variations in genetic information are thought to be the basis for the physical and functional differences between individuals. Some variations in a person's genetic code will have no effect on the protein that is produced; others can lead to disease or an increased susceptibility to a disease. (From U.S. Department of Energy, Human Genome Program: www.ornl.gov/hgmis.)

Transcription factors have a DNA binding site and a ligand binding site. This latter site can bind a small molecular weight “sensor” molecule (a **ligand**) that changes the conformation of the transcription factor and changes its ability to bind to DNA. In higher organisms binding may involve multiple transcription factors, each binding its specific ligand. Depending on the gene, multiple transcription factors may connect with

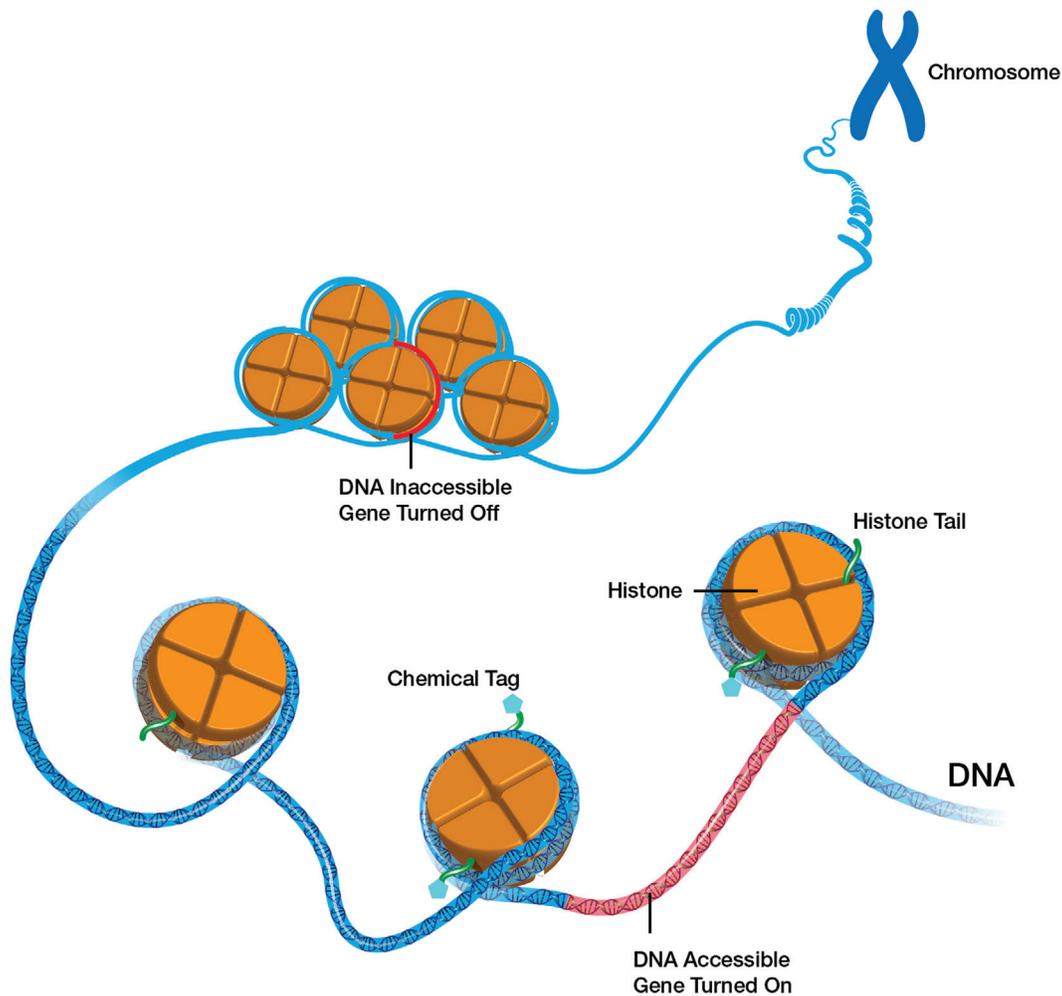

Fig. 6.5 Epigenetic regulation of gene expression through histone modification and DNA methylation. (Image credit: Darryl Leja, National Human Genome Research Institute, NIH.)

DNA individually or form a complex that then allows attachment to the DNA. The expression of some genes is activated by the complex and for others transcription is silenced.

Food plays key roles in the regulation of gene expression. The acetyl and methyl groups originate from food and many of the ligands that bind to transcription factors are derived from food. Food is an important source of information for all organisms to “sense” and respond to their environment. In lower organisms the interaction with DNA is direct. Food molecules placed into the growth medium surrounding the organisms, such as bacteria, can turn on or off genes. The classic examples of regulation of gene expression in lower organisms by food can be seen with the sugar lactose and the amino acid histidine. The disaccharide lactose is not typically in the bacterium’s growth medium. The genes coding for the proteins needed to move lactose into the cell and to cleave the sugar into its glucose and galactose components are silenced until lactose is detected. In contrast, the presence of the nutrient histidine in the growth medium silences the genes needed for its biosynthesis. Since histidine is an essential amino acid, these genes are normally expressed constitutively (always “on”). In this way the organism conserves its energy by sensing the environment, detecting histidine, silencing biosynthesis, and making use of the histidine in the environment.

In both the lactose and histidine examples, there is communication between the environment and the DNA to silence or activate genes, as

appropriate to the health of the organism. The process of sensing and responding to the external and internal environments differs in complexity among organisms but the basic motif is the same. Genes that encode routinely needed proteins are constitutively expressed and silenced by a feedback mechanism when the quantity of the end product is sufficient. As the end product level falls, gene expression resumes. Genes whose protein products are not routinely needed are silenced until needed, at which point gene expression is activated until the environmental trigger (such as lactose) is exhausted and expression is silenced.

Human beings have similar but more complex processes for sensing their environment and some of these aspects can be inherited. The process in higher organisms is called **signal transduction** and there are more steps and more players involved in the process. Food contains numerous bioactive molecules from plants and animals that play important roles in regulating gene expression by serving as “sensors” of the external environment. Among these bioactives are familiar compounds such as isoflavones from soybeans, curcumin from the spice turmeric, glucosinolates from cruciferous vegetables, and epigallocatechin-3-gallate from green tea. For additional information on food molecules as sensors, examples of common bioactive food molecules, and examples of the intricate system of transducing these environmental signals to silence or activate genes, see [Boxes 6.3](#) and [6.4](#).

BOX 6.3 How Food and Genes Communicate

Transcription factors are specialized proteins that bind DNA in one region of the protein and bind a small molecular weight ligand in another region. The complex then binds to DNA and influences gene expression. In this way, food-derived molecules (often referred to as **bioactive food components**) and nonfood molecules such as toxic environmental chemicals communicate with genes and influence which ones are switched on or off, as needed.

These ligands may regulate transcription of genes needed for their metabolism. Alternatively, they may communicate a broader message, such as the presence of chronic inflammation and the need to dampen the expression of genes that produce proinflammatory cytokines. Examples of bioactive food components include the omega-3 fatty acids involved in silencing transcription of proinflammatory genes, derivatives of vitamin A and vitamin D, and numerous plant-derived small molecular weight ligands (phytonutrients). See [Box 6.4](#) for further discussion of phytonutrients.

In human beings this process of sensing the environment and communicating with DNA is a more complex version of the ability of lower organisms to sense nutrients in the growth medium and turn on or off the expression of genes needed for nutrient metabolism. In higher organisms there are more steps and more players involved in the process but the basic theme is the same: to protect the organism by responding appropriately to the state of the ever-changing environment. If the molecule that triggers the switching on (or off) of a gene is fat-soluble (hydrophobic) and of small molecular weight, it typically can pass through the cellular and nuclear membranes and bind to DNA through DNA-binding transcription factors. Examples include the steroid hormones, vitamin A, vitamin D, and thyroid hormones. If the molecule is

large or water-soluble (hydrophilic), it will not readily pass through membranes. Instead it will dock with receptors on the outer cell membrane. Docking sets off the process of **signal transduction**, a multistep cascade that amplifies the initial signal and ultimately results in an activator molecule binding to a transcription factor that in turn binds to DNA and activates or inhibits expression of the target gene. Numerous food-derived molecules are involved in signal transduction.

The nuclear factor- κ B (NF- κ B) family of transcription factors provides an example of such a signal transduction model of gene regulation in higher organisms. These transcription factors regulate numerous genes involved with inflammation, immunity, cell proliferation and differentiation, and apoptosis (programmed cell death). The NF- κ B factors reside in the cytoplasm and are kept inactive by the binding of inhibitors. When a signal molecule from the environment connects to receptors on the cell surface, a stepwise cascade is initiated that activates the NF- κ B transcription factors. The active factors then translocate to the nucleus to bind to genes whose expression is under their regulation.

Activators of this family of transcription factors are molecules that sound the alarm that the organism is under attack, such as tissue necrosis factor alpha (TNF α), interleukin-1 (IL-1), and reactive oxygen species (free radicals). In contrast, several food phytonutrients have been shown to help maintain the inactive state of NF- κ B and protect against inflammation. These molecules have been found in the cruciferous vegetables (indole-3-carbinol, 3,3'-diindolylmethane), in soybeans (genistein and other isoflavones), and in curcumin, from the spice turmeric.

BOX 6.4 Bioactive Food Components: Phytonutrients

Food contains many thousands of biologically active molecules (referred to as “bioactive food components”) that are being investigated for their health benefits. Bioactives derived from plants are called “phytonutrients” (“phyto” in Greek meaning “plants”). The original term for these bioactives was “phytochemicals” but was changed to phytonutrients because expressed discomfort with the term “chemicals.” Although not technically nutrients, phytonutrients are emerging as important metabolic components.

From a dietary standpoint, the most commonly studied phytonutrients have been those from fruits, vegetables, legumes, cereal grains, nuts, seeds, teas, olive oil, wine, herbs, spices, and dark chocolate ([Upadhyay and Dixit, 2015](#); [Andreesu et al, 2018](#)). Phytonutrients regulate numerous cellular and molecular pathways, such as preventing cell proliferation and aggregation, protecting against inflammation and oxidative stress, potentiating signals from the environment, and regulating gene expression in response to environmental triggers. The benefits of these compounds are being investigated in many prevalent chronic disorders, such as cancer, vascular disease (hypertension, dyslipidemia, smooth muscle proliferation leading to intimal thickening), diabetes (glucose intolerance, insulin resistance), and neurodegeneration.

Polyphenols are the largest category of phytonutrients and include simple phenolic acids, stilbenes, curcuminoids, chalcones, lignans, flavonoids, and isoflavones. Common food sources of polyphenols include genistein and daidzein (soy), resveratrol (purple grape skins, red wine), quercetin (onions), catechins and epicatechins (beans, green tea, black tea, apricots, chocolate), proanthocyanidins (apples, cocoa, berries), and curcumin (turmeric, mustard, curries). Curcumin is also antiinflammatory and, as such, is potentially helpful

in virtually all of the chronic disorders since low-grade chronic inflammation is an underlying mechanism. Glucosinolates are sulfur-rich compounds that occur in cruciferous vegetables, such as broccoli, cauliflower, Brussels sprouts, and kale. Metabolism of glucosinolates yields isothiocyanates (e.g., sulforaphane) and indoles (e.g., indole-3-carbinol), which have been found to have anticarcinogenic properties ([Lampe and Peterson, 2002](#); [Peterson et al, 2002](#)). The cruciferous vegetables and their glucosinolate components also play an important role in biotransformation, which is a key mechanism for protecting the body against cancer.

Of the polyphenols, isoflavones, curcumin, glucosinolates, resveratrol, and epigallocatechin-3-gallate (EGCG) from green tea have been of particular interest because they are known to influence gene expression through epigenetic mechanisms ([Vanden Berghe, 2012](#)). Isoflavones, curcumin, and EGCG are important inhibitors of the proinflammatory NF- κ B signaling cascade. Resveratrol and curcumin are examples of polyphenols that can activate SIRT1, a histone deacetylase involved in inflammatory pathways, including NF- κ B. There are numerous cell signaling mechanisms involved in epigenetic regulation of gene expression; NF- κ B is an important example because it regulates several proinflammatory processes that contribute to chronic inflammation that underlies chronic disorders. Scientific research continues to support the recommendation for a mostly plant-based diet that includes a wide variety of foods as essential to long-term health. Several overviews of phytonutrients, their health benefits, and their mechanisms can be found in [Rescigno et al, 2018](#); [Lee et al, 2018](#); [Rescigno et al, 2017](#); [Upadhyay and Dixit, 2015](#); and [Gupta and Prakash, 2014](#).

In addition to these mechanisms, noncoding RNAs are also involved in regulating gene expression. These RNAs are produced during transcription but are not mRNA and therefore do not direct protein synthesis. There are long noncoding RNAs (lncRNA) and short noncoding RNAs (sncRNA), which include microRNAs

(miRNA) and small nucleotide RNAs (snRNA). The finding that these RNAs are not simply extra nucleotides that were removed during maturation of pre-mRNA into mRNA is fairly recent. The roles of these various RNAs are being investigated and include gene silencing as a major target ([Mattick, 2018](#)). Several thousand early-stage

studies in mouse models and human tissues have been reported. Both long and short RNAs have been linked to various metabolic disorders: diabetes, obesity, cardiovascular disease, cardiometabolic syndrome, neurologic disorders, nonalcoholic fatty liver disease, and various cancers.

Epigenomics and Gene Expression

The regulation of gene expression occurs at two levels: genomic and epigenetic. “Epi” in Greek means “above,” as in “above” the genetic code. Genomic control takes place within the regulatory region of genes, upstream from the promoters. **Epigenetics** and **epigenomics** relate to processes that alter gene expression through modification of histone proteins or DNA without changing the sequence of the DNA, thereby keeping the information in DNA intact. This point is important since DNA encodes the information for making RNAs and proteins, which are critical for the translation of this information into an operating system that generates human function. **Epigenetics** is concerned with the processes involved in regulating gene expression, how genes are turned on or off and the mechanisms involved. These processes are particularly critical during the various stages of normal human growth and development. **Epigenomics**, in contrast, is the collective set of epigenetic tags in a genome. Although the DNA sequence is the same from cell to cell, the pattern of gene expression is different among different cell types and these patterns can be inherited. The pattern of **epigenetic marks** (or “tags”) that are characteristic of each cell type determines the gene expression pattern (i.e., which genes are active or silent at any given point). Epigenetic marks represent an additional set of instructions beyond the DNA **genetic code** that governs the process of decoding DNA into RNA and protein. Epigenomic research focuses on understanding which epigenetic marks are within a genome, how changes arise, the influence of epigenetic patterns on physiologic function, and how the marks are inherited.

Epigenetic gene regulation is achieved through the addition or deletion of chemical groups to histone proteins or methyl groups to DNA. To date, the more common tags are acetyl groups added to histone proteins and methyl groups to DNA but phosphorylation, ubiquitylation, and sumoylation (attachment of SUMO groups—small ubiquitin-like modifiers) are also used. During development of the fertilized embryo most of the epigenetic marks are erased (genomic reprogramming) but some remain and are passed from parent to child. In this way the child inherits some of the parents’ life experiences that led to the epigenetic patterns in the egg and sperm. Research and advances in technology will likely expand the library of potential epigenetic tags as well as our understanding of epigenetic inheritance.

Identical (monozygotic) twins are a natural example of the influence of epigenetics in human beings. The twins are not identical phenotypically despite having identical genotypes. Epigenetic regulation of gene expression contributes to this phenomenon, which is called monozygotic discordance (also epigenetic drift). See **Box 6.5** for a further exploration of the role of epigenetics in the differences in anthropomorphic features and disease susceptibility as monozygotic twins age.

Epigenetic marks provide the instructions for the development and differentiation of each cell type and for directing their aggregation into tissues and organs. With the exception of red blood cells, which have no nucleus, each of the cells in higher organisms contains the full set of DNA in the nucleus. During development, these cells differentiate into the various types of cells needed to operate the organism, such as eye cells, bone cells, liver cells, heart cells, and so on. Each cell type is specialized for particular tasks, which requires that certain of its genes be transcribed and others be silenced. The importance of nutrition during the prenatal and postnatal developmental periods cannot be

BOX 6.5 Epigenetics and Identical Twins

Have you ever wondered why most identical twins and other monozygotic multiples have increasingly obvious phenotypic differences as they age in spite of having the same DNA? Commonly encountered differences include physical features, disease susceptibility, and personality. Twins reared apart tend to exhibit greater observable differences. However, not all monozygotic twins exhibit this pattern. The basis for these differences lies, at least in part, with different epigenetic signatures, which leads to differential regulation of gene expression and the phenomenon of “monozygotic discordance,” also called “epigenetic drift.” Early investigations by Fraga and colleagues (Fraga et al, 2005; Poulsen et al, 2007) found that monozygotic (MZ) twins were identical in their epigenetic patterns early in life but that the epigenetic patterns of DNA methylation and histone acetylation in older MZ twins was considerably different. These studies were significant in explaining how different phenotypes could arise from apparently identical genotypes.

Recently the situation has grown even more complex. Waterland and colleagues discovered that the timing of the restoration of the epigenetic marks in monozygotic twins determines how similar the marks are between the twins (Van Baak et al, 2018). These marks are erased during fertilization and restored during very early embryonic development. Monozygotic siblings form when the very early embryo splits in two and each embryo develops into a separate individual. If the epigenetic marks are reset before the embryo splits, the epigenetic pattern will be the same for both twins, called “epigenetic supersimilarity”. If the marks are reset after the embryo splits, there will be differences in epigenetic patterns between the twins. In both cases the DNA sequence is identical, but the epigenetic pattern is identical or different depending on the timing of resetting the epigenetic marks.

Two findings from this study are intriguing and under further study. One is the link between the genes involved in epigenetic supersimilarity and the development of cancer. The other is a rethinking of the use of monozygotic twins as a model system for estimating the risk of disease contributed by genes vs. environment. The lack of stratification of the twins in such studies based on their epigenetic pattern at birth may have led to an overestimation of genetic contribution to disease.

overemphasized because the diet is the source not only of the nutrients needed for growth but for the epigenetic marks that direct growth, development, and differentiation. Research suggests that many other stressors in addition to food insufficiency have an epigenetic effect, such as poverty, stress, and toxic exposure. A new discipline, social epigenomics, has arisen that focuses on social experiences throughout the lifespan and investigation of the key environmental triggers and their epigenetic effects. See **Box 6.6** for additional information.

MODES OF INHERITANCE

Three processes influence how traits are transmitted from one generation to the next: mendelian inheritance, mitochondrial inheritance, and epigenetic inheritance.

Mendelian Inheritance

Each cell’s nucleus contains a complete set of genetic material (genome), divided among 22 pairs of chromosomes (autosomes) and 2 sex chromosomes for a total of 46 chromosomes. During cell division (mitosis), all 46 chromosomes are duplicated and distributed to each new cell. During meiosis, one member of each of the autosome and sex chromosome pairs is distributed to an egg or sperm. Upon fertilization, the full set of 46 chromosomes is restored.

Because genes are carried on chromosomes, the rules governing the distribution of chromosomes during mitosis and meiosis

BOX 6.6 Social Epigenomics

Social epigenomics is concerned with the negative and positive influences of social experiences throughout the lifespan. These experiences do not alter the DNA sequence, only the epigenetic marks attached to the DNA and histone proteins. The epigenetic pattern (epigenome), in turn, alters gene expression. This feature is important because genes that might normally protect against a disease (such as cancer tumor-suppressor genes) may be turned off and genes that promote disease (such as cancer oncogenes) may be turned on.

The focus of research in this area is to investigate the key environmental drivers for altering the epigenetic pattern and their influences on function. Numerous factors are being found to cause changes in the epigenetic pattern, from food to stress to toxic chemicals to aging. The encouraging aspect of this work is that these influencers on epigenetic patterns are potentially modifiable. Research is identifying what the environmental triggers are and the mechanisms by which they influence gene expression.

Since 2008 the National Institutes on Minority Health and Health Disparities has established a program for funding research highlighting social epigenomics, particularly as it includes the health of minorities and health disparities in the U.S. population, especially as a result of racism and discrimination. The expectation is that, by identifying epigenetic modifications, it may be possible to detect disease susceptibilities early and tailor interventions that can prevent chronic conditions from manifesting. See the National Institutes of Health website on research on social epigenomics to address health disparities for information on the types of research studies that are being conducted.

govern the distribution of genes and any changes (mutations, gene variants) they may contain. These rules describe the **mendelian inheritance** of a gene, named after Gregor Mendel, who first deduced that the inheritance of traits was governed by a predictable set of rules. It is possible to track a mutation through multiple generations by knowing these rules of inheritance. This transmission is depicted typically as a pedigree and can be used to predict the probability of a genetic change being inherited by a particular family member. When the change causes a disease, a pedigree can be helpful in predicting the probability that another family member will inherit the disease. The Family History Initiative through the CDC offers helpful online tools for organizing information about your family history.

Mendelian transmission can be autosomal or sex-linked, dominant or recessive. There are five classic modes of mendelian inheritance: autosomal dominant, autosomal recessive, X-linked dominant, X-linked recessive, and Y-linked. An individual's genotype obeys the laws of inheritance, but the **phenotype** (the observable/measurable expression of the genotype) may not. Each gene in an individual is present in two copies (alleles), one on each chromosome (with the exception of traits carried on the male X or Y chromosome). When the alleles are the same (either both are the common or usual version or both are the mutant or variant form), the individual is said to be **homozygous**. If the alleles are different, the individual is **heterozygous** (also called a carrier).

Whether a gene is **dominant** or **recessive** refers to whether a trait is expressed (can be measured, observed) in a heterozygous individual who has one common allele and one variant allele. If a trait is expressed when only a single copy of a variant allele is present, the allele is said to be dominant (i.e., the variant allele determines the phenotype). Alleles that do not dominate the genotype when only a single copy is present are called recessive. The variant allele is present in the genome, but the trait is not expressed unless two copies of this allele are expressed. Further confounding the nomenclature is the

concept of **penetrance**. Even when a pedigree suggests that a gene is present that should lead to the individual displaying a certain phenotype, the phenotype (often a disease) may not be evident. Such a gene is said to have reduced penetrance, meaning that not everyone who has the gene expresses it in a form that is readily measurable. "Measurable form" much depends on what is able to be measured with current technology. Many alleles thought to be recessive 50 years ago can be detected today as the result of new and more sensitive technologies. Penetrance is of interest to nutrition professionals because it can also reflect the inability of a genetic variation to impair function and cause disease unless the individual is exposed to specific environmental triggers, such as diet and lifestyle factors. Modifying these factors potentially can improve outcomes for those with such variants. Expect the terminology to continue to be updated as knowledge advances about the associations among genes, lifestyle, and functional outcomes.

Mitochondrial Inheritance

Mitochondria are subcellular organelles that are essential for energy production and are thought to have originated from bacteria (therefore no chromosomes). In addition to genetic material in the nucleus, the mitochondria in each cell also contain DNA. Human **mitochondrial DNA (mtDNA)** codes for 14 proteins essential to oxidative phosphorylation and energy production and 2 ribosomal RNAs and 22 transfer RNAs needed for mitochondrial protein synthesis. The remainder of the proteins are coded for by nuclear DNA. In contrast to nuclear DNA, mtDNA is small (16,569 base pairs), circular, and exists in multiple copies within each mitochondrion, the number varying among cell types. As with nuclear DNA, changes in mtDNA can lead to disease.

Traits resulting from mitochondrial genes have a characteristic inheritance pattern; they are nonmendelian because mitochondria and their genetic material typically pass from mother to child, called **mitochondrial or maternal inheritance**. This biologic principle has become the basis for anthropological studies that trace lineage and population migration patterns through the centuries. It also has provided a way to trace familial diseases caused by changes in mtDNA.

Epigenetic Inheritance

Epigenetic inheritance illustrates another mechanism by which genetic information is passed between generations. Inheritance occurs by the genome being passed by parents through **germline** (egg and sperm) cells to their offspring. **Somatic** (body) cells also pass on their epigenetic marks each time they divide, which is essential for cells to maintain their specialization (as heart cells, kidney cells, etc.).

An important point here is that epigenetic marks appear not to be permanent (lifelong) at the time of fertilization. Lifestyle choices throughout the lifespan can alter these marks (the **epigenome**) as a result of the organism responding to information communicated from the ever-changing environment. The triggers may be traditional nutrients, phytonutrients, exercise, stress, sleep sufficiency, cytokines, toxins, hormones, and drugs. The fact that epigenetic marks are passed on to daughter cells, whether gametes or somatic cells, means that any changes in the marks can be inherited and can influence gene expression in subsequent generations. The quality of our lifestyle choices, and their appropriateness for our particular genetic makeup, matters.

Epigenetics is increasingly considered to be one important factor in sorting out why the presence, in the genome, of **single nucleotide polymorphisms** (SNPs) that appear to be strongly associated with a particular chronic disorder are typically not sufficient to lead to chronic disease. The presence of these gene variants, a change in a

nucleotide in a genetic sequence, can cause an aberration in coding of proteins and can increase the susceptibility for developing a chronic disease—but this is not a guarantee. Food and other lifestyle choices appear to be essential triggers for activating the susceptibility for chronic disease and epigenetic marks. With their ability to regulate gene expression, food and lifestyle choices appear to be at least some of the underlying mechanisms.

Groundbreaking research demonstrating the influence of diet on physiologic outcomes and the connection to epigenetics was conducted by Waterland and Jirtle (2003), showing the effect of specific nutrients on phenotype. See [Box 6.7](#) for more information on these

experiments. Applicability of these types of findings to human beings can be found in studies such as the Dutch Hunger Winter Families Study ([Roseboom et al, 2006](#); [Rooji et al, 2010](#); [Bygren, 2013](#)). The Dutch Hunger Winter study is a retrospective cohort study that supports the possibility of transgenerational epigenetic inheritance in human beings as well as the importance of prenatal nutrition. This study investigated the offspring of mothers who were pregnant during the Dutch Hunger Winter famine that followed World War II. Undernutrition during fetal development could be traced to health consequences for these children during later life. See [Box 6.8](#) for details.

BOX 6.7 Epigenetic Inheritance: Influence of Nutrition

Researching the underlying genetic and metabolic basis for a trait or disease requires the ability to control a number of the variables, such as mating, diet, and other lifestyle choices.

For this reason, model systems have evolved in which researchers can get an understanding of the genetic, biochemical, and physiological mechanisms prior to designing human studies. The laboratory mouse has been of particular value because it has a sufficiently similar operating system to that of human beings. This feature has allowed researchers to predict from mouse studies what is likely occurring in human beings. It was through the use of mice whose coat color could be controlled through genetic and dietary manipulation that Waterland and Jirtle (2003) were able to provide insight into the complexity of epigenetics and its heritability.

The researchers selected a strain of mice with a mutation in the *Asip* gene, more commonly referred to as the *agouti* (“a-goo-tee”) gene. The mutation involved the insertion of a DNA fragment into the promoter region of the *agouti* gene. The mutation is designated A^y (agouti viable yellow allele) and it is dominant. Genetically identical A^y/A^y mice with yellow coats were bred with a/a wild-type (“normal”) mice with dark brown coats and fed the standard laboratory mouse chow. The offspring (F1 generation) were genetically A^y/a . Since the A^y allele is dominant, all the offspring were expected to have yellow coats. Instead, there was a range of coat colors varying from yellow to yellow-brown (“mottled”) to brown and these colors persisted into adulthood. The insightful hypothesis of Waterland and Jirtle was that epigenetics was responsible for the coat color results, potentially caused by methylation of the A^y allele, and that this effect could be inherited.

The researchers then tested whether methylation was involved. They designed a study in which dark-coated a/a females were bred to A^y/A^y yellow males. The females were divided into two groups. Both groups received the standard laboratory chow, but half the mothers received a supplement of folate, vitamin B₁₂, choline, and betaine, which provided a methyl donor-rich diet. The supplement was begun 2 weeks before mating and continued during pregnancy and lactation. All the offspring were A^y/a . The unsupplemented mothers had offspring with yellow or yellow-brown coats, as expected. Most of the offspring from the mothers on the methyl-rich diet, however, had a mottled coat with a mix of brown and yellow (called *pseudoagouti*). Clearly, the mother’s diet affected the coat color of the offspring and these effects persisted into adulthood. An investigation into what may be causing the difference in phenotype among genotypically identical siblings detected a correlation between mottled coat and degree of methylation of the *agouti* gene, which suggested that the methyl-rich diet led to epigenetic silencing of the A^y allele.

Furthermore, this effect of diet was clearly heritable. In subsequent experiments ([Cropley et al, 2006](#)) found that feeding the females of the “grandmother” generation a methyl-rich diet but not enriching the daughter offspring’s diet still produced a number of second-generation offspring with mottled brown coats, which suggested that the effect the diet had on coat color could be transmitted to succeeding generations. These studies laid the groundwork for research investigating diet and other lifestyle factors for potential transgenerational effects.

BOX 6.8 Epigenetic Inheritance: The Dutch Famine Study

A retrospective cohort study suggests that the existence of transgenerational epigenetic inheritance that was seen in the mouse studies (see [Box 6.7](#)) also occurred in humans. The Dutch Hunger Winter Families Study investigated over 2414 offspring of mothers who were pregnant during the extreme famine in the Netherlands during the harsh winter of 1944 to 1945. The de Rooij et al study (2010) provides an overview of the history of the famine, which resulted from the coalescence of the food embargo during World War II and a particularly severe winter that decimated food crops. All social classes were affected. Daily caloric intake at the peak of the famine was extremely low for the adult population (estimated at 400 to 800 calories/day). Although pregnant women were allotted extra food, there was insufficient food to meet the need. The famine period was followed by plentiful food as these children grew to adulthood. Studies of adult offspring from these mothers found elevated rates of cardiovascular disease and accompanying altered lipid profiles, obesity, type 2 diabetes, and age-associated cognitive decline ([Roseboom et al, 2006](#); [de Rooij et al, 2010](#); [Bygren, 2013](#)).

As regrettable in terms of human suffering as the famine was, it has generated valuable understanding of the developmental origins of health and disease and

has increased awareness of the critical nature of diet and lifestyle during the prenatal period. Further, researchers have been able to correlate starvation during stages of gestation with effects of the famine on offspring ([de Rooij et al, 2010](#)). Children exposed to the famine in the latter third of pregnancy were small at birth and remained small throughout life. Impaired renal function was correlated with those exposed to starvation during midpregnancy ([Roseboom et al, 2006](#)). Those exposed in the early stages of pregnancy tended to have the elevated rates of cardiovascular disease, obesity, and cognitive decline in adulthood ([de Rooij et al, 2010](#)). More recently, Franke et al (2018) have used neuroimaging of these offspring compared with healthy individuals of the same age and found that undernutrition during early gestation resulted in distinct differences in brain structure as well as premature brain aging.

Changes in epigenetic marks are suspected of contributing to the health outcomes seen with undernutrition in prenatal life. Researchers are examining prenatal and adult epigenetic signatures in human beings and animal model systems to gain a better understanding of the influence of various types of stress during the prenatal period. A recent review by Cao-Lei et al (2017) summarizes the current understanding of this association.

At this time, epigenetic inheritance is the least understood of the mechanisms of inheritance but is under active study globally by numerous laboratories. At least three mechanisms are involved: histone modification, DNA modification, and noncoding RNAs. As discussed earlier, epigenetic marks resulting from histone and DNA modifications can be passed down through the generations. Just how far the reach extends is not yet known, but there is a clear pattern at least from grandparents to children to grandchildren. The importance here to nutrition professionals is that food and other lifestyle choices matter—what grandparents ate has the potential to influence subsequent generations. The details of these processes are beyond the scope of this chapter, but readers should be aware that diet and other lifestyle factors are powerful levers for changing one's health trajectory. As such, they are powerful tools for improving clients' health.

Expect that, in time, understanding epigenetic mechanisms will be essential for the development of effective nutrition therapy. Current reviews explore epigenetic inheritance in mammals as well as other animals and plants and in neurodevelopmental disorders, including current applications to autism (Radford, 2018; Dall'Aglio et al, 2018).

Genomic Imprinting

Typically, the human genome contains two working copies of each gene, one copy from each parent. For some genes, however, only one copy is switched on and transcribed. The other copy is epigenetically silenced through the addition of chemical groups. In other words, genes are silenced in a parent-of-origin specific manner. Epigenetic marks, typically methyl groups, are added in order to silence particular genes in the egg and other genes in the sperm. This process is called **genomic imprinting**.

The nucleotide sequences of the same gene in the father and the mother are much the same but not identical due to variations occurring over time. One parent may have a sequence that produces a functional protein from that gene. The other parent may have a change in their DNA, producing an altered protein that leads to impaired function. If the father's (paternal) copy of the gene is the one with the mutation and the mother's (maternal) copy is normal, the normal gene can usually compensate for the influence of the mutated gene (and vice versa if the maternal copy is mutated and the paternal copy is normal). However, if the gene involved is one that is epigenetically marked and it's the normal copy that's silenced, there will be insufficient normal protein to compensate and typically dysfunction and disease result. What's critical is which copy, paternal or maternal, is activated and which is silenced.

Imprinted genes are particularly important in the control of normal growth and development, including prenatal development, brain development, and postnatal metabolism (Girardot et al, 2013; Perez et al, 2016; Nilsson et al, 2018). Only a small number of genomic imprinting abnormalities have been reported to date. The reason is likely that the basis for such abnormalities can be difficult to detect and confirm. See Box 6.9 for examples of two well-known human disorders involving genomic imprinting and the importance of maternal and paternal genetic contributions. For additional examples of genomic imprinting and human disease, Kalish et al (2014) explores the role of imprinting in Beckwith-Wiedemann and Russell-Silver syndromes. Fifty percent of individuals with Beckwith-Wiedemann are estimated to have methylation defects, which suggests a role for nutrition therapy in addressing folate status (Dagar et al, 2018).

Current research efforts are now wide-ranging beyond chromosomal disorders. The potential role of genomic imprinting is being investigated in numerous diseases affecting growth, development, and differentiation. A few examples include cancer, autism spectrum disorders, the development of the brain and brain disorders, food allergy, and assisted reproductive technology (Liu et al, 2018).

BOX 6.9 Genomic Imprinting: Angelman and Prader-Willi Syndromes

Two examples of known developmental disorders arising from genomic imprinting abnormalities are Angelman's and Prader-Willi's syndromes. Both involve a microdeletion of chromosome 15. However, because of the phenomenon of genomic imprinting, which of the two syndromes develops is due to whether the deletion is passed from the father to the child or from the mother to the child.

Angelman's syndrome is a neurologic disorder with developmental disabilities; speech impediments; jerky gait; and a smiling, laughing demeanor. In this syndrome the genomically imprinted gene *UBE3A* associated with the ubiquitin pathway is involved. In Angelman's syndrome the paternal copy of this gene is silenced and the maternal copy is expressed.

If the maternal copy has a mutation in the imprinted gene or, as in the case of the microdeletion, the gene is lost, the gene is not present and cannot produce the normal protein needed. Angelman's syndrome develops.

Similarly, the *SNRPN* gene (which plays a role in mRNA splicing) is in the same region of the chromosome 15 microdeletion as the *UBE3A* gene but is associated with a different developmental disability, Prader-Willi's syndrome. In this case the maternal copy of the gene is silenced and the paternal copy is expressed. When the microdeletion is on the paternal contribution, the *SNRPN* gene is lost to deletion and the maternal gene is not expressed.

Prader-Willi's syndrome is also characterized by developmental disabilities, decreased muscle tone, and an extreme drive for food (see Chapter 43).

It is quite possible that these two examples are only the tip of the iceberg in terms of the developmental disabilities that likely involve genomic imprinting.

X-Inactivation

Another epigenetic example is X-inactivation, which may appear to be an example of genomic imprinting but is not. Imprinting involves the inactivation of working genes; X-inactivation involves inactivating an entire chromosome. Further, the two mechanisms are quite different. The need for X-inactivation stems from human males typically having one X chromosome and females having two X chromosomes. The assumption is that having twice the amount of gene expression from the X chromosome would be information overload due to the large number of genes (over 1000). Instead, one of the X chromosomes in females is inactivated early in development through a combination of epigenetic marks: hypermethylation of the DNA and condensation of the chromosome. The choice of whether the mother's or the father's X chromosome is inactivated appears to be random and varies from cell to cell. The selection occurs during early fetal development and continues through the numerous cell divisions required. Females therefore are mosaics. If the active X chromosome carries one or more genes associated with a disease and there are sufficient numbers of cells expressing this gene, symptoms characteristic of that disease may be observed. See Balaton et al (2018) for a review of the process of X-inactivation.

GENETIC VARIATION, INHERITANCE, AND DISEASE

Historically, human genetic research focused on identifying the mechanisms by which traits were passed from parent to child, such as physical traits or certain rare diseases that appeared within extended families. Genetic diseases were considered to be a separate category of disease, limited to those rare heritable disorders that resulted either from changes to a single gene or alterations at the chromosomal level. Either type of change can have a devastating effect on the metabolic and functional ability of the individual.

Today it is recognized that most diseases are genetic in origin, either from errors in the DNA nucleotide sequence and the information it encodes or from alteration in the expression of this information and its conversion into our functional abilities. Changes to the genetic material, whether to the chromosomal DNA, mtDNA, or even a single nucleotide, have the potential to alter one or more proteins that may be critical to the operation of the cells, tissues, and organs of the body. Changes to the genetic material at each of these levels can have important consequences to our metabolic and functional abilities.

Although DNA is physically quite stable, changes in the nucleotide sequence occur. Each time a cell divides or an egg or sperm cell forms, there's the potential for errors to occur in duplicating the DNA or distributing the chromosomes into the egg or sperm. Environmental exposures such as ultraviolet light and toxic chemicals can cause breaks in the DNA and changes may be introduced during repair. Changes to the DNA are commonly referred to as **mutations** but they're also called **genetic variations**, gene variants, or just "variants." They may involve a single nucleotide, a segment of a chromosome, or a whole chromosome. Although a change may be harmful to the organism, it may also be neutral or beneficial in effect. Mutation is the basis for evolution. When a change occurs that provides a survival benefit to the organism, that organism is able to grow to maturity and reproduce, and its descendants will continue to reproduce and contribute the mutation to the gene pool that characterizes that population.

The order of nucleotides within the DNA sequence determines the amino acid sequence of the protein that's produced. Which amino acid is altered determines the physical conformation (shape) of the protein, which influences how functional the protein is (Fig. 6.5). Whereas particular changes (mutations) in some genes have a devastating effect on function and lead to a disease, changes in other genes may have a much less drastic functional impact or no apparent effect at all. Some changes actually improve function, and many silent mutations have no effect. Where on the continuum the individual's functional ability falls depends on (1) how critical a gene is to the overall function of the organism, (2) whether a gene is expressed at the level needed and at the point in time needed, and (3) where in the gene the change occurs.

A change in the DNA sequence can affect the production or the function of the encoded protein and influence that protein's ability to fulfill its physiologic role. Either outcome can influence the extent of dysfunction that occurs. A classic example is the *HBB* gene, which encodes the beta-subunit of hemoglobin. A change in this gene involving

a single nucleotide causes the debilitating disease sickle cell anemia. The variant beta-hemoglobin molecule is impaired in its ability to bind and deliver oxygen to cells. Additionally, under conditions of low oxygen, the hemoglobin-carrying red blood cells assume a rigid sickle shape, which can cause blockage of small blood vessels, most commonly leading to severe pain crises but sometimes organ damage, stroke, and even death. As knowledge and technology related to the connections among genes, mutation, and disease has progressed, it has become clear that there is a spectrum of disease severity, depending on the location of the altered nucleotide within the *HBB* gene.

Clinically, this type of knowledge has been helpful in explaining why individuals with a mutation in the same gene can have quite different symptoms. As an example, over a thousand mutations have been identified in the DNA sequence of the cystic fibrosis transmembrane conductance regulator gene (*CFTR*). What is observed clinically (the phenotype) is a spectrum of functional outcomes ranging from severe cystic fibrosis to much milder disease (see Chapter 33). Clinicians will need to look more fully into the genetic makeup of an individual to determine where on the functional spectrum the mutations fall. Of particular interest are the functional consequences of changes in the structure of proteins coded for by genes that provide the metabolic machinery for the cells, such as enzymes, receptors, transporters, antibodies, hormones, neurotransmitters, and communicators.

Thus a gene can exist in slightly different forms as a result of a seemingly minor change, such as one nucleotide replacing another. The term for the different forms of a gene is allele (or **polymorphism** if multiple alleles have been detected for a gene). As a result, genes have protein products with differing amino acid sequences (isoforms) and often different functions. Polymorphism is an important concept because it explains why human beings, although 99.9% alike genetically, are distinctly different. The 0.1% difference is sufficient to explain the obvious physical variations among humans. It is also the basis for more subtle differences that may not be readily observable, such as in the functional ability of a key metabolic enzyme to catalyze its reaction. Such variations likely underlie many of the inconsistencies observed in therapeutic outcomes and in nutritional intervention research. Researchers around the world are working to make the connections among gene variants, health and disease outcomes, and effective therapeutic interventions with the goal of improving health outcomes. Directly editing the genome is one strategy to improve health. See **Box 6.10** to see how this technology is being applied in research and medicine.

BOX 6.10 Genome Editing: CRISPR

Genome editing has been a staple of science fiction for many years. In reality, gene editing has been a tool of scientists to introduce changes in the DNA of model organisms from bacteria to fruit flies and even large mammals so that the health effects of mutations (variants) can be studied. Genome editing has also been done to a variety of foods including corn, soybeans, zucchini, and sugar beets. The methods for introducing these mutations have been slow, expensive, and imprecise, sometimes creating random variants (such as with radiation) or requiring multiple generations to achieve the desired outcome.

A new technology called CRISPR (which stands for clusters of regularly interspaced short palindromic repeats) has given scientists a way to quickly, accurately, and inexpensively edit the genome. Adapted from the natural antiviral defense system in bacteria, CRISPR allows specific areas of the genome to be added, removed, or changed. The system uses small pieces of RNA to bind to a specific location in the target DNA, which then allows a CRISPR-associated protein (Cas) to cut the DNA. Cas9 is most often used, but other enzymes can also be combined with CRISPR such as Cas11 and Cpf1. The cell's DNA repair mechanism then repairs the break, introducing changes also encoded on the guide RNA.

Since CRISPR is much more accurate and efficient than previous genome editing technologies, researchers are exploring the possibility of using it to correct genetic diseases in humans. Single-gene disorders such as sickle cell anemia, cystic fibrosis, and other mendelian disorders are likely first candidates for this treatment. However, reports of changes in nontargeted parts of the genome (called off-target effects) raise the possibility of unintended consequences such as cancer or other diseases. The early failures of gene therapy and the availability of current disease-managing therapies have led health researchers to proceed with caution. The applicability of this technology to complex diseases and the line between fighting disease and unnecessary enhancement also remain provocative topics.

The technology also opens debate about responsible ways to edit human genomes. Editing a person's own cells, known as somatic editing, affects only the individual; editing germline cells (sperm and eggs) or those of embryos has the potential to affect future generations. Unregulated experiments on human embryos have already occurred, spurring the need for researchers, policymakers, and the public to discuss the ethics, limits, and potential of this powerful technology.

BOX 6.11 Detecting Gene Variants: Candidate Gene vs. GWAS

For a gene variant to be clinically useful, it must be well-characterized in terms of its association with a disease state, occur frequently in the population being studied (and, preferably, in multiple populations), and have a well-documented effective therapeutic intervention. There have been two main approaches to identifying gene variants that are associated with increased risk of developing common diseases: candidate gene studies and genome-wide association studies (GWAS). The **candidate gene approach** was the original tool. It focuses on functional variants and positional variants. Functional variants result from mutations in genes whose products are known to be involved in the mechanisms underlying the disease of interest. The positional approach is similar but searches for variants that are physically close to genes known to be involved in the underlying mechanisms. Candidate gene studies have the limitation that they're dependent on knowledge of the mechanisms underlying the disease of interest. If the mechanisms have not been thoroughly defined, it is likely that novel genes will not be detected. Further, a large cohort is often needed in order to include sufficient subjects homozygous for the risk allele. Candidate genes have been most successful for single gene disorders.

Lifestyle-related chronic diseases, however, tend to be complex traits and the complexity is further compounded by the epigenetic component. Development of

these diseases typically requires the interaction of a genetic susceptibility created by a gene variant with environmental factors. These factors are typically modifiable and involve lifestyle choices such as the food we eat, whether we exercise regularly, how well we manage our thoughts and emotions, the quality of relationships and systems of meaning, the quality and quantity of our sleep, and our exposure to toxins such as tobacco smoke and other air pollution, food-borne toxic chemicals, and alcohol.

With the rapid advances in genetic technology it has been possible and economically feasible to scan the entire genome in search of common genetic variations. For example, a GWAS scan might involve a set of individuals with the same diagnosis and search for common genetic variations among these individuals or between populations. There are no predetermined target genes and thousands of variants and thousands of individuals can be investigated, which has greatly increased the speed at which gene variants have been detected. The *Catalog of Published Genome-Wide Association Studies* can be searched by diseases of interest to learn which gene variants have been identified to date. The large amounts of data generated by either approach, but particularly by the GWAS approach, greatly benefits from the development of bioinformatics and its high-capacity computer organization and analysis.

The rate of progress of applying genomics in clinical applications is associated strongly with progress in identifying associations between diseases and **single nucleotide polymorphisms** (SNPs, pronounced “snips”). Once a strong association has been determined, diagnostic tests and appropriate diet and lifestyle interventions can be developed and tested for efficacy. As the name for this genetic variation suggests, the change involves a single nucleotide. The initial molecular approach to associating mutations with susceptibility to disease was to look for SNPs (changes) in genes that encoded important metabolic proteins. This approach has been somewhat successful but not sufficiently successful in understanding the genetic and environmental complexity of chronic disorders. As a result, more recently the speed of whole genome sequencing has increased substantially and the cost has decreased, which have allowed a shift to **genome-wide association studies (GWAS)** as the preferred genomic tool for detecting SNPs. GWAS allows the detection of patterns of multiple SNPs associated with a disease and is particularly useful for complex disorders. See [Box 6.11](#) for additional information.

In addition to SNPs, other types of variations also may play an important role in the genotypic and phenotypic variation among humans. Loss or gain of more than one nucleotide (deletions and insertions, respectively), duplication of nucleotide sequences, copy number variants, and restructuring of regions within a chromosome (inversions and translocations) also have important consequences to function. The most recent cataloging of human genetic variation has been the 1000 Genomes Project (www.internationalgenome.org) ([Box 6.12](#)). The earlier SNP cataloging was predominantly of individuals of European descent with some African American and Asian representation and is now undergoing expansion to multiple ethnic groups.

Disease at the Chromosomal Level

Change in the number of chromosomes, or the arrangement of DNA within a chromosome, is almost always detrimental and often fatal to the individual. Chromosomal disorders are detected by means of a **karyotype**, a visualization of all the chromosomes in picture form. Mutations that involve a change in the number or structure of a chromosome are often lethal events because chromosomes contain multiple genes and the ensuing chaos of having too little or too much

BOX 6.12 The 1000 Genomes Project

Like the Human Genome Project, the 1000 Genomes Project is a significant step forward in the goal of personalizing therapy. Advances in DNA technology and the subsequent cost-savings allowed researchers to expand the number of genomes and populations represented in the human genome database beyond the original Euro-centric data set. The genomes of 2504 individuals from 26 populations representing 5 continental regions were sequenced. The populations include a diverse sampling of the human population: African, American (north, central, and south American, including Native American), East Asian, European, and South Asian.

The goal of the project was to identify genetic variations that occurred in 1% or greater of the populations studied. Over 84.7 million single nucleotide polymorphisms (SNPs), 3.6 million short insertion/deletion structural variants, and 60,000 other structural variants were detected in these individuals, many clustered in haplotypes. The researchers estimate that >99% of the SNPs projected to be in the human genome at 1% or greater in frequency have been identified. This project is a major step forward for personalized health care. Future research will likely focus on detecting strong associations between specific genetic regions and particular diseases and then on developing effective therapeutic approaches. Bioinformatics has played a significant role in analyzing the extremely large data sets that were generated and will continue to be essential for subsequent research. The steady progress in knowledge, technology, and trained manpower focusing on genetic variation is revolutionizing the way clinicians think about the clinical aspects of medicine, pharmacology, and nutrition. Given the magnitude of variation among individuals, clinical approaches will increasingly accommodate the shift from one-size-fits-all to personalized approaches (1000 Genomes Project Consortium, 2015).

information, or information being expressed at the wrong time, is detrimental to the organism. However, it is possible that parts of chromosomes will break away and attach to another chromosome or that a region of a chromosome will be duplicated. Such events are not always lethal but do typically cause abnormal symptoms. There are numerous chromosomal aberrations that have been defined, many of which have nutritional implications such as assistance with feeding. Descriptions of the changes and their consequences can be found in clinical genetics textbooks as well as online in resources such as the

Genetic and Rare Diseases Information Center and the Mendelian Inheritance in Man compendium.

An example of a nonfatal chromosomal abnormality is trisomy 21 (Down's syndrome). Typically seen is an extra copy of the whole chromosome resulting from an error in distributing the chromosomes during sperm or egg formation. However, the characteristics of Down's syndrome are due to a small region of chromosome 21, so that even if only that tiny piece of DNA is present in triplicate, the syndrome results. Other developmental syndromes are caused by the loss of a portion of a chromosome (a partial deletion). In Beckwith-Wiedemann's syndrome (a chromosome 11 deletion), changes are characterized by organ overgrowth, including an oversized tongue, which leads to feeding difficulties and undernutrition.

Nutrition professionals play an important role in the therapy of those with chromosomal disorders, because these individuals often have oral-motor problems that affect their nutritional status and cause growth problems in early life. Later in development, body weight may become an issue, and nutrition therapy is helpful in controlling weight, diabetes, and cardiovascular complications. Varying degrees of mental insufficiency often complicate therapy. Nutrition professionals can help mitigate the detrimental effects of these disorders on nutritional status (see Chapter 43).

Disease at the Mitochondrial Level

Due to the major role that mitochondria play in energy production, alterations in mtDNA are frequently degenerative and have varied clinical manifestations because of the multiple copies of mtDNA, not all of which may contain the genetic change. Mutations in mtDNA can manifest at any age and include neurologic diseases, cardiomyopathies, and skeletal myopathies. An increasing number of diseases are being linked to mutations in mtDNA. One of the earliest disorders to be traced to mtDNA is Wolfram's syndrome, a form of diabetes with associated deafness. Subsequently, gene variants have been found that relate to each of the components of the oxidative phosphorylation pathway. The physiologic consequences of these mutations typically involve organs that have a high demand for energy, such as the heart, kidneys, brain, and muscles. See the National Institutes of Health Genetics Home Reference website for information on mtDNA-based disorders and MITOMAP, a human mitochondrial genome database, for specifics on human mtDNA variants.

Disease at the Molecular Level

The majority of disease conditions associated with genomics involve changes at the molecular level. Changes to the DNA typically involve a single nucleotide change or several nucleotides within a single gene through substitutions, additions, or deletions in the regulatory, promoter, or coding regions. Alterations in the regulatory or promoter region may increase or decrease the quantity of protein produced or alter the ability of the gene to respond to environmental signals. Alterations in the coding region may affect the amino acid sequence of the protein, which in turn can affect the conformation and function of the protein and thereby the functioning of the organism. Because the majority of human genes reside on chromosomes, gene variations are transmitted according to **mendelian inheritance** and are subject to modification from epigenetic markings.

Autosomal dominant single-gene disorders that have nutritional implications include several that may result in developmental disabilities, oral-motor problems, susceptibility to weight gain, and difficulties with constipation. Examples include Albright hereditary osteodystrophy, which commonly results in dental problems, obesity, hypocalcemia, and hyperphosphatemia; chondrodysplasias, which often result in

oral-motor problems and obesity; and Marfan syndrome, which involves cardiac disease, excessive growth, and increased nutritional needs. Familial hypercholesterolemia (type 2 familial dyslipidemia) results from a defective low-density lipoprotein receptor (*LDLR* gene), transmitted as an autosomal dominant trait. Symptoms include elevated levels of total cholesterol, elevated levels of LDL cholesterol, and increased risk of atherosclerosis.

Autosomal recessive disorders are more common. They were traditionally detected because the mutation had a detrimental effect on the newborn infant that led to serious developmental consequences or death. Sickle cell anemia is an example of an autosomal recessive disease, caused by inheriting two copies of the variant *HBB* gene. Metabolic disorders of amino acid, carbohydrate, and lipid metabolism, designated as inborn errors of metabolism (IEM), are similarly heritable and associated with a particular mutation. IEM disorders are the earliest known examples of nutritional genomics, and dietary modification remains the primary treatment (see Chapter 42). A brief overview of IEM from a genetic perspective is included here to emphasize the important role of the nutrition professional in restoring health to these individuals and to contrast IEM with chronic disorders, which result from the same type of genetic change but affect function less severely. A classic example of an IEM of amino acid metabolism is phenylketonuria (PKU), which is an autosomal recessive disorder. PKU results from a mutation in the gene coding for the enzyme phenylalanine hydroxylase, leading to an inability to convert phenylalanine to tyrosine. Lifelong dietary restriction of phenylalanine enables individuals with PKU to live into adulthood and enjoy a quality life.

Hereditary fructose intolerance (HFI) is another example of an autosomal recessive IEM of carbohydrate metabolism. A mutation in the *ALDOB* gene encoding aldolase B (fructose-1,6-biphosphate aldolase) impairs the catalytic activity of the enzyme and prevents fructose from being converted to glucose. Breast-fed infants are typically asymptomatic until fruit is added to the diet. Nutrition therapy involves the elimination of fructose, sorbitol, and the fructose-containing disaccharide sucrose. In the absence of understanding the presence of this genetic lesion and the need to eliminate these sweeteners from the diet, the individual typically proceeds to develop hypoglycemia, vomiting, and ultimately kidney failure, leading to death.

These disorders highlight the power of understanding the underlying genetic mutation when developing nutrition therapeutic approaches. First, the family history may give a hint that a genetic mutation is present. Although the genetic mutation (**genotype**) is permanent, the **phenotype** is not. In spite of an individual having mutations that predispose to disease, eliminating specific foods and food ingredients essentially keeps the disease susceptibility silent, and the infant will enjoy normal development. Nutrition professionals are invaluable for being able to detect the problem and recommend the appropriate therapy sufficiently early to prevent disease symptoms from manifesting and causing serious developmental issues.

The X-linked dominant fragile X syndrome also affects nutritional status. Fragile X syndrome is characterized by developmental delays, mental impairment, and behavioral problems. The lesion occurs within the *FMRI* gene on the X chromosome in which a cytosine-guanine-guanine trinucleotide segment is repeated more times than the usual number for human beings. The multiple repeats of this trinucleotide make the X chromosome susceptible to breakage. Another X-linked dominant disorder is a form of hypophosphatemic rickets. This disorder is found in males and females, is resistant to vitamin D therapy, and is characterized by bone anomalies, which include dental malformations and resultant feeding challenges.

X-linked recessive conditions include nephrogenic diabetes insipidus, adrenoleukodystrophy, and Duchenne muscular dystrophy (DMD) disorders. Individuals with X-linked recessive nephrogenic diabetes insipidus are unable to concentrate urine and exhibit polyuria and polydipsia. This disorder usually is detected in infancy and can manifest as dehydration, poor feeding, vomiting, and failure to thrive. X-linked recessive adrenoleukodystrophy results from a defect in the enzyme that degrades long-chain fatty acids. These fats accumulate and lead to brain and adrenal dysfunction and ultimately motor dysfunction. X-linked recessive DMD is characterized by fatty infiltration of muscles and extreme muscle wasting. Children typically are confined to a wheelchair by the time they reach their teens and need assistance with feeding.

Y-linked inheritance disorders primarily involve male sex determination. At this time no nutrition-related disorders have been assigned conclusively to the Y chromosome.

In summary, any gene potentially can undergo mutation, which can affect the function of its protein and the health of the individual. Its location within the nuclear DNA or mtDNA determines its mode of inheritance. See Chapter 42 for more information about genetic and metabolic disorders.

Disease at the Epigenetic Level

Although epigenetic mechanisms are major contributors to chronic disease through the gene-environment interactions, much remains to be discovered regarding the usual epigenomic patterns of each gene involved and the mechanisms by which that pattern is altered in response to environmental triggers. Details must await the outcomes of the many studies currently underway. Instead, let's take a moment to acknowledge the valuable contributions of nutrition pioneers who alerted the field to the importance of nutrition-related epigenetics to health. Ornish demonstrated the power of nutrition and lifestyle therapy to change cardiovascular disease and prostate cancer outcomes and linked the latter work to regulation of prostate gene expression (Ornish et al, 2008). Kallio et al (2007) demonstrated that changing the carbohydrate composition of the diet affects gene expression, which includes genes that regulate insulin signaling. Stover has long studied the basis for individual differences in diet-related disease from an epigenetic standpoint and sounded an early alarm on the need to use care in the concentration of folate used in enriching flour products, dietary supplements, and medication because of folate's role as the primary source of methyl groups used to silence gene expression (Stover et al, 2018). Their insight has contributed substantially to the understanding that nutrition is critically important at the molecular level as well as the biochemical, metabolic, and physiologic levels.

NUTRITIONAL GENOMICS AND CHRONIC DISEASE

Health care providers are gradually incorporating the various "omic" disciplines into assessment, diagnosis, intervention, and monitoring/evaluation. To do so requires a deep foundation of knowledge that connects genetic and epigenetic signatures to particular disease states so that an appropriate target for therapy is identified. Additionally, assessment and diagnosis must be followed by interventions known to restore health to those with existing disease or to prevent future disease in those susceptible who do not yet manifest symptoms. This overall approach is well underway for the single gene disorders for which gene variants have been identified and connected to the biochemical and physiologic consequences, and for which effective interventions have been developed, tested, and applied.

In contrast, the majority of clinic visits are for patients with one or more complex chronic diseases. Restoring health or preventing disease

in the case of chronic disorders is an ambitious undertaking that will likely require decades of basic and clinical research before the potential is fully realized. Even when there are not yet well-defined nutritional genomics protocols for particular disorders, diet-and-lifestyle therapy can often be helpful.

Of particular interest to nutrition professionals is the emerging discipline of nutritional genomics and its role in precision/personalized nutrition. **Nutritional genomics** is a field of study focused on the interaction between genes, diet, lifestyle factors, and human health. Included within nutritional genomics are **nutrigenetics**, **nutrigenomics**, and nutrition-related aspects of **epigenetics** and **epigenomics**, which provide insight into how environmental factors regulate gene expression. Nutritional genomics and its subdisciplines encompass numerous other disciplines: molecular biology, biochemistry, intermediary metabolism, transcriptomics, proteomics, metabolomics, the microbiome, neuroscience, and behavioral change. See the Academy of Nutrition and Dietetics review on nutritional genomics for an overview of current progress in the field (Rozga and Handu, 2018). As these disciplines evolve, practitioners will increasingly be able to tailor diet and lifestyle choices to the genetic makeup of each client.

Nutrigenetics concerns the effect of genetic variation on the response to nutrients and other dietary input. For example, an often-cited illustration of nutrigenetics involves a variant in the 5,10-methylenetetrahydrofolate reductase (*MTHFR*) gene. Mutations in this gene can result in a substantial decrease in enzyme activity which is responsible for converting dietary folate or folic acid into 5-methyl folate, the active form. Individuals with such a mutation would need additional folate in the diet for optimal health.

Nutritional genomics is being advanced for clinical applications to common chronic disorders such as cancer, type 2 diabetes, obesity, and vascular disease, as well as important physiologic processes such as inflammation and biotransformation. At this time human clinical studies are limited, and the field is focused on developing the research foundation to be able to make the connections among gene variants, disease, functional impact, and effective interventions. Early adopters are developing nutrigenetic test panels intended to guide practitioners and their clients in identifying susceptibilities and offering recommendations for health promotion. Clients are bringing their test results to nutrition professionals for help with implementing these recommendations. Where there are variants common across nutrigenetic panels, these will be briefly discussed in order to make readers aware of what they may encounter in practice. Expect considerably more variants to be identified and increasingly targeted interventions to be developed in the years ahead.

Genetic Testing and Nutrition Care Process

The long-term promise of nutritional genomics is the ability to identify diet-gene interactions and translate this information into diet-and-lifestyle approaches personalized to the individual. In the shorter term, the expectation is that the information can be used to move away from one-size-fits-all to identifying categories of individuals with chronic disease who would benefit from a similar therapeutic approach based on their genetic makeup and modified for their specific environmental challenges. Genomics will be fundamental in this effort since gene variants will be the basis for identifying susceptibility. Epigenetics will be similarly important because it is the key to gene expression patterns in response to lifestyle choices.

The first step in nutrigenetic testing is assessment. Genome sequencing is used to query the client's genome to identify genetic variants present. Epigenomics will potentially be added in the not-too-distant future to identify epigenetic signatures and their influence on gene expression. Genomic analysis is accomplished either by

genetic technology that detects specific variants (typically referred to as microarray chips), through sequencing of the gene-related parts of the genome (whole exome sequencing), or through whole genome sequencing. The evolution of DNA sequencing technology to the present next-generation sequencing has greatly decreased the cost and the time needed for sequencing and is rapidly becoming the preferred technology for chronic disease research. Once the sequence is obtained, there are numerous computer algorithms that can detect particular gene variants of interest. Some filters are readily available; others are proprietary to companies in the business of converting the presence of gene variants into recommendations for improving health and decreasing disease susceptibility.

The following points should be considered before taking a nutrigenetic test or when assisting your clients in understanding the test results that they or their providers have ordered.

- Evaluate the credentials of the company/laboratory that will be doing the testing. Is testing being conducted in an appropriately credentialed laboratory (at least CLIA-certified)?
- How will the client's privacy be protected?
- What is the cost of the test?
- To whom will the test results be sent?
- How long before the results will be available?
- Is the DNA sample destroyed following analysis? If saved, how will it be used in the future? The consumer will need to provide written consent to have their sample retained and used for future analyses.
- What will be included in the report of the test results?
- Which variants will be examined and are rs numbers reported along with the SNP?
- What is the association of each variant with a disease? Does the company make the studies available that link the variants (SNPs) with diseases?
- Which lifestyle choices are particularly important in promoting disease when this variant is present?

Several prominent nutritional genomics researchers have proposed guidelines for evaluating the validity of nutrigenetic testing and its use for dietary advice (Grimaldi et al, 2017). Additionally, the Academy of Nutrition and Dietetics' 2014 nutritional genomics position paper describes the various governmental agencies that have at least some oversight of nutritional genomics, particularly direct-to-consumer testing (Camp and Trujillo, 2014).

The information that is generated by genetic tests can provide insight into an individual's present health status and future disease susceptibilities to a much greater degree than has been possible to date. Clients will want to know that their information will be held private like any other health care data and that it cannot be used to discriminate against them in obtaining employment or insurance. Unintended consequences of genetic testing are often causes of concern for clients, and the increase in genetic testing across health care makes understanding those consequences especially important for nutrition professionals. See Box 6.13 for more on this topic.

Working with nutrigenetic test reports requires familiarity with the nomenclature used. Variants are named by the gene they represent, typically as three to five letters and written in italics. For the vast number of genes, human beings have two copies. Therefore when describing the gene and nucleotides present (whether wild-type/usual or variant/mutant) certain conventions are used. If the two nucleotides are wild-type, the individual is described as being homozygous wild-type. If one wild-type and one variant are present, the individual is heterozygous, also called a "carrier." If both nucleotides are the variant nucleotide, the individual is homozygous variant. Wild-type and variant states may be referred to as the wild-type allele and the variant or risk allele, which simply refers to the fact that either the wild-type sequence is present or the variant sequence is present or, in the case of a carrier, one of each is present.

The *MTHFR* gene is a now classic example of a nutrigenetic biomarker. A variant of this gene, *MTHFR* C677T (also written as 677C>T) involves the normal nucleotide C (for cytidine) being replaced by a T (thymidine) nucleotide at position 677 in the *MTHFR* gene sequence. Individuals homozygous wild-type have a C at this position in both copies of this gene. Heterozygotes have 1 C and 1 T and those homozygous for the variant have a T at this position in both copies of the gene.

Additionally, each variant is assigned an "rs number" (reference SNP cluster ID). The above *MTHFR* variant is rs1801133. A different variant within this same gene is the *MTHFR* A1298C and is labeled rs1801131). The rs number is critical because it denotes a specific location within the DNA and different mutations often create different functional outcomes. The lack of rs numbers in the earlier genomic literature has often made it difficult to discern which mutation is being analyzed for its gene-environment interactions. Both researchers and

BOX 6.13 ELSI: Ethical, Legal, and Social Implications of Genomics

For the various "omic" technologies to be helpful in the clinic, clients must be comfortable with their use. Of particular concern to clients has been whether genetic information in the hands of insurers or employers could lead to discrimination against applicants. These and other issues are the subject of debate and research into the ethical, legal, and social implications (ELSI) of genetic research and technologies.

From the beginning of the Human Genome Project, scientists, policymakers, and the public have worked to address ELSI issues in genetic research and technologies to inform and protect the public. Some of the potential harms have been addressed by legislation. Genetic-related information is defined as Protected Health Information by the passage of the Health Insurance Portability and Accountability Act (HIPAA). The passage of the Genetic Information Nondiscrimination Act (GINA) in 2008 is another important milestone in ensuring that genetic information will not be used to discriminate against Americans with respect to employment or health insurance. This legislation specifically prohibits the use of genetic information by health insurers to deny healthy individuals coverage or to charge higher than usual premiums because that individual may develop a disease in the future. It also bars employers from making hiring, firing, promotion, or job placement decisions based on genetic information.

However, as the popularity of direct-to-consumer genetic testing has increased, the issue of privacy and nondiscrimination continues to be of concern to consumers and to various governmental agencies. The Federal Trade Commission has begun taking a careful look at how companies supplying these tests protect the consumer's privacy. The nutrition professional should be aware of this concern and be ready to educate clients who are considering genetic testing.

Research into ELSI topics is ongoing and is emerging as a research field in its own right. The National Human Genome Research Institute's ELSI research program, established in 1990, continues to conduct research into ELSI issues. A list of the types of research being conducted can be found on the National Human Genome Research Institute website under ELSI. The European Union's Horizon 2020 research and innovation program is developing another asset, the ELSI Knowledge Desk which is also available on their website. Databases are also available that can be helpful to researchers and consumers, such as the ELSI Helpdesk and ELSI Knowledge Database online funded by the European Union's Horizon 2020 research and innovation program.

commercial companies typically now give the rs number along with the variant's gene and mutation. SNPs, such as *MTHFR*, are the most common type of mutation encountered in nutrigenetic testing but be aware that other types of mutations are possible, such as deletions, insertions, and copy number variants and that each variant has an rs number.

The next step is to take the variants identified and make predictions as to which variants increase one's susceptibility to particular diseases and then to select appropriate health-promoting interventions for these susceptibilities. Many genomics researchers and health care professionals question the reliability of the testing and its present clinical utility. The weakness would seem not to be the technology itself, which has been in place for decades and is a mainstay in research laboratories and, more recently, in clinical laboratories. The weakness is the link between a particular variant and the strength of its association with promoting disease and in the efficacy of the recommended therapeutic intervention. Be aware that the research into which variants are strongly associated with which diseases is early-stage. Many, many variants have been identified but few exhibit both a strong association and prevalence within multiple populations. In most cases, multiple genes variants, not a single SNP, as well as specific environmental exposures are needed for a disease to develop. The nutrition professional will need to be able to translate the implications of the variants in the nutrigenetic test report and the potential disease susceptibilities and link them to a therapeutic plan that can reasonably be expected to improve the client's health. The report accompanying the test results should be helpful in this regard, coupled with the nutrition professional's knowledge of appropriate nutritional approaches and of the lifestyle changes that will be needed for health restoration and sustained health promotion.

Inflammation

Chronic inflammation is an underlying mechanism for virtually all chronic diseases. Diet-and-lifestyle interventions are typically anti-inflammatory in nature across the board for each of the primary lifestyle recommendations: nutrition, physical activity, managing thoughts and emotions, developing supportive relationships, obtaining sufficient quantity and quality of sleep, and minimizing toxin exposure. Interventions

focus on preventing inflammation and on antiinflammatory approaches to existing inflammation. See Chapter 7 for a comprehensive discussion of inflammation, biomarkers, and antiinflammatory therapy.

Commonly used gene variants considered to increase susceptibility to an inflammatory state are those associated with inflammatory biomarkers: C-reactive protein (*CRP*), interleukin-1beta (*IL1β*), interleukin-6 (*IL6*), and tumor necrosis factor alpha (*TNF*). *CRP* is produced by the liver in response to inflammation. Interleukin-1 and interleukin-6 proteins are cytokines produced as part of the inflammatory process. These proteins function as cell signaling molecules that activate the immune system, which involves inflammatory processes. Inflammation is typically self-limiting and abates when the infection or injury is under control. In the case of chronic disease, however, the inflammatory response is essentially stuck in the "on" position.

Biotransformation (Detoxification)

A parallel between pharmacogenomics and nutritional genomics can be seen with the phase I and phase II biotransformation/detoxification pathways that are active in the digestive tract and liver. In a two-phase process, this metabolic system converts drugs and other potentially toxic molecules into chemical forms that can be excreted. Phase I activates the toxic molecule to form a reactive oxygen species (free radical) through the activity of various cytochrome P450 enzymes (*CYPs*). Subsequently, in Phase II glutathione-S-transferases (*GSTs*) and other enzymes add chemical groups to the activated molecule to render it more soluble and less toxic. Knowing the genomic status of the genes that code for these various enzymes would be helpful for predicting which nutritional approaches would be beneficial to support the biotransformation process and when specific medications are used (see [Box 6.14](#)).

The gene variants commonly found in genetic test panels that include biotransformation are from the family of *CYP* genes, the *GST* genes, and two super oxide dismutase (*SOD*) genes. One or more of the *CYP* genes typically include: *CYP2D6*, *CYP2C19*, *CYP3A4*, *CYP1A2*, *CYP29*, *CYP2B6*, and *CYP2E1*. There are three common *GST* variants: *GSTM*, *GSTP1*, and *GSTT1*. The *SOD* genes represented are *SOD1* (copper-zinc *SOD*) and *SOD2* (manganese-dependent *SOD*) that

BOX 6.14 Application of Pharmacogenomics: Warfarin

One of the earliest clinical applications of the "omic" disciplines has been in pharmacogenomics, which is similar in concept to nutritional genomics. Pharmacogenomics involves using genomics to analyze the genetic variations in the genes that encode the drug-metabolizing enzymes and predict the outcomes when variants interact with specific drugs. Genetic variability can lead to differing function in these enzymes, which explains why a drug may have the intended effects for one person, be ineffective for another, and be harmful to a third. By identifying known mutations in biochemical pathways involved in the drug's metabolism, it becomes possible to identify individuals for whom the drug therapy will be beneficial but also to assist with calculating the appropriate dose from the outset of therapy. For drugs with narrow therapeutic windows of efficacy, prescribing the correct dosage from the outset of therapy improves efficacy and reduces the potential for adverse events. Several drugs have now been associated with gene variants and genetic testing is available before beginning therapy.

The blood-thinning medication warfarin has a narrow therapeutic window and is widely used. Associated with frequent adverse events, warfarin was one of the earliest drugs to which pharmacogenomics was applied. Variation in the *CYP2C9*, *VKORC1*, or *CYP4F2* genes influence its safe use. The most recent comprehensive trial to test the clinical utility of warfarin pharmacogenetics is the Clarification of Optimal Anticoagulation Through Genetics (COAG) trial

([Gage et al, 2017](#)). The data demonstrated that genotype-guided dosing of warfarin was superior to standard management in two ways: (1) efficacy, in increasing the amount of drug in the therapeutic range over the period of the trial and (2) safety, for reducing adverse events up to 30 days following the end of the trial.

An interesting aspect of this trial points out a major limitation of genomics to date: the database of gene variants has been developed primarily from individuals of European descent. Gene pools vary among different ancestral populations and, to be effective, recommendations must be based on the gene variants appropriate to each population. The COAG trial did not test for the *CYP2C9*8* variant that is an important predictor of warfarin dose in African Americans ([Nagai et al, 2015](#)). These individuals spent less time within the therapeutic window and did not receive the full effect of the drug. Because the study population was 91% white, the overall effectiveness of the drug for the genotyped arm was not affected. However, genotyping for warfarin will likely not be recommended for African Americans until further research clarifies the set of gene variants that best provides safety and efficacy for this population. This limitation in the gene variant database is well recognized by researchers and a global effort is underway to expand the database. See [Box 6.12](#) for additional information. This project is expanding the populations included and helping identify common mutations associated with specific ethnic groups. Additionally, various countries are establishing databases that represent their specific populations.

protect against free radicals generated during biotransformation. Gene variants in any of the proteins involved in biotransformation can potentially alter the effectiveness of the process.

Cancer

“Omic” clinical research and applications are currently the most advanced for cancer compared with other chronic diseases. The influence of epigenetic marks on gene expression is directly associated with the development of cancer and its characteristic unregulated growth. The expression of oncogenes (tumor-promoting genes) and tumor suppressor genes must be carefully orchestrated to maintain normal growth and development. Oncogenes are typically silenced epigenetically and tumor suppressor genes are activated. If either of these systems malfunction, the risk for cancer could be increased. An example would be a methyl group attaching to a tumor suppressor gene by mistake and turning off its expression. Or, if someone lacked sufficient folate in the diet, an oncogene may not be sufficiently turned off.

Although total personalization of cancer therapy, or any other medical therapy, for an individual is in the forefront of discovery, a number of early steps using “omic” technologies have already been successful in helping tailor therapy and for early detection of treatment failure. Cytotoxic chemotherapy has been the prevailing cancer therapy to date. Although successful in many respects, this approach is relatively nonspecific in that it targets both cancerous and noncancerous cells. One of the goals of precision health is to harness the “omic” disciplines into personalized therapy appropriate for individuals and their particular type of cancer. This approach requires knowledge of the molecular landscape in which the cancer exists (i.e., the person’s genomic and epigenomic makeup and the molecular characteristics of the cancer itself). Molecular defects in the individual’s genome and epigenome, and in the cancer itself, can provide valuable information about potential therapeutic targets. See Luoh and Flaherty (2018) for an overview of the types of cancers being studied and treated using this approach.

Gene Variants and Cancer

Well-known examples of applying genomics to cancer include detection of BRCA1 and BRCA2 genes in diagnosing breast cancer and the hMLH1 and hMSH2 genes in diagnosing hereditary nonpolyposis colorectal cancer (HNPCC). Genetic testing is also available for detecting susceptibility to these types of cancer. Genomic testing is also being used to distinguish specific tumor characteristics to help differentiate one cancer from another. Genetic diagnostics help determine which therapeutic approach will likely be successful and, during therapy, help detect early treatment failure. As options for early detection and prevention emerge, tailored diet-and-lifestyle options will become common in treatment of cancer.

Epigenetics and Cancer

Dietary nutrients and bioactive food components can affect epigenetic processes in multiple ways, from providing nutrients needed to protect against cancer to suppressing gene expression of key components in the signal cascades that lead to cancer promotion (or the enzymes needed for DNA methylation or histone acetylation) to changing the availability of substrates needed for the various enzymatic reactions involved. The nutritional genomics/epigenomics-oriented research being conducted focuses on dietary nutrients and bioactive food components that change gene expression through epigenetic mechanisms (Andreescu et al, 2018).

With traditional nutrients, a main focus is on one-carbon metabolism, which supplies the methyl groups for DNA methylation and histone acetylation, in addition to numerous other important processes

such as DNA repair. These nutrients include folate and folic acid, riboflavin, pyridoxine, vitamin B₁₂, choline, and methionine. Other common dietary components being studied for their cancer-protective properties include dietary fiber, vitamin C, vitamin E, and selenium. In addition to serving as ligands for transcription factors, polyunsaturated fats are essential for downregulating the expression of those transcription factors involved in switching on proinflammatory genes. Examples include transcription factors used for hepatic metabolism of carbohydrates, lipids, and bile acids (Jump et al, 2013).

For the bioactive food components, identification of bioactives from plants is a particularly active area of research because a substantial number of health benefits have been reported for these compounds. The polyphenol and glucosinolate categories of phytonutrients are the most studied for cancer treatment and prevention. Epigenetic changes to tumor suppressor genes can silence these genes and lead to increased risk of tumor development.

Type 2 Diabetes

Type 2 diabetes mellitus (T2DM) is a chronic disorder that accounts for the vast majority of individuals with diabetes (see Chapter 29). T2DM is complex and results from gene variants interacting with bioactive food components and other lifestyle triggers that result in epigenetic modifications to the genome. The hallmarks of this type of diabetes are insulin resistance and failure of the insulin-producing beta cells of the pancreas. Numerous studies have reported the efficacy of diet-and-lifestyle approaches for managing and preventing T2DM. Nutritional genomics will add to the understanding of this complex disease by identifying gene variants that significantly increase the risk of developing T2DM. Additionally, nutritional genomics research will identify gene–diet/lifestyle interactions and mechanisms by which these interactions epigenetically influence gene expression, which will help in developing new and effective interventions.

Gene Variants and T2DM

A few rare mutations have been found that predispose to T2DM, but they do not explain the high prevalence of the disease. Rather than resulting from a single gene mutation, T2DM appears to be due to the contributions of a number of variants interacting with diet-and-lifestyle triggers. Some of the variants are in genes that have obvious connections to glucose homeostasis, but many are not. The following variants are among the more promising in terms of the strength of their association with risk of developing type 2 diabetes: Transcription factor 7-like 2 (*TCF7L2*), solute carrier family 30 member 8 (*SLC30A8*), peroxisome proliferator activated receptor gamma (*PPARG*), adiponectin (*ADIPOQ*), fat mass and obesity protein/alpha-ketoglutarate dependent dioxygenase (*FTO*), clock circadian regulator (*CLOCK*), and melanocortin 4 receptor (*MC4R*). *SLC30A8* is a zinc transporter that is required for insulin synthesis and secretion. The *ADIPOQ*, *CLOCK*, *FTO*, and *MC4R* variants are associated with obesity and increased risk for developing T2DM. *PPARG* is a transcription factor involved with lipid metabolism and adipocyte differentiation that regulates the expression of multiple genes. It has been implicated in diabetes, obesity, cancer, and atherosclerosis. For further depth into any of these variants, visit the Gene website from the National Center for Biotechnology Information or the Genetics Home Reference website from the National Institutes of Health.

TCF7L2 is involved with insulin secretion and exhibits the strongest association by far with susceptibility to T2DM. The *TCF7L2* gene encodes a transcription factor that plays a key role in the WNT signal transduction pathway. Further, *TCF7L2* has been detected in multiple populations. In studies with Indian (Chandak et al, 2007), Chinese Han (Dou et al, 2013), Japanese (Horikoshi et al, 2007), Mexican

American (Lehman et al, 2007), African (Yako et al, 2016), and white European (Groves et al, 2006) populations, the variant occurred frequently and increased the risk of T2DM by 30% to 50%. *TCF7L2* has also been found to predispose individuals with metabolic syndrome to developing T2DM (Katsoulis et al, 2018).

Epigenetics and T2DM

Studies have long suggested that T2DM is strongly associated with diet-and-lifestyle choices, most notably food choices (especially dietary fat) and exercise habits. T2DM has been assumed to be genetic in origin but, with the exception of *TCF7L2*, the large number of gene variants that have been identified appear to weakly contribute to T2DM susceptibility. The answers appear to be (1) there are multiple genes involved and (2) epigenetic mechanisms involving diet-and-lifestyle triggers are important contributors. Research to detect epigenetic changes in response to nutrients and bioactive food components is in progress.

A nutrient-sufficient antiinflammatory diet in which carbohydrate and fat consumption is controlled for quantity and quality continues to be a cornerstone of T2DM care. Increasingly, a focus is being placed on the incorporation of a variety of phytonutrients into the diet. Results from the Nurses' Health Study (NHS) and its follow-up (NHS II) (Sun et al, 2015), as well as the Health Professionals Follow-Up Study (Wedick et al, 2012), suggest that regular consumption of phytonutrient-rich plant foods helped lower the risk of developing T2DM.

In addition to diet and exercise, other daily lifestyle choices influence the physiologic imbalances that lead to chronic inflammation and must be incorporated into lifestyle change programs if the positive changes are to be sustained long term. Examples include chronic psychological and physiological stress and exposure to chemicals and toxins. Hopefully, health care will move toward approaches for T2DM and for chronic disease in general that target the underlying chronic inflammation along with contemporary neuroscience-based behavioral change programs that enable those at risk to address their barriers to making healthy lifestyle choices.

For more in-depth information about the genomic and epigenetic aspects of T2DM, see recent reviews by Silveira et al (2019), Xue et al (2018), and Ortega et al (2017).

Obesity

Obesity is usually indicated by body mass index (BMI), which is measured in kg/m^2 . It is important to assess each person individually, including weight history, waist circumference, and body composition as people with larger body sizes can be metabolically healthy in some cases. Different countries use somewhat different BMI scores to define obesity, but a common global standard is that set by the World Health Organization (WHO), which classifies a BMI of $\geq 25 \text{ kg}/\text{m}^2$ in adults as overweight/preobese, a BMI $\geq 30 \text{ kg}/\text{m}^2$ as obese, and a BMI $\geq 40 \text{ kg}/\text{m}^2$ as extremely obese. WHO has also set BMI standards for children up to 5 years old and 5 to 19 years old. The prevalence of obesity is steadily rising. In the United States the 2015 to 2016 National Health and Nutrition Examination Survey found 39.8% of adults and 18.5% of youth to be obese (Hales et al, 2017).

In addition to being a storage organ ready to provide for future energy needs, adipose tissue is an active metabolic tissue that is important in whole body energy balance. Adipose tissue secretes adipokines, which are cell signaling proteins. Adipokine examples include leptin, adiponectin, and proinflammatory adipokines, such as the interleukins and tumor necrosis alpha cytokines discussed in the type 2 diabetes section. When leptin (*LEP*) binds to leptin receptors (*LEPR*) in the hypothalamus, binding sends the signal of satiety, followed by a reduction in the desire to eat and a stimulated thermogenesis. The

foundational work was done in mouse model systems and subsequently found to be operative in human beings (Ghilardi et al, 1996; Dullloo et al, 2002). Adiponectin is a protein hormone adipokine encoded by the *ADIPOQ* gene and produced by adipocytes. It appears to be important for metabolic balance, particularly in reference to the insulin resistance, oxidative stress, and chronic inflammation characteristic of the metabolic syndrome (Achari and Jain, 2017). In particular the balance between adiponectin and leptin has been correlated with the obesity component of metabolic syndrome. A decrease in the adiponectin/leptin ratio increases the risk of obesity, inflammation, and development of the metabolic syndrome (Frühbeck et al, 2017).

ADIPOQ is a gene of interest because of its association with obesity but also potentially for type 2 diabetes and metabolic syndrome. One of the SNPs in this gene (-11391G>A, rs17300539) appears to link increased levels of adiponectin with decreased risk of obesity. In white Americans, those with one or more copies of the variant allele (A) had elevated adiponectin levels and decreased weight, waist and hip circumference, and BMI (Warodomwicheit et al, 2009). These researchers further detected a gene-diet interaction between the variant allele (A) and monounsaturated fat (MUFA). When MUFA intake was equal to or greater than 13% of total energy, those with one or more copies of the A allele (AA or AG genotype) had a lower BMI compared with individuals with the GG genotype (2 copies of the non-variant G allele). No effect of the A allele was seen for waist circumference, insulin resistance or for saturated fat or polyunsaturated fats. Other researchers have reported increased risk of obesity in the presence of SNPs in *ADIPOQ* in the North Indian Punjabi population (Kaur et al, 2018) and in the Tunisian population (Zayani et al, 2018). These interesting findings with *ADIPOQ* will likely continue to be studied in multiple populations and under varying dietary conditions.

As with leptin, much of the initial work with adiponectin has been carried out using mouse model systems, with research in human beings following more recently. Given the apparent importance of these genes in energy metabolism, the lack of consistency is likely due to a large volume of research but very few polymorphisms are linked to increased risk of developing obesity across multiple populations. Additionally, the complexity of obesity and the multitude of molecules involved has made it challenging to untangle the multiple interactions that increase or decrease risk of developing obesity (Jagannadham et al, 2016). A recent review by Unamuno et al (2018) provides insight into the complexity of dysfunctional adipose tissue and the ensuing dysregulation of adipokine secretion, which leads to chronic inflammation and increased risk of chronic disorders such as insulin resistance, type 2 diabetes, atherosclerosis, cancer, and, most likely, obesity.

The focus of the various research studies is highly varied, from identifying genes that increase risk of obesity, to identifying the environmental cues that trigger overeating and epigenetic changes in the brain, adipose tissue, and liver; from factoring in the composition of the food supply with its increased toxin load and abundance of high-calorie processed foods, to understanding the complex behavioral aspects of why we make the food choices we do. The epigenetic mechanisms that link obesity to increased risk of T2DM and cardiovascular disease add yet more complexity. Clearly, why and how humans become obese is multifaceted and multiple disciplines will be involved in defining the mechanisms and finding effective solutions. The addition of contemporary neuroscience and behavioral research to the search for answers as to why and how we become obese is expanding our insight into this challenging dilemma (see Chapter 20).

The sections that follow highlight genes and gene variants that are among those with a stronger association with obesity than most variants, along with a discussion of the role of epigenetics in obesity. The fact that environmental factors play a major role in triggering the

development of obesity reminds us of the difficulties of identifying even the primary factors within today's obesogenic environment. It also provides encouragement that attention to the behavioral aspects of making health-promoting choices day-by-day throughout the lifespan can have a positive influence on shifting one's health trajectory from disease susceptibility to health and vitality.

Gene Variants and Obesity

In terms of its genetic basis, obesity has been categorized as both monogenic and polygenic. Monogenic (single gene) obesity has historically referred to those genes that, when mutated, lead to severe obesity. Examples of well-studied gene variants associated with monogenic obesity include mutations in *MC4R* (melanocortin-4 receptor), *LEP*, and *LEPR*. In contrast, **polygenic** (multigene) obesity has been referred to as "common obesity" where multiple genes and environmental triggers are involved. This basis for obesity occurs frequently. In common obesity, mutation in a single gene contributes only a small degree of risk; development of the susceptibility to becoming obese is strongly dependent on the interaction with environmental triggers. However, the recent finding by Fairbrother et al (2018) that mutations in *MC4R* are found frequently in obese individuals in the general population makes this type of all or nothing categorization questionable. This revelation is not surprising given that most, if not all, gene-function-disease associations are being found to constitute a continuum of phenotypes ranging from silent to mild to severe effects on function. However, be aware that this type of classification is in the literature and can cause confusion. In this section the focus will be on what has, to date, been termed common obesity involving multiple genes and multiple environmental triggers.

Also not surprising is the large number of genes identified as contributors to the predisposition for obesity, particularly since GWAS studies have come to be used routinely in the search for genes of interest and their polymorphisms. One gene that has for several years been found to have a strong association with common obesity and to occur frequently in multiple populations is *FTO* (Loos and Yeo, 2014). This gene encodes the fat mass and obesity protein (an alpha-ketoglutarate dependent dioxygenase). Its mechanism of action appears to be related to the regulation of adipose tissue development, which suggests body composition is affected (Yang et al, 2017). Variations in the *FTO* gene have been found in multiple populations. Its effect is greater in European descendants than in African or Asian populations (Loos and Yeo, 2014; Merritt et al, 2018).

Gene-diet interactions have been reported for SNPs in the *FTO* gene. Data from a cross-sectional study found that those with the A allele of *FTO* gene who reported high levels of dietary fat and low levels of physical activity had higher BMI values than those with the A allele who reported a lower-fat diet (Sonestedt et al, 2009). A low-carbohydrate diet appeared to attenuate the effect of the high-fat diet in those with the risk allele. Lappalainen and colleagues (2012) investigated the effect of this same SNP on BMI in subjects in the Finnish Diabetes Prevention Study. This group also found elevated BMI values in those consuming a high-fat diet. More recently Vimalaswaran et al (2016) reported a gene-diet interaction in a second *FTO* SNP in an Asian Indian population. Individuals with the SNP who also consumed a high-carbohydrate diet had increased risk of being obese. Physical inactivity seemed to also influence obesity risk in these individuals.

Two other genes that influence not only obesity but also insulin sensitivity/resistance are the suppressor of cytokine signaling 3 (*SOCS3*) gene and the peroxisome proliferator-activated receptor gamma (*PPARG2*) gene. *SOCS3* inhibits cytokine signal transduction (part of the inflammatory response) through the Janus kinase/signal

transducer and activator of transcription (JAK/STAT) signaling pathway. *SOCS3* is frequently overexpressed in obesity and diabetes (Galici et al, 2014). In an **expression genome-wide association study (eGWAS)**, Xu et al (2018) found that the *SOCS3* promoter was hypomethylated in obese individuals. Within this low-methylated *SOCS3* group, those who had had five or more majorly stressful life events were at increased risk of obesity.

The *PPARG* gene is a nuclear receptor that functions as a transcription factor and is a key contributor to fat cell formation. It is frequently referred to as the "master regulator" of adipogenesis and differentiation (Mukherjee et al, 1997). Gene-diet interactions for the *PPARG* gene have been reported, originally by Memisoglu et al (2003) and more recently by Rodrigues and colleagues (2017). In a subgroup of the Nurses' Health Study, Memisoglu and colleagues investigated the interaction between the *PPARG2* Pro12Ala SNP (the Pro allele is the wild-type allele and the Ala allele the variant allele) and dietary fat intake. Those with the Pro/Pro genotype who also had the highest dietary fat intake had significantly higher BMI values than those who had the lowest dietary fat intake. There did not appear to be a gene-diet interaction with the Ala allele with respect to BMI. Rodrigues et al (2018) reported on severely obese individuals and found that those with one or more copies of the Ala allele had higher BMI values and higher polyunsaturated fat intake. It is not unusual to encounter these types of inconsistencies as researchers attempt to identify SNPs that influence physiologic processes in response to lifestyle choices. Typically the pattern will become clearer as the volume of studies increases.

Because of the large number of variants that have been reported since GWAS became the primary tool for identifying obesity-related variants and the need to screen multiple populations to detect variants that occur frequently in several populations, expect the research to be ongoing.

Additionally, the variants will need to be strongly associated with particular environmental triggers. Obesogenic environments are highly variable among individuals even within the same population, which further compounds the amount of work ahead to clearly link variants with effective clinical interventions.

Epigenetics and Obesity

Beyond the methylation, acetylation, and miRNA studies being conducted with the various gene variants, environmental triggers that promote epigenetic modifications are being studied to gain insight into how these triggers promote the transformation of obesity susceptibility into overt disease. Today's environment is frequently referred to as obesogenic. Two aspects of the environment that are under study are environmental pollutants and their role in promoting obesity and the composition of the gut microbiota. The term "**obesogen**" refers to environmental pollutants that promote obesity but the term has expanded over time as it has become apparent that a wide variety of pollutants lead to oxidative stress and inflammation, which promote not only obesity but diabetes, vascular disease, cancer, and various other inflammatory disorders (Grün and Blumberg, 2006). Categories of common pollutants include persistent organic pollutants (POPs), heavy metals, and air pollution. POPs include polychlorinated biphenyls (PCBs), organochloride pesticides, and endocrine disruptors, hormone-like compounds that mimic natural hormones and disrupt the normal functioning of the endocrine system, which includes altering normal gene expression patterns. See reviews by Muscogiuri et al (2017) and by Darbre (2017) for additional information.

The gut microbiota refers to the community of different microorganisms (bacteria, yeast, viruses) that live within the digestive tract. The gut "**microbiome**" that is often spoken of technically refers to the genomes of these various microbes but is often used synonymously with the organisms themselves (the "microbiota"). These organisms

can be beneficial or pathogenic. The benefits include maintenance of the integrity of the digestive tract, which promotes digestive functions and the integrity of the barrier function of a healthy gut mucosa. The microbiota also contribute nutritionally by synthesizing folate, biotin, and vitamin K and digesting insoluble fiber to generate short-chain fatty acids that serve as fuel for enterocytes. Earlier in this chapter it was noted that genomic technology has been successfully applied to identifying the microbes, which has been helpful for research purposes but also for laboratory testing so that pathogenic microbes can be rapidly identified and antimicrobial therapy begun.

The presence of pathogens in the microbiota can cause mild to severe digestive tract imbalances and can lead to infection and erosion of the gut barrier, chronic activation of the immune system, and chronic inflammation. One of the side effects of the presence of gram-negative bacteria is that, as they die, they release lipopolysaccharide (LPS) molecules from their cell walls. LPS is a potent activator of the innate immune system as well as a number of proinflammatory systems, which further promotes and sustains chronic inflammation.

The microbiota composition also appears to be important in weight management. When the gut microbiota of lower weight and obese human beings are compared, the overweight/obese individuals have lower fecal bacterial diversity, impaired glucose regulation, dyslipidemia, and greater low-grade inflammation (Le Chatelier et al, 2013; Mathur & Barlow, 2015). Studies suggest that one of the potentially important differences in obesity is that the *Firmicutes:Bacteroidetes* ratio changes substantially and that a Western-style diet high in refined carbohydrates and fat influences the quantity and composition of the microbiota associated with weight gain (Ley et al, 2005; Jumpertz et al, 2011). See reviews by Duranti et al (2017), Selber-Hnatiw et al (2017), Davis (2016), and Castaner et al (2018) for details on the role of the microbiota in health and disease.

Nutrition can exacerbate or protect against the effects of environmental toxins and the gut microbiota (Hoffman et al, 2017). Dietary fats such as saturated fats can enhance the proinflammatory effects of pollutants whereas omega-3s can interfere with the signaling process and downregulate inflammation. Diets rich in bioactive components that serve as antioxidants or antiinflammatory agents can diminish the negative impact of obesogens (see Box 6.4). Similarly, nutrition can alter the microbiota and promote health or disease.

Finally, identifying the mechanisms by which environmental cues lead to alterations in gene expression is a major research focus. One of the epigenetic associations that's been identified relates to the distinction between inflammation induced by obesity compared with inflammation induced by infection or tissue trauma. Obesity-induced inflammation is systemic rather than localized and is a low-intensity but chronic reaction whereas the classic inflammatory process is self-limiting. The toll-like receptor (TLR) signaling pathway involves a family of proteins. TLR4 is a major component of obesity-induced inflammation. Activation of this signaling system promotes gene expression of inflammatory cytokines and NF- κ B regulated proinflammatory genes (Rocha et al, 2016; Rogero and Calder, 2018).

Activation of the TLR4 pathway occurs through the presence of environmental triggers, such as saturated fatty acids (supplied by the diet or from triglycerides stored in adipose tissue) and LPS (produced by bacteria that populate the microbiome). Rocha et al (2018) suggest that saturated fatty acids alter the microbial ecology of the gut and result in increased bacterial production of LPS, which is a known activator of the TLR4 signaling pathway. Further, this increase in LPS leads to oxidative stress that in turn triggers the production of atherogenic lipids such as oxidized LDL and oxidized phospholipids that are also known triggers of the TLR4 system. The elevated levels of saturated fatty acids further exacerbate the situation by contributing additional LDL-cholesterol in the presence of oxidative stress that increases the

amount of oxidized LDL, which further promotes atherogenesis. The TLR4 signaling pathway is also connected to the activation of transcription factors such as NF- κ B (see Box 6.3), which regulates expression of a number of proinflammatory genes that produce cytokines and other inflammatory mediators. It's easy to see how the obesity-induced inflammatory response, once initiated, would self-perpetuate in the presence of such environmental conditions. The omega-3 polyunsaturated fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) supplied through food or dietary supplements are able to interfere with signaling cascades and have an antiinflammatory effect by preventing activation by either the saturated fats or LPS. Reviews by Lopomo et al (2016) and Hoffman and Hennig (2017) examine various topics relating to how epigenetic modifications are related to obesity, including the transgenerational effects of these changes and what that means for future generations.

Vascular Disease

The complexity of vascular disease provides numerous opportunities for genomic analysis to help distinguish among the various subtypes as well as to apply pharmacogenomic testing. Two applications already in use concern medications relating to blood clotting (warfarin) and platelet aggregation (clopidogrel). Box 6.14 gives an overview of the clinical utility of this type of testing.

A large proportion of the vascular disorders commonly seen in clinic are those with strong associations to diet and lifestyle: hypertension and dyslipidemia (cardiovascular, cerebrovascular, and peripheral vascular diseases; elevated LDL-cholesterol, decreased HDL-cholesterol, and hypertriglyceridemia). Each of these chronic disorders decreases quality of life, increases medical costs, and elevates risk of premature death. As with other chronic disorders, low-grade inflammation and oxidative stress are assumed to play an important role in converting disease susceptibility to development of disease. Fortunately, the major environmental triggers that promote vascular disease are lifestyle choices: diet, exercise, and smoking, each of which is modifiable.

Gene Variants and Vascular Disease

The earliest gene variants incorporated into assessment testing are candidate genes that encode proteins known to be associated with vascular disease: those that suggested predisposition to chronic inflammation and oxidative stress, formation of blood clots, predisposition to high blood pressure, or development of dyslipidemia (Curti et al, 2011). The proinflammatory variants include *CRP*, *IL1B*, *IL6*, and *TNF* discussed in the Inflammation section of this chapter. Oxidative stress predisposition has been associated with the glutathione-S-transferase genes *GSTM1*, *GSTP1*, *GSTT1*, and the superoxide dismutase enzymes *SOD2* and *SOD3*. For blood clot formation and susceptibility to venous thrombosis, the most commonly included variant is Factor V Leiden (*F5*). The hypertension variant has been *ACE*, the gene that encodes angiotensinogen-converting enzyme. Dyslipidemia variants are those that code for the proteins involved in the various lipoproteins, such as *APOA1*, *APOA2*, *APOA5*, and *APOE*.

Considering the multiple aspects of both cardiovascular and cerebrovascular disease, there will likely be many more variants identified before a comprehensive vascular genetic panel is constructed. That said, information from the presently available variants can provide insight into potential susceptibilities to developing vascular disease but expect stronger associations to be identified as research continues. In addition to the goal of screening multiple populations to find variants that occur frequently and have a strong association with vascular disease, there is also a need to identify variants that predict susceptibility among the specific populations. For example, venous thromboembolism (VTE) is more prevalent in African Americans than in other

populations but frequently missed by gene panels that derive from European populations. One promising lead has come from a GWAS study that found three variants in the thrombomodulin gene (THBD) that decreases expression and increases the risk of VTEs in African Americans (Hernandez et al, 2016).

At this point a combination of candidate gene and GWAS studies has identified over 400 variants that influence hypertension susceptibility alone. Similar to challenges with categorizing cancer as a single disease, the complexity of vascular disease makes it challenging to identify gene variants that have a strong association with a specific aspect of susceptibility to developing vascular disorders. As a result, each aspect of this complex disease will continue to be investigated to find variants that have a strong association with distinct subcategories of vascular disease.

Epigenetics and Vascular Disease

As it has become obvious that numerous environmental factors increase susceptibility to developing vascular disorders, epigenetic mechanisms have become an additional focus of nutritional genomic research into vascular disease. Epigenetic research will help define the mechanisms by which lifestyle choices influence gene expression. It also provides insight into lifestyle-oriented therapeutic options for managing existing disease and preventing future disease.

Given the complexity of vascular disease and the large number of associated candidate gene and GWAS loci found to have an association with these disorders, the most effective health-promoting approach for nutrition professionals is to address the modifiable lifestyle choices available to clients. With the escalating global prevalence of vascular disease, as well as obesity and T2DM that increase vascular susceptibility, expanding the therapeutic approach to include modifiable lifestyle factors beyond food choices will be needed. These behavioral changes entail eliminating smoking, curbing alcohol intake, avoiding food- and air-borne toxins, adopting an antiinflammatory diet, exercising, managing stress, developing supportive relationships, and getting sufficient quantity and quality of sleep. The epigenetic component of chronic disease development appears to be strong, which suggests that all of us have at least some level of susceptibility that, if continually challenged with inappropriate lifestyle choices, will lead to manifestation of any number of inflammation-based chronic disorders.

The nutrition practice of the future will incorporate aspects of not only genomics and epigenomics but contemporary neuroscience and behavioral change as well. Nutrition professionals are ideally suited to deliver this information but also to counsel clients as they address the often-challenging behavioral changes that are needed to restore their health from vascular and other chronic diseases and prevent disease susceptibility from becoming an inevitability.

SUMMARY

Genomics, epigenetics, and the various “omic” disciplines that have emerged are adding a new dimension to nutrition science and medical nutrition therapy. It has opened up a new way of thinking about how food influences gene expression and, ultimately, our disease susceptibility and health. As nutrition moves into an era of precision health, the molecular and biochemical aspects of nutrition will become increasingly important tools for nutrition professionals. As a human being, each client will be generally like other members of our species yet have sufficient genetic heterogeneity to give each distinctive differences. The vision for the era ahead is to get ever closer to being able to assess, diagnose, intervene, monitor, and evaluate each client’s unique situation. This depth of information will be helpful in developing interventions that will more effectively manage existing disease

and restore health, as well as identify early genetic susceptibilities and prevent them from developing into disease.

During the past 50 years the focus for health care has been on treating disease, and physicians have had increasingly sophisticated drugs, surgery, and technologies available to meet this challenge. However, with the understanding that chronic disease is genetically based but environmentally influenced, the focus is now on targeted intervention and prevention. Although the first applications of this changed focus in health care involve the medical and pharmaceutical aspects of acute care, nutrition therapy is expected to figure prominently as a cornerstone of care in preventing and managing chronic, diet-and-lifestyle-related diseases.

Although our genetic makeup sets the stage, environmental factors such as nutrition and other lifestyle choices determine who among the susceptible actually develops chronic disease (Henning et al, 2018). In addition to our food choices, other lifestyle choices also epigenetically influence function and are as central as food if our clients are to enjoy robust health. A comprehensive overview by Abdul et al (2018) on the influence of lifestyle choices on epigenetic mechanisms and health suggests that the role of the nutrition professionals will be expanding in the years ahead. Similarly, social epigenomics is a developing field that will appeal to nutrition professionals given our history of concern for the health of the underserved individuals in our society. Nutrition professionals are well-positioned to play a major role in this new era of personalized health care. You can prepare to meet this challenge by developing a solid foundation in the various sciences needed for effective lifestyle therapy, from molecular nutrition to nutritional genomics/epigenetic-related disciplines to neuroscience and contemporary behavioral change programs.

CLINICAL CASE STUDY

Amalia is a 32-year-old Hispanic female who was diagnosed with depression 3 years ago by her primary care physician and referred to the clinic’s psychologist. Multiple family members suffer from depression in Amalia’s family. Amalia has been faithfully attending her monthly counseling sessions since that time and, although her affect has improved somewhat, she feels like she’s not getting better. In fact, has recently been getting worse. Her chief complaint is exhaustion, to the extent that she has lost interest in her church work and social activities that in the past have brought her pleasure. Increasingly she feels too tired to manage self-care such as cooking. She has been eating fast-food take out and snacking on ready-to-eat processed foods. Her physician prescribed an antidepressant, but she stopped taking it some time ago because she says she does not want to take medication to feel better. Her comprehensive metabolic panel is unremarkable; however, a genetic panel reveals she has a homozygous mutation in the *MTHFR* C677T gene. The psychologist has referred her for nutrition and genetic counseling.

Nutrition Diagnostic Statements

- Undesirable food choices related to fatigue and depression as evidenced by consumption of highly processed, nutrient-poor fast foods.
- Altered nutrition-related laboratory value related to personal genetic variation as evidenced by a mutation in the *MTHFR* C677T and potential increased need for B vitamins, especially folate.

Nutrition Care Questions

1. What is the difference between a heterozygous and a homozygous mutation in a gene?
2. What are your thoughts about what might be causing Amalia’s symptoms of depression and fatigue?
3. What is the significance of having a *MTHFR* C677T mutation?
4. What foods may help improve Amalia’s nutrition status, especially foods that would support her genetic aberration?

Inflammation and the Pathophysiology of Chronic Disease

Diana Noland, MPH, RDN, CCN, IFMCP, LD

KEY TERMS

adipokines	genesis of disease	prostaglandins
allostasis	glutathione	protectins
antecedents	health continuum	reactive oxygen species (ROS)
autoimmune	hyperinsulinemia	resolvins
autophagy	inflammation	quercetin
biochemical individuality	interleukin-6 (IL-6)	sarcopenia
body fluid viscosity	leukotrienes	sarcopenic obesity
C-reactive protein–high sensitivity (CRP-hs)	lipic acid	sedimentation rate
coenzyme Q ₁₀	lipoxins	specialized proresolving mediators (SPM)
conditionally essential	lipoxygenases (LOX)	systems biology
curcumin	long-latency nutrient insufficiencies	total inflammatory load
cyclooxygenases (COX)	maresins	triage theory
cytochrome P450 enzymes	mediators	triggers
cytokines	metabolic syndrome	tumor necrosis factor alpha (TNF- α)
delta-6-desaturase	“new-to-nature” molecules	vagal nerve
eicosanoid cascade	nutrient-partner principle	visceral adipose tissue (VAT)
enteroimmunology	nutrition transition	xenobiotics
	prolonged inflammation	

EPIDEMIC OF CHRONIC DISEASE

Chronic disease in the twenty-first century is a recent phenomenon in the history of the human race. Its recognition began after World War II at the same time the very significant **nutrition transition** began to occur, first in industrialized countries, then globally (see Chapter 10 *Focus On: Nutrition Transition*). The nutrition transition includes technology that enables synthesis of “**new-to-nature**” **molecules** (Bland, 2007), rapid increases in environmental toxin exposure, and decreased physical activity. New behavior patterns have promoted a decrease in home cooking along with increases in convenience food consumption and eating out. All of these changes are accompanied by the increased use of processed, less nutrient-dense food; decreased intake of whole fruits and vegetables; and increased consumption of sugar and high-sugar-containing foods. These components of the nutrition transition do not appear to have been beneficial to the human race, because the effects are rapidly and globally increasing the risk of being overweight and obese, along with producing epidemic levels of chronic diseases at earlier ages (Hruby and Hu, 2015) (see *Clinical Insight: Is Chronic Disease an Epidemic?*).

Despite the fact that the United States spends more money on health care than any other country, according to a report by the Centers for Disease Control and Prevention (CDC), 90% of the health care dollars in the United States are spent on chronic disease management (CDC, 2018). As people are living longer, the number of years spent living with disability has increased. The fact of the growing

CLINICAL INSIGHT

Is Chronic Disease an Epidemic?

- According to the Centers for Disease Control (CDC, 2018) and the World Health Organization (WHO, 2018):
- 1 out of 3 U.S. adults will have diabetes by 2050.
- 70% of U.S. deaths will be from chronic disease.
- Global cancer rates could increase by 70% 2015 to 2035.
- Two of three U.S. adults will be overweight or obese.
- One-third of cancer deaths will be due to the five leading behavioral and dietary risks (high BMI, low fruit and vegetable intake, lack of physical activity, smoking, and alcohol use).
- Younger Americans will likely face a greater risk of mortality throughout life than previous generations (related to obesity).
- The three most preventable risk factors are unhealthy diet, smoking, and physical inactivity.

incidence of chronic disease has driven the global civilian and governmental health care systems to seek new answers to this nearly universal challenge.

The global effort to improve understanding of this chronic disease phenomenon is bringing the realization that these chronic diseases have long incubation periods (years to decades), thus they may not be observable during their early stages and may be present in an otherwise

healthy-looking person. Focusing on preventive care with earlier detection of signs, symptoms, and biomarkers that were previously thought insignificant allows for a chance to reverse the disease process before it becomes a serious affliction. The new phenotype of “fat, fatigued, and in pain” in combination with associated conditions is descriptive of many chronic disease states considered to be preventable “lifestyle” diseases. The genotype, or genetic makeup, of a person may increase the propensity toward a chronic disease, but lifestyle—what one eats and thinks and where one lives—may be the most powerful cause of these “lifestyle” chronic diseases (CDC, 2018; Elwood et al, 2013).

CONCEPTS OF CHRONIC DISEASE PATHOPHYSIOLOGY

An understanding of the following basic concepts is essential when addressing the newly identified characteristics of chronic disease pathophysiology: **systems biology**, **allostasis**, **autophagy**, the **health continuum**, **genesis of disease**, **long-latency nutrient insufficiencies**, and **nutrient-partner** principle.

Systems Biology

The emerging new paradigm of systems biology is the basis for a broader understanding of chronic disease. Systems biology is based on the understanding that all body systems work together interdependently. It is an interdisciplinary field that focuses on complex interactions within biological systems and includes the intersection of biology, informatics, computer science, physics, and engineering. Using this collaborative approach, scientists can identify biomarkers and genetic, dietary, and lifestyle influences on health and construct innovative models for prevention and treatment of disease (Trachana et al, 2018).

The global movement in health care toward systems biology and holistic and personalized approach to medicine is expanding. The registered dietitian nutritionist (RDN), as a member of the health care team, has a larger role to improve the nutritional status of each individual with dietary and lifestyle modifications as a foundational component of addressing chronic disease.

Allostasis

This is a condition of metabolic stability with adjustments for environmental influences and stresses through physiologic changes. Allostasis will be established even under inflammatory conditions but not always for optimal function. The maintenance of these changes over a long period of time can lead to wear and tear of the body. **Inflammation** may be initiated for tissue adaptation and yet may involve collateral damage. Inflammation is particularly relevant to obesity and its associated adverse health conditions, such as type 2 diabetes, cardiovascular disease, autoimmunity, and cancer. The ensuing systemic low-grade inflammation promotes a multitude of pathologic and self-perpetuating events, such as insulin resistance (Mather et al, 2013), endothelial dysfunction, and activation of oncogenic pathways (Baffy and Loscalzo, 2014).

For the nutritionist in clinical practice, the challenge is assessing metabolism and levels of inflammation at the cellular-molecular level available indirectly by using improved laboratory testing technology and scientific discovery of biochemical markers. For example, the biomarker **C-reactive protein–high sensitivity (CRP-hs)** has been shown to be the strongest univariate predictor of the risk of cardiovascular events. It is a systemic marker of inflammation within the internal milieu related most often to bacterial infection, trauma, and neoplastic activity with acute and chronic expression. Some studies indicate that the omega-3 fat eicosapentaenoic acid (EPA) from fish and fish oil has

an antiinflammatory effect and suppresses CRP-hs. Refer to Chapter 5 for additional information about CRP-hs.

Autophagy

Autophagy, or “self-eating,” is a major regulatory cellular mechanism providing the cells an ability to clean up “cellular debris” occurring from normal metabolic activity. It is a survival mechanism required for maintaining cellular homeostasis after infection, mitochondrial damage, or endothelial reticulum stress. Autophagy results in the lysosomal degradation of organelles, unfolded proteins, or foreign extracellular material that provides a microenvironment supportive of healthy tissue. Defects in autophagy have been shown to result in pathologic inflammation influencing health and disease (Abraham and Medzhitov, 2011; Moloudizargari et al, 2017; Prado et al, 2014).

Health Continuum

Health is measured on a continuum from birth to death. “Health is the perfect, continuing adjustment of an organism to its environment” (Wyle, 1970). Chronic disease management for an individual must include considering the entire **health continuum** history to determine which factors along the way relate to one’s current health condition. When collecting the patient’s history during the assessment, plotting the person’s health milestones as they relate to major life events can be helpful. This is often referred to as a health timeline.

Genesis of Disease

Triggers, **antecedents**, and **mediators** are critical terms that are part of the genesis of disease that underlies the patient’s signs and symptoms, illness behaviors, and demonstrable pathology. Triggers are the distinct entities or events that provoke disease or its symptoms. They are usually insufficient for disease formation; host response is an essential component. Antecedents are congenital or developmental aspects of the individual that can include gender, family history, and genomics. These act to set the stage for the body’s response to the trigger. Mediators are intermediates that are the primary drivers of disease; these are biochemical (Di Gennaro and Haeggström, 2012) but can be influenced by psychosocial factors such as smoking or stress (Avitsur et al, 2015; see Fig. 5.9 in Chapter 5).

Long-Latency Nutrient Insufficiencies

Long-latency nutrient insufficiencies (i.e., subclinical [below-optimum] or deficient nutrient pools resulting from chronic poor intake and genotype) contribute over time to development of chronic disease. New tools have to be included in nutrition practice to expand beyond just detection of overt clinical deficiencies (Heaney, 2012). There must be further identification of biomarkers, usually biochemical and phenotypic, which are indicative of early chronic disease and are evidence based.

The nutrient deficiencies defined in the early 1900s are the end-stage and the result of specific index diseases. An example of this is the discovery that vitamin C deficiency caused scurvy in British sailors. Scurvy produces obvious clinical symptoms and death within months of the absence of vitamin C intake. In contrast, a more recent discovery is that years of subclinical vitamin C deficiency (without classic scurvy symptoms) can cause a less recognizable form of scorbutic progression in the form of periodontal gum disease (periodontitis) (Alagl and Bhat, 2015; Japatti et al, 2013). Many other functions of vitamin C are compromised because of this “subclinical” deficiency. Pioneering biochemist Bruce Ames proposed that there should be two categories of nutrients according to their essentiality for immediate survival and reproduction (survival-nutrients), and nutrients that function in long-term health (longevity-nutrients) (Ames, 2018).

Nutrient-Partner Principle

Nutrient balance is the foundation of nutrition science, and this concept is expanding to appreciate the principle that, in addition to macronutrients requiring balance, there are known partner nutrients involved in an individual's nutrition and inflammatory status. An example of application of the **nutrient-partner principle** is the common recommendation for adults to take calcium supplements along with vitamin D. Another example is calcium and magnesium. For years, no attempt was made to routinely assess an individual's intake of magnesium, even though the National Health and Nutrition Examination Survey (NHANES) studies showed that 70% to 80% of the U.S. population had magnesium intakes below the recommended daily allowance (RDA). With recent recognition of this calcium-magnesium partnership, many calcium supplements now contain magnesium in a 2:1 or 1:1 Ca:Mg ratio, and nutrition guidelines include the consumption of more vegetables and greens containing magnesium and calcium. The principle of nutrients as well as metabolic systems having synergistic relationships are seen in [Box 7.1](#).

Triage Theory

The concept of nutrient **triage theory** states that “during poor dietary supply, nutrients are preferentially utilized for functions that are important for survival.” As a consequence, some tissues may be lacking during times of insufficiency. As proposed by the triage theory, a modest deficiency of nutrients/cofactors triggers a built-in rationing mechanism that favors the proteins needed for immediate survival and reproduction (survival proteins) while sacrificing those needed to protect against future damage (longevity proteins). Impairment of the function of longevity proteins results in an insidious acceleration in the risk of diseases associated with aging. This may result in a chronic deficiency in the person with inadequate nutrient intake that occurs for years and often for decades ([Ames, 2006](#); [Ames, 2010](#); [McCann and Ames, 2011](#)).

To summarize ([Ames, 2018](#); [Maggio et al, 2014](#)):

- Most tissues need most nutrients.
- Inadequate intakes of most nutrients impair the function of most systems.
- The classical deficiency diseases occur at only the extremes of “inadequacy” (see [Fig. 5.2](#) in Chapter 5).

BOX 7.1 Nutrient and System Partner Principles

Nutrient Partners

- Calcium – Zinc – Copper
- Omega 6 GLA/DGLA – Arachidonic Acid – Omega 3 EPA/DHA
- Sodium chloride – potassium – calcium
- B Complex (B1-B2-B3-B5-B6-B9 (folate)-B12-Biotin-Choline)
- Antioxidants – reactive oxygen species (ROS)
- Albumin – globulin

System Partners and Rhythm Cycles:

- Autonomic Nervous System: sympathetic – parasympathetic
- Circadian Rhythm: 24-hour balanced rhythm
- Acid-Base Balance
- Microbiome: oral, nasal, skin, lung, vaginal, gastrointestinal
- Hormones-biochemistry
 - Cortisol – insulin – glucose
 - Estrogen – progesterone – testosterone
 - T4-T3 (total and free forms)
 - HPTA axis – Hippocampus – Pituitary – Thyroid – Adrenal

- The role of nutritional status as a key factor of successful aging is very well recognized ([McCann and Ames, 2011](#)).
- “Adequate” adult nutrition can be best conceptualized as preventive maintenance.

INFLAMMATION: COMMON DENOMINATOR OF CHRONIC DISEASE

Inflammation is the natural, reaction of a healthy immune system as it responds to injury or infection, or flight or fright scenarios. See [Box 7.2](#) for a classic description of inflammation.

The immune system's response to physiologic and metabolic stress is to produce proinflammatory molecules such as **adipokines** and **cytokines**. These cell-signaling molecules aid in cell-to-cell communication and stimulate the movement of cells toward sites of inflammation in conditions of infection and injury. Thus the immune system responds and the resulting inflammation is intimately connected.

According to Undurti N Das, MD, in the *Molecular Basis of Health and Disease*:

Inflammation is the complex biological response of vascular tissue to harmful stimuli such as pathogens, damaged cells or irritants that consists of both vascular and cellular responses. Inflammation is a protective attempt by the organism to remove the injurious stimuli and initiate the healing process and to restore both structure and function. Inflammation may be local or systemic. It may be acute or chronic.

Optimally, the immune system's function is to keep the body healthy, responding appropriately with an inflammatory response to environmental influences, such as short-lived infection and injury, and then returning the body to an alert system of defense. This function depends on the body's ability to recognize “self” and “nonself.” When the immune response is successful, the tissue returns to a state of wellness, or metabolic stability described as *allostasis*. If many areas of the body's defense system, such as the gastrointestinal barrier, stomach acidity, skin, or various orifices (e.g., eye, ear, nose, lung, vagina, uterus), are compromised, there is diminishing recognition of “self” and “nonself” until the body is repaired. The longer the physiologic injury continues, the greater the loss of the ability to recognize “self” and “nonself” ([Fasano, 2012](#); [Wu et al, 2014](#)).

If the underlying cause is not resolved, the immune response can get “stuck” in a state of prolonged inflammation. Locked into this state for a while, the immune system loses its ability to recognize “self” and “nonself,” a critical survival skill and the core of immunology ([Gonzalez et al, 2011](#); [Paul, 2010](#)).

Prolonged Inflammation

Prolonged inflammation, known as chronic inflammation, sustained inflammation, or nonresolving inflammation, leads to a progressive

BOX 7.2 The Five Classic Signs of Inflammation, First Described and Documented by Aulus Cornelius Celsus (ca 25 BC-ca 50), a Roman Physician and Encyclopaedist

- **Dolor** - “pain”
- **Calor** - “heat”
- **Rubor** - “redness”
- **Tumor** - “swelling”
- **Functio laesa** - “injured function” or “loss of function.”

shift in the type of cells present at the site of inflammation and is characterized by simultaneous destruction and healing of the tissue from the inflammatory process. Multiple studies have suggested that prolonged inflammation plays a primary role in the pathogenesis of chronic diseases (e.g., cardiovascular disease, cancer, diabetes), when the immune response is to increase the ratio of proinflammatory to antiinflammatory cytokines (Bauer et al, 2014; Franceschi and Campisi, 2014).

In the chronology of chronic disease progression, inflammation is at first subclinical, often referred to as “silent inflammation.” This insidious inflammation remains below the threshold of clinical diagnosis. Cellular and tissue damage can occur in the body for years before being noticed. It is like a “smoldering” fire with a small whiff of smoke and heat being evident before it finally bursts into a flame. Some refer to early chronic disease as a “smoldering disease” (Noland, 2013). Inflammation in chronic disease is described as:

Low-grade, chronic, systemic inflammation may be defined as a 2- to 3-fold elevation of circulating inflammatory mediators, usually associated with the innate arm of the immune system. It is a state that develops slowly (in contrast to pathologic acute

inflammatory responses, to sepsis for example), and its origin cannot be easily identified (in contrast to chronic inflammatory diseases such as rheumatoid arthritis and inflammatory bowel disease, where additional symptoms identify local dysregulated inflammation). This makes it difficult to develop appropriate therapeutic strategies that target both cause and symptom (inflammation) in a concerted fashion (Calçada et al, 2014).

Of concern is the initiation of prolonged inflammation in utero from the maternal inflammatory environment, thereby programming the fetus for a lifetime of chronic disease (European Foundation for the Care of Newborn Infants [EFCNI], 2015; Lane, 2014; Fisher et al, 2012; Fleisch et al, 2012; see Chapter 14).

Inflammation is a very complex condition, and there are many protein biomarkers that are acute phase reactants. Clinical elevations of inflammatory biomarkers, such as CRP-hs (plasma), **sedimentation rate**, **interleukin-6 (IL-6)**, and **tumor necrosis factor alpha (TNF- α)**, represent systemic markers of inflammation that are exacerbated by insulin resistance (IR) and **hyperinsulinemia** (Das, 2010, 2011; see Table 7.1). Diseases associated with increased levels of inflammatory markers include heart disease, diabetes, **autoimmune** diseases, and

TABLE 7.1 Biomarkers of Prolonged Inflammation

Test	Reference	Association
Blood Specimen		
8-hydroxy-2-deoxyguanosine	< 7.6 ng/mL	DNA increased ROS and cell proliferation*
Asymmetric dimethylarginine (ADMA)	<18 years: not established ≥18 years: 63-137 ng/mL	Inhibitor of L-arginine (Arg)-derived nitric oxide (NO)
C-reactive protein sensitivity	≤3.0 mg/L	Systemic inflammation related to bacterial infection, trauma, VAT, neoplastic activity
CA-125	0-35 U/mL	Inflammation in abdomen Ovarian cancer Uterine fibroids
CA 15-3/CA 27-29	<32 U/mL	Breast cancer, advanced
CA-19-9	<55 U/mL	Pancreatic cancer
Carbohydrate Ag 19-9 (screening test)	Up to 20% of individuals do not express CA 19-9.	Infections in liver, gallbladder, and pancreas.
CEA (other specimens also)	12-100 years: 0-5.0 ng/mL	Cancer
CD4 Lymphocyte CD4%		HIV infections, autoimmune
CD8 Count		Infections Lymphoma
Ceruloplasmin (bound copper/ acute phase reactant)	18-46 mg/dL	Acute phase reactant Cancer (elevated) Wilson's Disease (low) Menkes syndrome (low)
Eosinophils	1%-4%	Elevated inflammatory marker of allergies / sensitivities, helminthic, parasites, autoimmune, neoplasms
Ferritin (storage iron)	Males ≥5 years: 24-150 ng/mL Females ≥5 years: 12-150 ng/mL	Acute Phase Reactant Hemochromatosis (genetic) Iron Toxicity
Fibrinogen / Platelets	150-450 mg/dL / 150-450 billion/L	Disseminated intravascular coagulation (DC) Liver disease
Homocysteine (Hcy)	0-15 μ mol/L	Block in homocysteine metabolism to cystathionine relate to B ₆ , B ₁₂ , folate, betaine cofactors

Continued

TABLE 7.1 Biomarkers of Prolonged Inflammation—cont'd

Test	Reference	Association
IgA Total or IgA specific	50-350 mg/dL	Elevated in lymphoproliferative disorders; chronic infections; autoimmune; celiac disease
IgE Total or IgE specific	800-1500 mg/dL	Elevated immediate-response inflammatory allergic disorders; parasitic infections
IgG Total or IgG specific	800-1500 mg/dL	Elevated inflammation marker of delayed sensitivities; chronic infections
Interleukin-1 (IL-1)	<3.9 pg/mL	Bone formation, insulin secretion, appetite regulation, fever reduction, neuronal development
Interleukin 8 (IL-8)	<17.4 pg/mL < or = 5 pg/mL (2014)	Neoplasms / promotes angiogenesis Obesity Oxidative stress
Insulin (Korkmaz, 2014)	2.0-12.0 μ U/mL	Elevated inflammatory insulin resistance
Lipid Peroxides	<2.60 nmol/mL	Inflammatory elevation when risk of oxidative stress / elevated triglycerides
Liver enzyme: ALT	0-35 U/L	Inflammatory elevation in liver disease
Liver enzyme: AST	0-35 U/L	Inflammatory elevation with liver, kidney, muscle infection, or injury
Liver enzymes: Alk Phos	30-120 U/L	Inflammatory elevation related to liver, bone, placenta
Liver enzyme: GGT	0-30 U/L	Elevated inflammatory marker of liver disease, neoplasms, toxicity
Liver enzyme: LDH	50-150 U/L	
Prostate Specific Antigen (PSA)	Total PSA \leq 4.0 ng/mL % Free PSA $>$ 25 % (calc)	Prostate inflammation Prostate cancer
Rheumatoid Factor (RF)	Less than 40-60 U/mL Less than 1:80 (1-80) titer	Rheumatoid arthritis Sjogren's Autoimmune disease
Sedimentation Rate (ESR) Westergren	Male <50 years old: <15 mm/hr Male >50 years old: <20 mm/hr Female <50 years old: <20 mm/hr Female >50 years old: <30 mm/hr	Systemic inflammation marker related to autoimmune; viral infections; rouseaux; carcinoid influence
Total Protein	60-80 g/L (6.0-8.0 g/dL)	Total protein in serum
Albumin	35 - 50 g/L (3.5-5.0 g/dL) (half-life ~ 20 days)	Acute phase reactant
Globulin	2.6-4.6 g/dL	Chronic inflammation, low albumin levels, and other disorders
TH17 Interleukin 17 (IL-17)	0.0-1.9 pg/mL	Fungal, bacterial, viral infections, autoimmune conditions
TNF- α	1.2-15.3 pg/mL	Systemic inflammation Acute phase reactant Alzheimer's, infection, depression, IBD, cancer
Uric Acid	2-7 mg/dL	Antioxidant, elevated in abnormal urate cycle exacerbated by protein in diet, gout, other
VEGF	31-86 pg/mL	Cancer, angiogenesis
White blood cell count	4.5- 11 x 10 ³ / μ L	(Elevated) Leukocytosis, bacterial infections, anemia, cigarette smoking (Low) Cancer, radiation, severe infection
Stool Specimen		
Calprotectin	2-9 years 166 μ g/g of feces 10-59 years 51 μ g/g of feces \geq 60 years 112 μ g/g of feces	Inflammatory bowel disease Intestinal inflammation Neoplasms
Lactoferrin	Negative	Intestinal inflammation
Pancreatic elastase I	> 200 μ g/g	Exocrine pancreatic function
Urine		
5-hydroxyindoleacetate (5-HIAA)	1.6-10.9 μ g/mL creatinine	Elevated with inflammatory breakdown of serotonin
p-hydroxyphenyllactate (HPLA)	<1.45 μ g/mL creatinine	Inverse relationship to depletion of ascorbic acid

*Normal value ranges may vary slightly among different labs

TABLE 7.2 Autoimmune Specific Inflammatory Markers

Biomarker Test	Reference Range	Specimen	Association
Sedimentation Rate (ESR)	Men: 0-15 mm/h Women: 0-20 mm/h	Blood serum	Collagen diseases Inflammatory diseases Infections Toxicity, heavy metals
C-Reactive Protein-hs (CRP-hs)	<1.0 mg/dL	Blood	Systemic inflammation Metabolic Syndrome
Rheumatoid Factor (RF)	0-39 IU/mL nonreactive 40-79 IU/mL weakly reactive >80 reactive	Blood	Rheumatoid arthritis Sjögren's syndrome Joint pain Rheumatoid conditions
Antigliadin Antibody Deamidated Gliadin Antibody, IgA, IgG	0-19 Negative 20-30 Weak Positive >30 Moderate to Strong positive	Blood serum	Celiac disease Dermatitis herpetiforme Non-Celiac gluten sensitivity
Endomysial antibody test (IgA-EMA)	Negative normal individuals Negative Gluten-free diet		Dermatitis herpetiforme, celiac disease
Tissue Transglutaminase IgA/IgG (tTG-IgA)	<4.0 U/mL (negative) 4.0-10.0 U/mL (weak positive) >10.0 U/mL (positive) Reference values apply to all ages.	Blood serum	Celiac disease (indicates Rx biopsy, gene HLA_DQ2/DQ8) Dermatitis herpetiforme Villi Atrophy
SS-A Sjögren's/Ro IgG	<1.0 U (negative) > or = 1.0 U (positive) Reference values apply to all ages.	Blood	Connective tissue disease (Systemic lupus erythematosus, Sjögren's, Rheumatoid arthritis)
SS-B Sjögren's	<1.0 U (negative) > or = 1.0 U (positive) Reference values apply to all ages.	Blood	Connective tissue disease, including Sjögren's syndrome, systemic lupus erythematosus (SLE)
ANA antibody titer	<1:40 normal (or < 1/0 IU) is negative	Blood serum	Multiple autoimmune conditions, systemic lupus erythematosus (SLE)
Anti-dsDNA Test IgG	<30.0 IU/mL (negative) 30.0-75.0 IU/mL (borderline) >75.0 IU/mL (positive) Negative is considered normal. Reference values apply to all ages.	Blood	
Cyclic Citrullinated Peptide Antibody (Anti-CCP)	<20.0 U (negative) 20.0-39.9 U (weak positive) 40.0-59.9 U (positive) > or = 60.0 U (strong positive) Reference values apply to all ages.	Blood	Rheumatoid arthritis Arthritis
Anti-Desmoglein 1/3 IgG antibody Blister biopsy	negative	Blood Skin tissue	Pemphigus vulgaris Pemphigus foliaceus Epidermolysis bullosa acquisita

possibly cancer and Alzheimer's disease (Birch et al, 2014; Luevano-Contreras et al, 2017; Wu, 2013). See Tables 7.2 through 7.4 and Boxes 7.3 and 7.4 for more examples of common disease specific biomarkers.

Other common physiologic changes shared by these inflammatory conditions include changes in nutrient tissue pools, plasma, and red blood cell (RBC) membrane composition of polyunsaturated fatty acids and antioxidants. This multifactorial syndrome (referred to as **metabolic syndrome**) is related to obesity, and more importantly, insulin resistance and **visceral adipose tissue (VAT)** as evidenced by central adiposity. (See Chapter 29 for discussion of the metabolic syndrome). However, the expression of prolonged inflammation is individual and doesn't necessarily manifest in all the characteristics described above.

For the nutritionist and dietitian to incorporate the related factors of prolonged inflammation into the nutrition assessment, it is useful to conceptualize an overview of a person's **total inflammatory load** (Fig. 7.1). It is a compilation of every factor in the patient's history or story that contributes to the inflammation that a person carries.

As various factors are identified within diet, lifestyle, environment, and genetics, the pattern of where the most inflammatory risk is being generated becomes clear and gives a basis of how to intervene with a plan for medical nutrition therapy (MNT).

Antigens

Antigens are a source of inflammation that become amplified with chronic exposure (see Chapter 25). During assessment of the total

TABLE 7.3 Neurologic Specific Inflammatory Markers

Biomarker Test	Reference	Specimen	Association
RBC Fatty Acid Analysis	Mean +/- SD	Blood	Membrane integrity
Lipid Panel	170-200 mg/dL	Blood	CHD risk
Triglycerides	50-80 mg/dL	Blood	Adult: CHD risk
Total Cholesterol	Men: 37-40 mg/dL	Blood	Child: abnormal cholesterol metabolism
HDL	Women: 40-85 mg/dL		
LDL	Adult <130 mg/dL or <3.4 mmol/L Child <110 mg/dL or <2.8 mmol/L		
CREATINE KINASE			
Creatinine	0.76-1.27 mg/dL	Blood	Kidney function
BUN	8-27 mg/dL		
GFR	>60 mL/min/BSA		
Glucose, fasting	65-99 mg/dL	Blood, urine	Glucose status
Insulin, fasting	2.0-19.6 μ U/mL	Blood	Insulin status
HgbA1C	4.8%-6.4%	Blood	Average BS over 120 days
25OH vit D	30-150 ng/mL	Blood, saliva	Vitamin D status

TABLE 7.4 Endocrine (noncancer) Specific Inflammatory Markers

Biomarker Test (Mother)	Reference	Specimen	Association
RBC Fatty Acid Analysis	Mean +/- SD	Blood	Membrane integrity
Lipid Panel	170-200 mg/dL	Blood	CHD
Total Cholesterol	Men: 37-40 mg/dL		Cholesterol/lipid metabolism
HDL-cho	Women: 40-85 mg/dL		Liver stress
LDL-cho	Adult <130 mg/dL or <3.4 mmol/L		CHD risk
Triglycerides	Child <110 mg/dL or <2.8 mmol/L <150 mg/dL		CHD risk Abnormal cholesterol Metabolic syndrome Carnitine insufficiency High simple sugar/alcohol diet CHD risk
Celiac Panel	<4 U/mL no antibody detected		Small intestine villi atrophy
tTG IgG/IgA	<20 Units antibody not detected		Gluten sensitivity
Anti-Gliadin antibody tissue Transglutaminase IgG/IgA			Gluten-free diet
Antigen (Food IgG/IgE)	Per laboratory		
Insulin, fasting	2.0-19.6 μ U/mL	Blood	Insulin status
HgbA1C	4.8%-6.4%	Blood	Average BS over 120 days
TSH	Adult 0.2-5.4 mU/L blood	Blood	Thyroid function
Vitamin D ₂₅ -OH	30-150 ng/mL	Blood, saliva	Vitamin D status

inflammatory load of an individual, the “antigenic load” is important. Antigens usually are thought to come from foods to which one is either allergic or sensitive, but also can be derived from cosmetics, clothing, inhalants, furniture, household building materials, and other substances in the environment. Antigens from food are much more likely to be significant when a person has lost gut barrier integrity and a situation of intestinal permeability, sometimes referred to as “leaky gut” exists (Fasano, 2012). This condition provides access for larger molecules to enter the internal microenvironment, setting off a cascade of immunologic responses (see Chapters 25 and 27).

Genomics

Predictive genomic testing, family history, and personal history are gathered as the practitioner hears the patient’s story during an assessment. This information helps paint a picture of **biochemical**

individuality, that each person has genetic and chemical uniqueness, which influences the response to inflammation. Since the completion of the Human Genome Project (2003), the rapid development of genomic testing for clinical application has greatly enhanced the toolbox of the nutrition practitioner. Nutrigenomics, nutrigenetics, and epigenetics are new fields of study about the way the individual metabolically interacts with their environment (Dick, 2015; see Chapter 6).

Body Composition

Chronic diseases are related directly to increased body fat exacerbated by physical inactivity, poor diet, lack of restorative sleep, and immune stress, all of which drive increased inflammation. Of equal importance with increased body fat percentage is the fat distribution. Central adiposity at all ages is the most serious health concern. VAT has been discovered to have endocrine functions with the secretion of several

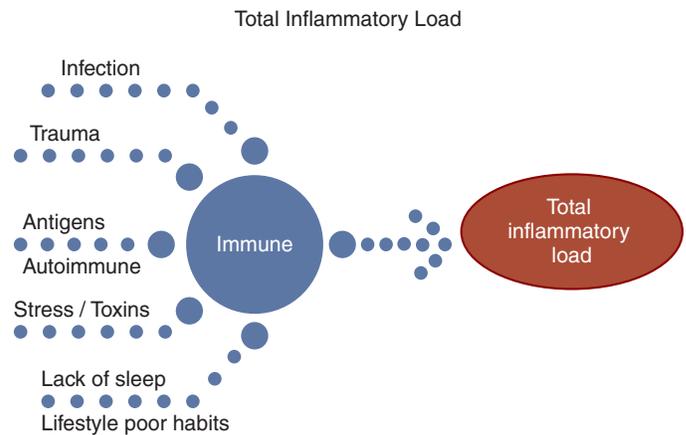

BOX 7.3 Cardiometabolic Specific Inflammatory Markers

- Increased body fat %, most often with elevated BMI and VAT.
 - BMI
 - Waist Circumference
 - Waist/Height Ratio
 - Waist/Hip Ratio
 - Body fat % (bioelectric impedance, air or water displacement plethysmograph, DEXA, calipers)
- Blood Biomarkers of prolonged inflammation in CVD/cardiometabolic syndrome with diabetes
 - Hyperlipidemia/Hypertriglyceridemia
 - Total Cholesterol/HDL Ratio
 - Fasting Glucose/Fasting Insulin
 - HgbA1C
 - C-Reactive Protein-high sensitivity (CRP-hs or CRP-cardio)
 - Homocysteine
- Imaging: Coronary calcium scan
- Myeloperoxidase (blood)
- Other associations for CVD/cardiometabolic syndrome/diabetes:
 - Sympathetic dominant metabolism (metabolic stress)
 - Stress (biochemical, glandular, emotional, environmental, smoking)
 - Poor sleep
 - Apnea

BOX 7.4 Cancer-Specific Inflammatory Markers

- Various metabolic markers measuring inflammatory hallmarks of cancer
 - Adhesion: Fibrinogen and platelets (blood)
 - Metastasis promoters:
 - Copper (Cu): Zinc Ratio 1.0 or less (rate limiting to metastatic enzymes)
 - Ceruloplasmin (contributes to the total Cu load)
 - Angiogenesis promoters (Dai et al, 2014): VEGF, adhesion factors.
- Tumor-promoting inflammation: Specific type of cancer markers (examples: ovarian cancer CA 125, breast cancer CA 15-3, prostate cancer PSA). Various proinflammatory cytokines and chemokines: TNF- α , IL-8, IL-6, etc.
 - Glycolysis (Warburg Effect: sugar is primary fuel of cancer cells)
 - Growth factors
 - Genome instability/mitochondrial DNA
 - Loss of apoptosis/cell immortality

known inflammatory adipokines, such as resistin, leptin, and adiponectin, and TNF- α —all contributing to the systemic total inflammatory load (Hughes-Austin et al, 2014). **Sarcopenia** results from a wasting of lean body mass and muscle strength from the ongoing inflammatory burden and is exacerbated by decreased physical activity (da Silva et al, 2019). **Sarcopenic obesity** is accompanied by increased body fat percentage, especially the deposit of VAT with increasing waist circumference, but for some individuals the loss of muscle and increased fat mass percentage can exist for any body mass index (BMI) range—underweight, normal weight, or overweight and obesity. This underscores the importance of assessing more detail than only BMI (Gonzalez et al, 2017; Norman and Matthews, 2008). The BMI alone does not adequately characterize the distribution of adipose tissue and recommendations exist for more specific measures with better predictive value (Gonzalez et al, 2017). The nutritionist's tools for assessing sarcopenia vary from using the waist-to-hip ratio, waist-to-height ratio, bioelectric impedance analysis (BIA), handgrip strength (dynamometer), or dual-energy x-ray absorptiometry (DXA), when available (Springstroh et al, 2016) (see Chapter 5 and *Clinical Insight: Sarcopenic Obesity*).

Copyright 2013 Diana Noland, MPH RD CCN LD

Fig. 7.1 Total Inflammatory Load.

Body composition can be assessed, and if found to be abnormal based on an individual's lean body mass (LBM) and fat mass (FM), it should be considered a primary marker for monitoring prolonged inflammation (Biolo et al, 2015; Juby, 2014).

According to Khan, S et al, (2014):

Obesity today stands at the intersection between inflammation and metabolic disorders causing an aberration of immune activity, and resulting in increased risk for diabetes, atherosclerosis, fatty liver, and pulmonary inflammation to name a few.

Energy Dysregulation

Another underlying physiologic system involved in inflammation is compromised mitochondrial production of adenosine triphosphate (ATP) (Cherry and Piantadosi, 2015). Assessment of mitochondrial function focuses on structure and function by considering nutrients such as **coenzyme Q₁₀**, and **alpha-lipoic acid** and gamma(γ)-linolenic acid (GLA) (already produced by the body), and their protective effects against inflammation and oxidative stress. Quelling systemic prolonged inflammation promotes a healthier microenvironment for improved mitochondrial function and energy production.

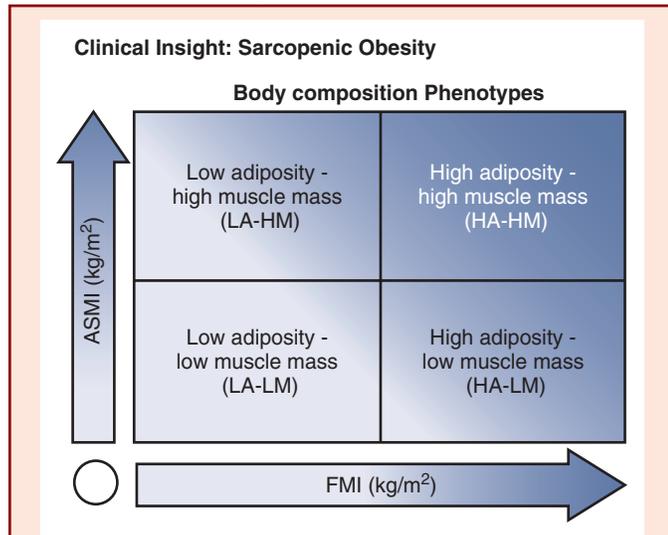

Mitochondrial disease or dysfunction is an energy production problem. Almost all cells in the body have mitochondria that produce a body's essential energy, ATP. Mitochondrial diseases disturb cellular function and reduce mitochondrial energy output. When that happens, some body systems may be impaired causing muscle weakness, organ dysfunction, hormone imbalance, disrupted cognition, and lowered immunity (Miller et al, 2018). The complaint of fatigue is the most common phenotypic expression of mitochondrial dysfunction (see *Clinical insight: Inflammaging*).

The ratios of carbohydrate, fat, and protein influence mitochondrial function, primarily affecting glucose-insulin regulation. During each assessment, determination of the most favorable macronutrient ratios and individual nutrient requirements provides the foundation for the most effective interventions for restoring mitochondrial health and general wellness. There is an increasing popularity and evidence base for low-carbohydrate, paleo, and ketogenic diets for mitochondrial support for some conditions, such as epilepsy, neurodegenerative diseases, and oncology (Allen et al, 2014). It is worth noting that the nutritional assessment of an individual should include a diet history to evaluate the macronutrients consumed. Because of the common tendency for a high protein intake as part of a low-carbohydrate diet, the excess protein may potentially increase gluconeogenesis, thus thwarting the benefit of low carb by increasing available metabolic glucose. The principle of the ketogenic diet (KD) replaces all but

low and nonstarchy vegetable carbohydrates (20 to 100 g cholesterol [CHO]) with low to moderate amounts of proteins (0.8 to 1.0 g protein/kg ideal body weight) and high amounts of short-chain, medium chain and monounsaturated, and polyunsaturated fats, preferably from whole and unprocessed foods (Miller et al, 2018; see Appendix 19).

CLINICAL INSIGHT

Sarcopenic Obesity

In this figure, body composition is depicted by a spectrum of ASMI and FMI (low to high). On the basis of the Baumgartner model (Waters and Baumgartner, 2011), these phenotypes can be depicted as follows:

LA-HM = low adiposity with high muscle mass (individuals with low FMI and high ASMI)

HA-HM = high adiposity with high muscle mass (individuals with high FMI and ASMI)

LA-LM = low adiposity with low muscle mass (individuals with low ASMI and FMI)

HA-LM = high adiposity with low muscle mass (individuals with high FMI and low ASMI).

Those with **LA-HM would be the least healthy.**

Cutoffs were defined according to the following deciles:

LA-HM (ASMI: 50-100; FMI: 0-49.99)

HA-HM (ASMI: 50-100; FMI: 50-100)

LA-LM (ASMI: 0-49.99; FMI: 0-49.99)

HA-LM (ASMI: 0-49.99; FMI: 50-100).

ASMI, Appendicular skeletal muscle mass index; FMI, fat mass index. Carla MM Prado et al: A population-based approach to define body-composition phenotypes, *Am J Clin Nutr*, 99:1369, 2014.

CLINICAL INSIGHT

Inflammaging

Aging is a ubiquitous complex phenomenon that results from environmental, genetic, and epigenetic events in different cell types and tissues and their interactions throughout life. A pervasive feature of aging tissues and most, if not all, age-related diseases is chronic inflammation. "Inflammaging" describes the low-grade, chronic, systemic inflammation in aging, in the absence of overt infection ("sterile" inflammation) and is a highly significant risk factor for morbidity and mortality in the elderly (Franceschi and Campisi, 2014).

Microbiome

After the Human Genome Project, the National Institutes of Health (NIH) launched studies for genomic identification and characterization of the microorganisms associated with healthy and diseased humans. The exciting findings focus on five body sites (mouth, skin, vagina, nose/lung, and the gastrointestinal [GI] tract). The total number of genes in the human microbiome is 10 times greater than the human genome. When the delicate microbiome community in and on the body is disturbed and altered from healthy baseline, it becomes a factor in promoting prolonged inflammation and affects the way food is metabolized in the body. The loss of microbiome diversity and the presence of specific undesirable or virulent bacteria appears to be a common finding related to various diseases (Fasano, 2012; Viladomiu et al, 2013).

The cause of these changes in the patterns of microbiota from "healthy" to dysfunctional appears to be influenced by genetics, diet, exposure to environmental toxins, and antibiotic use (National Institutes of Health [NIH], 2014). After a pathology has been determined, the systems biology-based practitioner often uses stool testing to provide more quantitative and specific functional information regarding the condition of the gut environment and microbiology. Laboratory tests for inflammatory markers such as calprotectin, lactoferrin, and pancreatic elastase 1 in the gut, much like sedimentation rate or CRP-hs and immunoglobulin A (IgA) are markers of inflammation in the blood (Gommerman, 2014). Because the GI tract contains about 70% of the immune system, it is important to assess the condition of the GI tract—from the mouth to the anus—as part of the total inflammatory load of an individual (Underwood, 2014). A new field of study regarding diseases that are related to disturbances in the gut environment and the immune system is called **enteroimmunology** (Lewis, 2014; Tsai, 2018; Fig. 7.2).

Hypercoagulation

With inflammation comes an increasingly unhealthy degree of coagulation within body fluids. At some point, the microenvironment becomes too congested, facilitating the development of chronic diseases such as cancer, cardiovascular disease, autoimmune diseases, and infectious diseases (Karabudak et al, 2008). This increase in **body fluid viscosity** promotes secretion of more proinflammatory immune cytokines and chemokines that can set the stage for chronic disease. **Autophagy** is the normal response to raise the level of proteolytic enzymes to "clean up" the cell debris and prepare it for recycling or elimination (Gottlieb and Mentzer, 2010; Gurkar et al, 2013; Rahman and Rhim, 2017; Wallace et al, 2014).

Dietary factors helping maintain healthy fluid viscosity are hydration, plant-based diets, polyunsaturated fatty acids (PUFAs), and monounsaturated fats (MUFAs) (Naghedi-Baghdar et al, 2018). Common biomarkers of increased body fluid viscosity are blood fibrinogen with platelets, and urinalysis measurements of specific gravity and the presence of "cloudiness" or mucus.

Infection

Acute infections are easily recognized and diagnosed because of their blatant signs and symptoms such as fever, leukocytosis, pus, and tachycardia. Subclinical infection processes, on the contrary, may go unnoticed for years or decades while promoting a "smoldering," under-the-radar, inflammatory condition that wears away at the integrity of the body cells and tissues. Good examples are hepatitis C virus (HCV), which begins as an acute infection but persists as a chronic infection in the liver (Vescovo et al, 2014), and human papilloma virus (HPV), which becomes chronic in cervical tissue and may lead to cervical cancer.

All chronic infections raise the level of immune response to produce inflammatory mediators and are exacerbated by nutrient insufficiencies

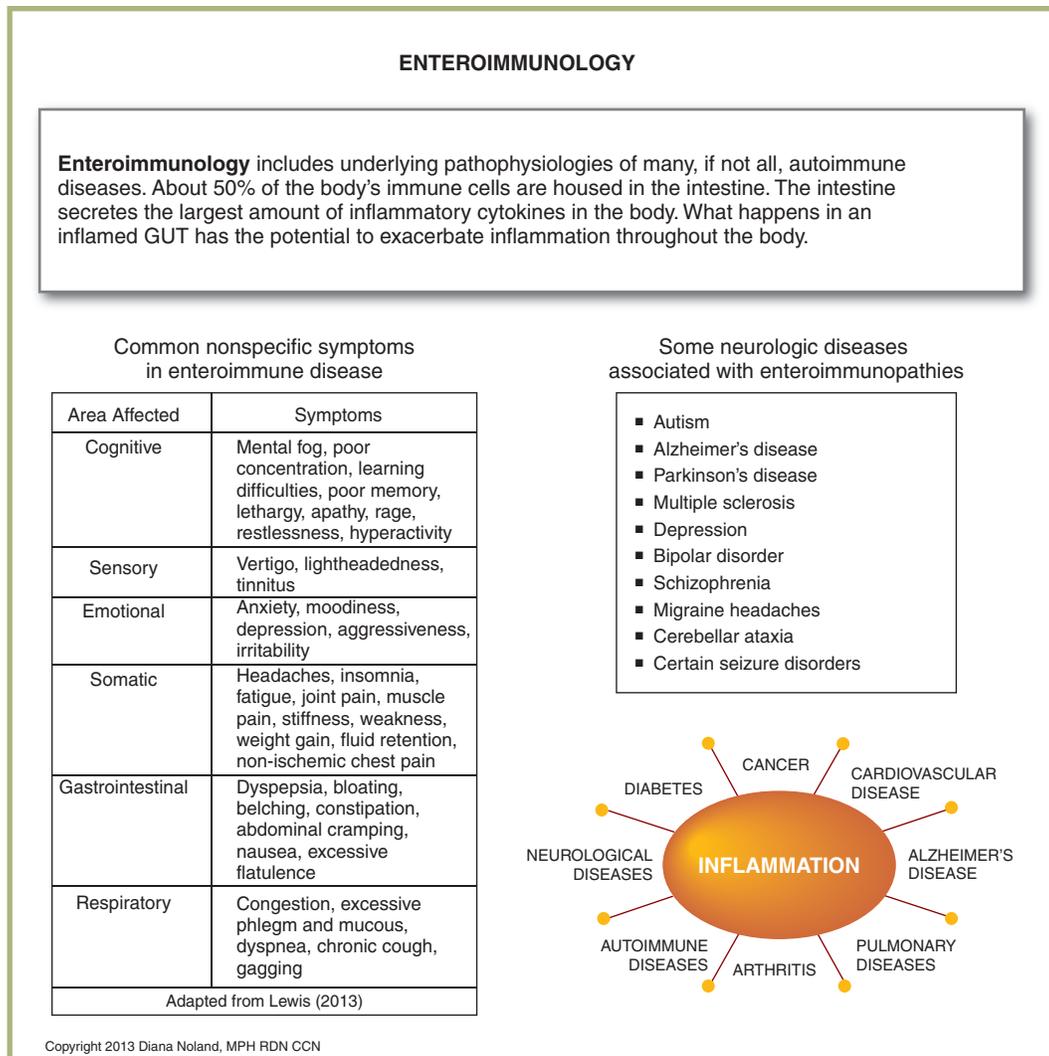

Fig. 7.2 Enteroimmunology.

and deficiencies and imbalances between prooxidant and antioxidant conditions (Cokluk et al, 2015). Other nutrients, when insufficient for optimum function, are involved in permitting chronic infections to persist over decades include vitamin D, vitamin C, and methylation nutrients such as folate, B₁₂, B₆, and B₂, which act as cofactors in inflammation and immune-control mechanisms (Ames, 2010). In addition, the health of the microbiome in the gastrointestinal tract, the skin, and other body orifices plays a critical role in inflammation and immune strength or weakness.

Stress

Stress is proinflammatory. The sources of metabolic stress may include injury, infection, musculoskeletal misalignment, lack of sleep, strong emotions, unhealthy diet, smoking, quality-of-life challenges, or lack or excess of physical activity. Whatever the source, stress can increase nutrient requirements contributing to depletion and the level of oxidative stress risks damage to body cells and tissues.

NUTRIENT MODULATORS OF INFLAMMATION

For the three **prostaglandins** and their metabolites formed from the **eicosanoid cascade**, there are vitamin, mineral, and antioxidant nutrients and hormones that act as rate-limiting cofactors for the shared

delta-5 and delta-6 desaturase and the elongase enzymes. These enzymes are required for conversion of the essential fatty acids (EFA) and PUFAs to prostaglandins. These cofactors, listed in Figs. 7.3 and 7.4, have the important ability to modulate the fatty acids and their antiinflammatory products that have key roles in the pathophysiology of chronic disease and systemic inflammation that contributes to its progression.

In addition to nutrient cofactors and hormones (like insulin) influencing the biochemistry of the eicosanoid and fatty acid metabolism of an individual, there is emerging evidence of genotype and epigenetic effects from environmental triggers that affect the genetic expression. The key genes modulating the conversion enzymes are FAD1, FAD2, and ELOVL5 (see Chapter 6). The omega-6 and omega-3 eicosanoids also share the three genes that can influence an individual's activity and efficiency of the desaturase and elongase enzymes used in conversion of the eicosanoid molecules (see Fig. 7.3).

If genomic test data is available for the nutritionist in developing a nutritional intervention, the knowledge of the influence of FAD1, FAD2, and ELOVL5 on the eicosanoid desaturases and elongase enzymes can help guide an intervention (Chisaguano et al, 2013). Chisaguano and colleagues in 2013 described the findings that children who have heterozygous or homozygous single polymorphisms for the FAD2 and ELOVL5 genes are at much higher risk of developing the inflammatory condition of atopic eczema. Upon fatty acid testing

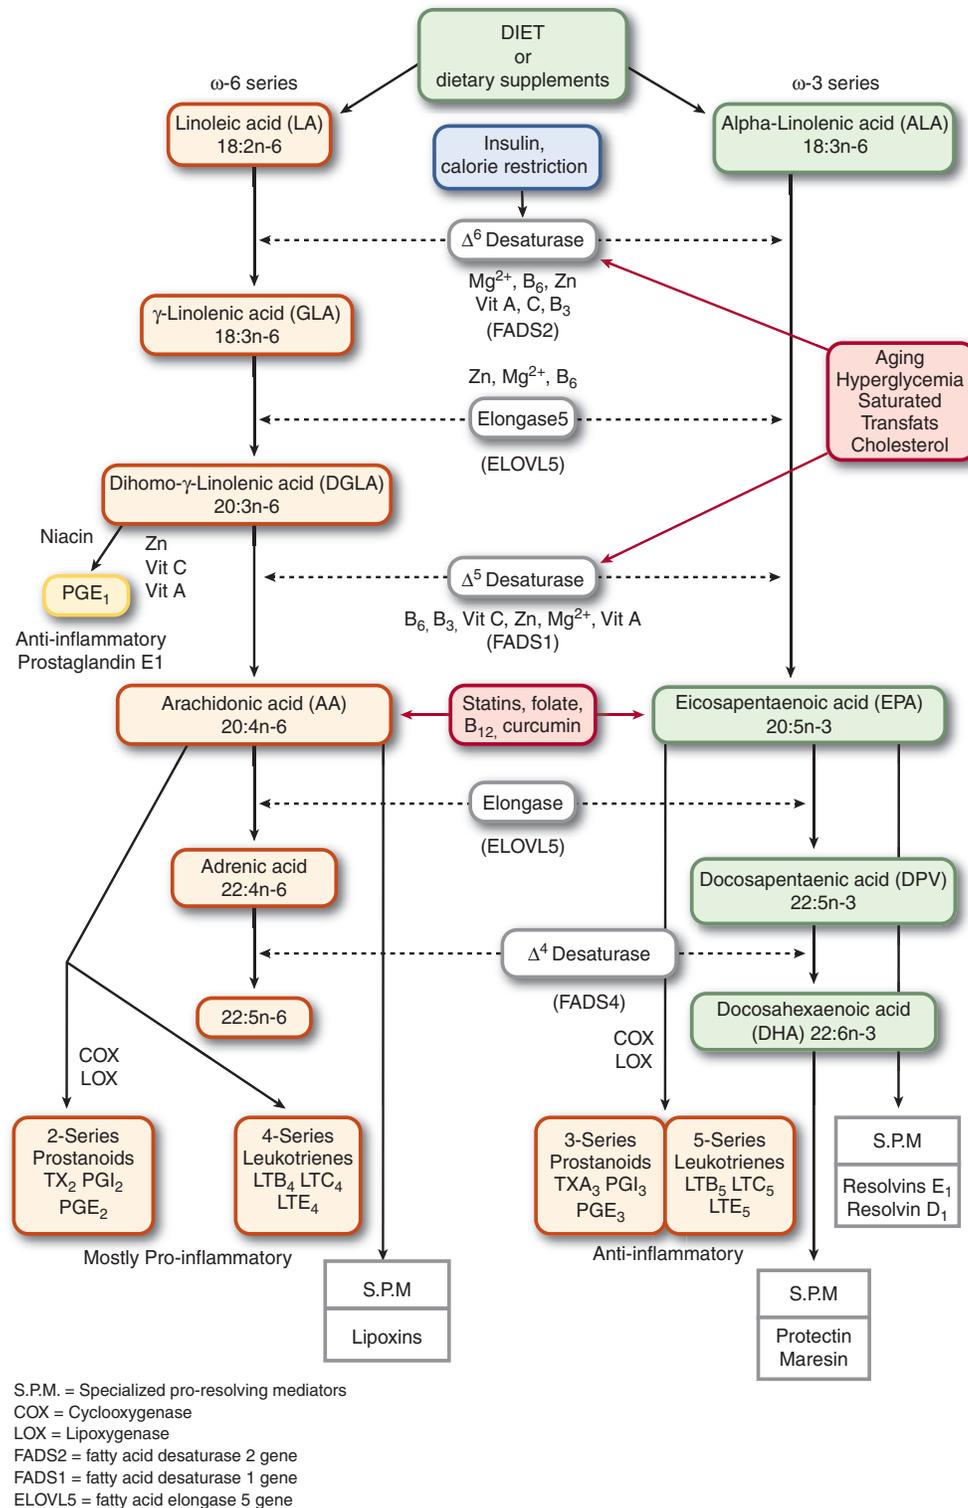

Fig. 7.3 Mechanisms of essential fatty acids and eicosanoid metabolites in modulating inflammation.

Inflammatory biological responses are driven by a balance between feedback loops, much like a “toggle” switch, influenced by messages from hormones, lifestyle, and nutrient cofactors (see primary enzyme nutrient-cofactors listed in diagram). The eicosanoid biological cascade responses receive environmental messages from diet, lifestyle, infection, and trauma. From the essential fatty acids (LA, ALA), downstream metabolites are produced dependent on hormonal messages, genotype, and adequate nutrient cofactors of enzymatic conversion activity. Acute inflammatory triggers to initiate a healing response from infection or trauma are then resolved to homeostasis by specialized proresolving mediators (SPM) in healthy subjects. This complex dance of biochemical activity is handicapped by interfering conditions (see activity in RED) noted in the diagram above). Nutrition status from regular intake over the life span of essential fatty acids and nutrient dense whole foods build the foundation for healthy eicosanoid management of acute and prolonged inflammation.

these children were found to have lower omega-6 dihomo- γ -linolenic acid (DGLA) and arachidonic acid (AA) (Chisaguano et al, 2013). Clinical application of this information and thorough assessment of an individual's fatty acid status and dietary intake can be used when developing a nutrition plan to support adequate intake of essential fatty acids (see Figs. 7.3 and 7.4).

Nutrient insufficiencies and imbalances that accompany prolonged inflammation initially can go unrecognized. Along with possible insufficient dietary intake of nutrients, there can potentially be imbalances of the body nutrient reservoirs. Various stressors or genomic single nucleotide polymorphisms (SNPs) (see Chapter 6) can also cause increased nutrient requirements to meet metabolic needs, and those depleted nutrients become “conditionally essential” for an individual. Dr. Robert P. Heaney has provided a simplified conceptual diagram called the sigmoid curve to illustrate the concepts of dynamic varied nutrient needs of the physiologic “nutrient needs spectrum” (Fig. 7.5).

Nutriture is a term that refers to the state of nutrition. Skill in assessing the nutriture of body tissues requires knowledge about nutrient interactions with other molecular compounds (e.g., hormones, nutrients, reactive oxygen species [ROS]). Manipulating biologic function with nutrition must include consideration of the “rate limiting” restrictions on a biochemical system. Like a food recipe, if any ingredient is inadequate or missing, the final product is flawed.

Examples of some critical nutrient-partner balances are omega-6 and omega-3 fatty acids, vitamin D and vitamin A, magnesium and calcium, and folate, B₆, B₂, and B₁₂. In whole or unprocessed foods,

these nutrients naturally exist in balance, such as vitamin A and D in cod liver oil, in liver, and in eggs (see Box 7.1).

The nutrient partners most strongly associated with influencing prolonged inflammation are discussed below.

Omega-6 Linoleic Acid and Omega-3 Alpha-Linolenic Acid (Essential Fatty Acids)

Fish ingestion several times a week has been associated with reduced risk of chronic disease, especially cardiac disease. It is a characteristic of the Mediterranean Diet (Pallauf et al, 2013), the Asian Diet (Kruk, 2014), and the more recently studied Nordic or Viking Diet described in the Systems Biology in Controlled Dietary Interventions and Cohort Studies (SYSDIET) (Kolehmainen et al, 2015; Uusitupa et al, 2013). The human metabolism of oils in fish and their bioactive mediators provide important factors in inflammatory processes. The relationship of diet to inflammatory biochemistry supports a strong position for the nutritionist to develop individualized interventions to ensure adequate balance of the eicosanoid-producing foods that decrease inflammation.

Three main groups of prostaglandin metabolites are formed from the two initial essential fatty acids in the eicosanoid cascade (linoleic acid [LA] and alpha-linolenic acid [ALA]): prostaglandin 1 (PGE1) (omega 6 DGLA-derived antiinflammatory), prostaglandin 2 (PGE2) (omega 6 arachidonic-derived proinflammatory), and prostaglandin 3 (PGE3) (omega 3-derived antiinflammatory). These metabolites are precursors for a wide range of bioactive lipid mediators influencing

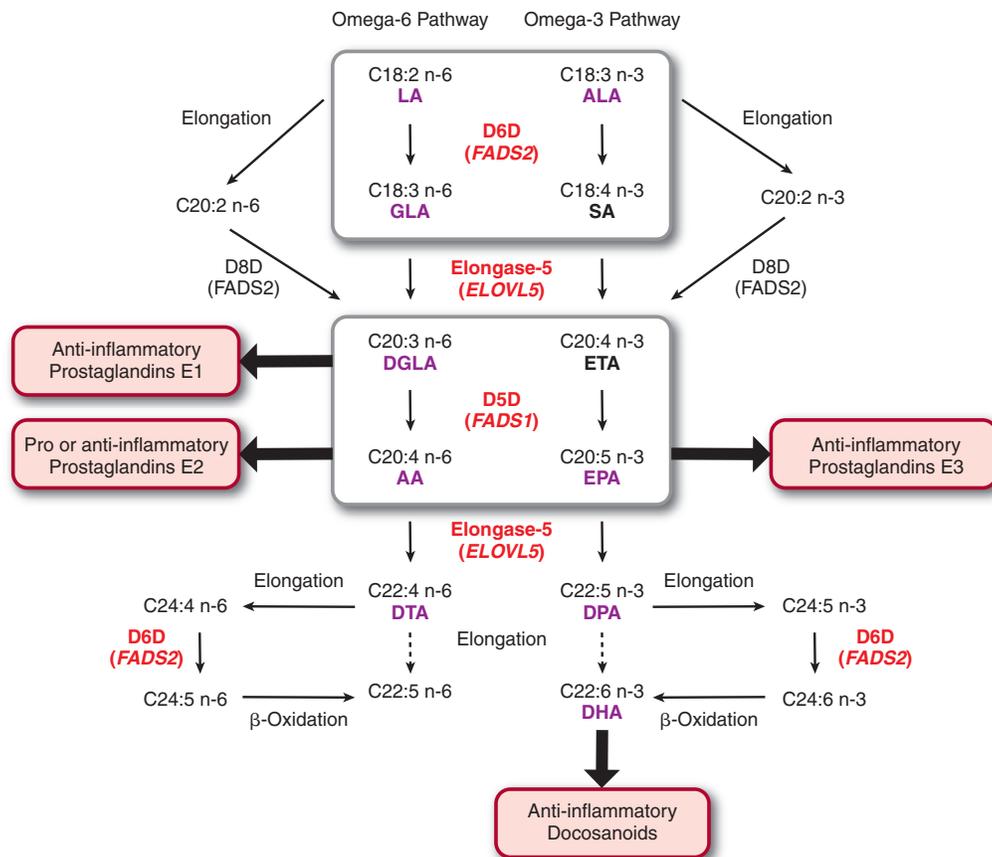

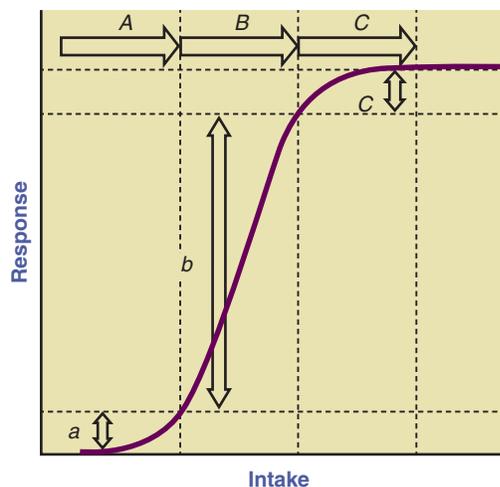

Fig. 7.4 Summary of primary eicosanoid metabolites and the genes responsible for conversion to downstream metabolites. Chisaguano M, Montes R, Pérez Berezo T, et al. Gene expression of desaturase (FADS1 and FADS2) and elongase (ELOVL5) enzymes in peripheral blood: association with polyunsaturated fatty acid levels and atopic eczema in 4-year-old children. *PLoS One* 2013; 8, e78245.

Typical sigmoid curve showing physiological response as a function of nutrient intake. Depicted are the expected responses from *equal* increments in intake, starting from a low basal intake, and moving to progressively higher starting levels. Intake increments A, B, and C produce responses, a, b, and c, respectively. Only intakes in the B region produce responses large enough adequately to test the hypothesis that the nutrient concerned elicits the response in question. (Copyright Robert P. Heaney, MD., 2010. inflammation. The RDN can assess and then develop an individualized intervention to return the individual's metabolic balance in these three groups of metabolites of the eicosanoid series. The most accurate way to assess fatty acid status is to evaluate dietary fat intake (Table 7.5), absorptive capacity (bile adequacy, pancreatic function), and RBC fatty acids (Kelley et al, 2009). Collecting this nutrition data for an individual during assessment can reveal important underlying physiologic imbalances.

The balance between the two eicosanoid signaling molecule pathways (derived from the essential PUFAs, omega-3 ALA, and omega-6 LA or dietary intake), exerts inflammatory control in response to the metabolic environment (Gil et al, 2015; Patton, 2014, Zreik and Behrman, 2018). Prostaglandins contribute to the regulation of vascular tone, platelet function, and fertility (Ricciotti and FitzGerald, 2011; Stipanuk and Caudill, 2013; Kemiläinen et al, 2016). They also play key roles as inflammatory mediators and modulators of tumor biology and are major regulators of growth and transport in epithelial cells (Varga et al, 2014). The metabolism of these hormone-like molecules is modulated by dietary intake and are of primary importance to the RDN when considering the source of chronic inflammation. The hormone-like prostaglandins formed as downstream metabolites are the primary metabolic control for acute and chronic inflammation. The seminal observation that omega-3 EPA could modulate eicosanoid biosynthesis to suppress arachidonic acid biosynthesis, an omega-6 fatty acid, was first made in 1962 (Machlin) and 1963 (Mohrhauer and Holman) and initiated research on the use of fish and fish oil supplements to reduce inflammation by suppressing the proinflammatory arachidonic acid. Omega-3 DHA (C22) is an interesting molecule formed from the eicosanoid 20-carbon cascade with antiinflammatory effects (Shichiri et al, 2014; Kemiläinen et al, 2016). EPA and docosahexaenoic acid (DHA) are found in fish oil, as well as DHA being found in algae. DHA and EPA are biochemically reversible, meaning they can be

metabolized from one molecule to the other. DHA is a critical component of many body tissues such as the eye and brain, and it contributes to modulation of metabolic inflammation. EPA, DHA, and AA can produce the more newly recognized **specialized proresolving mediators (SPMs)**, including **resolvins**, **protectins**, **maresins**, and **lipoxins**, that reduce inflammation during events like injury, infection, and antigen exposure. The body has redundant systems to provide essential molecules for metabolism.

The key eicosanoid metabolic intersections in the **eicosanoid cascade** are omega-6 GLA, DGLA, and AA promoting the antiinflammatory PGE1 and proinflammatory PGE2 series while coexisting with omega-3 EPA and DHA, promoting the antiinflammatory PGE3 series. As the knowledge of the functions of these eicosanoid metabolites has matured over the past 50 years, their synergistic relationships and the need to keep them in homeostatic balance is now appreciated (Das, 2011). The omega-6 and omega-3 eicosanoids share the same desaturase and elongase enzymes, so there is a competition between the two, where production of biologically active EPA and DHA is dependent on the availability of cofactor nutrients (Reed et al, 2014).

It is now known that fatty acid intake can influence and change physiologic responses to inflammation by modification of eicosanoid metabolism to favor synthesis of antiinflammatory prostaglandins and **leukotrienes** (produced by the oxidation of AA). Assessment of dietary fat intake and tissue status provides more targeted information that can help manage chronic inflammation (Arm et al, 2013; Dahlin and Weiss, 2016). As more randomized controlled trial (RCT) studies are available, it is hoped this will result in an improved model for the study of nutrient synergistic influences on metabolism. Wergeland and colleagues designed a multivariable study of a combination of fatty acid therapies that showed a suppression of inflammation in multiple sclerosis described as a “beneficial disease-modifying effect of increased intake of polyunsaturated fatty acids (PUFAs)” (Wergeland et al, 2012). Even as far back as 1993, Berth-Jones and Graham-Brown hypothesized that “since both ω 6 and ω 3 essential fatty acids may possess antiinflammatory properties, it is possible that giving both together will have a synergistic effect” (1993). There are a growing number of studies targeting key eicosanoid and downstream lipid mediators with the ability to modulate physiologic processes involving immunity, hormonal balance, inflammatory mediators, and cell membrane integrity including GLA (Horrobin et al, 2002), DGLA (Chisaguano et al, 2013), AA (Carlson et al, 2018; Amézaga et al, 2018), EPA, and DHA (Harris et al, 2017).

Metabolically, the five primary eicosanoids (GLA, DGLA, AA, EPA, DHA) collaborate and compete for shared enzymes in forming the prostaglandin groups: PGE1, PGE2, and PGE3 series (see Figs. 7.3 and 7.4). Each plays a critical role in the control of inflammatory conditions. Until the research interest in the 1990s of the dynamic influence omega-3 EPA has on elevated omega-6 AA, dietary intake of the essential fatty acids was the main determinant of the levels of these fatty acids in tissue composition.

However, as awareness of omega-3 and its function increased, a large portion of the U.S. population is now adding omega-3 fatty acids to their regular nutraceutical intake. In some individuals who take more than 500 mg EPA and/or DHA daily, this may cause AA and GLA biosynthesis to be suppressed with the potential to unbalance the levels of these two molecules (Horrobin et al, 2002). “Nutrient partners” require balance for optimum metabolic function. A nutrition assessment should consider the fatty acid supplements a client is taking and for how long, in addition to the amount in the diet to assess the potential for imbalance of eicosanoid and other lipid cellular components. If laboratory testing of fatty acid parameters is available, a quantitative evaluation of RBC or plasma fatty acids can be added to the nutritional assessment (Djoussé et al, 2012; Guo et al, 2010).

TABLE 7.5 Fat-Oil Dietary Intake Survey

Fats and Oils		
Please indicate how many times PER WEEK you eat the following fats/oils.		
OMEGA 9 (<i>stabilizer</i>) Oleic Fatty Acid ~50% of daily fat calories	<input type="checkbox"/> Almond Oil <input type="checkbox"/> Almonds <input type="checkbox"/> Almond butter <input type="checkbox"/> Avocados <input type="checkbox"/> Peanuts <input type="checkbox"/> Peanut butter (natural/soft)	<input type="checkbox"/> Olives / Olive Oil <input type="checkbox"/> Cashews <input type="checkbox"/> Sesame Seeds/Tahini <input type="checkbox"/> Hummus (tahini oil) <input type="checkbox"/> Macadamia Nuts <input type="checkbox"/> Pine Nuts
OMEGA 6 (<i>controllers</i>) Essential Fatty Acid Family ~30% of daily fat calories LA→GLA→DGLA→AA	<input type="checkbox"/> Eggs (whole), organic (AA) <input type="checkbox"/> Meats (commercial) (AA) <input type="checkbox"/> Meats (grass-fed, org) (AA) <input type="checkbox"/> Brazil nuts (raw) <input type="checkbox"/> Pecan (raw) <input type="checkbox"/> Hazelnuts/Filberts (raw) <input type="checkbox"/> Seed oils (cold-press)	<input type="checkbox"/> Evening Primrose (GLA) <input type="checkbox"/> Black Currant Oil (GLA) <input type="checkbox"/> Borage Oil (GLA) <input type="checkbox"/> Hemp Oil / seeds <input type="checkbox"/> Grapeseed Oil <input type="checkbox"/> Sunflower Seeds (raw) <input type="checkbox"/> Pumpkin seeds (raw)
OMEGA (<i>fluidity/communicators</i>) Essential Fatty Acid Family ~10% of daily fat calories ALA→EPA→DHA	<input type="checkbox"/> Fish Oil capsule: ↑ DHA <input type="checkbox"/> Fish Oil capsule: ↑ TEPA <input type="checkbox"/> Fish (salmon/fin-fish) <input type="checkbox"/> Fish (shellfish) <input type="checkbox"/> Flax seeds/meal	<input type="checkbox"/> Flax Oil (cold-press) <input type="checkbox"/> UDO's DHA Oil <input type="checkbox"/> Algae <input type="checkbox"/> Greens Powder w/algae <input type="checkbox"/> Chia seeds
BENEFICIAL SATURATED (<i>structure</i>) Short-chain/Medium-chain Triglycerides ~10% of daily fat calories	<input type="checkbox"/> Coconut Oil <input type="checkbox"/> Butter, organic <input type="checkbox"/> Ghee (clarified butter) <input type="checkbox"/> Dairy, raw & organic	<input type="checkbox"/> Meats, grass-fed <input type="checkbox"/> Wild game <input type="checkbox"/> Poultry, organic <input type="checkbox"/> Eggs, whole organic
DAMAGED FATS/OILS (<i>promoting stress to cells & tissues</i>) Should be <5% (try to avoid) Trans Fats Acrylamides Odd-Chain Fatty Acids VLCFA/damaged	<input type="checkbox"/> Margarine <input type="checkbox"/> Reg. vegetable oils (corn, sunflower, canola) <input type="checkbox"/> Mayonnaise (Commercial) <input type="checkbox"/> Hydrogenated Oil (as an ingredient) <input type="checkbox"/> "Imitation" cheeses <input type="checkbox"/> Tempura	<input type="checkbox"/> Doughnuts (fried) <input type="checkbox"/> Deep-fried foods <input type="checkbox"/> Chips fried in oil <input type="checkbox"/> Regular salad dressing <input type="checkbox"/> Peanut Butter (JIF, etc.) <input type="checkbox"/> Roasted nuts / seeds <input type="checkbox"/> Products with hydrogenated fats

Prostaglandin 1 Series (PGE1): Antiinflammatory

PGE1 metabolites are part of the balancing act between prostaglandin groups to manage inflammation, with a primary antiinflammatory effect on the tissue microenvironment. PGE1 is particularly important for the effects of GLA and its conversion to DGLA in managing inflammation. GLA not only attenuates intracellular inflammation by converting to DGLA (Arm et al, 2013) but also reduces inflammation in the extracellular matrix as is present in diabetic nephropathy (Kim et al, 2012). Evidence suggests skin integrity involved with autoimmune and other inflammatory conditions has a "conditionally essential" (DiSilvestro et al, 2017) need for GLA (Chung et al, 2018; Andersson-Hall et al, 2018).

Another physiologic function of the fatty acids is that GLA, DGLA, EPA, and DHA, if kept in balance, can function as inhibitors of tumor cell proliferation and migration in in-vitro and in-vivo conditions (Rahman et al, 2013; Wang et al, 2012; Yao et al, 2014).

Prostaglandin 2 Series (PGE2): Proinflammatory When in Excess

PGE2's ability to increase tissue inflammation when in excess is part of the cause of inflammation with pain, swelling, fever, redness, and constriction of blood vessels that lead to loss of function. AA increases with acute injury to trigger inflammation and increased blood flow for tissue healing, but with the prolonged character of

chronic disease, AA can get "stuck" in an elevated state and continue to damage tissue and encourage degeneration. Neoplastic disease can overproduce PGE2 in the tumor environment and has been found to simulate the growth and formation of a substantial number of carcinomas (Goodwin, 2010).

AA can become dangerously elevated, especially when dietary intake is deficient in omega-3 ALA, EPA, and DHA to act as an AA counterbalance. In the United States and most industrialized countries, some populations have high AA levels because of low intake of omega-3 oils and large intakes of highly processed PUFAs and trans fats.

The preponderance of information about AA is that it increases inflammation. It is important to acknowledge that AA in healthy humans can also help stabilize cell membranes and reduce inflammation. AA has essential functions in platelet aggregation and vasoconstriction, for example. Targeted nutrition therapy must have a goal of healthy homeostasis requiring monitoring to ensure omega-3 supplementation does not cause AA levels to fall too low (Khan, S et al, 2014).

Prostaglandin 3 Series (PGE3): Antiinflammatory

Another aspect of antiinflammatory action lies in the PGE3 prostaglandin group and their metabolites, leukotriene-5 series and others, which promote suppression of AA, GLA, and DGLA. They have been

most studied in relation to cardiovascular pathologies such as vascular and coagulation health, but often the suppression of GLA goes unnoticed and unappreciated potentially suppressing production of the antiinflammatory PGE1 prostaglandins derived from DGLA.

Lipoxygenases (LOX)

Lipoxygenases (LOX) are AA downstream intermediates that produce inflammatory leukotrienes-4 (PGE2) or antiinflammatory leukotrienes-5 (PGE3). LOX-4 and LOX-5 molecules can modulate inflammation, mostly as mediators of cell signaling and as modifiers of cell membrane structures. Practical examples of structural changes are in red blood cell maturation, modification of lung barrier function to improve bronchial function in asthma conditions, and others. The LOX molecules also act as a substrate in the mobilization of fatty acids in membranes involving beta-oxidation metabolism of fatty acids. The LOX are expressed more intensely under physiologic stress (Allaj et al, 2013).

Cyclooxygenases (COX)

Another group of eicosanoid metabolites, the **cyclooxygenase (COX)** products, have an important role in reproduction and in the inflammatory response with inflammatory COX (PGE2) molecules and anti-inflammatory COX (PGE1 and PGE3).

Specialized Proresolving Mediators (SPM)

More recent recognition of further downstream metabolites of a different class are called SPMs derived from both w3 and w6 PUFA. These SPM lipid molecules are capable of initiating a resolution phase of inflammation to return metabolism to tissue homeostasis. These SPMs are lipoxins, resolvins, protectins, and maresins (see Fig. 7.3). These mediators appear to explain some of the antiinflammatory effects of PGE1, PGE2, and PGE3 metabolites (Chiang and Serhan, 2017).

REDUCING INFLAMMATION IN THE BODY

Modern research of EFAs and their metabolites has been concerned mainly with the therapeutic impact on the inflammatory process. However, as with all systems in the body, there are opposing mediators in the body's regulation of these systems to achieve homeostasis or allostasis to promote survival. Among the primary mediators of inflammation are biogenic amines, such as histamine and serotonin, cytokines, prostaglandins, thromboxanes, and leukotrienes. The PGE1 and PGE3 antiinflammatory action opposes and balances the PGE2 inflammatory systems. Both are required for a healthy metabolism. For instance, derivatives of the omega-6 GLA and DGLA acids regulate the inflammatory process through their opposed activity and synergism with EPA, by directing formation at the crossroads to the antiinflammatory PGE1, or the inflammatory PGE2 molecules. In parallel metabolism, the derivatives of the omega-3 ALA, EPA, DHA, and others form the antiinflammatory PGE3 metabolites, while at the same time inhibiting the transformation of AA to leukotrienes and conversion of DGLA to the PGE1 molecules. This antiinflammatory action of the omega-3 eicosanoids is most researched because of their powerful suppression of AA associated with cardiovascular disease (Tousoulis et al, 2014).

It is important to understand the enzymes responsible for healthy metabolic conversions from the essential fatty acids, LA and ALA, and how to target them with foods and nutrients. These enzymes are illustrated on the eicosanoid cascade (see Fig. 7.3). The desaturase enzymes (delta-5 and delta-6) and the elongase enzymes are shared and are in competition between the omega-6 and omega-3 pathways.

Delta-6-desaturase transforms LA into GLA and ALA to EPA by adding additional double bonds. Of all the endogenous conversion steps in the eicosanoid cascade, the one driven by delta-6-desaturase is the least efficient. It is not biochemically equipped to handle the conversion of high dietary intake of LA found in the standard American diet (Kurotani et al, 2012). The delta-6-desaturase can also be less efficient in the presence of hyperinsulinemia which is associated with obesity and the metabolic syndrome (Simopoulos, 2017). In the competition for the enzyme between the omega-6 and omega-3 metabolites, a preference has been shown toward the omega-3s. However, these enzyme systems are affected by the adequacy of nutrient cofactors such as zinc, vitamin B₆, and magnesium and other physiologic and pathologic factors, such as hyperglycemia, that can lead to GLA deficiency.

The ratio of omega-6 to omega-3 fatty acids in the Western diet is between 10:1 and 21:1, whereas the diet of ancestral humans had a ratio of closer to 1:1; the ratio in the Western diet has been related to chronic disease (Simopoulos, 2016). Poor eicosanoid-related enzyme function is seen often in type 2 diabetes related to the hyperglycemia in the early stages of that disease (Forouhi et al, 2016). GLA supplementation has been shown to bypass the inefficient rate-limiting delta-6-desaturase system in the formation of LA to GLA and then to DGLA, and determines which pathway it will follow—either antiinflammatory PGI or inflammatory AA-PG2 and their derivatives. EPA has been shown in the omega-3 pathway to bypass the delta-6-desaturase conversion of ALA to EPA (Innis, 2014; see Fig. 7.3). A balance of essential fatty acids is important to quell excessive prolonged inflammation.

A targeted approach using dietary, nutraceutical, and/or enteral and parenteral lipids directs PUFAs to shift the metabolism of eicosanoids toward homeostasis, thereby attributing potent antiinflammatory effects (Triana Junco et al, 2014; Waitzberg and Torrinhas, 2015; see Chapter 12). There are promising research data from Europe where olive oil-based intravenous lipids have been used for a decade, indicating that by using different intravenous appropriate fat sources, inflammation can be reduced.

Short-term and long-term inflammatory stimulation influence COX pathways in shifting them to the “less inflammatory” COX (PGE3 and thromboxane [TX]-3), and the **resolvins** derived from EPA and DHA polyunsaturated fatty acids (LC PUFAs) through COX-2 enzymatic epoxidation (5-lipoxygenase), thereby offering protection against inflammation (Khan, S et al, 2014; Uddin, 2011).

Dietary therapies to improve balance and promote adequate GLA to DGLA conversion that directs DGLA toward conversion to the PGE1 prostanoids include weight management, improving insulin sensitivity, and adequate nutrient stores of vitamin D, EFA, zinc, magnesium, B₆, and others, as well as increased intake of GLA-rich oils (evening primrose, black currant, borage). Nutraceuticals and food sources studied include GLA-rich plant oils from evening primrose, black currant, and borage (Pickens et al, 2015).

The nutritionist who is skilled in assessing an individual's fatty acid balance, by first performing a dietary intake survey (see Table 7.5), and more specifically by obtaining an RBC fatty acid analysis, can more accurately target interventions to see improved outcomes in managing inflammation. With the information from an RBC fatty acid test, one can calculate an Omega-3 Index, a prognostic indicator of eicosanoid and EFA balance especially related cardiovascular disease (Harris et al, 2012; von Schacky, 2014; Fig. 7.6).

These assessment parameters provide a roadmap that is able to guide individualized lipid interventions. With this information, the levels of lipids in the body can be manipulated toward a healthy composition, restoring a degree of optimum inflammation-immune

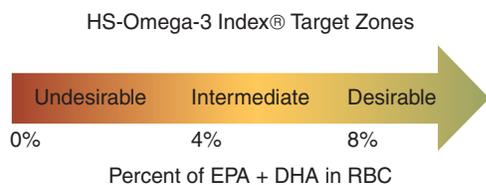

Fig. 7.6 HS-Omega-3 Index® Target Zones.

response in all systems of the body. Targeted nutrient therapy using food, dietary supplements, and functional foods can be mediators of these metabolic enzyme systems and help take advantage of the membrane and tissue malleability affected by dietary and lifestyle changes. These therapies usually require 2 to 12 months of nutrient therapy to achieve successful outcomes.

Cytochrome P450 Enzymes

Cytochrome P450 (CYP450) enzymes are essential for the production of cholesterol, steroids, prostacyclins, and thromboxane A_2 . They are also involved in the first-pass hydroxylation of endogenous and exogenous toxic molecules in the biotransformation and transport of toxins for elimination via the feces and bile, urine, and sweat. If the enzyme function is suppressed by poor integrity of the enzyme structure, abnormal pH microenvironment, hepatic inflammation, altered availability of nutrient cofactors, or CYP450 genotypes, then there is a backup of toxins and an increase in an individual's toxic load. These CYP450 enzymes are expressed primarily in the liver, but they also occur in the small intestine, kidneys, lungs, and placenta.

More tools for assessment of all the systems of the body's metabolism are becoming available. Testing for the CYP450 SNP, for instance, allows recognition of a person's metabolic strengths and weaknesses that can influence nutritional interventions (see Chapter 6). Although the science is still evolving and being validated, nutrigenomic testing may be helpful for providers (including dietitians) to personalize food and nutrition recommendations.

Vitamin D

Vitamin D (cholecalciferol) actually functions as a prohormone with multiple roles, including hormone and immune modulation, anti-inflammatory and antitumor effects, and apoptosis support (Pfothenauer and Shubrook, 2017). This suggests that vitamin D is able to physiologically contribute to the regulation of all immune responses, by means of the vitamin D receptor (VDR) expressed in the nucleus of these cells. Epidemiologic, genetic, and basic studies indicate a potential role of vitamin D in the pathogenesis of certain systemic and organ-specific autoimmune diseases (Agmon-Levin et al, 2013).

Vitamin D is activated in the skin upon exposure to UV sunlight or artificial rays (therapeutically used in northern and southern extreme latitudes), as well as obtained by dietary sources (fatty fish, fish eggs or caviar, organ meats, egg yolk, and mushrooms; see Appendix 38). The past decade has spotlighted attention on an apparent global epidemic of low vitamin D status. Many chronic diseases are associated with increased prevalence of lowered vitamin D levels as vitamin D 25-OH vit D levels fall below 30 ng/mL (75 nmol/L) (see Chapter 5). Recommendations to test for 25-OH vit D and supplement vitamin D are common to increase blood levels to a goal of at least 30 ng/mL (75 nmol/L), but some recommend higher. Optimal serum levels of vitamin D have not been defined (see Chapter 5). An estimate is that for each additional 1000 IU/day of vitamin D intake, the serum 25(OH) vit D may increase by 4 to 5 ng/mL (10 to 20 nmol/L) (Stipanuk and Caudill, 2013).

Vitamin D exhibits antiinflammatory effects (Khan, M et al, 2014; Krishnan et al, 2012; Krishnan et al, 2013). Also, as a nutrient partner, vitamin A (retinol/retinyl palmitate) has a relationship with vitamin D in the sharing of the retinoid X receptor (RXR) with the VDR, establishing a synergistic effect between the two. In nature, vitamins A and D are always found together (e.g., liver, egg yolk; see Appendix 38). Because of the close proximity to this RXR nuclear receptor in all cells, there is a synergistic relationship. If one is too high or too low, it can affect the function of the other. For optimal health, it is important to have adequate intake of vitamin A and optimal vitamin D status (Schmutz et al, 2016).

Minerals

Magnesium

Magnesium is involved with more than 300 identified enzyme systems in metabolism and blood levels are inversely correlated with C-reactive protein blood values (Dibaba et al, 2015). NHANES data involving over 14,000 people between 1971 and 2006 revealed 60%-80% of the population had low serum levels (Zhang et al, 2018b). The potential beneficial effect of magnesium intake on chronic disease may be, at least in part, explained by its inhibition of inflammation (Dibaba et al, 2015).

The NHANES 1999 to 2000 study revealed that 60% of the U.S. population consumed inadequate dietary magnesium from low vegetable and whole grain intake. Low dietary magnesium intake has been related to several health outcomes, including those related to metabolic and inflammatory processes such as hypertension, metabolic syndrome (DiNicolantonio et al, 2017), type 2 diabetes (Hruby et al, 2017), cardiovascular diseases (Liu and Chacko, 2013; Stevanovic et al, 2011), osteoporosis, and some cancers (e.g., colon, breast) (Nielsen, 2010).

Magnesium requires the microenvironment of other essential nutrients, especially its nutrient-partners, calcium and zinc. Dietary intake of chlorophyll-rich vegetables, nuts, and seeds and whole grains provides adequate magnesium if digestion and absorption are functioning well (see Appendix 43). Recently López-Alarcón and colleagues, in their study linking low-grade inflammation with obesity in children, looked at several inflammation-related biomarkers and concluded that the most significant determinants of inflammation were a magnesium-deficient diet and central obesity (López-Alarcón et al, 2014).

Zinc

Zinc is a primary cofactor for more than 300 enzymes, many of which are involved in inflammatory processes. See Appendix 47 for food sources of zinc. Intracellular zinc is required for cell signaling within the intestinal tissue triggered by the inflammatory cytokine TNF- α (Ranaldi et al, 2013). Zinc deficiency leads to thymic atrophy and decreased function. The thymus gland is responsible for the production of T-lymphocytes, a critical part of immunity.

Zinc is the nutrient partner to copper, so when assessing zinc status, copper also should be considered. Gibson and colleagues (2008) have described loss of taste (especially in the elderly) with zinc deficiency, and this should be noted when taking a history from an individual. Because alkaline phosphatase (Alk Phos) is a zinc-dependent/zinc sensitive enzyme, a low measurement may suggest further investigation is needed for zinc deficiency. Serum zinc levels only provide information about frank zinc deficiency and are not reliable to assess for marginal status. Currently, assessing for dietary intake is the most efficient way to estimate zinc adequacy.

Methylation

Methylation is universal throughout metabolism, and methyl donors are primary promoters of healthy methylation. The B complex vitamins work synergistically and are critical to the methylation process. Folate, B₆, B₂, and B₁₂ have been shown to be the most rate-limiting when insufficient. Although the results are preliminary, there may be metabolic advantages to supplementing with methylated forms of B vitamins. This is true, for example, with the methylation defect SNPs MTHFR 677C or MTHFR 1298C when the 5-MTHF form of folate rather than the synthetic folic acid is used (Bailey et al, 2010; Manshadi et al, 2014; Miller, 2010; Vollset, 2013) (see *Clinical Insight: Synthetic and Bioactive B-Complex Vitamins*).

CLINICAL INSIGHT

Synthetic and Bioactive B-Complex Vitamins

B-Complex Vitamins	Synthetic Form/Common Name	Bioactive Natural Form in Foods
B1	Thiamin mononitrate Thiamin hydrochloride	Thiamin (benfotiamine)
B2	Riboflavin	Riboflavin-5-phosphate
B3	Nicotinic acid Niacin (generic term)	Nicotinamide adenine dinucleotide (NAD) NAD phosphate (NADP) Niacinamide
B5	Pantothenic acid D-pantothenate Panthenol	Pantothenate
B6	Pyridoxine-HCl	Pyridoxine-5-phosphate (P5P)
B12	Cyanocobalamin	Methylcobalamin Hydroxycobalamin Adenosylcobalamin
B9	Folic Acid	Folinic Acid 5-Methyltetrahydrofolate 5-Formyltetrahydrofolate
B7	Biotin	Biotin (Biocytin)

To date, the methylation system most associated with inflammation of chronic disease is the methylation of DNA, which is especially sensitive. Chronic diseases related to methylation from epigenetic influences from the environment relate to potential development and promotion of cancer (Ehrlich, 2002), inflammatory bowel disease such as Crohn's disease (Karatzas et al, 2014), cognitive dysfunction, mood disorders (Hing et al, 2014), and cardiovascular disease (Delbridge et al, 2015).

The mechanisms supporting methylation have important implications in inflammation and immune response (Kaminsky et al, 2010). These mechanisms rely on B vitamin cofactors and the role they play in homocysteine metabolism as well as the eicosanoid cascade which produces the inflammation reducing prostaglandins (Nazki et al, 2014). These methyl factors are involved in turning on gene expression associated with neurotransmitters, nitric oxide (NO), and methionine metabolism, which are precursors to antiinflammatory compounds that protect against oxidative stress.

The methylation genes are currently the most studied of the SNPs and able to provide data for clinical application. Most national laboratories provide testing for the genes MTHFR C667T, MTHFR 1298C, and COMT. Others are available at specialty labs (see Chapter 6 and Fig. 7.7).

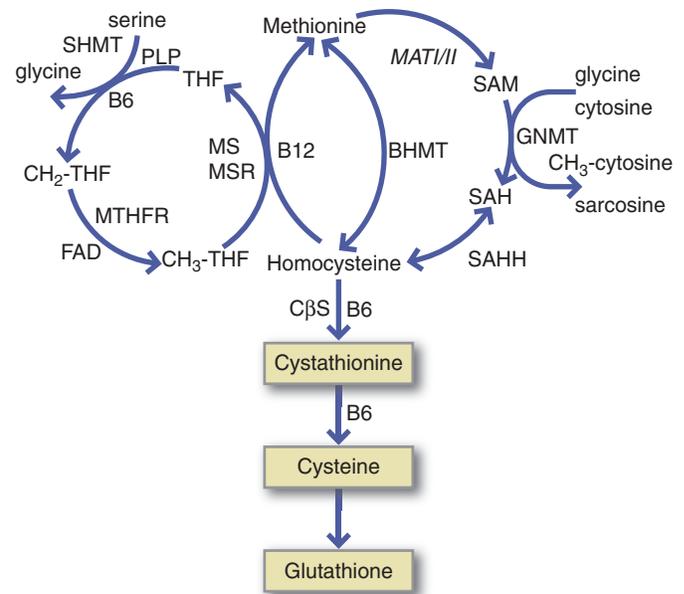

Fig. 7.7 Methylation Mechanism.

Flavonoids and Antioxidant Nutrients

Flavonoids or bioflavonoids are phytonutrients associated with the varied colors found in fruits and vegetables. These phytonutrients provide antiinflammatory antioxidant functions beneficially messaging the immune system (Islam et al, 2016; Jeena et al, 2013). They provide protection against free radical and reactive oxygen species (ROS) activity that cause inflammation, and they modulate epigenetic effects by interacting with the fatty acid and prostaglandin status of a person.

When the antioxidant and flavonoid status is inadequate to protect cells and tissues, accelerated damage occurs, promoting degeneration, and depleting the health of the individual. The most studied flavonoid compound researched to date is **curcumin**, a component of the spice turmeric (Agrawal et al, 2015; Tuorkey, 2014). Another example is **quercetin**, a component of citrus pulp, apples, and onions, which is a yellow flavonoid with antiinflammatory action toward mast cells. Quercetin-rich foods are helpful in quelling allergic or sensitivity reactions (Kim et al, 2014; Lee et al, 2013). Both of these flavonoid compounds, as well as others, are also available in supplemental form for targeted nutritional therapy when indicated (Box 7.5).

Several antioxidant systems are involved in protection against these ROS—especially within the electron transport system in the mitochondria. Among the 80 or more known antioxidants, ascorbate (vitamin C) has been shown to react with other biologic antioxidants referred to as the “antioxidant network.” Ascorbate acts as a central reducing agent regenerating other biologic antioxidants (Stipanuk and Caudill, 2013). Ascorbate interacts with the vitamin E complex to provide protection to water- and lipid-soluble surfaces in membranes.

BOX 7.5 Selected Flavonoid Antioxidants

Alpha Lipoic Acid	Glutathione
Astaxanthin	Lutein
Citrus Bioflavonoids	Lycopene
CoQ10	Quercetin
Curcumin	Resveratrol
Epigallocatechin 3 Gallate (EGCG)	Zeaxanthin

Other key members of the antioxidant network are **glutathione**, another water-soluble antioxidant that is synthesized in all cells and which supports the central role of ascorbate and vitamin E; **lipoic acid** with its water and lipid molecular components and sometimes considered the “universal antioxidant”; and **coenzyme Q₁₀** that functions in protecting lipid structures, especially in cardiac muscle and mitochondrial membranes. Antioxidants work synergistically to quell ROS activity. These nutrients are natural metabolites in healthy individuals and can be used as supplements for health-compromised individuals if indicated.

Gut Ecology and the Microbiome

The gastrointestinal tract has many functions in the health of an individual, and one of them is in immune integrity. This is because the largest immune organ is located within the gastrointestinal tract as gut-associated lymphoid tissue (GALT) and mucosa-associated lymphoid tissue (MALT), containing innate and acquired immune systems as well as about 3 pounds of symbiotic microbial organisms. The condition of the gut lymphoid tissue and the microbial ecology has a large influence on the body’s inflammatory state (Lewis, 2014). The inverse relationship of gut barrier integrity and ecology with organ specific or systemic inflammation is well documented (Goldman and Schafer, 2012; Hold et al, 2014; Kinnebrew and Pamer, 2012; Pastorelli et al, 2013; Ruth and Field, 2013).

Medical nutrition therapy recommendations to support the microbial ecology include increasing intake of fermented foods and fiber, decreasing highly processed foods, and avoiding inflammatory antigens, especially those that affect the gastrointestinal tract (such as food allergens). Therapeutic use of functional foods (Abuajah, 2015), pre- and probiotics (Isolauri and Salminen, 2015), and fiber supplements can sometimes be used to restore optimum gut function and reduce inflammation (Luoto et al, 2013; see Chapters 25 and 27).

Lifestyle

Lifestyle factors such as poor sleep, physical inactivity, and smoking contribute to inflammation and chronic disease. Toxic environmental exposures, stress, social isolation and poor interpersonal relationships have also been identified as influencing factors (Tay et al, 2013; Umberson and Montez, 2010).

Sleep: Circadian Rhythm

The CDC targets sleep insufficiency as an important public health challenge with 50 to 70 million U.S. adults diagnosed with sleep disorders (CDC, 2018; CDC 2014a). Sleep quality and duration, “feeling refreshed” upon awaking, and having good energy throughout the day until bedtime are the signs of adequate sleep. Good-quality sleep helps reduce blood markers of inflammation including CRP-hs (Irwin et al, 2016). Common habits that disrupt sleep include watching TV or looking at computers and cell phones. Electronic devices produce penetrating light that reduces the body’s production of melatonin (the natural sleep hormone responding to darkness). Sleep apnea, snoring, and for some, consumption of caffeinated food and drinks also contribute to poor sleep quality. The cumulative effects of poor sleep affect metabolic activities that may lead to weight gain, mood disorders, and feelings of stress (Heaney, 2012). Sleep problems can contribute to diseases such as hypertension, heart disease, depression, and diabetes.

Clinical Insight

The Role of the Vagus Nerve in Inflammation

The status of a person’s vagus nerve is often not considered in assessing chronic inflammation. The vagus nerve the longest cranial nerve

connecting the brain to the body, and regulating many systems, especially gastrointestinal function and inflammation. Poor vagal tone inhibits the ability to achieve parasympathetic function influencing optimum digestion (Yuen et al, 2017; Gerritsen et al, 2018). During a physical examination a simple screening for vagal tone is having a patient perform a gag reflex status by using a tongue depressor pushing down on the tongue starting at the tip and incrementally proceeding toward the back of the tongue till sensing a beginning gag response. The healthy vagal tone should produce a gag response within 1 to 2 cm of depressing the tip of the tongue. An important role of the **vagal nerve** is controlling the promotion of SPM and resolution of inflammation. This would be important if a patient history includes a vagotomy (Mirakaj et al, 2014). Lifestyle interventions can be recommended that have strong evidence to improving vagal tone and function, effecting control of inflammation (e.g., meditation, yoga, laughing, gargling) (Gerritsen et al, 2018; Loizzo, 2016).

Physical Activity

In the medical literature, physical activity is often associated with an improvement in inflammatory markers. Participants in the Multi Ethnic Study of Atherosclerosis (mean age 64) who exercised from a moderate to vigorous level had reduced blood levels of multiple inflammatory markers including IL-6, leptin, and resistin (an adipocyte specific hormone associated with insulin resistance). These results were found in all ethnicities and were not diminished by the presence of obesity or other cardiometabolic risk factors (Vella et al, 2016). Multiple studies have shown an inverse relationship between physical activity and inflammatory markers such as CRP-hs and TNF- α (Woods et al, 2012). In young sedentary adults, 12 weeks of aerobic training improved aerobic capacity but did not reduce inflammatory markers. In some cases, inflammatory markers were increased leading the authors to conclude that the antiinflammatory potential of physical activity may be population and situationally specific (Sloan et al, 2018). Although studies on the effect on inflammation are mixed, the overall health benefit of physical activity in most people cannot be disputed.

Stress of Life

Some health professionals and researchers have theorized that prolonged unresolved stress on the body is one of the primary promoters of early aging and chronic disease. The unresolved state of stress, whether emotional, physical, or perceived, or from infection or injury, triggers the immune system to respond with more inflammatory cytokines. The analogy used to describe unrelenting stress is getting ready for the “fight or flight” response, with nowhere to run. Under the influence of a short-term stressor, the body is able to clear the inflammatory and stress signals. That cannot happen with unrelenting chronic stress (Liu et al, 2017)

Toxin Load

Toxins are endogenous and exogenous **xenobiotics**, toxic substances within a biologic organism, that damage the metabolism.

In the modern world, since World War II, there have been 80,000 or more synthetic chemicals and many toxic metals released into the environment, increasing the exposure of plant and animal life to an unprecedented level (NRDC, 2019). Although many historical compounds such as smoking are toxic (Adams et al, 2015), many toxic compounds are “new-to-nature” molecules not before present in the environment (Aris and Leblanc, 2011; Bland, 2007). An example is trans fatty acids (Ganguly and Pierce, 2015).

The metabolisms of plants and animals usually have difficulty providing the systems to process and eliminate these toxins when

incorporated into the organism. Industrial and food industry pressures have challenged attempts at governmental regulation of these toxic compounds. The result has been increasing tissue levels of some of these toxins when tissue testing is performed. Examples of these increased levels are shown in studies of newborn cord blood, which have found multiple environmental chemicals in a population of urban U.S. newborns (Morello-Frosch et al, 2016).

Another example is studies of toxic cadmium and lead metals in Korean populations residing near abandoned metal mines. A study of more than 5000 Koreans found notably higher toxic metal levels in those residing within a 2-km radius of the mines than in the general population in Korea and other countries (Park et al, 2014). Cadmium and lead are known carcinogens and are related to central nervous system (CNS) disturbances and cardiovascular and renal diseases with accompanying prolonged inflammation.

A study on hermetic (low-level) exposure to cadmium and arsenic related to clinical symptoms found that low dietary protein intake affected enzyme activity such that depressed biologic systems and long-term adaptations were inadequate (Dudka et al, 2014). Lack of dietary vegetable micronutrient and phytonutrient intake has repeatedly been shown to increase the inflammatory effects of toxins such as toxic metals, chemicals, and pesticides (Bakırcı et al, 2014, Jeena et al, 2013). Adequate intake of macro- and micronutrients may provide protection from toxin exposures such as from high intake of vegetables and adequate protein.

Assessment and Reducing Prolonged Inflammation in Chronic Diseases

The Patient's Story

Nutrition assessment includes gathering information about the whole person and begins by hearing the patient's story and forming the therapeutic relationship that is foundational for the most effective outcomes. It is a type of detective work partnering with the client to uncover root causes of underlying physiologic imbalances, including inflammation that frame the intervention.

The **patient's story** is a term inclusive of the whole of the patient's history and current state of health; it is a collection of all data that potentially can contribute to the individual's health. In the therapeutic encounter the data is collected from the personal interview, study of medical records, family history from multiple generations if possible, clinical observation, and current laboratory records. Most often a pattern suggesting metabolic genotypes can be recognized. Examples like cardiovascular, autoimmune, or neurologic events repeated in family members, especially at young ages or in multiple relatives, should prompt the nutritionist to investigate possible metabolic mechanisms and SNPs. Quantitative laboratory or clinical confirmation of an altered metabolism may be appropriate before planning an intervention.

Personal health history, from gestation through the present, can be obtained via creation of a timeline of major life events and health challenges. This can give insight into patterns that have contributed to a person's current state of health or disease. For example, infants not breastfed are found to have more difficulty in maintaining healthy gut microbiota, and increased incidence of allergies and asthma. These infants may benefit from probiotic supplementation (Prescott and Nowak-Węgrzyn, 2011).

Medical History and Data

Inflammation is a common denominator in nearly every chronic disease. Most evidence of this phenotype among humans, centers around various aspects of the **metabolic syndrome** described as presenting with a cluster of risk factors including insulin resistance (IR)/**hyperinsulinemia**, increased VAT (increased body fat percentage and waist circumference), elevated blood triglycerides (TG)/lowered

high-density cholesterol (HDL-cholesterol), hypertension, and raised fasting glucose (dysglycemia) (Watson, 2014). An additional biomarker is seen commonly as elevated CRP-hs blood values greater than 1.0. Increased understanding of dysregulation of glucose metabolism and its various causes helps define the complex condition of prolonged inflammation (Patel and Patel, 2015).

Biochemical markers also can be important factors in personalizing an individual's "total inflammatory load." Inflammatory markers such as sedimentation rate (blood) are significant in monitoring the progression of chronic inflammatory processes (see Chapter 5).

Predictive genomic testing has provided new tools for personalizing assessment of individual metabolism. The use of SNP testing is growing at a rapid pace. It is important to appreciate the SNP as a "predictive" value and not as a "diagnostic" tool. An example is the identification of an association between a vitamin D receptor SNP with breast cancer (VDR genes such as CDX2 and BGL) (Khan, M et al, 2014). The VDR gene may influence risks of some cancers and their prognosis. This encourages closer monitoring of vitamin D status in cancer patients (Huss et al, 2019).

Vitamin D is involved in enhancing the management of metabolic inflammation because of its "prohormone" and immune modulating effects. This comprehensive candidate-gene analysis demonstrates that the risk of multiple VDR polymorphisms results in lower VDR mRNA levels. Polymorphisms of the vitamin D receptor gene (VDR) have been shown to be associated with several complex diseases, including osteoporosis. This could affect the vitamin D signaling efficiency and may contribute to the increased fracture risk in some populations (Zhang et al, 2018a).

Gathering the patient's story and combining it with other data like anthropometrics, medical history, and the nutrition focused physical examination (see Appendix 11) allows a pattern to emerge of nutritional and metabolic priorities. This provides the clinician with important information to develop a nutrition intervention to promote optimal health and wellness.

Developmental Inflammatory-Related Conditions

Developmental inflammatory-related conditions bring a focus to the uterine environment, where there is recognition of the importance of preprogramming the fetus. Epigenetic messages to the fetus can impact long-term health and risk of disease. In the infant and toddler years, negative physical and psychosocial exposures, including violence, abuse, bullying and racism, can also influence health into adulthood. If the fetus and young child do not grow in a healthy environment, the inflammatory processes of chronic disease take root and will challenge the individual throughout their life (Claycomb et al, 2015; EFCNI, 2015; Lane, 2014; see Chapters 15 and 16).

SUMMARY

Chronic disease is an epidemic that is affected by diet and lifestyle, and chronic disease pathophysiology is the result of genetics and epigenetic influences. Sustained inflammation is the common denominator in most chronic disease. Nutrition and lifestyle are modulators of sustained inflammation (Box 7.6).

The nutritionist has an important role in the interdisciplinary management of chronic disease. Having the skills to recognize early signs and symptoms of inflammation enable the nutritionist to identify nutritional priorities and individual strategies to reduce inflammation and restore health and well-being.

Whole foods, "functional foods," targeted dietary supplements when indicated, and lifestyle changes can be foundational in achieving wellness. Dietitians with an understanding of the immune and inflammatory response and its relationship to chronic disease will have the capacity for more effective nutrition assessments and interventions.

BOX 7.6 Food, Nutraceuticals, and Lifestyle as Medicine to Manage Inflammation

Food	Nutraceuticals	Lifestyle
Whole Foods Diet	Quercetin	Sleep
Mediterranean Diet	Rutin	Physical activity
Med-Asian Diet	Curcumin	Beliefs
Nordic Diet	Proteolytic enzymes	Community
Fruits and vegetables	Enzyme therapy	
Beneficial fats	Rx nutrition therapy	
Pure water	Guidance for dietary supplements	
Targeted nutrients		
Low-antigen foods for the individual		
Low toxin-containing foods		
Foods and cookware toxin-free (aluminum, BPA, perfluorooctanoic acid [PFOA]-free)

Behavioral-Environmental: The Individual in the Community

Judith L. Dodd, MS, RDN, LDN, FAND

KEY TERMS

biosecurity	National Food and Nutrition Survey (NFNS)	social determinants of health
bioterrorism	National Health and Nutrition Examination Survey (NHANES)	Special Supplemental Nutrition Program for Women, Infants, and Children (WIC)
community needs assessment	National Nutrient Databank (NND)	Supplemental Nutrition Assistance Program (SNAP; formerly the food stamp program)
Department of Homeland Security (DHS)	National Nutrition Monitoring and Related Research (NNMRR) Act	Sustainable Development Goals (SDGs)
Federal Emergency Management Agency (FEMA)	nutrition policy	tertiary prevention
food defense	pandemic	U.S. Department of Health and Human Services (USDHHS)
food desert	policy development	What We Eat in America
Food Safety and Inspection Service (FSIS)	primary prevention	
food security	public health assurance	
foodborne illness	risk assessment	
genetically modified organisms (GMOs)	risk management	
Hazard Analysis Critical Control Points (HACCP)	secondary prevention	
Hunger-Free Kids Act		

Community nutrition is a constantly evolving and growing area of practice with the broad focus of serving the general population across all cultures, genders, geographic locations, and socioeconomic conditions. Although this practice area encompasses the goals of public health, in the United States the current model has been shaped and expanded by prevention and wellness initiatives that evolved in the 1960s. Because the thrust of community nutrition is to be proactive and responsive to the needs of the community, current emphasis areas include access to a nutritionally adequate and safe food supply along with disaster and **pandemic** control, food and water safety, and controlling environmental risk factors related to obesity and other health risks. Food safety continues to be in the public health picture. Although traditional safety concerns continue to exist, potential safety issues such as genetic modification of the food supply is a new and growing concern and must be recognized as a part of community nutrition. In addition, the reliance on eating food away from home and previously processed foods adds to the risk for food borne illness.

Historically public health was defined as “the science and art of preventing disease, prolonging life, and promoting health and efficiency through organized community effort.” The public health approach, also known as a population-based or epidemiologic approach, differs from the clinical or patient care model generally seen in hospitals and other clinical settings. In the public health model the client

is the community, a geopolitical entity. The focus of the traditional public health approach is **primary prevention** with health promotion, as opposed to **secondary prevention** with the goal of risk reduction, or **tertiary prevention** with rehabilitation efforts. Changes in the health care system, technology, and attitudes of the nutrition consumer have influenced the expanding responsibilities of community nutrition providers. Growing involvement in and access to technology, especially social media, has framed new opportunities and challenges in public health and community nutrition.

In 1988 the Institute of Medicine published a landmark report that promoted the concept that the scope of community nutrition is a work in progress. This report defined a mission and delineated roles and responsibilities that remain the basis for community nutrition practice. The scope of community-based nutrition encompasses efforts to prevent disease and promote positive health and nutritional status for individuals and groups in settings where they live and work. The focus is on well-being and quality of life. “Well-being” goes beyond the usual constraints of physical and mental health and includes other factors that affect the quality of life within the community. Today’s terminology promotes “wellness,” and like the definition for “well-being,” this state goes beyond the absence of illness to a dynamic process. Community members need a safe environment and access to housing, safe and nourishing food, income, employment, and education. The mission of community nutrition is to promote standards and conditions in which all people can be healthy and can achieve a state of wellness.

Portions of this chapter were written by Cynthia Taft Bayerl and Lisa Mays.

SOCIAL DETERMINANTS OF HEALTH

The **social determinants of health** are the conditions in which people are born, grow, live, work, and age. These circumstances are shaped by the distribution of money, power, and other resources at global, national, and local levels. A summary report of conditions throughout the world, including the United States, by the World Health Organization (WHO) describes how stress, social exclusion, discrimination, working conditions, unemployment, lack of social support, addiction, quality of the food, and access to transportation affect opportunities in life and overall health (WHO, 2011). The report described how people with fewer economic resources suffer from more acute and chronic disease and ultimately have shorter lives than their wealthier counterparts. This disparity drew attention to the remarkable sensitivity of health to the social environment, including psychological and social influences, and how these factors affect physical health and longevity. The report proposed that public policy can shape a social environment, making it more conducive to better health for all. Although such action was described as a challenging task, WHO leadership noted that if policy makers and advocates focused on policy and action for health needs to address the social determinants of health, the stage could be set addressing the causes of ill health before they lead to problems. (WHO, 2011; Wilkinson and Marmot, 2011). In 2015 WHO affiliated countries adopted **Sustainable Development Goals (SDGs)** meant to provide specific targets to be achieved over 15 years. Since 2005 WHO has continued to publish world health statistics. In 2016 the focus of the series was on monitoring the progress of SDGs. The 2018 series provides information on 36 health-related indicators (WHO, *World Health Statistics 2018: Monitoring Health for the SDGs*, 2018).

Programming and services can be for any segment of the population. The program or service should reflect the diversity of the designated community, such as the politics, geography, culture, ethnicity, ages, genders, socioeconomic issues, and overall health status. Along with primary prevention, community nutrition provides links to programs and services with goals of disease risk reduction and rehabilitation.

In the traditional model, funding sources for public health efforts were monies allocated from official sources (government) at the local, state, or federal level. Currently nutrition programs and services are funded alone or from partnership between a broad range of sources, including public (government), private, and voluntary health sectors. As public source funding has declined, the need for private funding has become more crucial. The potential size and diversity of a designated “community” makes collaboration and partnerships critical, because a single agency may be unable to fund or deliver the full range of services. In addition, it is likely that the funding will be for services or product (in-kind) rather than cash. Creative funding and management skills are crucial for a community nutrition practitioner.

NUTRITION PRACTICE IN THE COMMUNITY

Nutrition professionals recognize that successful delivery of food and nutrition services involves actively engaging people in their own community. The pool of nutrition professionals delivering medical nutrition therapy (MNT) and nutrition education in community-based or public health settings continues to expand. Telemedicine has become a growth area both through private practice and organized health care. In addition, community outreach is evidenced by the presence of registered dietitian nutritionists (RDN), and other health professionals in for-profit or retail settings such as supermarkets, big-box stores, or pharmacies as well as in gyms and fitness-oriented clubs.

The objectives of *Healthy People 2020* offer a framework of measurable public health outcomes that can be used to assess the overall health of a community. Although the settings may vary, there are three

core functions in community nutrition practice: (1) community needs assessment, (2) policy development, and (3) public health assurance. These areas are also the components of community nutrition practice, especially community needs assessment as it relates to nutrition. The findings of these needs assessments shape policy development and protect the nutritional health of the public.

Although there is shared responsibility for completion of the core functions of public health, official state health agencies have primary responsibility for this task. Under this model, state public health agencies, community organizations, and leaders have responsibility for assessing the capacity of their state to perform the essential functions and to attain or monitor the goals and objectives of *Healthy People 2020*. Along with monitoring and evaluation, work is continuing on what will be the 2030 edition of *Healthy People*. This, along with work on the *Dietary Guidelines for 2025*, provides an opportunity for local involvement as well as shaping the national initiatives.

A Framework for Public Health Action: Friedan’s Pyramid

Local health agencies are charged with protecting the health of their population groups by ensuring that effective service delivery systems are in place. In 2010 Dr. Thomas Frieden, MD, at the Centers for Disease Control published an article that described a new way of thinking about community-based health services (Frieden, 2010). In his article “A Framework for Public Health Action: The Health Impact Pyramid,” Frieden describes a five-tier pyramid derived from evidence-based research (Fig. 8.1). The Pyramid describes the potential impact of various types of public health interventions and provides a framework to improve health. Each layer describes the spheres that influence the involvement of the community in health services including nutrition. The foundation of this Pyramid (see Fig. 8.1) depicts the largest and broadest involvement of partners and communities, which Frieden describes as more powerful in influencing positive health outcome than the more traditional model of one-to-one intervention (depicted at the top of the figure).

Frieden’s Pyramid illustrates, in ascending order, the interventions that could change the context to make an individual’s default decisions healthy (Frieden, 2010). In addition, the Pyramid includes clinical interventions that require limited contact but confer long-term protection, ongoing direct clinical care, health education, and counseling. Frieden’s point is that interventions focusing on lower levels of the Pyramid tend to be more effective because they reach broader segments of society and require less individual effort. Implementing interventions at each of the levels can achieve the maximum possible sustained public health.

Government’s Role in Public Health

The federal government can support the development and dissemination of public health knowledge and provide funding. **Box 8.1** provides a list of government agencies related to food and nutrition. Typical settings for community nutrition include public health agencies (state and local), including the **Special Supplemental Nutrition Program for Women, Infants, and Children (WIC)**. WIC is a federal program that allocates funds to states and territories for specific foods, health care referrals, and nutrition education for low-income, nutritionally at-risk pregnant, breastfeeding, and non-breastfeeding postpartum women; infants; and children up to age 5 years. This program is a specific, nutrition-based food package that has evolved over the years to provide for the individual needs of the client and has adapted to changes in society and in health needs. Inclusion of fresh fruits and vegetables, foods that meet the needs of a diverse client base and food intolerances or allergies are examples of how this program is tailored and evolving.

The expansion of community-based practice beyond the scope of traditional public health has opened new employment and outreach opportunities for nutrition professionals. Nutrition professionals often serve as consultants or may establish community-based practices. Nutrition services are often available in programs for senior adults, in community health centers, in early intervention programs, within health maintenance organizations, at food banks and shelters, in schools (including Head Start), and in physicians' offices or clinics through direct contact and telemedicine models.

Effective practice in the community requires a nutrition professional who understands the effect of economic, social, and political issues on health. Many community-based efforts are funded or guided by legislation resulting in regulations and policies. Community practice requires an understanding of the legislative process and an ability to translate policies into action. In addition, the community-based professional needs a working knowledge of funding sources and resources at the federal, state, regional, and local level in the official, nonprofit, and private sectors.

NEEDS ASSESSMENT FOR COMMUNITY-BASED NUTRITION SERVICES

Nutrition services should be organized to meet the needs of a "community." Once that community has been defined, a **community needs assessment** is developed to shape the planning, implementation, and evaluation of nutrition services. Evidence-based assessment tools are available to aid in this process. The Centers for Disease Control and Prevention's (CDC) *Community Guide* is a work-in-progress source of tools. This source provides information on various topics related to health risk factors, such as nutrition, obesity, physical activity, tobacco use, and diabetes. Information on policies, programs or services, funding, research, and education are included. Community needs are ever changing and this site provides an opportunity to be updated as new information is shared (CDC, 2018).

Box 8.2 lists other organizations and centers such as involved in healthcare policy. Resources are available to communities for use in health and **nutrition policy** (course of action adopted by government, community agency or business) that include technical assistance to

 Urban Institute
 Robert Wood Johnson Foundation

support communities in the process of developing policies and conducting assessments. Such tools and assistance can result in meaningful strategies and programming.

Community Needs Assessment

A community needs assessment is a current snapshot of a defined community with a goal of identifying the health risks or areas of greatest concern to the community's well-being. To be effective, the needs assessment must be a dynamic document responsive to changes in the community. A plan is only as good as the research used to shape the decisions, so a mechanism for ongoing review and revision should be built into the planning.

A needs assessment is based on objective data, including demographic information and health statistics. Information should represent the community's diversity and be segmented by such factors as age, gender, socioeconomic status, disability, and ethnicity. Examples of information to be gathered include current morbidity and mortality statistics, number of low-birth-weight infants, deaths attributed to chronic diseases with a link to nutrition, and health-risk indicators such as incidence of smoking or obesity. *Healthy People 2020* outlines the leading health indicators that can be used to create target objectives. Ongoing evaluation of progress on these indicators builds on objectives and adds new direction. Subjective information such as input from community members, leaders, and health and nutrition professionals can be useful in supporting the objective data or in emphasizing questions or concerns. The process mirrors what the business world knows as market research.

Another step should be cataloging accessible community resources and services. As an example, consider how environmental, policy, and societal changes have contributed to the rapid rise in obesity over the past few decades. Resources to consider are affordable access to walkable neighborhoods, housing, recreation facilities, and health-promoting foods (CDC, 2014).

In nutrition planning the goal is to determine who and what resources are available to community members when they need food or nutrition-related products or services. For example, what services are available for MNT, nutrition and food education, home care, child care, or job or home-related skills training? Are there safe areas for exercise or recreation? Is there access to affordable transportation? Is there compliance with disability legislation? Are mechanisms in place for emergencies that may affect access to adequate and safe food and water?

At first glance some of the data gathered in this process may not appear to relate directly to nutrition, but an experienced community nutritionist or a community-based advisory group with public health professionals can help connect this information to nutrition- and diet-related issues. Often the nutritional problems identified in a review of nutrition indicators are associated with dietary inadequacies, excesses, or imbalances that can be triggers for disease risk (Box 8.3). Careful attention should be paid to the special needs of adults and children

BOX 8.3 Possible Nutrition Trigger Areas in a Community Needs Assessment

- Presence of risk factors for cardiovascular disease; diabetes and stroke
 - Elevated blood cholesterol and lipid levels
 - Inactivity
 - Smoking
 - Elevated blood glucose levels
 - High body mass index (BMI)
 - Elevated blood pressure
- Presence of risk factors for osteoporosis
- Evidence of eating disorders
- High incidence of teenage pregnancy
- Evidence of hunger and food insecurity
- Disease clusters

with disabilities or other lifestyle-limiting conditions. Once evaluated, the information is used to propose needed services, including MNT as discussed in other chapters, as part of the strategy for improving the overall health of the community.

Sources for Assessment Information

Community practitioners must know how to locate relevant resources and evaluate the information for validity and reliability. Knowing the background and intent of any data source and identifying the limitations and the dates when the information was collected are critical points to consider when selecting and using such sources. Census information is a starting point for beginning a needs assessment. Morbidity and mortality and other health data collected by state and local public health agencies, the CDC, and the National Center for Health Statistics (NCHS) are useful. Federal agencies and their state program administration counterparts are data sources; these agencies include the [U.S. Department of Health and Human Services \(USDHHS\)](#), U.S. Department of Agriculture (USDA), and the Administration on Aging. Local providers such as community hospitals and agencies, WIC, child care agencies, health centers, and universities with a public health or nutrition department are additional sources of information. Nonprofit organizations such as the March of Dimes, the American Heart Association (AHA), the American Diabetes Association, and the American Cancer Society (ACS) also maintain population statistics. Health insurers are a source for information related to health care consumers and geographic area. Food banks and related agencies may be able to provide insights into food access and security (see Box 8.3).

NATIONAL NUTRITION SURVEYS

Nutrition and health surveys at the federal and state level provide information on the dietary status of a population, the nutritional adequacy of the food supply, the economics of food consumption, and the effects of food assistance and regulatory programs (Box 8.4). Public guidelines for food selection usually are based on survey data. The data are also used in policy settings; program development; and funding at the national, state, and local levels. Until the late 1960s, the USDA was the primary source of food and nutrient consumption data. Although much of the data collection is still at the federal level, other agencies and states are now generating information that can build a comprehensive picture of the health and nutrition of the public.

National Health and Nutrition Examination Survey

The [National Health and Nutrition Examination Survey \(NHANES\)](#) provides a framework for describing the health status of the nation.

BOX 8.4 Community Nutrition Assessment Sources

NHANES, National Health and Nutrition Examination Survey
 NFNS, National Food and Nutrition Survey
 CSFII, Continuing Survey of Food Intake of Individuals

Sampling the noninstitutionalized population, the initial study began in the early 1960s, with subsequent studies on a periodic basis from 1971 to 1994. NHANES has been collected on a continuous basis since 1999. NHANES scientists and technicians travel the country in specialized buses equipped with mobile examination rooms. The process includes interviewing approximately 6000 individuals each year in their homes and following approximately 5000 individuals with a complete health examination. Since its inception, each successive NHANES has included changes or additions that make the survey more responsive as a measurement of the health status of the population. NHANES I to III included medical history, physical measurements, biochemical evaluation, physical signs and symptoms, and diet information using food frequency questionnaires and a 24-hour recall. Design changes added special population studies to increase information on underrepresented groups. NHANES III (1988 to 1994) included a large proportion of persons age 65 years and older. This information enhanced understanding of the growing and changing population of senior adults. Currently, reports are released in 2-year cycles. Sampling methodology is planned to oversample high-risk groups not previously covered adequately (low income, those older than the age of 60, African Americans, and Hispanic Americans). Information on NHANES including currently analyzed materials is cataloged at the CDC website.

Continuing Survey of Food Intake of Individuals: Diet and Health Knowledge Survey

The Continuing Survey of Food Intake of Individuals (CSFII) was a nationwide dietary survey instituted in 1985 by the USDA. In 1990 CSFII became part of the USDA National Nutrition Monitoring System. Information from previous surveys is available from the 1980s and 1990s. The Diet and Health Knowledge Survey (DHKS), a telephone follow-up to CSFII, began in 1989. The DHKS was designed as a personal interview questionnaire that allowed individual attitudes and knowledge about healthy eating to be linked with reported food choices and nutrient intakes. Early studies focused on dietary history and a 24-hour recall of dietary intake from adult men and women ages 19 to 50. The 1989 and 1994 surveys questioned men, women, and children of all ages and included a 24-hour recall (personal interview) and a 2-day food diary. Household data for these studies were determined by calculating the nutrient content of foods reported to be used in the home during the survey. These results were compared with nutrition recommendations for persons matching in age and gender. The information derived from the CSFII and DHKS is still useful for decision makers and researchers in monitoring the nutritional adequacy of American diets, measuring the effect of food fortification on nutrient intakes, tracking trends, and developing dietary guidance and related programs. In 2002 both surveys merged with NHANES to become the **National Food and Nutrition Survey (NFNS)**, or **What We Eat in America**.

National Food and Nutrition Survey: What We Eat in America

The integrated survey What We Eat in America is collected as part of NHANES. Food-intake data are linked to health status from other NHANES components, allowing for exploration of relationships

between dietary indicators and health status. The USDHHS is responsible for sample design and data, whereas the USDA is responsible for the survey's collection and maintenance of the dietary data. Data are released at 2-year intervals and are accessible from the NHANES website ([USDA, Agricultural Research Service, 2014](#)).

National Nutrition Monitoring and Related Research Act

In 1990 Congress passed Public Law 101-445, the **National Nutrition Monitoring and Related Research (NNMRR) Act**. The purpose of this law is to provide organization, consistency, and unification to the survey methods that monitor the food habits and nutrition of the U.S. population and to coordinate the efforts of the 22 federal agencies that implement or review nutrition services or surveys. Data obtained through NNMRR are used to direct research activities, develop programs and services, and make policy decisions regarding nutrition programs such as food labeling, food and nutrition assistance, food safety, and nutrition education. Reports of the various activities are issued approximately every 5 years and provide information on trends, knowledge, attitudes and behavior, food composition, and food supply determinants. They are available from the National Agricultural Library database.

National Nutrient Databank

The **National Nutrient Databank (NND)**, maintained by the USDA, is the United States' primary resource of information from private industry, academic institutions, and government laboratories on the nutrient content of foods. Historically the information was published as the series *Agriculture Handbook 8*. Currently, the databases are available to the public on tapes and on the Internet. The bank, which is updated frequently, is computer based and is currently available online at the USDA website. This databank is a standard source of nutrient information for commercial references and data systems on ingredients, raw and cooked products. When using sources other than the USDA site, clinicians should check the sources and the dates of the updates for evidence that these sources are reliable and current.

The Centers for Disease Control and Prevention

The CDC is a component of the USDHHS. It monitors the nation's health, detects and investigates health problems, and conducts research to enhance prevention. The CDC is also a source of information on health for international travel. Housed at CDC is the NCHS, which is the lead agency for NHANES, morbidity and mortality, BMI, and other health-related measures. Public health threats also are monitored by CDC.

NATIONAL NUTRITION GUIDELINES AND GOALS

Policy development describes the process by which society makes decisions about problems, chooses goals, and prepares the means to reach them. Such policies may include health priorities and dietary guidance.

Early dietary guidance had a specific disease approach. The 1982 National Cancer Institute (NCI) landmark report, *Diet, Nutrition and Cancer*, evolved into *Dietary Guidelines for Cancer Prevention*. These were updated and broadened in 2004, combining recommendations on energy balance, nutrition, and physical activity. The ACS and the American Institute for Cancer Research (AICR) are excellent resources along with materials from the NCI. Another federal agency, the National Heart, Lung, and Blood Institute, provided three sets of landmark guidelines for identifying and treating lipid disorders between 1987 and 2010.

AHA guidelines continue to focus on reducing risks for hypertension and coronary artery disease (see Chapter 32). The guidelines now

have a common focus on increasing the intake of fruits, vegetables, legumes, and nuts and recommend a Mediterranean diet pattern (see Appendix 24) or DASH plan (see Appendix 18).

Building on another consumer-friendly, single health guideline (5-a-Day for Better Health), the NCI, the National Institutes of Health (NIH), and the Produce for Better Health Foundation put a focus on fruits and vegetables in all forms (fresh, frozen, canned, dried). This guidance was built around the message that fruits and vegetables are naturally low in fat and good sources of fiber, several vitamins and minerals, and phytonutrients. In keeping with evidence-based messages, five to nine servings of fruits and vegetables a day are recommended to promote good health under the name of “Fruits and Veggies: More Matters” (Produce for Better Health Foundation, 2019). Understanding serving sizes that meets personal needs has become another key message. The *More Matters* banner continues as the branding for health guidelines and is an ongoing message for My Plate and the *Dietary Guidelines for Americans* (DGA) (U.S. Dietary Guidelines for Americans). In addition, this provides further support for incorporating a plant-based focus on health-supporting eating (Produce for Better Health Foundation, 2018).

The release of My Plate after the update on the DGA in 2010 made this a source of a strong and ongoing public health message with materials focusing across the life cycle, professional and consumer updates, and a robust social media presence (see Chapter 10).

Dietary Guidelines for Americans

Senator George McGovern and the Senate Select Committee on Nutrition and Human Needs presented the first *Dietary Goals* for the United States in 1977. In 1980 the goals were modified and issued jointly by the USDHHS and the USDA as the *Dietary Guidelines for Americans* (DGA). The original guidelines were a response to an increasing national concern for the rise in overweight, obesity, and chronic diseases such as diabetes, coronary artery disease, hypertension, and certain cancers. The approach continues to be one of health promotion and disease prevention, with special attention paid to specific and often underserved population groups (see Chapter 10).

The release of the DGA led the way for a synchronized message to the community. The common theme has been a focus on a diet lower in sodium and saturated fat, with emphasis on foods that are sources of fiber, complex carbohydrates, and lean or plant-based proteins. The message is based on food choices for optimal health using appropriate portion sizes and calorie choices related to a person's physiologic needs. Exercise, activity, and food safety guidance are standard parts of this dietary guidance. The current DGA are evidence based. The expert committee report provides scientific documentation that is used widely in health practice. The ongoing work for the next edition is continuing to support the need for evidence-based advice by validated experts. The DGA have become a central theme in community nutrition assessment, program planning, and evaluation; they are incorporated into programs such as the School Meals program and Congregate Meals for seniors. Updated every 5 years, the 2010–2015 revision, released in 2015, is currently undergoing discussions to formulate the next steps. Included are webinars and online meetings open to both professionals and the public to solicit input.

The 2010 DGA created the path for our current food guide, My Plate, and set the stage for programs such as More Matters to evolve. The 2015–2020 DGA are setting the stage for what will be released in 2020. Guidelines are continuing to move toward an emphasis on plant-based choices with a focus on inclusion of omega-3 and mono-unsaturated fats and on reducing added sugars and sodium (Dietary Guidelines 2015–2020). Since discussions are open to the public, nutrition professionals should monitor and provide input to the shaping of these guidelines. To access the portal for input contact the U.S. Dietary Guidelines website.

Food Guides

In 1916 the USDA initiated the idea of food grouping in the pamphlet *Food for Young Children*. Food grouping systems have changed in shape (wheels, boxes, pyramids, and plates) and numbers of groupings (four, five, and seven groups), but the intent remains consistent: to present an easy guide for healthful eating. In 2005 an Internet-based tool called *MyPyramid.gov: Steps to a Healthier You* was released. In 2011 *MyPyramid.gov* was replaced with My Plate (chooseMyPlate.gov) along with a version for children called chooseMyPlate.gov/kids. These food guidance systems focus on health promotion and disease prevention and are updated whenever DGA guidance changes. This program has become a leading public education resource. Resources available include downloadable tip sheets and a variety of resources for both the public and the educator.

Healthy People and the Surgeon General's Report on Nutrition and Health

The 1979 report of the Surgeon General, *Promoting Health/Preventing Disease: Objectives for the Nation*, outlined the prevention agenda for the nation with a series of health objectives to be accomplished by 1990. In 1988 *The Surgeon General's Report on Nutrition and Health* further stimulated health promotion and disease prevention by highlighting information on dietary practices and health status. Along with specific health recommendations, documentation of the scientific basis was provided. Because the focus included implications for the individual as well as for future public health policy decisions, this report remains a useful reference and tool. *Healthy People 2000: National Health Promotion and Disease Prevention Objectives* and *Healthy People 2010* were the next generations of these landmark public health efforts. Both reports outlined the progress made on previous objectives and set new objectives for the next decade.

During the evaluation phase for setting the 2010 objectives, it was determined that the United States made progress in reducing the number of deaths from cardiovascular disease, stroke, and certain cancers. Dietary evaluation indicated a slight decrease in total dietary fat intake. However, during the previous decade there has been an increase in the number of persons who are overweight or obese, a risk factor for cardiovascular disease, stroke, and other leading chronic diseases and causes of death.

Objectives for *Healthy People 2020* have specific goals that address nutrition and weight, heart disease and stroke, diabetes, oral health, cancer, and health for seniors. These goals are important for consumers and health care providers. The website for *Healthy People 2020* offers an opportunity to monitor the progress on past objectives as well as on the shaping of future health initiatives.

National School Lunch Program and School Breakfast Program

The National School Lunch Program (NSLP) and School Breakfast Program (SBP) are federal assistance programs that provide free or reduced-cost meals for low-income students in public schools and in nonprofit private residential institutions. These are administered at a state level through the education agencies that generally employ RDNs and registered dietetic technicians. In 1998 the program was expanded to include after-school snacks in schools with after-hours care. This program, along with backpack or weekend and summer programs, has continued to be expanded. Local community groups are often involved in expanding the reach to underserved populations.

Currently the guidelines for calories, percent of calories from fat, percent of saturated fat, and the amount of protein and key vitamins and minerals must meet the DGA, but there is ongoing evaluation and interpretation to stay in line with population needs. Efforts have been made to meet My Plate guidelines for whole grains, more fruits and vegetables, and skim or 1% milk. In addition, the issues of education of recipients to accept these foods and use of local foods and community gardens are evolving processes that are happening in communities.

A requirement for wellness policies in schools that participate in the NSLP and SBP is in place (USDA, Local School Wellness). The *School Nutrition Dietary Assessment Study IV*, a nationally representative study fielded during school year 2009–2010 to evaluate nutritional quality of children's diets, identified that most schools offered and served NSLP lunches and SBP met the School Meal Initiative (SMI) and DGA minimum levels of target nutrients. Progress was made on meeting the SMI standard for reducing fat. However, few schools offered or served meals that met all the SMI standards. Efforts continue on increasing whole grains, fresh fruits, and a greater variety of vegetables as well as reducing the level of fat and added sugars.

On December 14, 2010, the **Hunger-Free Kids Act** was signed into law. It expanded the after-school meal program, created a process for a universal meal program that allows schools with a high percentage of low-income children to receive meals at no charge, allowed states to increase WIC coverage from 6 months to 1 year, mandated WIC use electronic benefits by 2020, and improved the nutritional quality of foods served in school-based and preschool settings by developing new nutrition standards.

The Recommended Dietary Allowances and Dietary Reference Intakes

The recommended dietary allowances (RDAs) were developed in 1943 by the Food and Nutrition Board of the National Research Council of the National Academy of Sciences. The first tables were developed at a time when the U.S. population was recovering from a major economic depression and World War II; nutrient deficiencies were a concern. The intent was to develop intake guidelines that would promote optimal health and lower the risk of nutrient deficiencies. As the food supply and the nutrition needs of the population changed, the intent of the RDAs was adapted to prevention of nutrition-related disease. Until 1989 the RDAs were revised approximately every 10 years.

The RDAs always have reflected gender, age, and life-phase differences; there have been additions of nutrients and revisions of the age groups. However, recent revisions are a major departure from the single list some professionals still view as the RDAs. Beginning in 1998 an umbrella of nutrient guidelines known as the dietary reference intakes (DRIs) was introduced. Included in the DRIs are RDAs, as well as new designations including guidance on safe upper limits (ULs) of certain nutrients. As a group the DRIs are evaluated and revised at intervals, making these tools reflective of current research and population base needs (see Chapter 10).

FOOD ASSISTANCE AND NUTRITION PROGRAMS

Public health assurance addresses the implementation of legislative mandates, maintenance of statutory responsibilities, support of crucial services, regulation of services and products provided in the public and private sector, and maintenance of accountability. This includes providing for **food security**, which translates into having access to an adequate amount of healthful and safe foods.

Food security, or access by individuals to a readily available supply of nutritionally adequate and safe foods programs, is an ongoing challenge. The **Supplemental Nutrition Assistance Program (SNAP)**, formerly known as food stamps, along with food banks and pantries, home-delivered meals, child nutrition programs, supermarkets, and other food sources have been highlighted to focus on the issues of quality, access, and use. For example, research on neighborhood food access indicates that low availability of health-promoting food in area stores is associated with low-quality diets of area residents (Rose et al, 2010). See **Table 8.1** for a list of food and nutrition assistance programs. *Clinical Insight: The History of the Supplemental Nutrition Assistance Program (SNAP)* provides additional information on this program.

There is an ongoing movement to encourage goals emphasized in My Plate, to add more vegetables and fruits, to increase minimally processed

foods, and to increase education for SNAP recipients as well as other food and nutrition assistance programs. The presence of **food deserts** is a concept that has become a focus of research and community planning. **Food deserts** are described as neighborhoods and rural areas with limited access to fresh, healthy, affordable food. This is a definition that continues to be disputed and updated (USDA Food Dessert Locator). USDA has described it as a neighborhood where the nearest supermarket or grocery store is 1 to 3 miles away for urban residents and 10 miles for rural settings. One of the complicating factors of a description is that convenience stores, gas stations, all-purpose shopping areas and pharmacies, as well as home delivery sites, have included food in their offerings. What is real is the potential for food insecurity and for selections of health-promoting foods to be limited. The Economic Research Service (ERS) of the USDA estimated that in 2016, 12.3% of U.S. households (about 15.6 million households reaching over 41 million people) experienced food insecurity at some time during the year. Food insecurity is when lack of resources limits access to adequate food for all household members. SNAP, WIC, School Meals, Senior Meals were the resource for about 59% food-insecure households in 2016 (Oliveira, 2018). It is critical for the community-based RDN to have accurate and up-to-date knowledge on the specific community they serve.

FOODBORNE ILLNESS

The CDC has estimated that each year at least one in six Americans (or 48 million people) get sick, 128,000 are hospitalized, and 3000 die of foodborne diseases (**Table 8.2**). The majority of **foodborne illness** outbreaks reported to the CDC result from bacteria, followed by viral outbreaks, chemical causes, and parasitic causes. Segments of the population are particularly susceptible to foodborne illnesses; vulnerable individuals such as pregnant women and the elderly are more likely to become ill and experience complications. Availability of safe food access, storage, and preparation skills vary in populations and may not be predictable by national or even local guidance.

The 2000 edition of the DGA was the first to include food safety, important for linking the safety of the food and water supply with health promotion and disease prevention. This acknowledges the potential for foodborne illness to cause acute illness and long-term chronic complications. Since 2000 all revisions of the DGA have made food safety a priority. Persons at increased risk for foodborne illnesses include young children; pregnant women; older adults; persons who are immunocompromised because of human immunodeficiency virus or acquired immunodeficiency syndrome, steroid use, chemotherapy, diabetes mellitus, or cancer; alcoholics; persons with liver disease, decreased stomach acidity, autoimmune disorders, or malnutrition; persons who take antibiotics; and persons living in institutionalized settings. The latter includes those living in group home care settings. Costs associated with foodborne illness include those related to investigation of foodborne outbreaks and treatment of victims, employer costs related to lost productivity, and food industry losses related to lower sales and lower stock prices. **Table 8.2** describes common foodborne illnesses and their signs and symptoms, timing of onset, duration, causes, and prevention.

All food groups have ingredients associated with food safety concerns. There are concerns about microbial contamination of fruits and vegetables, especially those imported from other countries. An increased incidence of foodborne illness occurs with new methods of food production or distribution and with increased reliance on commercial food sources (AND, 2014). Improperly cooked meats can harbor organisms that trigger a foodborne illness. Even properly cooked meats have the potential to cause foodborne illness if the food handler allows raw meat juices to contaminate other foods during preparation. Sources of a foodborne illness outbreak vary, depending on such factors as the type of organism involved, the point of contamination, and the duration and temperature of food during holding.

TABLE 8.1 U.S. Food Assistance and Nutrition Programs

Program Name	Goal/Purpose	Services Provided	Target Audience	Eligibility	Funding	Level of Prevention*
After-School Snack Program	Provides reimbursement for snacks served to students after school	Provides cash reimbursement to schools for snacks served to students after the school day. Snacks must contain two of four components: fluid milk, meat/meat alternate, vegetable or fruit or full-strength juice, whole-grain or enriched bread.	Children younger than 18 whose school sponsor a structured, supervised after-school enrichment program and provide lunch through the NSLP	School programs located within the boundaries of eligible low-income areas may be reimbursed for snacks served at no charge to students.	USDA	Primary, secondary
Child and Adult Care Food Program	Provides nutritious meals and snacks to infants, young children, and adults receiving day care services, as well as infants and children living in emergency shelters	Provides commodities or cash to help centers serve nutritious meals that meet federal guidelines	Infants, children, and adults receiving day care at child-care centers, family day care homes, and homeless shelters		USDA FNS	Primary, secondary
Commodity Supplemental Food Program	Provides no-cost monthly supplemental food packages composed of commodity foods to populations perceived to be at nutritional risk	Provides food packages; nutrition education services are available often through extension service programs; program referrals provided	Generally children ages 5-6, postpartum non-breastfeeding mothers from 6-12 months' postpartum, seniors	Between 130% and 185% of the poverty guideline	USDA FNS	Primary, secondary
Disaster Feeding Program	Makes commodities available for distribution to disaster relief agencies	Commodities are provided to disaster victims through congregate dining settings and direct distribution to households.	Those experiencing a natural disaster	Those experiencing a natural disaster	USDA FNS	Primary
TEFAP	Commodities are made available to local emergency food providers for preparing meals for the needy or for distribution of food packages.	Surplus commodity foods are provided for distribution.	Low-income households	Low-income households at 150% of the federal poverty income guideline	USDA FNS	Primary
EFSP	Funds are used to purchase food and shelter to supplement and extend local services.	EFSP provides funding for the purchase of food products, operation costs associated with mass feeding and shelter, limited rent or mortgage assistance, providing assistance for first month's rent, limited off-site emergency lodging, and limited utility assistance.	Those in need of emergency services	Primary	FEMA	Primary
Head Start	Provides agencies and schools with support and guidance for half- and full-day child development programs for low-income children	Programs receive reimbursement for nutritious meals and snacks and USDA-donated commodities, support for curriculum, social services, and health screenings.	Low-income children ages 3-5; parents are encouraged to volunteer and be involved.	Same as NSLP	USDA (food) USDHHS (health)	Primary, secondary
National School Breakfast Program	Provides nutritionally balanced, low-cost or free breakfasts to children enrolled in participating schools	Participating schools receiving cash subsidies and USDA-donated commodities in return for offering breakfasts that meet same criteria as school lunch and offering free and reduced-price meals to eligible children.	Children preschool age through grade 12 in schools; children and teens 20 years of age in residential childcare and juvenile correctional institutions	Same as NSLP	USDA FNS	Primary, secondary
NSLP	Provides nutritionally balanced, low-cost or free lunches to children enrolled in participating schools	Participating schools receive cash subsidies and USDA-donated commodities in return for offering lunches that meet dietary guidelines and $\frac{1}{3}$ of RDA for protein, iron, calcium, vitamins A and C, and calories and for offering free and reduced-price meals to eligible children	Children preschool age through grade 12 in schools; children and teenagers 20 years of age and younger in residential childcare and juvenile correctional institutions	185% of federal poverty income guideline for reduced-price lunches; 130% for free lunches	USDA FNS	Primary, secondary

Nutrition Program for the Elderly/ Area Agencies on Aging	Provides commodity and cash assistance to programs providing meal services to older adults	Provides nutritious meals for older adults through congregate dining or home-delivered meals	Older adults	No income standard applied	USDHHS administers through state and local agencies; USDA cash and commodity assistance	Primary
Seniors' Farmers Market Nutrition Program	Provides fresh, nutritious, unprepared, locally grown fruits, vegetables, and herbs from farmers' markets, roadside stands, and community-supported agriculture programs to low-income seniors	Coupons for use at authorized farmers' markets, roadside stands, and community-supported agriculture programs (Foods that are not eligible for purchase with coupons by seniors are dried fruits or vegetables, potted plants and herbs, wild rice, nuts, honey, maple syrup, cider, and molasses.)	Low-income adults older than age 60	Low-income seniors with household incomes not exceeding 195% of the federal poverty income guideline	USDA FNS	Primary
SNAP	Provides benefits to low-income people that they can use to buy food to improve their diets	Provides assistance such as food stamps	Any age	For households in the 48 contiguous states and the District of Columbia. To get SNAP benefits, households must meet certain tests, including resource and income tests.	USDA FNS	Primary, secondary
Special Milk Program	Provides milk to children in participating schools who do not have access to other meal programs	Provides cash reimbursement for milk with vitamins A and D at RDA levels served at low or no cost to children; milk programs must be run on nonprofit basis.	Same target audience as school lunch and school breakfast programs	Eligible children do not have access to other supplemental foods programs.	USDA FNS	Primary, secondary
Summer Food Service Program	Provides healthy meals (per federal guidelines) and snacks to eligible children when school is out, using agriculture commodity foods	Reimburses for up to two or three meals and snacks served daily free to eligible children when school is not in session; cash based on income level of local geographic area or of enrolled children	Infants and children 18 years of age and younger served at variety of feeding sites		USDA FNS	Primary, secondary
WIC	Provides supplemental foods to improve health status of participants	Nutrition education, free nutritious foods (protein, iron, calcium, vitamins A and C), referrals, breastfeeding promotion	Pregnant, breastfeeding, and postpartum women up to 1 year; infants, children up to 5 yrs.	185% of federal poverty income guideline nutritional risk	USDA FNS, home state support	Primary, secondary, tertiary
WIC FMNP	Provides fresh, unprepared, locally grown fruits and vegetables to WIC recipients, and to expand the awareness, use of and sales at farmers' markets	FMNP food coupons for use at participating farmers' markets stands; nutrition education through arrangements with state agency	Same as WIC recipients	Same as WIC recipients	USDA FNS	Primary

*Level of prevention rationale: Programs that provide food only are regarded as primary; programs that provide food, nutrients at a mandated level of recommended dietary allowances, or an educational component are regarded as secondary; and programs that used health screening measures on enrollment were regarded as tertiary.

EFSP, Emergency Food and Shelter Program; *FEMA*, Federal Emergency Management Agency; *FMNP*, Farmers Market Nutrition Program; *FNS*, Food and Nutrition Service; *NSLP*, National School Lunch Program; *RDA*, recommended daily allowance; *SNAP*, Special Nutrition Assistance Program; *USDA*, U.S. Department of Agriculture; *USDHHS*, U.S. Department of Health and Human Services; *WIC*, Special Supplemental Nutrition Program for Women, Infants, and Children.

TABLE 8.2 Common Foodborne Illnesses

Illness	Signs and Symptoms	Onset and Duration	Causes and Prevention	Comments
<i>Bacillus cereus</i>	Watery diarrhea, abdominal cramping, and vomiting	6-15 hours after consumption of contaminated food; duration 24 hours in most instances	Meats, milk, vegetables, and fish have been associated with the diarrheal type; vomiting-type outbreaks have generally been associated with rice products; potato, pasta, and cheese products; food mixtures such as sauces, puddings, soups, casseroles, pastries, and salads may also be a source.	<i>B. cereus</i> is a gram-positive, aerobic spore former.
<i>Campylobacter jejuni</i>	Diarrhea (often bloody), fever, and abdominal cramping	2-5 days after exposure; duration 2-10 days	Drinking raw milk or eating raw or undercooked meat, shellfish, or poultry; to prevent exposure, avoid raw milk and cook all meats and poultry thoroughly; it is safest to drink only pasteurized milk; the bacteria also may be found in tofu or raw vegetables. Hand-washing is important for prevention; wash hands with soap before handling raw foods of animal origin, after handling raw foods of animal origin, and before touching anything else; prevent cross-contamination in the kitchen; proper refrigeration and sanitation are also essential.	Top source of foodborne illness; some people develop antibodies to it, but others do not. In persons with compromised immune systems, it may spread to the bloodstream and cause sepsis; may lead to arthritis or to GBS; 40% of GBS in the United States is caused by campylobacteriosis and affects the nerves of the body, beginning several weeks after the diarrheal illness; can lead to paralysis that lasts several weeks and usually requires intensive care.
<i>Clostridium botulinum</i>	Muscle paralysis caused by the bacterial toxin: double or blurred vision, drooping eyelids, slurred speech, difficulty swallowing, dry mouth, and muscle weakness; infants with botulism appear lethargic, feed poorly, are constipated, and have a weak cry and poor muscle tone	In foodborne botulism symptoms generally begin 18-36 hours after eating contaminated food; can occur as early as 6 hours or as late as 10 days; duration days or months	Home-canned foods with low acid content such as asparagus, green beans, beets, and corn; outbreaks have occurred from more unusual sources such as chopped garlic in oil, hot peppers, tomatoes, improperly handled baked potatoes wrapped in aluminum foil, and home-canned or fermented fish. Persons who home-can should follow strict hygienic procedures to reduce contamination of foods; oils infused with garlic or herbs should be refrigerated; potatoes that have been baked while wrapped in aluminum foil should be kept hot until served or refrigerated; because high temperatures destroy the botulism toxin, persons who eat home-canned foods should boil the food for 10 minutes before eating.	If untreated, these symptoms may progress to cause paralysis of the arms, legs, trunk, and respiratory muscles; long-term ventilator support may be needed. Throw out bulging, leaking, or dented cans and jars that are leaking; safe home-canning instructions can be obtained from county extension services or from the U.S. Department of Agriculture; honey can contain spores of <i>C. botulinum</i> and has been a source of infection for infants; children younger than 12 months old should not be fed honey.
<i>Clostridium perfringens</i>	Nausea with vomiting, diarrhea, and signs of acute gastroenteritis lasting 1 day	Within 6-24 hours from the ingestion	Ingestion of canned meats or contaminated dried mixes, gravy, stews, refried beans, meat products, and unwashed vegetables. Cook foods thoroughly; leftovers must be reheated properly or discarded.	
<i>Cryptosporidium parvum</i>	Watery stools, diarrhea, nausea, vomiting, slight fever, and stomach cramps	2-10 days after being infected	Contaminated food from poor handling. Hand washing is important.	Protozoa causes diarrhea among immune-compromised patients.
Enterotoxigenic <i>Escherichia coli</i> (ETEC)	Watery diarrhea, abdominal cramps, low-grade fever, nausea, and malaise	With high infective dose, diarrhea can be induced within 24 hours	Contamination of water with human sewage may lead to contamination of foods; infected food handlers may also contaminate foods; dairy products such as semisoft cheeses may cause problems, but this is rare.	More common with travel to other countries; in infants or debilitated elderly persons, electrolyte replacement therapy may be necessary.

TABLE 8.2 Common Foodborne Illnesses—cont'd

Illness	Signs and Symptoms	Onset and Duration	Causes and Prevention	Comments
Escherichia coli O157:H7 Enterohemorrhagic E. coli (EHEC)	Hemorrhagic colitis (painful, bloody diarrhea)	Onset is slow, usually approximately 3-8 days after ingestion; duration 5-10 days	Undercooked ground beef and meats, from unprocessed apple cider, or from unwashed fruits and vegetables; sometimes water sources; alfalfa sprouts, unpasteurized fruit juices, dry-cured salami, lettuce, spinach, game meat, and cheese curds Cook meats thoroughly, use only pasteurized milk, and wash all produce well.	Antibiotics are not used because they spread the toxin further; the condition may progress to hemolytic anemia, thrombocytopenia, and acute renal failure, requiring dialysis and transfusions; HUS can be fatal, especially in young children; there are several outbreaks each year, particularly from catering operations, church events, and family picnics; E. coli O157:H7 can survive in refrigerated acid foods for weeks
Listeria monocytogenes (LM)	Mild fever, headache, vomiting, and severe illness in pregnancy; sepsis in the immunocompromised patient; meningoencephalitis in infants; and febrile gastroenteritis in adults	Onset 2-30 days; duration variable	Processed, ready-to-eat products such as undercooked hot dogs, deli or lunchmeats, and unpasteurized dairy products; post-pasteurization contamination of soft cheeses such as feta or Brie, milk, and commercial coleslaw; cross-contamination between food surfaces has also been a problem. Use pasteurized milk and cheeses; wash produce before use; reheat foods to proper temperatures; wash hands with hot, soapy water after handling these ready-to-eat foods; discard foods by their expiration dates.	May be fatal Caution must be used by pregnant women, who may pass the infection on to their unborn child.
Norovirus	Gastroenteritis with nausea, vomiting, and/or diarrhea accompanied by abdominal cramps; headache, fever/chills, and muscle aches also may be present.	24-48 hours after ingestion of the virus, but can appear as early as 12 hours after exposure	Foods can be contaminated either by direct contact with contaminated hands or work surfaces that are contaminated with stool or vomit or by tiny droplets from nearby vomit that can travel through air to land on food; although the virus cannot multiply outside of human bodies, once on food or in water, it can cause illness; most cases occur on cruise ships.	Symptoms are usually brief and last only 1 or 2 days; however, during that brief period, people can feel very ill and vomit, often violently and without warning, many times a day; drink liquids to prevent dehydration.
Salmonella	Diarrhea, fever, and abdominal cramps	12-72 hours after infection; duration usually 4-7 days	Ingestion of raw or undercooked meat, poultry, fish, eggs, unpasteurized dairy products; unwashed fruits and raw vegetables (melons and sprouts) Prevent by thorough cooking, proper sanitation, and hygiene.	There are many different kinds of Salmonella bacteria; S. typhimurium and S. enteritidis are the most common in the United States. Most people recover without treatment, but some have diarrhea that is so severe that the patient needs to be hospitalized; this patient must be treated promptly with antibiotics; the elderly, infants, and those with impaired immune systems are more likely to have a severe illness.
Shigellosis	Bloody diarrhea, fever, and stomach cramps	24-48 hours after exposure; duration 4-7 days	Milk and dairy products; cold mixed salads such as egg, tuna, chicken, potato, and meat salads Proper cooking, reheating, and maintenance of holding temperatures should aid in prevention; careful hand washing is essential.	This is caused by a group of bacteria called Shigella; it may be severe in young children and the elderly; severe infection with high fever may be associated with seizures in children younger than 2 years old.

Continued

TABLE 8.2 Common Foodborne Illnesses—cont'd

Illness	Signs and Symptoms	Onset and Duration	Causes and Prevention	Comments
<i>Staphylococcus aureus</i>	Nausea, vomiting, retching, abdominal cramping, and prostration	Within 1-6 hours; rarely fatal; duration 1-2 days	Meat, pork, eggs, poultry, tuna salad, prepared salads, gravy, stuffing, cream-filled pastries Cooking does not destroy the toxin; proper handling and hygiene are crucial for prevention.	Refrigerate foods promptly during preparation and after meal service.
<i>Streptococcus pyogenes</i>	Sore and red throat, pain on swallowing; tonsillitis, high fever, headache, nausea, vomiting, malaise, rhinorrhea; occasionally a rash occurs	Onset 1-3 days	Milk, ice cream, eggs, steamed lobster, ground ham, potato salad, egg salad, custard, rice pudding, and shrimp salad; in almost all cases, the foodstuffs were allowed to stand at room temperature for several hours between preparation and consumption.	Entrance into the food is the result of poor hygiene, ill food handlers, or the use of unpasteurized milk. Complications are rare; treated with antibiotics.
<i>Vibrio vulnificus</i>	Vomiting, diarrhea, or both; illness is mild	Gastroenteritis occurs about 16 hours after eating contaminated food; duration about 48 hours	Seafood, especially raw clams and oysters, that has been contaminated with human pathogens; although oysters can only be harvested legally from waters free from fecal contamination, even these can be contaminated with <i>V. vulnificus</i> because the bacterium is naturally present.	This is a bacterium in the same family as those that cause cholera; it yields a Norovirus; it may be fatal in immunocompromised individuals.
<i>Yersinia enterocolitica</i>	Common symptoms in children are fever, abdominal pain, and diarrhea, which is often bloody; in older children and adults, right-sided abdominal pain and fever may be predominant symptom and may be confused with appendicitis.	1-2 days after exposure; duration 1-3 weeks or longer	Contaminated food, especially raw or undercooked pork products; postpasteurization contamination of chocolate milk, reconstituted dry milk, pasteurized milk, and tofu are also high-risk foods; cold storage does not kill the bacteria. Cook meats thoroughly; use only pasteurized milk; proper hand washing is also important.	Infectious disease caused by the bacterium <i>Yersinia</i> ; in the United States most human illness is caused by <i>Y. enterocolitica</i> ; it most often occurs in young children. In a small proportion of cases, complications such as skin rash, joint pains, or spread of bacteria to the bloodstream can occur.

GBS, Guillain-Barré Syndrome; *HUS*, hemolytic uremic syndrome.

CLINICAL INSIGHT

The History of the Supplemental Nutrition Assistance Program (SNAP)

In the years after World War II, hunger and extreme malnutrition was a serious and pervasive problem in the United States. By the mid-1960s, one fifth of American households had poor diets. Among low-income households, this rate nearly doubled to 36% (United States Department of Agriculture [USDA] and Agricultural Research Service [ARS], 1969). According to studies at the time, these rates of hunger, especially in low-income areas of the South, had a serious effect on the public at the time because of malnutrition and vitamin deficiency (Wheeler, 1967). Many Americans learned how serious the problem was in their living rooms when CBS News aired a landmark documentary, *Hunger in America*, in 1968. The documentary featured malnourished children with distended bellies and stories from everyday people about how hunger affected their lives—something that other Americans couldn't believe was happening in their backyard (Center on Budget and Policy Priorities, November 2008). A public outcry resulted in the federal government's modern nutrition assistance system that began in the early 1960s as the Food Stamp program. Originally created as a small program during World War II to help bridge the gap between plentiful farm surpluses and urban hunger, it was discontinued in the 1950s because of the prosperous economy. President John F. Kennedy reintroduced it through an executive order in 1961 as a broader pilot program. As part of President Lyndon B. Johnson's War on

Poverty initiative, Congress finally made it permanent. It has since been reauthorized and strengthened several times and is today known as the Supplemental Nutrition Assistance Program (SNAP) (USDA Food and Nutrition Service [FNS], 2010). Another important supplemental food program is for Women, Infants, and Children (WIC) and was developed in the 1970s to provide specialized nutrition assistance and support to low-income pregnant women, infants, and children up to age 5 (USDA and Economic Research Service [ERS], 2009).

In 2013 SNAP helped more than 47 million Americans afford a nutritionally adequate diet in a typical month. It also kept about 4.9 million people out of poverty in 2012, including 1.3 million children (Center on Budget and Policy Priorities, 2015). A recent study has shown that after these expansions in the 1960s and 1970s, disadvantaged children with access to nutrition assistance in early childhood and who had mothers that received assistance during pregnancy, had improved health and education outcomes, better growth curves, and fewer diagnoses of heart disease and obesity (Hoynes et al, 2012). Today, state agencies administering SNAP have the option of providing nutrition education to SNAP participants through federal grants and matching fund programs (USDA, 2017).

Erik R. Stegman, MA, JD

Targeted food safety public education campaigns are important. However, the model for food safety has expanded beyond the individual consumer and now includes the government, the food industry, the food growers, and the general public. Several government agencies provide information through websites with links to the CDC, the USDA Food Safety and Inspection Service (FSIS), the Environmental Protection Agency (EPA), the National Institute of Allergy and Infectious Diseases (NIAID), and the Food and Drug Administration (FDA). A leading industry program, ServSafe, provides food safety and training certification and was developed and administered by the National Restaurant Association. Because the U.S. food supply comes from a global market, food safety concerns are worldwide. The 2009 Country of Origin Labeling (COOL) legislation requires that retailers provide customers with the source of foods such as meats, fish, shellfish, fresh and frozen fruits and vegetables, and certain nuts and herbs (USDA, 2013). The USDA Agricultural Marketing Service has responsibility for COOL implementation. Future practice must include awareness of global food safety issues (see *Focus On: Global Food Safety*).

Hazard Analysis Critical Control Points

An integral strategy to reduce foodborne illness is risk assessment and management. **Risk assessment** entails hazard identification, characterization, and exposure. **Risk management** covers risk evaluation, option assessment and implementation, and monitoring and review of progress. One formal program, organized in 1996, is the **Hazard Analysis Critical Control Points (HACCP)**, a systematic approach to the identification, evaluation, and control of food safety hazards. HACCP involves identifying any biologic, chemical, or physical agent that is likely to cause illness or injury in the absence of its control. It also involves identifying points at which control can be applied, thus preventing or eliminating the food safety hazard or reducing it to an acceptable level. Restaurants and health care facilities are obligated to use HACCP procedures in their food handling practices.

FOCUS ON

Global Food Safety

The United States imports produce, meat, and seafood from other countries to meet the consumer demands for foods that are not readily available in the country. Global importation creates potential danger to the public. Our current food supply is becoming much harder to trace to a single source. Because of this, safety concerns must be addressed globally, as well as in the United States. Leadership from food growers, producers, distributors, and those involved in food preparation is essential to ensure a safe food supply. Protecting the food supply chain requires several safety management systems such as hazard analysis, critical control points, good manufacturing practice, and good hygiene practice. Food safety also includes attention to issues such as the use of toxins and pesticides in countries where standards and enforcement may be variable, as well as the importance of clean water. Finally, the effect of global warming on food production is an increasing concern.

Those who serve populations at the greatest risk for foodborne illness have a special need to be involved in the network of food safety education and to communicate this information to their clients (Fig. 8.2). Adoption of the HACCP regulations, food quality assurance programs, handling of fresh produce guidelines, technologic advances designed to reduce contamination, increased food supply regulations, and a greater emphasis on food safety education have contributed to a substantial decline in foodborne illness.

FOOD AND WATER SAFETY

Although individual educational efforts are effective in raising awareness of food safety issues, food and water safety must be examined on a national, systems-based level (AND, 2014). Several federal health initiatives include objectives relating to food and water safety, pesticide and allergen exposure, food-handling practices, reducing disease incidence associated with water, and reducing food- and water-related exposure to environmental pollutants. Related agencies can be found in Table 8.3.

Contamination

Controls and precautions concerning limiting potential contaminants in the water supply are of continuing importance. Water contamination with arsenic, lead, copper, pesticides and herbicides, mercury, dioxin, polychlorinated biphenyls (PCBs), chlorine, and *Escherichia coli* continues to be highlighted by the media. Lead has become a major concern in some areas due to old water pipes and plumbing. It was estimated that many public water systems, built using early twentieth-century technology, will need to invest more than \$138 billion during the next 20 years to ensure continued safe drinking water (AND, 2014). The aging infrastructure has become an ongoing concern in older urban areas. The effect on the potential safety of food and drinks (including baby formula requiring water to be added) that have contact with these contaminants is an ongoing issue being monitored by advocacy and professional groups and governmental agencies.

Of interest to many is the issue of the potential hazards of ingestion of seafood that has been in contact with methyl mercury present naturally in the environment and released into the air from industrial pollution. Mercury has accumulated in bodies of water (i.e., streams, rivers, lakes, and oceans) and in the flesh of seafood in these waters (USDA and EPA, n.d.). The body of knowledge on issues such as this is being updated constantly, and current recommendations are to restrict the consumption of certain fish such as shark, mackerel, tilefish, tuna, and swordfish by pregnant women (FDA, 2013; Centers for Food Safety and Applied Nutrition et al, 2013). (See Chapter 14 for further discussion.) Other contaminants in fish, such as PCBs and dioxin, are also of concern (California Office of Environmental Health Hazard Assessment [OEHHA], 2014). Disposal of plastic containers and water bottles are another ongoing issue that merits researching the effect to the fishing industry and the consumer and the steps being taken.

Precautions are in place at the federal, state, and local levels that must be addressed by nutrition and dietetics professionals whose roles include advocacy, communication, and education. Members of the public and local health officials must understand the risks and the importance of carrying out measures for food and water safety and protection. The EPA and the Center for Food Safety and Applied Nutrition (CFSAN) provide ongoing monitoring and guidance. In addition, food and water safety and foodborne illness issues are monitored by state and local health departments.

Organic Foods and Pesticide Use

The use of pesticides and contaminants from the water supply affect produce quality. The debate continues about whether organic foods are worth the extra cost. However, the beneficial effects of organic farming also must be considered (see *Focus On: Is It Really Organic, and Is It Healthier?*).

Genetic Modification/Genetic Engineering

An emerging safety issue is that of **genetically modified organisms (GMOs)**. A GMO is a plant or animal in which the genetic material has been altered in a way that does not occur naturally. The process of

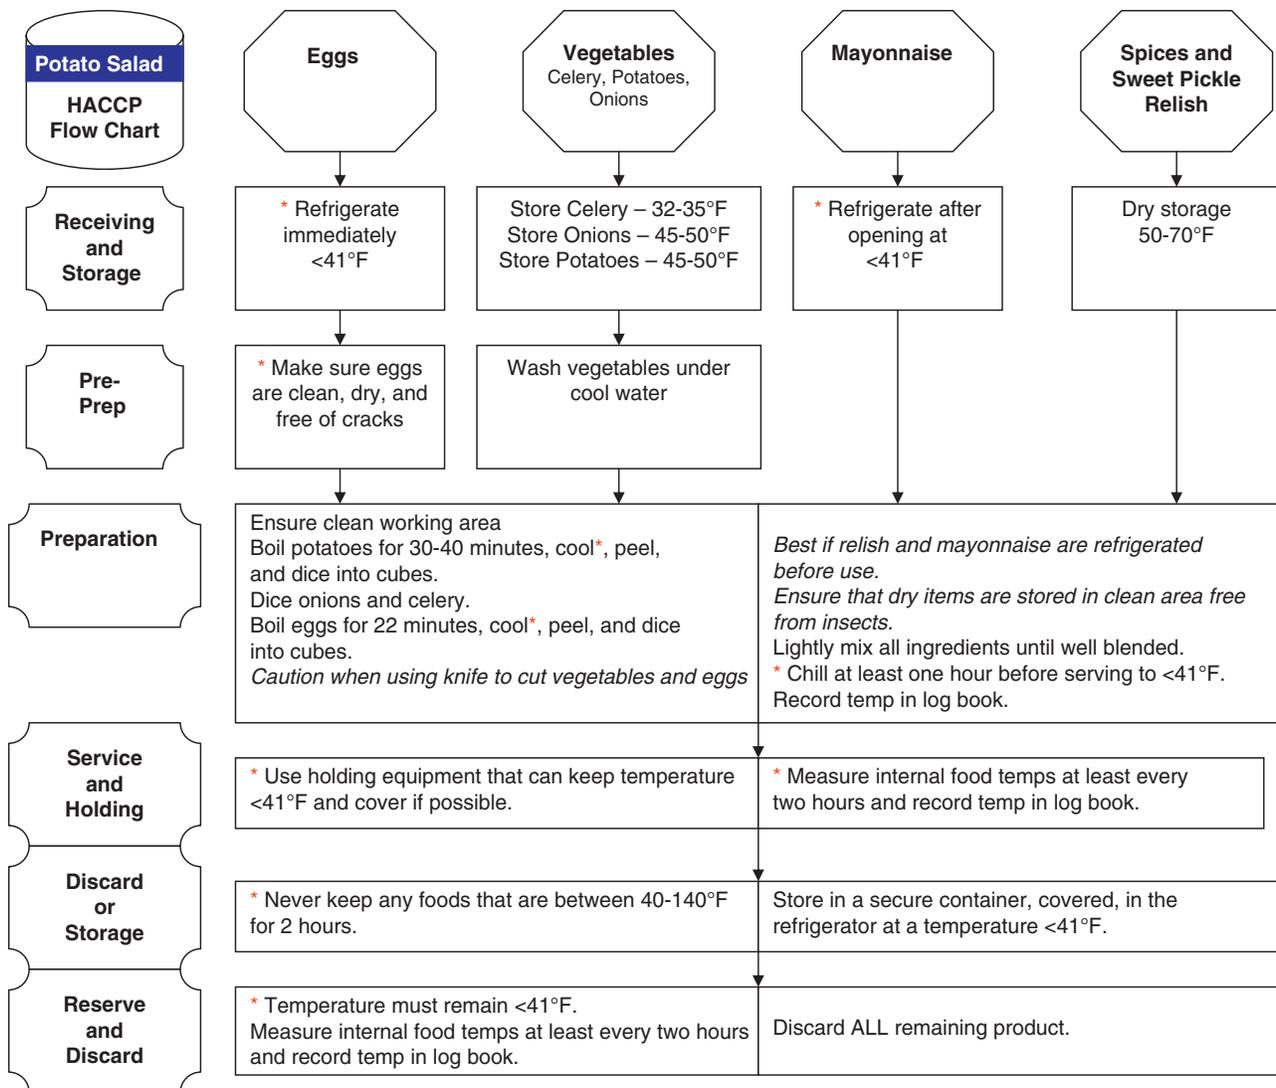

Fig. 8.2 The Six Steps of HACCP and a sample flow chart.

making GMOs is called genetic engineering (GE). The most recent data from the International Service for the Acquisition of Agri-biotech Applications shows that more than 18 million farmers in 26 countries—including 19 developing nations—planted over 185 million hectares (457 million acres) of GMO crops in 2016. This is a 3% increase over 2015. More than 26 countries have total or partial bans on the use of GMO crops and they remain controversial in the United States. Currently labeling of GMO/GE foods is voluntary, but there continues to be public demand to require it be labeled. The FDA is studying the issue. Once again, this is an issue that should be on the monitoring list of nutrition and dietetics professionals to be alert to valid and current research.

Bioterrorism and Food-Water Safety

Bioterrorism is the deliberate use of microorganisms or toxins from living organisms to induce death or disease. Threats to the nation's food and water supplies have made food **biosecurity**, or precautions to minimize risk, an issue when addressing preparedness planning. The CDC has identified seven foodborne pathogens as having the potential to be used by bioterrorists to attack the food supply: tularemia, brucellosis, *Clostridium botulinum* toxin, epsilon toxin of

Clostridium perfringens, *Salmonella*, *Escherichia coli*, and *Shigella*. These pathogens, along with potential water contaminants, such as mycobacteria, *Legionella*, *Giardia*, viruses, arsenic, lead, copper, methyl butyl ether, uranium, and radon, are the targets of federal systems put in place to monitor the safety of the food and water supply. Current surveillance systems are designed to detect foodborne illness outbreaks resulting from food spoilage, poor food handling practices, or other unintentional sources, but they were not designed to identify an intentional attack.

Consequences of a compromised food and water supply are physical, psychological, political, and economic. Compromise could occur with food being the primary agent such as a vector to deliver a biologic or chemical weapon or with food being a secondary target, leaving an inadequate food supply to feed a region or the nation. Intentional use of a foodborne pathogen as the primary agent may be mistaken as a routine outbreak of foodborne illness. Distinguishing normal illness fluctuation from an intentional attack depends on having in place a system for identification, preparedness planning, rapid communication, and central analysis. FDA has organized information for **food defense**, or protecting the food and water supply from deliberate attacks. (FDA, 2018).

FOCUS ON

Is It Really Organic, and Is It Healthier?

There are a variety of reasons why organic foods can be considered as facilitating the creation of a healthful, sustainable food system (McCullum-Gómez and Scott, 2009; Scialabba, 2013). First, some organic fruits, vegetables, and juices may contain more antioxidants and polyphenols compared with their conventionally grown counterparts (Barański et al, 2014), although there is an ongoing debate regarding the potential nutritional advantages of consuming organic versus conventional fruits and vegetables and other plant products (Barański et al, 2014; Smith-Spangler et al, 2012). Other researchers reported that organic soybeans contain significantly more total protein and zinc, and less saturated fat and total omega-6 fatty acids than conventional and genetically engineered soybeans (Böhn et al, 2014). Second, organically raised meat may reduce the development of human antibiotic resistance and lessen air and water pollution (American Medical Association, 2009). Researchers have found a lower prevalence of antibiotic-resistant *Salmonella* (Sapkota et al, 2014) and antibiotic-resistant Enterococci (Sapkota et al, 2011) on U.S. conventional poultry farms that transitioned to organic practices. Third, a published meta-analysis (Palupi et al, 2012) found that organic dairy products contained significantly higher protein, total omega-3 fatty acids, and conjugated linoleic acid than those of conventional types. Another study reported that individual omega-3 fatty acid concentrations and the concentration of conjugated linoleic acid were higher in organic milk (Benbrook et al, 2013). In an ongoing cohort study, consumption of organic dairy products was associated with a lower risk of eczema during the first 2 years of life. These authors hypothesize that “a high intake of omega-3 fatty acids and/or conjugated linoleic acids from organic dairy products by the child is protective against eczema (independent of atopy) and that . . . the mother’s intake of these fatty acids during pregnancy and lactation contributes

to this protection” (Kummeling et al, 2008). More recent research found that cows fed a 100% organic grass- and legume-based diet produce milk with elevated levels of omega-3 fatty acids and conjugated linoleic acid, thus providing a healthier balance of fatty acids (Benbrook et al, 2018).

Fortunately, organic foods are increasing their presence in the marketplace. Organic sales account for over 4% of total U.S. food sales, although organic products account for a much larger share in some food product categories. Certified organic acreage and livestock have been expanding in the U.S., particularly for fruits, vegetables, dairy, and poultry (Greene, 2014). In 2017 organic sales totaled 49.4 billion dollars with fruits and vegetables accounting for 16.5 billion dollars (McNeil, 2018). These foods are produced following practices described in the USDA National Organic Program (NOP), a marketing program with a certification process throughout the production and manufacturing chain, which describes the practices that are required for labeling a product “organic” (USDA, n.d.). Organic foods that are certified through the USDA NOP must also meet the same state and federal food safety requirements as nonorganic foods (Riddle and Markhart, 2010).

In organic farming, raw animal manure must be composted (§205.203), “unless it is: i) applied to land used for a crop not intended for human consumption; ii) incorporated into the soil not less than 120 days before the harvest of a product whose edible portion has direct contact with the soil surface or soil particles; or iii) incorporated into the soil not less than 90 days before the harvest of a product whose edible portion does not have direct contact with the soil surface or soil particles” (Electronic Code of Federal Regulations, Title 7: Agriculture, Part 205 – National Organic Program, 2017).

Organic agriculture offers numerous opportunities to reduce exposure to agricultural pesticides through the community food and water supply, which may

Continued

Is It Really Organic, and Is It Healthier?—cont'd

be detrimental to human health—particularly for high-risk groups including pregnant women, infants, young children, farmers, and farmworkers (American College of Obstetricians and Gynecologists Committee Opinion, 2013; Costa et al, 2014; Misiewicz and Shade, 2018). Long-term/low-dose exposure to pesticides has also been linked to neurodegenerative diseases such as Parkinson's disease and Alzheimer's disease (Baltazar et al, 2014). Studies with children reveal that there are dramatic reductions in organophosphate (OP) pesticide exposure with the consumption of organic food (Lu et al, 2008). Research with adults found that the consumption of an organic diet for 1 week significantly reduced OP pesticide exposure. These authors recommend consumption of organic food as a precautionary approach to reducing pesticide exposure (Oates et al, 2014). More recently, researchers compared French adults who frequently consumed organic foods to those who never consumed organic foods and found a 25% reduction in overall cancer risk. More specifically, eating an organic diet significantly reduces the risk of developing non-Hodgkin lymphoma (86%),

all lymphomas (76%), and postmenopausal breast cancer (34%) (Baudry et al, 2018).

Organically grown foods also promote a more sustainable food system by reducing energy requirements for production, impacting local economic development, reducing soil erosion, rehabilitating poor soils, and sequestering carbon in soil, which may reduce carbon levels in the atmosphere (Gattinger et al, 2012; Jaenicke, 2016; Scialabba, 2013; Williams et al, 2017). In addition, biodiversity is enhanced in organic agricultural systems (Tuck et al, 2014), which makes these farms more resilient to unpredictable weather patterns and pest outbreaks. Organic farming also favors insect-pollinated for species richness and flower cover, presumably due to the lack of herbicide use (Happe et al, 2018). Finally, public investment in organic agriculture facilitates wider access to organic food for consumers, helps farmers capture high-value markets, and conserves natural resources including soil and water.

by Christine McCullum-Gomez, PhD, RDN

Experience with the series of hurricanes in 2005 emphasized the need to provide access to a safe food and water supply after emergencies and disasters. Access to food and water may be limited, which results in social disruption and self-imposed quarantine. These situations require a response different from the traditional approach to disaster relief, during which it is assumed that hungry people will seek assistance and have confidence in the safety of the food that is offered. In the event of a disaster, dietetics professionals can play a key role by being aware of their environment, knowing available community and state food and nutrition resources, and participating in coordination and delivery of relief to victims of the disaster.

DISASTER PLANNING

Dietetics and health professionals working in food service are expected to plan for the distribution of safe food and water in any emergency situation. This may include creating and choosing food preparation and distribution sites, establishing temporary kitchens, preparing foods with limited resources, and keeping prepared food safe to eat through HACCP procedures. One of the most vulnerable groups is infants. The American Academy of Pediatrics has guidelines for infant feeding during disasters (<https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Breastfeeding/Documents/InfantNutritionDisaster.pdf>).

Planning, surveillance, detection, response, and recovery are the key components of public health disaster preparedness. The key agencies are the USDA, the **Department of Homeland Security (DHS)**, the **Federal Emergency Management Agency (FEMA)**, the CDC, and the FDA. In conjunction with DHS, USDA operates Protection of the Food Supply and Agricultural Production (PFSAP). PFSAP handles issues related to food production, processing, storage, and distribution. It addresses threats against the agricultural sector and border surveillance. PFSAP conducts food safety activities concerning meat, poultry, and egg inspection and provides laboratory support, research, and education on outbreaks of foodborne illness.

Ready.gov of the DHS is an education toolkit on how to prepare for a national emergency, including possible terrorist attacks. In addition, the USDA Food Safety and Inspection Service (FSIS) operates the Food Threat Preparedness Network (PrepNet) and the Food Biosecurity Action Team (F-Bat). PrepNet ensures effective coordination of food security efforts, focusing on preventive activities to protect the food supply. F-Bat assesses potential vulnerabilities along the farm-to-table continuum, provides guidelines to industry on food security and increased plant

security, strengthens FSIS's coordination and cooperation with law enforcement agencies, and enhances security features of FSIS laboratories (Bruemmer, 2003).

CDC has three operations relating to food security and disaster planning: PulseNet, FoodNet, and the Centers for Public Health Preparedness. PulseNet is a national network of public health laboratories that performs deoxyribonucleic acid fingerprinting on foodborne bacteria, assists in detecting foodborne illness outbreaks and tracing them back to their source, and provides linkages among sporadic cases. FoodNet is the Foodborne Diseases Active Surveillance Network, which functions as the principle foodborne disease component of the CDC's Emerging Infections Program, providing active laboratory-based surveillance. The Centers for Public Health Preparedness fund academic centers linking schools of public health with state, local, and regional bioterrorism preparedness and public health infrastructure needs.

CFSAN in the FDA is concerned with regulatory issues such as sea-food HACCP, safety of food and color additives, safety of foods developed through biotechnology, food labeling, dietary supplements, food industry compliance, and regulatory programs to address health risks associated with foodborne chemical and biologic contaminants. CFSAN also runs cooperative programs with state and local governments.

FEMA, under the DHS, provides emergency support functions after a disaster or emergency. FEMA identifies food and water needs, arranges delivery, and provides assistance with temporary housing and other emergency services. Agencies that assist FEMA include the USDA, the Department of Defense, the USDHHS, the EPA, and the General Services Administration. Major players include nonprofit volunteer agencies such as the American Red Cross, the Salvation Army, and community-based agencies and organizations. Disaster management is evolving as it is tested by manufactured and natural disasters.

HEALTHY FOOD AND WATER SYSTEMS AND SUSTAINABILITY

This chapter began with a note that community nutrition is a constantly evolving and growing area of practice with the broad focus of serving the population at large with a thrust to be proactive and responsive to the needs of the community. Today's communities and community needs differ, but regardless of environmental, social, and geographic variations, a goal of all nutrition and dietetics professionals is to promote and sustain access to safe, affordable, and health-promoting food sources.

In 2014 the Academy of Nutrition and Dietetics issued *Standards of Professional Performance* that addressed building and supporting sustainable, resilient, and healthy food and water systems (AND, 2014). These standards are meant to provide guidance to every RDN beyond the usual safety standards. This paper identifies sustainability as the ability to maintain the system for the long term. Resilience means a system can withstand interruptions that occur. From a community nutrition aspect, a practical example of resilience is that standards are in place for access to health-supporting and safe food and water even after a flood, natural disaster, or funding interruption. The sustainability is rooted in how the system is built, guided, and nourished. Public and private programs and resources are critical components and must meet the tests of resiliency to be sustainable to meet funding requirements.

The safety, adequacy, and quality of the food and water supply along with energy sources are components that build sustainability and resiliency. The nutrition and dietetics professional can be a major player but must have the expertise and competency as well as the initiative to build as well as promote standards and conditions in which people can reach the goal of being healthy.

SUMMARY: A WORK IN PROGRESS

This chapter is a work in progress, a snapshot of the evolving world of community nutrition that is changing even faster with Internet access. Changes are inherent in food, health, food access and safety, and our global environment. The nutrition and dietetics professional is an important player but needs to be current; engaged; and alert to legitimacy, science, and currency of sources. Networking with other community professionals, agencies, schools, universities, and organizations can provide both access and resources. However, as nutrition and dietetics professionals, decisions and actions need to be defensible as meeting both ethical and science-based standards. This means seeking updated and science-based sources and resources.

Nutrition Diagnosis and Intervention

The type of nutrition care provided to an individual or population varies depending on the findings of the assessment process (step one of the nutrition care process). The environment, surgery or trauma, food allergies, inadequate access to safe or sufficient food, stage of growth and development, harmful beliefs, lack of knowledge, and socioeconomic issues can all affect whether an individual or population maintains adequate nutrition status. In the healthy individual or population, omission of a specific food group or intake of high-energy, nutrient-poor foods does not lead to failed nutritional status overnight. It is the prolonged imbalanced intake that leads to chronic disease. Dramatic and acute insufficiency combined with acute disease also leads to undesirable nutritional consequences. Indeed, inadequacy of the types or amounts of macro- or micronutrients, fluid, or even physical activity may cause a decline in health status or immunity and dysfunction and disease.

The establishment of nutrition diagnoses helps define and promote effective care according to specific nutrition problems. Such problems may be found in an individual, a group (such as persons who have diabetes or celiac disease), or even a community (such as sites where local produce is grown in mineral-depleted soil.)

Step two of the nutrition care process involves an analysis of the factors affecting adequacy of the current nutritional intake and overall nutritional status. In most cases, institutions use standards of care, national or disease-specific evidence-based practice guidelines that describe recommended actions in the **nutrition care process (NCP)**. These comparative standards serve as the basis for assessing the quality of care provided.

Step three of the NCP is intervention, which involves planning and implementation. This includes the selection and carrying out of interventions that resolve, lessen, or manage the cause of the nutrition problem. For example, nutrition education is an appropriate intervention for the person who has little knowledge of how to manage a gluten-free diet. And this requires a counseling approach that takes into account the client's level of readiness to change. It may be helpful to refer the individual to available cookbooks, health services, and support groups. Manipulation of dietary components, provision of enteral or parenteral nutrition, or in-depth nutrition counseling may also be needed. Coordination of care between hospital and home and community is important for life long management of nutrition and chronic disease.

The final step of the NCP is specific to the client's (individual or population) monitoring and evaluation, and is focused on the important and relevant signs and symptoms identified in the assessment. The findings of monitoring and evaluation become the basis for reassessment as the NCP cycle repeats with subsequent interactions (encounters or visits) with the client.

Overview of Nutrition Diagnosis and Intervention

Nutrition care is a systematic group of professional activities that aim to identify nutritional needs and provide care to address these needs. Nutrition care can occur in a variety of settings and populations, involving members of the multidisciplinary team, as appropriate. For example, nutrition care occurs in schools with children and in collaboration with a school nurse and the education staff as well as in public health departments with a variety of populations and in collaboration with public health officials. Nutrition care also occurs in clinical settings (e.g., skilled nursing facilities, dialysis clinics, and hospital settings), in populations who are acutely or chronically ill, and in collaboration with the medical team (e.g., nurses, physicians, pharmacists, physical therapists). Comprehensive care may involve different health care providers (e.g., the physician, registered dietitian nutritionist [RDN], nurse, pharmacist, physical or occupational therapist, social worker, speech therapist, and case manager) who are integral in achieving desired outcomes, regardless of the care setting. The client is a core member of the team that participates actively in all major decisions throughout the care process, whenever possible. Overall, the **nutrition care process model (NCPM)** (the graphic representation of the NCP) defines the term client as the individual and/or populations, and this definition encompasses supportive members such as

family, caregivers, and structures including social service agencies and faith-based organizations (Swan et al, 2017). For consistency, the same definition of the term client will be used throughout the present chapter.

A collaborative approach helps ensure that care is coordinated and that team members and the client are aware of all goals and priorities. Team conferences, formal or informal, are useful in all settings: a clinic, a hospital, the home, the community, a long-term care facility, or any other site where nutrition problems may be identified. Coordinating the activities of health care professionals also requires documentation of the process and regular discussions to offer complete nutritional care. Standardization of the care process (the nutrition care process, NCP) improves consistency and quality of care and enables collection and assessment of nutrition related outcome measures.

THE NUTRITION CARE PROCESS

The **nutrition care process (NCP)** is a standardized framework of professional activities for the provision of nutrition care established by the Academy of Nutrition and Dietetics (AND, known as the Academy, formerly the American Dietetic Association [ADA]). The NCP model has been embraced by nutrition and dietetics professionals across borders. Most importantly, international input has been a salient influence on the model's continuous improvement (Swan et al, 2017). Per the Academy, the NCP is a process for identifying, planning for, and meeting nutritional needs. The nutritional needs referred to in this definition may be of an individual, specific group, or population. Furthermore, the NCP gives the profession a framework for critical thinking and decision making, which

Portions of this chapter were written by Pamela Charney, PhD, RDN, CHTS-CP and Alison Steiber, PhD, RDN. Sections of this chapter were written by Sylvia Escott-Stump, MA, RDN, LDN for previous editions of this text.

may assist in defining the roles and responsibilities of registered dietitian nutritionists (RDN) and registered nutrition and dietetic technicians (NDTR) in all practice settings and professional levels (AND, 2018).

The current update of the model highlights the following themes: support for people-centered care (PCC) where the individual or population is at the very center (see Fig. 4.3), use of concise language, and professionals' responsibility for outcomes management (Swan et al, 2017). The NCP includes four steps that are the responsibility of the RDN: (1) nutrition assessment, (2) **nutrition diagnosis**, (3) nutrition intervention, and (4) monitoring and evaluation (Swan et al, 2017). Nutrition screening and outcomes management are vital to safe, high-quality nutrition care; however, they are not included as separate steps in the NCP because they are not unique to nutrition and dietetics and may be performed by others qualified professionals.

Each step of the NCP has corresponding terminology that allows for standardized documentation. This terminology is called the **nutrition care process terminology (NCPT)** (previously the international dietetics and nutrition terminology [IDNT]) (Swan et al, 2019). Originally, the terminology was available in print form. Currently, the complete terminology of approximately 1700 terms can only be accessed in a web-based format known as the electronic NCPT (eNCPT) for a nominal cost (AND, 2018a). Also, a select subset of the current NCPT is found in print form (AND, 2017). Using standardized terminology within the documentation process is critical. Systematic and accurate collection of outcomes data allows caregivers a process to determine whether interventions are effective in improving or resolving the nutrition diagnosis. To facilitate the collective aggregation of nutrition care data using the NCPT, the Academy has developed a web-based tool, the Academy Nutrition and Dietetics Health Informatics Infrastructure (ANDHII) (Murphy and Steiber, 2015). Also, an evaluation method to check if the NCP is used appropriately has been applied in different settings. This method is known as the NCP Chains (Hakel-Smith et al, 2005; Murphy et al, 2018). This is important methodology for all nutrition and dietetics students, educators, and professionals who have a vested interest in checking the quality of NCP application. If an RDN works in a public health department and has implemented a program for reducing obesity in an inner city population, he or she would have to be able to collect standardized parameters pre- (assessment) and post (monitoring) intervention and compare them for change (evaluation) to determine whether the intervention was effective. Without standardized language and corresponding definitions, different terms are used for the same condition and thus reduce the ability to show effectiveness of interventions. Recently, the eNCPT added a new collection of terms focused on public health interventions. The eNCPT continues to add terminology to meet the evolving needs of the nutrition and dietetics profession using a rigorous terminology submission process (AND, 2018b).

Nutrition Screening

The purpose of **nutrition screening** is to identify clients who are at nutrition risk and thus should be referred to the RDN for assessment of nutritional status. Nutrition screening can be done in all settings: hospitals, clinics, long-term care facilities, schools, and food banks. When available, population-specific, validated tools should be used for screening (see Chapter 4). Regulatory agencies, including The Joint Commission (TJC), include nutrition screening in their standards. Most health care facilities have developed a multidisciplinary admission screening process that is completed by nursing staff during admission to the facility. Nutrition screening can be incorporated into this admission assessment. Facilities that use an **electronic health record (EHR)** should build an automatic referral to the RDN when screening criteria are met. The nutrition risk screen should be quick, easy to administer, and cost effective. Table 9.1 lists information that is

TABLE 9.1 Nutrition Risk Screening

Responsible Party	Action	Documentation
Admitting health care professional	Assess weight status— Has the client lost weight without trying before admission?	Check yes or no on admission screen.
Admitting health care professional	Assess GI symptoms— Has the client had GI symptoms preventing usual intake over the past 2 weeks?	Check yes or no on admission screen.
Admitting health care professional	Determine need to consult RDN.	If either screening criterion is “yes,” consult RDN for nutrition assessment.

GI, Gastrointestinal; *RDN*, registered dietitian nutritionist.

included frequently in a nutrition screen. Also see Box 4.3 and Fig. 4.4 in Chapter 4 for additional examples.

When the Academy's Evidence Analysis Library (EAL) team conducted a systematic review of acute care screening tools, they determined that the Malnutrition Screening Tool (MST), the Mini-Nutrition Assessment-short form (MNA), and the Nutrition Risk Screen-2002 (NRS) had acceptable reliability and validity in various hospital settings (AND, 2010). See Chapter 4 for a description of these screening tools. When used in a hospital setting, rescreening should occur at regular intervals during the admission. Policies for nutrition rescreening should take into account the average length of time a client will stay at the facility.

Nutrition Assessment and Reassessment

The purpose of nutrition assessment is to obtain, verify, and interpret data needed to identify nutrition-related problems and their causes, importance, and relevance. Nutrition assessment data that is used to justify the nutrition diagnosis (the step that follows nutrition assessment) is typically recorded as “signs and symptoms” in the nutrition diagnosis statement and is also referred to as “evidence.” Nutrition assessment is needed when the screening tool identifies the client to be at nutritional risk (see Chapter 4 through Chapter 7 for detailed discussions of nutrition assessment). The Integrative and Functional Medicine radial in Fig. 9.1 presents a summary of all the aspects of the client's lifestyle that go into a functional assessment as designated in the center with ADIME (assessment, diagnosis, intervention, monitoring and evaluation), and personalized nutrition care. Nutrition assessment parameters have specific corresponding terms, which should be used during documentation. These terms are classified into five domains (food/nutrition related history, anthropometrics, biochemical, nutrition-focused physical examination findings, and client history) (AND, 2017a). The NCPT also provides comparative standards. **Comparative standards** are criteria, or relevant norms and standards against which nutrition assessment data is compared with to identify nutrition problems (see Chapter 4 and Appendices 12 and 13).

Nutrition Diagnosis

RDNs evaluate all the information from the nutrition assessment to determine a nutrition diagnosis. Accurate diagnosis of nutrition problems is guided by critical evaluation of assessment data combined with good judgment and decision-making skills. The purpose of identifying the presence of a nutrition diagnosis is to identify and describe a

The Radial: Integrative and Functional Medical Nutrition Therapy

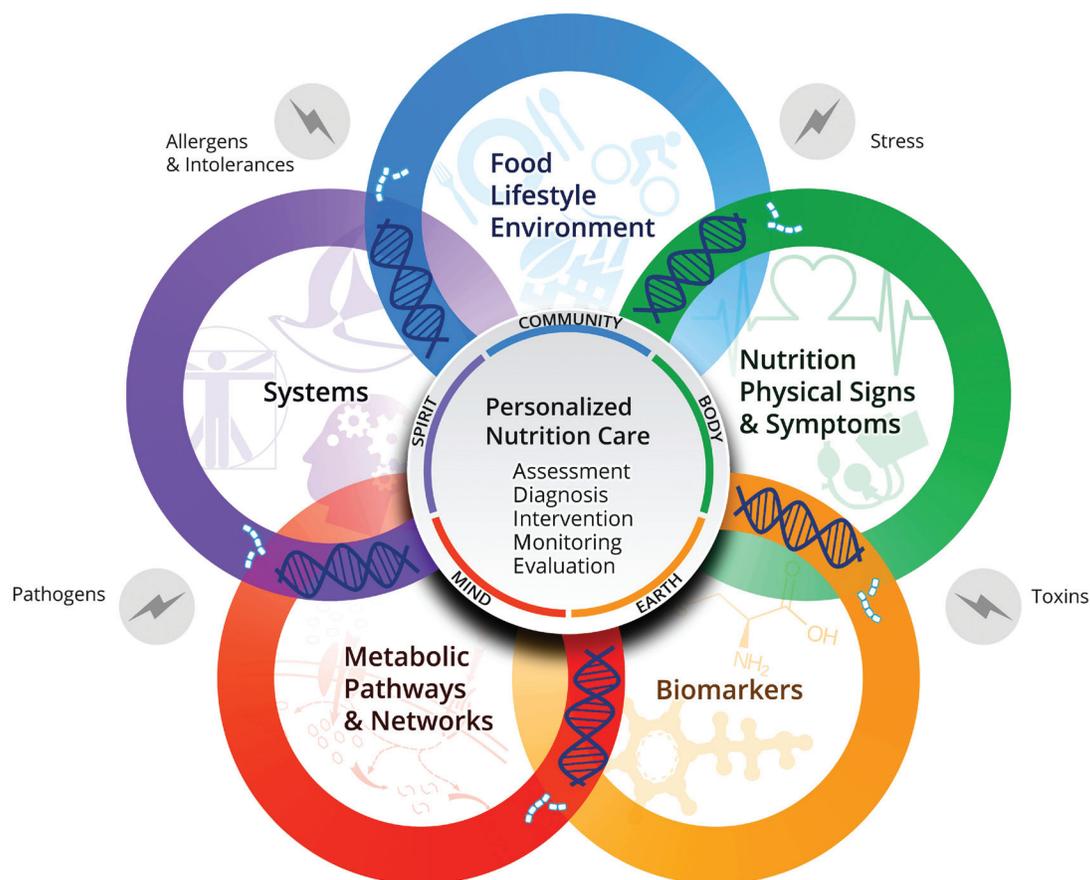

Fig. 9.1 The Integrative and Functional Medicine Radial. (Copyright 2010, 2018. KM Swift, D Noland and E. Redmond.)

specific problem or problems that can be resolved or improved through nutrition intervention by a nutrition and dietetics professional (Swan et al, 2017). Clients with nutrition diagnoses may be at higher risk for nutrition-related complications, such as increased morbidity, increased length of hospital stay, and infection with or without complications. Nutrition-related complications can lead to a significant increase in costs associated with hospitalization, lending support to the early diagnosis of nutrition problems followed by prompt intervention (AND, 2015).

The process of aggregating assessment data and using critical thinking to determine important and relevant nutrition diagnoses should also lead to the identification of the “cause” or **etiology** of the problem. For example, while assessing a client with significant recent weight loss, the RDN may discover that the person is food insecure because of a lack of money or food assistance. Although the RDN can diagnose “unintended weight loss” and begin providing a high calorie diet to the client during a hospital stay, this treatment will not resolve the root cause of the diagnosis (lack of food in the home). Conversely, by provision of nutrition education to the client while in the hospital and enrolling the client into a food assistance program such as Meals on Wheels after he or she gets home, the RDN may prevent the diagnosis from reoccurring. Identification of the etiology is not always possible; however, when it is, it allows for greater understanding of the conditions in which the diagnosis came about and allows for an individualized intervention. Additionally, when the etiology cannot be changed, the focus

of the interventions should be directed at managing or lessening the signs and symptoms of the nutrition problem.

Many facilities use standardized formats to facilitate communication of nutrition diagnoses. The nutrition diagnosis is documented using the **problem, etiology, signs, and symptoms (PES)** format in a simple, clear statement. A basic rule of the NCPT is that the problem must be a nutrition diagnosis term from the NCPT without deviations (verbatim). Correct application of the NCPT supports standardized documentation and consequent aggregation of related data for research, reporting, and analytics. For example, “inadequate energy intake” (an official NCPT nutrition diagnostic term) will have to be documented and not a similar variation of it such as “lack of sufficient caloric consumption.” In some instances there are formally accepted synonyms, and these can be used interchangeably. For example, “food- and nutrition-related knowledge deficit” may be replaced by “limited food and nutrition related knowledge.” The etiology component can be either an NCP term or a free-text explanation of the root cause of the problem. When constructing a PES statement, it is advised to use the nutrition diagnosis etiology matrix (available in the NCPT) to identify whether the selected nutrition problem is matched to the selected etiology category (AND, 2017a). The **nutrition diagnosis etiology matrix** is a table that categorizes all nutrition diagnosis terms by all described etiology categories (there are 10 etiology categories). It is also important to review carefully the reference sheet (a comprehensive profile of an NCP term) of the selected nutrition diagnosis term to understand the definition of that term, the

various etiologies listed, and common signs and symptoms associated with the nutrition problem. (AND, 2017a). These are just some of the fundamental benefits of reviewing the reference sheets. Signs and symptoms should be documented in as specific and quantifiable a manner as possible. For example, it is best practice to write that a client has “lost 15 lbs within the last 3 months” rather than write “recent weight loss.” Methods used for documenting nutrition care in the health record are determined at the facility level. RDNs in private practice should also develop a systematic method for documenting care provided. Signs and symptoms listed in the PES statement need to be data already documented in the assessment step. Assessment data that are selected as signs and symptoms and justify/support the nutrition problem constitute the “evidence” component when assessing NCP application completeness (Murphy et al, 2018).

Nutrition Intervention

Nutrition interventions are the actions taken to treat nutrition problems by resolving the etiology and/or reducing/managing the related signs and symptoms. Nutrition intervention involves two steps: planning and implementation. Whenever possible, the nutrition intervention should target the etiology identified during the assessment step of NCP. Thus if the nutrition diagnosis is *Excessive Carbohydrate* and the etiology is *lack of knowledge about high-carbohydrate foods*, then the appropriate intervention could be *Nutrition Education, Priority Modifications (education focused on which foods are high in carbohydrate)*.

As previously stated, intervention directed at the etiology is not always possible. When the RDN cannot treat the etiology of the nutrition diagnosis directly, the treatment should focus on ameliorating and/or managing the signs and symptoms of the diagnosis. For example, a frequent etiology of malnutrition in hospitalized adult clients is inflammation. The RDN may not be able to intervene directly in the inflammatory process; however, inflammation can increase the client’s nutritional needs. Therefore although the RDN may not be able to reduce the inflammation, the RDN can increase the amount of nutrients provided to the client through high-calorie foods, nutritional supplements, or other nutrition support therapies.

During the planning phase of the nutrition intervention, the RDN, client, and others as needed collaborate to identify goals that will signify success of the intervention. Whether in an inpatient or outpatient clinical setting, a significant component of the plan may be the nutrition prescription. A **nutrition prescription** is a detailed description of the nutrient needs of that particular client. Typically, this can include recommended needs for energy, protein, and fluid but also may include nutrients pertinent to the client’s condition such as carbohydrate needs in diabetes, potassium needs in renal disease, or sodium needs in hypertension.

Client-centered goals are set first, and then implementation begins. Interventions may include food and nutrition therapies, nutrition education, counseling, or coordination of care such as providing referral for financial or food resources. Because the care process is continuous, the initial plan may change as the condition of the client changes, as new needs are identified, or if the interventions prove to be unsuccessful.

Interventions should be specific; they are the “what, where, when, and how” of the client’s care. For example, in a client with “inadequate oral food or beverage intake,” a goal may be to increase portion sizes at two meals per day. This could be implemented through provision of portions that are initially 5% larger with a gradual increase to 25% larger portion sizes. Interventions should be communicated to the health care team and discussed with the client to ensure understanding of the intervention and its rationale, whenever possible. Thorough communication by the RDN increases the likelihood of adherence to the intervention. **Box 9.1** presents the NCP applied to a sample client, JW.

The nutrition intervention terminology is organized in five categories (domains) within the NCPT: (1) food and/or nutrient delivery, (2) nutrition education, (3) nutrition counseling, (4) coordination of nutrition care by a professional, and (5) population-based nutrition action. Interventions can occur in all settings. For example, a woman with little knowledge of heart-healthy foods may need a group class on cooking or an educational session on changing the type of fats in her diet (nutrition education). An RDN working for the Women Infant and Children (WIC) clinic may counsel a pregnant woman on initiating breastfeeding as an intervention (nutrition counseling). A clinical RDN may write orders for initiation and progression of enteral feeding for a child with cystic fibrosis (food and/or nutrient delivery). The RDN may communicate to the social worker the nutrition needs for a client post discharge to ensure that the client continues to improve (coordination of nutrition care). As an example of a population-based nutrition action, an RDN working at the lobbying level may aim to achieve legislative action to facilitate supportive infrastructure, guidelines, and regulations for farm-to-table initiatives.

All of these are types of interventions that RDNs may plan and implement.

Monitoring and Evaluation of Nutrition Care

The fourth step in the NCP involves monitoring and evaluation of the effect of nutrition interventions. This clarifies the effect that the RDN has in the specific setting, whether health care, education, consulting, food services, or research. During this step, the RDN first determines indicators that should be monitored. These indicators should match the signs and symptoms identified during the assessment process. For example, if excessive sodium intake was identified during the assessment, then an evaluation of sodium intake against criteria (a comparative standard or a mutually agreed goal level) is needed at a designated time for follow-up.

In the clinical setting the objective of nutrition care is to achieve and maintain optimal nutrition status for the client or population being served; thus interventions must be monitored and progress toward goals or criteria must be evaluated frequently. This ensures that unmet goals are addressed, and care is evaluated and modified in a timely manner. Evaluation of the monitored indicators provides objective data to demonstrate effectiveness of nutrition interventions, regardless of the setting or focus. If goals are written in measurable terms, evaluation is relatively easy because a change in the indicator is compared with the status of the indicator before implementation of the nutrition intervention.

An example in clinical practice is the sample case in **Box 9.1**. Here, monitoring and evaluation include weekly reviews of nutritional intake, including an estimation of energy intake. If intake was less than the goal of 1800 kcal, the evaluation may be: “JW was not able to increase his calorie intake to 1800 kcal because of his inability to cook and prepare meals for himself.” This also points to a missed nutrition diagnosis: JW does not have access to tools and supplies needed to cook for himself. A revision in the care plan and implementation at this point may include the following: “JW will be provided a referral to local agencies (Meals on Wheels) that can provide meals at home.” The new diagnosis and intervention then are implemented with continued monitoring and evaluation to determine whether the new goal can be met.

When evaluation reveals that goals are not being met or that new needs have arisen, the process begins again with reassessment, identification of new nutrition diagnoses, and formulation of a new NCP cycle. For example, in JW’s case, during his hospitalization, high-calorie snacks were provided. However, monitoring reveals that JW’s usual eating pattern does not include snacks, and thus he was not consuming them when in the hospital. The evaluation showed these snacks to be an ineffective intervention. JW agrees to a new intervention: the addition of one more food to his meals. Further monitoring and evaluation

BOX 9.1 Applying the Nutrition Care Process for Patient JW

JW is a 70-year-old male who was admitted to the hospital for mitral valve replacement surgery. JW lives alone in his own home. JW is a widower and states that he hasn't been able to prepare meals for the past 6 months. The nutrition risk screen reveals that he has lost weight without trying and has been eating poorly for several weeks before admission, leading to referral to the RDN. Client reports 15 lb weight loss in the last 3 months.

Assessment (Step 1)

Chart review, client interview, and nutrition-focused physical examination reveal the following:

Biomedical Data, Medical Tests and Procedures

Glucose and electrolytes: WNL

Albumin: 3.8 g/dL

Cholesterol/triglycerides: WNL

Anthropometric Measurements

Height: 70"

Admission weight: 130 lb (15 lb weight loss over 3 months)

Usual Body Weight: 145 lb

BMI: 18.3 < 18.5

Food/Nutrition-Related History

Food intake: Client reports indicate estimated intake of 1200 kcal/day, irregular meals, drinks 4-6 cups of coffee per day.

Client History

History of hypertension, thyroid dysfunction, asthma, prostate surgery

Medications: Inderal, Lipitor, and levothyroxine

New widower; reports depression and loneliness without his wife

Has some social support from neighbors and community center but states he doesn't like to ask for help

Comparative standard: 1600 kcal (based on 25-30 kcal/kg current body weight)

Nutrition Diagnosis (Step 2)

Basic critical thinking: JW has been consuming fewer calories than required and has little interest in eating. There is support available in the community but JW doesn't like to "impose" on others.

RDN diagnoses nutrition problems and establishes objectives for his care.

PES Statements

- Unintended weight loss *related to* self-reported depression *as evidenced by* 10% weight loss in 3 months and reported intake of less than 75% of estimated requirements.
- Inadequate oral intake *related to* self-reported depression *as evidenced by* estimated inadequate energy intake, reported intake less than 75% of estimated requirements, weight loss of 15 lbs in 3 months.
- Limited access to food *related to* lack of food planning and purchasing skills *as evidenced by* estimated inadequate energy intake (less than 75% of estimated requirements), weight loss of 15 lbs in 3 months, and current BMI = 18.3.

Method to Progress to Nutrition Intervention

Identification of the nutrition diagnoses allows the RDN to focus the nutrition intervention on treatment of the cause of the problem (in this case the missing meals). As a reminder the nutrition intervention consists of two parts planning and implementation. A nutrition prescription and a collection of supporting goals may comprise the planning portion of the intervention (Step 3). Goal setting to establish short-term and long-term plans are often

needed. In the education process the client and the RDN must jointly establish achievable goals. Goals should be expressed in behavioral terms and stated in terms of what the patient will do or achieve when the goals are met. Goals should reflect the educational level and the economic and social resources available to the client and the family.

Nutrition Intervention (Step #3)

Plan

Nutrition prescription: 1800 kcal regular diet

Overall goals

Provide diet to meet JW's needs during hospitalization

Monitor weight

Refer to social services following discharge

Short-Term Goal

During the hospitalization, JW will maintain his current weight; after discharge he will begin to slowly gain weight up to a target weight of 145 lb.

Implementation:

While in the hospital, JW will include nutrient-dense foods in his diet, especially if his appetite is limited.

Coordination of Nutrition Care by a Nutrition Professional:

Nursing to weigh patient daily.

Nutrition Education – Content: Priority modifications:

Educate patient on importance of adequate energy intake to meet nutrient needs to prevent further weight loss until he is able to return to adequate oral intake.

Verbalize understanding of Nutrition Education—Content: Priority modifications for current course of dietary intake to prevent further weight loss.

Long-Term Goal

JW will modify diet to include adequate calories through the use of nutrient-dense foods to prevent further weight loss and eventually promote weight gain.

Implementation:

After discharge, JW will attend a local senior center for lunch on a daily basis to help improve socialization and caloric intake.

Coordination of Nutrition Care by a Nutrition Professional:

Social worker to coordinate referral to local senior center.

Method to monitor progress and evaluation

Choosing the means for monitoring if the interventions and nutritional care activities have met the goals is important. Evaluation of the monitoring criteria will provide the RDN with information on outcomes, and this should occur over time. Finally, documentation is important for each step of the process to ensure communication between all parties.

For JW, weekly weight measurements and nutrient intake analyses are required while he is in the hospital and biweekly weight measurements are taken at the senior center or clinic when he is back at home. If nutrition status is not improving, which in this case would be evidenced by JW's weight records, and the goals are not being met, it is important to reassess JW and perhaps develop new goals for new implementation approaches.

Monitoring and Evaluation (Step 4)

Indicator: energy intake

Criteria: 1800 kcal/day, will monitor energy intake weekly

Indicator: body weight

Criteria: target weight: 145 lb, will monitor weight weekly during hospital stay

will be needed to ascertain if this new intervention improves his intake. The monitoring and evaluation step may function as the stepping stone for reassessment. In this fashion, the NCP is not static but continues to a next cycle of steps using prior information and relevant, new information that has been identified and informs next NCP steps.

Evidence-Based Guidelines

In health care, providers must use the best available evidence in caring for clients. The Center for Evidence Based Medicine defines evidence-based practice as “the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients.” Best evidence includes properly designed and executed prospective, randomized controlled trials (PRCT), systematic reviews of the literature, and meta-analysis to support decisions made in practice (CEBM, 2014; Sackett et al, 1996). **Evidence-based guidelines (EBGs)** are developed by first conducting a systematic review and then using the conclusion of the systematic review to develop practice-based guidelines. A work group of subject matter experts and specially trained analysts work together to evaluate the research and to develop recommendations for client care. These guidelines give providers a summary of the best available evidence by which to conduct their practice.

Appropriate use of EBGs may lead to improved quality of care. RDNs must be able to evaluate the EBG and determine whether a guideline is appropriate in a given situation for a given client. Many health care professional organizations and practice specialties have developed EBGs. Because of potential significant differences in quality and applicability, RDNs must be able to evaluate these guidelines.

In the 1990s, the Academy began developing nutrition practice guidelines and evaluating how guideline use affected clinical outcomes; diabetes management was among the first clinical situations examined. These **evidence-based nutrition practice guidelines (EBNPGs)** are disease- and condition-specific recommendations with corresponding toolkits. The EBNPGs include major recommendations, background information, and a reference list. To assist the RDN in implementing the EBNPG into their routine care, the guidelines are organized by the NCP steps as appropriate, and NCPT is used in guidelines and within the toolkits (Papoutsakis et al, 2017).

EBNPGs and associated toolkits assist nutrition and dietetics professionals to provide effective nutrition care, especially for clients with diabetes and early stages of chronic kidney disease (CKD). Medical nutrition therapy (MNT) provided by a Medicare Part B licensed provider can be reimbursed when the EBNPGs are used and all procedural forms are documented properly and coded (Parrott et al, 2014). Benefits of nutrition therapy can be communicated to physicians, insurance companies, administrators, or other health care providers using evidence provided from these guidelines.

To define professional practice by the RDN, the Academy published a Scope of Dietetics Practice Framework, a Code of Ethics, and the **Standards of Professional Performance (SOPPs)** (AND, 2018). Specialized standards for knowledge, skills, and competencies required to provide care at the generalist, specialist, and advanced practice level for a variety of populations are now complete for many areas of practice.

The Academy’s EAL is a credible and current resource to answer questions that arise during provision of nutrition care. Use of the EAL may protect the professional and the public from the consequences of ineffective care. These guidelines are extremely valuable for educating students, staff orientation, competence verification, and training of RDNs.

Accreditation and Surveys

Accreditation by **The Joint Commission (TJC)** and other accrediting agencies involves review of the systems and processes used to deliver health care along with evaluation of actual care processes. TJC survey teams evaluate health care institutions to determine the level of

compliance with established minimum standards. For example, TJC requires that nutrition screening be completed within 24 hours of admission to acute care but does not mandate a method to accomplish screening. However, policies must be applied consistently and must reflect commitment to provision of high-quality, timely nutrition services to all clients.

The “Care of the Patient” section of the *TJC Accreditation Manual for Hospitals* contains standards that apply specifically to medication use, rehabilitation, anesthesia, operative and other invasive procedures, and special treatments, as well as nutrition care standards. The focus of the nutrition **standards of care** is provision of appropriate nutrition care in a timely and effective manner using an interdisciplinary approach. Appropriate care requires screening of clients for nutrition needs, assessing and reassessing client needs, developing a nutrition care plan, ordering and communicating the diet order, preparing and distributing the diet order, monitoring the process, and continually reassessing and improving the nutrition care plan. A facility can define who, when, where, and how the process is accomplished, but TJC specifies that a qualified dietitian must be involved in establishing this process. A plan for the delivery of nutrition care may be as simple as providing a regular diet for a client who is not at nutritional risk or as complex as managing enteral feedings in a ventilator-dependent client, which involves the collaboration of multiple disciplines.

RDNs are involved actively in the survey process. Standards set by TJC play a large role in influencing the standards of care delivered to clients in all health care disciplines. For more information, see the TJC website.

Dietitians also are involved with surveys from other regulatory bodies, such as a state or local health department, a department of social services, or licensing organizations. Introduction of diagnostic-related groups (DRG) in the mid-1980s led to decreasing acute care length of stay (LOS). However, some clients who no longer need acute hospital care but are not ready to care for themselves at home are admitted to “subacute” care units (these are often called rehabilitation units) that are regulated by **Centers for Medicare and Medicaid Services (CMS)**. Subacute units also undergo an annual review by CMS. (See Chapter 19 for more information.)

Sentinel events are unanticipated events that involve death, serious physical or psychological injury, or the risk thereof (TJC, 2017). When there is a sentinel event, the outcomes must be documented in the medical record and there must be clinical and administrative follow-up to document steps taken to prevent recurrence of the event. Regardless of the source of the survey, clinicians must follow all regulations and guidelines at all times and not just when a survey is due.

DOCUMENTATION IN THE NUTRITION CARE RECORD

MNT and other nutrition care provided must be documented in the health or medical record. The health record is a legal document; if interventions are not recorded, it is assumed that they have not occurred. Documentation affords the following advantages:

- It ensures that nutrition care will be relevant, thorough, and effective by providing a record that identifies the problems and sets criteria for evaluating the care.
- It allows the entire health care team to understand the rationale for nutrition care, the means by which it will be provided, and the role each team member must play to reinforce the plan and ensure its success.

The health record serves as a tool for communication among members of the health care team. Most health care facilities are using or in the process of implementing electronic health records (EHRs) to document client care, store and manage laboratory and test results, communicate with other entities, and maintain information related to an individual’s health. During the transition to EHRs, those using paper documentation maintain paper charts that typically include sections for physician orders, medical history and physical examinations,

laboratory test results, consults, and progress notes. Although the format of the health record varies depending on facility policies and procedures, in most settings all professionals document care in the medical record. The RDN must ensure that all aspects of nutrition care are summarized succinctly in the medical record. The NCPT developed by the Academy is used to document the NCP in several countries around the world including Australia, Canada, China, Denmark, Sweden, New Zealand, Norway, and Taiwan (AND, 2017a).

Medical Record Charting

Problem-oriented medical records (POMR) are used in many facilities. The POMR is organized according to the client's primary problems. Entries into the medical record can be done in many styles. A common form is the **subjective, objective, assessment, plan (SOAP) note format** (Table 9.2).

The **assessment, diagnosis, interventions, monitoring, evaluation (ADIME) format** reflects the steps of the NCP (Box 9.2; Table 9.3).

BOX 9.2 Chart Note Using ADIME

Nutrition Assessment

- Pt is 66-year-old woman admitted with heart failure
- Ht: 162 cm; Wt: 56 kg; IBW: 52-58 kg
- Laboratory values within normal limits
- Estimated energy needs: 1570-1680 kcal (28-30 kcal/kg/day)
- Estimated protein needs: 56-73 g protein (1-1.3 g/kg/day)
- Current diet order is "Regular - no added salt" with pt consuming 95% of meals recorded
- Consult for nutrition education received

Nutrition Diagnosis

- Food- and nutrition-related knowledge deficit related to lack of prior nutrition-related education on low sodium diet as evidenced by client reports no prior education provided, new Heart Failure medical diagnosis.

Nutrition Intervention

Plan:

- Nutrition prescription: 1600 kcal/day no added salt (3 g Na) diet

Implementation:

Nutrition education – Content: Priority modifications:

- Provided client with written and verbal instruction on a no added salt diet (3 g) diet.
 - Client verbalized understanding of Nutrition Education – Content: Priority Modifications for current salt restriction (3 g Na) to manage heart failure.
 - To develop and provide client 1-day menu using dietary restrictions.
- Coordination of Nutrition Care by a Nutrition Professional:
- Provided contact information for outpatient clinic.

Monitoring and Evaluation

- Indicator: dietary Na intake
 - Criteria: 3 g Na/day via 24 hr dietary recall
- J Wilson, MS, RDN 1/2/18

See Table 9.4 for examples of nutrition diagnostic (PES) statements. However, each client and situation is different, and the NCP should be individualized appropriately.

Documentation must be accurate, clear, and concise and must be able to convey important information to the physician and other health care team members. All entries made by the RDN should address the issues of nutrition status and needs. Those using EHRs

must use great caution when using “copy and paste” functions to document care.

Electronic Health Records and Nutrition Informatics

Beginning in the 1990s, costs for computer memory decreased, hardware became more portable, and computer science advanced to make computers and technology a permanent fixture in health care.

Additional impetus to change standard practice came with publication of several Institute of Medicine (IOM) reports that brought to light a high rate of preventable medical errors along with the recommendation to use technology as a tool to improve health care quality and safety (Institute of Medicine, 2000).

Clinical information systems used in health care are known by different names; although some use **electronic medical record (EMR)**, **electronic health record (EHR)**, and **personal health record (PHR)** interchangeably, there are important differences. An EHR describes information systems that contain all the health information for an individual over time regardless of the care setting. An EMR is a clinical information system used by a health care organization to document client care during one episode of care or admission. EHRs and EMRs are maintained by health care providers or organizations. In contrast, the PHR is a system used by individuals to maintain health information. A PHR can be web or paper based or integrated into a facility's EMR. Information in the PHR is controlled by the person, not the provider or health care organization.

EHRs include all of the information typically found in a paper-based documentation system along with tools such as clinical decision support, electronic medication records, computerized provider order entry, and alert systems that support clinicians in making decisions regarding client care. Current government regulations include requirements to implement and “meaningfully use” EHRs to enter, store, retrieve, and manage information related to client care. Dietitians must have at least a basic understanding of technology and health information management to ensure a smooth transition from paper to EHR and to use effectively the powerful tools provided by a well-designed EHR. Such transitions include development of nutrition screens for client admission, documentation, information sharing, decision support tools, and order entry protocols. Customization capabilities vary depending on vendor contracts and facility requirements. Because it can take several years to implement an EHR, RDNs managing nutrition services must be involved in EHR system decisions from the very beginning. The Academy's EHR toolkit, which is available on the eNCPT website, is an important resource to help RDNs communicate effectively their specific EHR needs (AND, 2017a). Also, there are standards that have been developed to “spell-out” what RDNs need to have included in the EHR in order to apply the NCP. The Academy has developed such a standard by the name of Electronic Nutrition Care Process Record System (ENCPRS) (Health Level Seven International, 2010). In paper and electronic formats, health records and the information contained are vital conduits for communicating client care to others, providing information for quality evaluation and improvement, and serving as a legal document. RDN documentation includes information related to NCPs. Documentation must follow the facility policy and be brief and concise while accurately describing actions taken to those authorized to view the record. Fig. 9.2 shows how a computerized health record may look when using the ADIME method.

Current efforts are focused on ensuring that health information stored in clinical information systems can be exchanged safely and securely between providers and facilities. Systems that are able to share information seamlessly are “interoperable.” Although this concept seems simple on the surface, problems with interoperability can be very difficult and expensive to overcome. RDNs in private practice and ambulatory care must ensure that systems they are using have the capability to share health information.

The transition from paper health records to EHRs is facilitated by thorough planning, training, and support. Many health care

professionals do not have sufficient experience with health care technology to understand the practice improvement that can be realized with proper implementation and use of technology. Others may resist any change in the workplace that interrupts their current workflow. These clinicians are not resisting change because they are afraid of technology; instead, resistance is based on real or imagined fears that technology will impede their workflow or hinder client care.

INFLUENCES ON NUTRITION AND HEALTH CARE

The health care environment has undergone considerable change related to the provision of care and reimbursement in the last decade. Governmental influences, cost containment issues, changing demographics, and the changing role of the client as a “consumer” have influenced the health care arena. The United States currently spends more on health care than any other nation, yet health care outcomes lag far behind those seen in other developed nations. Exponential increases in health care costs in the United States have been a major impetus for drives to reform how health care is provided and paid for in the United States.

Confidentiality and the Health Insurance Portability and Accountability Act

Privacy and security of personal information are a concern in all health care settings. In 1996 Congress passed the **Health Insurance Portability and Accountability Act (HIPAA)** (Centers for Medicare and Medicaid Services, 2018). The initial intent of HIPAA was to ensure that health insurance eligibility is maintained when people change or lose jobs. The Administrative Simplification provisions of HIPAA require development of national standards that maintain privacy of electronically transmitted **protected health information (PHI)**. In 2013 the HIPAA Omnibus Rule expanded client rights to their own health information, strengthened rules surrounding privacy and confidentiality of PHI, and increased penalties for unauthorized sharing or loss of PHI (U.S. Department of Health and Human Services, 2015).

HIPAA requires that health care facilities and providers (covered entities) take steps to safeguard PHI. Although HIPAA does not prevent sharing of client data required for care, clients must be notified if their medical information is to be shared outside of the care process, or if protected information (e.g., address, email, income) is to be shared. Violations of HIPAA rules have resulted in large fines, loss of jobs, and criminal prosecution. In an effort to avoid the serious repercussions of HIPAA violations, health care institutions have implemented mandatory annual education on HIPAA for each employee.

Payment Systems

One of the largest influences on health care delivery in the last decade has been changes in health care payment methods. There are several common methods of reimbursement: private insurance, cost-based reimbursement, negotiated bids, and DRGs. DRG codes is a collection of codes that determines how much money Medicare and some health insurance agencies will pay for a patient's hospital stay. Under the DRG system, a facility receives payment for a client's admission based on the principal diagnosis, secondary diagnosis (comorbid conditions), surgical procedure (if appropriate), and the age and gender of the client. Approximately 500 DRGs cover the entire spectrum of medical diagnoses and surgical treatments. **Preferred-provider organizations (PPOs)** and **managed-care organizations (MCOs)** also are changing health care. MCOs

TABLE 9.4 Sample PES Statements Based on Medical Diagnosis*

Medical Diagnosis	Nutrition Diagnosis** (Problem)	Etiology (E)	Signs/Symptoms (S)
Obesity	Obesity	Excessive energy intake and physical inactivity	Current weight 175% desired body weight, BMI 38 kg/m ² , reported overconsumption of energy-dense food and large amounts of computer use and other sedentary activities
	Excessive energy intake	Food and nutrition-related knowledge deficit concerning energy intake	Diet history; intake approximately 150% estimated requirements, and BMI 38 kg/m ²
	Physical inactivity	Time constraints	Reports of 8-10 hours of daily screen time (computer and television), BMI > 30
Cancer	Unintended weight loss	Decreased ability to consume sufficient energy	Cancer chemotherapy, reports of nausea and poor intake (<50% of estimated needs), weight loss of 10% usual body weight within 30 days
	Inadequate oral intake	Decreased ability to consume sufficient energy	Nausea from chemotherapy, weight loss of 10% usual body weight within 30 days, reports of insufficient intake of energy from diet (<50% of estimated needs).
Newly diagnosed type 2 diabetes	Food- and nutrition-related knowledge deficit	Lack of prior nutrition-related education	New medical diagnosis of Type 2 Diabetes Mellitus, and measured fasting glucose of 230 mg/dL
Major trauma GI surgery with complications	Altered GI function	Decreased ability to consume sufficient energy	Intubation after GI surgery, NPO × 48 hours.
Anorexia nervosa	Disordered eating pattern	Environmental-related obsessive disorder to be thin	BMI < 17.5, estimated energy intake < 25% of estimated needs at least 7 days before admission, and anorexia nervosa
Heart failure	Excessive fluid intake	Cardiac dysfunction	Heart Failure, reported estimated fluid intake 150% more than physician-ordered restriction
	Inability to manage self-care	Food- and nutrition-related knowledge deficit concerning self-care	Three admissions for fluid overload in past 2 months, Congestive Heart Failure
Dysphagia	Limited food acceptance	Decreased ability to consume sufficient energy	Reports of inadequate intake (<75% of estimated needs), inability to consume most foods served
	Swallowing difficulty	Cerebrovascular accident	Dysphagia, abnormal swallow study, decreased estimated food intake (<75% of estimated needs).
Referral for social services	Limited access to food	Lack of financial resources	Lack of resources for food, Patient/SWS reports disqualified from SNAP program

*These are only examples. Each client is different; each nutrition problem diagnosed by the RDN has an etiology and signs/symptoms that are unique to that client.

**Each client may have more than one nutrition diagnosis.

finance and deliver care through a contracted network of providers in exchange for a monthly premium, changing reimbursement from a fee-for-service system to one in which fiscal risk is borne by health care organizations and physicians.

The Patient Protection and Affordable Care Act (PPACA) was signed into law by President Obama on March 23, 2010. PPACA is the most significant change to the U.S. health care system since the 1965 passage of legislation that created Medicare and Medicaid. The goal of PPACA or the **Affordable Care Act (ACA)** is to ensure that affordable health insurance is available to all Americans. ACA uses several methods to improve access to health insurance including subsidies, state insurance exchanges, and assurance of coverage for preexisting conditions (**U.S. Government**

Publishing Office, 2010) (see *Clinical Insight: The ACA: How Does Nutrition Fit?*)

Quality Management

To contain health care costs while providing efficient and effective care that is consistently of high quality, practice guidelines, or **standards of care**, are used. These sets of recommendations serve as a guide for defining appropriate care for a client with a specific diagnosis or medical problem. They help ensure consistency and quality for providers and clients in a health care system and, as such, are specific to an institution or health care organization. **Critical pathways**, or care maps, identify essential elements that should occur in the client's care and define a timeframe in which

each activity should occur to maximize client outcomes. They often use an algorithm or flowchart to indicate the necessary steps required to achieve the desired outcomes. **Disease management** is designed to prevent a specific disease progression or exacerbation and to reduce the frequency and severity of symptoms and complications. Education and other strategies maximize compliance with disease treatment. Educating a client with type 1 diabetes regarding control of blood glucose levels would be an example of a disease management strategy aimed at decreasing the complications (nephropathy, neuropathy, and retinopathy) and the frequency with which the client needs to access the care provider. Decreasing the number of emergency room visits related to hypoglycemic episodes is a sample goal.

Patient-Centered Care and Case Management

The **case management** process is aimed at achieving client care goals in a cost-effective, efficient manner. It is an essential component in delivering care that provides a positive experience for the client, ensures optimal clinical outcomes, and uses resources wisely. Case management involves assessing, evaluating, planning, implementing, coordinating, and monitoring care, especially in clients with chronic disease or those who are at high risk. In some areas, dietitians have added skill sets that enable them to serve as case managers. Client-centered care has become a movement in the United States that puts more decision making in the hands of the consumer. It places more emphasis on outcomes, sometimes at the expense of physician autonomy (Bardes, 2012). In long-term care the goal is focused on ensuring dignity as well as choice (see Chapter 19).

Utilization management is a system that strives for cost efficiency by eliminating or reducing unnecessary tests, procedures, and services. Here, a manager usually is assigned to a group of clients and is responsible for ensuring adherence to pre-established criteria.

The **patient-centered medical home (PCMH)** is a new development that focuses on the relationship between the client and personal physician. The personal physician takes responsibility for coordinating health care for the client and coordinates and communicates with other providers as needed. Other providers such as nurses, dietitian nutritionists, health educators, and allied health professionals may be called on by the client or personal physician for preventive and treatment services. When specialty care is needed, the personal physician becomes responsible for ensuring that care is seamless and that transitions between care sites go smoothly. The RDN should be considered part of the medical home treatment plan.

Regardless of model, the facility must manage client care prudently. Nutrition screening can be important in identifying clients who are at nutrition risk. Early identification of these factors allows for timely intervention and helps prevent the comorbidities often seen with malnutrition, which may cause the LOS and costs to increase. CMS has identified conditions such as heart failure, heart attack, and pneumonia, to name a few, for which no additional reimbursement will be received if a client is readmitted to acute care within 30 days of a prior admission. Although many view this rule as punitive, it does provide an opportunity for RDNs to demonstrate how nutrition services, including client education, can save money through decreased readmissions.

Other recent developments include “never events.” Never events are those occurrences that should never happen in a facility that provides

CLINICAL INSIGHT**The ACA: How Does Nutrition Fit?**

To get paid for their services of nutritional counseling under the Affordable Care Act (ACA), registered dietitian nutritionists (RDNs) must gain an understanding of the language and steps involved in reimbursement as well as how to become a provider. According to Medicare standards, a medical nutrition therapy (MNT) provider must have completed the educational and clinical experience required of an RDN (AND, 2018). Next, he or she has to obtain the 10-digit **National Provider Identifier (NPI)**, required for billing and credentialing (a term used by insurance companies, the payers, for enrolling service providers). Credentialing is a binding contract of services, conditions, and diseases for which nutritional counseling will be paid, codes to use, and the fee schedule. The diagnosis code (ICD-10) and Common Procedure Terminology (CPT) are required for billing purposes. The ICD-10 describes the person's medical condition, obtained from the physician, and the CPT documents the procedure performed by the RDN. MNT has been designated as 97802 (initial visit), 97803 (follow-up), 97804 (group [2 or more individuals]) procedural codes that are applicable for nutritional counseling for the ACA.

By researching insurance companies, RDNs can find out if MNT is covered, if RDNs are accepted into network, the covered diagnosis and procedure codes, the limits to MNT, and the fee schedules. The fee schedule is the payment per billing unit (blocks of 15 minutes, or per visit). Plans differ, even if they are offered by the same insurance company.

From changes stimulated by the passage of the ACA, it is evident that the chronic care model is replacing the acute care model. A **chronic care**

model (CCM) is a multidisciplinary and multifaceted approach for chronic disease management and prevention, whose premise is the development of self-management skills while enhancing the patients' relationships to their care and the team providing that care (Coleman et al, 2009). With this CCM comes development of the Patient-Centered Medical Home (PCMH), Accountable Care Organizations (ACOs) and Comprehensive Primary Care Initiative Projects (CPCI), which combine PCMH and ACOs. A PCMH's focus is on the patient-provider relationship incorporating the team approach (Boyce, 2012).

After the passage of the ACA, ACOs were formed to provide a team approach for coordinating the care provided by doctors, hospitals, and other allied health providers for Medicare patients. Seven states and regions participate in the CPCI, but it is expected to grow, requiring the dietitian-nutritionist to think beyond the traditional MNT model of fee for service, to comprehensive care and new areas of practice, such as primary care settings rather than hospitals (AND, 2018). A survey conducted in 2014 demonstrated that RDNs have inadequate awareness (about 40%) of and poor participation (20%) in the PCMH, which adds to the urgency for RDNs to become educated about the ACA and their activity in its implementation (AND, 2014).

high-quality, safe, **people-centered care (PCC)**. CMS will not reimburse facilities for additional costs of care related to “never events.” RDNs must pay attention to new or worsening pressure ulcers and central line infections as potential “never events.”

Staffing

Staffing also affects the success of nutrition care. Clinical RDNs may be centralized (all are part of a core nutrition department) or decentralized (individual dietitians are part of a unit or service that provides care to clients), depending on the model adopted by a

specific institution. Certain departments such as food service, accounting, and human resources remain centralized in most models because some of the functions for which these departments are responsible are not related directly to client care. Dietitians should be involved in the planning for any redesign of client care (see *Focus On: Nutrition Standardized Language and Coding Practices*). The methods of the *Registered Dietitian Staffing and Productivity Benchmarking Study* is an important resource on how a staffing model could be applied to determine RDN staffing requirements (Hand et al, 2015).

FOCUS ON**Nutrition Standardized Language and Coding Practices**

The history of the International Classification of Diseases (ICD) can be traced to the mid-1600s and the London Bills of Mortality. It was not until the late 1800s that ICD codes were introduced in health care. The ICD coding system has been revised and updated several times and is used by most countries. Because ICD initially was developed as a system to track causes of death, its use for coding medical diagnoses has been criticized. The United States has been using ICD-10 since October 2015.

Medical records departments review medical records and assign codes to the medical diagnoses based on specific findings documented by health care providers as well as complicating factors (“comorbidities”) to determine reimbursement rates. Commonly, pulmonary, gastrointestinal, endocrine, mental disorders,

and cancer can lead to malnutrition as a comorbid factor. Thus coordinated nutrition care and coding for malnutrition are important elements in patient services.

A study by Parrott et al (2014) found that self-employed RDNs are more likely to be reimbursed by private or commercial payers, and RDNs working in clinic settings are more likely to be reimbursed by Medicare. RDNs must know and be accountable for the business and clinical side of their nutrition practices (Parrott et al, 2014).

In private practice, use of correct codes and following payers' claims processing policies and procedures are essential. For example, an NPI is a 10-digit number that is required on claims. To apply for an NPI, RDNs can complete the online application at the NPPES website.

ICD, International Classification of Disease; NPI, National Provider Identifier; NPPES, National Plan and Provider Enumeration System; RDN, registered dietitian nutritionist.

NUTRITION INTERVENTIONS

The RDN is responsible for provision of food and nutrition services that are reliable and highly individualized. RDNs are responsible for using evidence-based practice that is not compromised by market forces.

The evaluation of general and modified diets requires in-depth knowledge of the nutrient content of foods. In particular, it is essential to be aware of the nutrient-dense foods that contribute to dietary adequacy and to be able to recommend how foods can be fortified to increase their nutrition value (see *Focus On: Food First* in Chapter 19.). A knowledge of protein-rich foods required for healing is also essential. As outlined in the later disease-focused chapters, balance and professional judgment are needed. For example, sometimes a person with healing needs also has kidney dysfunction so the amount of protein and type of protein recommended is more complex.

Interventions: Food and Nutrient Delivery

The **nutrition prescription**, written by the RDN, designates the type, amount, and frequency of nutrition based on the individual's disease process and disease management goals. The prescription may specify a caloric level or other restriction to be implemented. It also may limit or increase various components of the diet, such as carbohydrate, protein, fat, alcohol, fiber, water, specific vitamins or minerals, bioactive substances such as phytonutrients, or probiotics. RDNs write the nutrition prescription after the diagnosis of nutrition problems.

The CMS issued a rule in 2014 that allows RDNs employed in hospitals to enter diet orders independently into a client's health record, without requiring the supervision or approval of a physician or other practitioner (*Centers for Medicare and Medicaid Services, 2014*). Specifically, RDNs are permitted to become privileged by hospital medical staff to enter independent diet orders (and optionally order laboratory tests to monitor effectiveness of dietary plans and orders) subject to state laws governing licensing and scope-of-practice. The process of obtaining ordering privileges requires medical staff or review board evaluation of each practitioner's qualifications and demonstrated competency to perform these tasks. Recent information shows that providing nutrition-related **order-writing privileges (OWPs)** to RDNs enhances the quality of client care, improves related outcomes, and controls costs associated with provided care (*Phillips and Doley, 2017*). In states where licensure laws or other regulations preclude RDNs from ordering diets directly, the nutrition prescription should be conveyed to the responsible licensed health care provider (e.g., physicians, physician assistants, and advanced practice nurses) to approve and enter the appropriate orders for oral diet, oral nutritional supplements, and enteral or parenteral nutrition. The ability to enter orders does not absolve the RDN of the need to communicate and coordinate care with the provider who is ultimately responsible for all aspects of client care.

Therapeutic or modified diets are based on a general, adequate diet that has been altered to provide for individual requirements, such as digestive and absorptive capacity, alleviation or arrest of a disease process, and psychosocial factors. In general, the therapeutic diet should vary as little as possible from the individual's normal diet. Personal eating patterns and food preferences should be recognized, along with socioeconomic conditions, religious practices, and any environmental factors that influence food intake, such as where the meals are eaten and who prepares them (see "Cultural Aspects of Dietary Planning" in Chapter 10).

A nutritious and adequate diet can be planned in many ways. One foundation of such a diet is the chooseMyPlate Food Guidance System described in Chapter 10. This is a basic plan; additional foods or more of the foods listed are included to provide additional

energy and increase the intake of required nutrients for the individual. The Dietary Guidelines for Americans also are used in meal planning and to promote wellness. The dietary reference intakes (DRIs) and specific nutrient recommended dietary allowances are formulated for healthy persons, but they also are used as a basis for evaluating the adequacy of therapeutic diets. Nutrient requirements specific to a particular person's genetic makeup, disease state, or disorder always must be taken into account during diet planning.

Modifications of the Normal Diet

Normal nutrition is the foundation on which therapeutic diet modifications are based. Regardless of the type of diet prescribed, the purpose of the diet is to supply needed nutrients to the body in a form that it can handle. Adjustment of the diet may take any of the following forms:

- Change in consistency of foods (liquid diet, pureed diet)
- Increase or decrease in energy value of diet (weight-reduction diet, high-calorie diet)
- Increase or decrease in the type of food or nutrient consumed (sodium-restricted diet, lactose-restricted diet, fiber-enhanced diet, high-potassium diet)
- Elimination of specific foods (MSG-free, gluten-free diet)
- Adjustment in the level, ratio, or balance of protein, fat, and carbohydrate (diet for blood sugar control, ketogenic diet, renal diet, high protein diet)
- Rearrangement of the number and frequency of meals (diet for someone elderly, postgastroectomy diet)
- Change in route of delivery of nutrients (enteral or parenteral nutrition)

Diet Modifications in Hospitalized Clients

Food is an important part of nutrition care. Attempts must be made to honor client preferences during illness and recovery from surgery. This means that the client must be involved in the decision to follow a therapeutic diet. Imagination and ingenuity in menu planning are essential when planning meals acceptable to a varied client population. Attention to color, texture, composition, and temperature of the foods, coupled with a sound knowledge of therapeutic diets, are required for menu planning. However, to the client, good taste and attractive presentation are most important. When possible, client choices of food are most likely to be consumed. The ability to make food selections gives the client an option in an otherwise limiting environment.

Hospitals and long-term care facilities are required to adopt a nutrition care manual that serves as the reference for the diets served in the facility. For this purpose, the Academy has developed online nutrition care manuals (*AND, 2018c*). All hospitals or health care institutions have basic, routine diets designed for uniformity and convenience of service. These standard diets are based on the foundation of an adequate diet pattern with nutrient levels as derived from the DRIs. Types of standard diets vary but generally can be classified as general or regular or modified in consistency. The diets should be realistic and meet the nutritional requirements of the clients. The most important consideration of the type of diet offered is providing foods that the client is willing and able to eat and that accommodate any required dietary modifications. Shortened lengths of stay in many health care settings result in the need to optimize intake of calories and protein, and this often translates into a liberal approach to therapeutic diets. This is especially true when the therapeutic restrictions may compromise intake and subsequent recovery from surgery, stress, or illness.

Regular or General Diet

“Regular” or “general” diets are used routinely and serve as a foundation for more diversified therapeutic diets. In some institutions a diet that has no restrictions is referred to as the regular or house diet. It is used when the client’s medical condition does not warrant any limitations. This is a basic, adequate, general diet of approximately 1600 to 2200 kcal; it usually contains 60 to 80 g of protein, 80 to 100 g of fat, and 180 to 300 g of carbohydrate. Although there are no particular food restrictions, some facilities have instituted regular diets that are low in saturated fat, sugar, and salt to follow the dietary recommendations for the general population. In other facilities the diet focuses on providing foods the client is willing and able to eat, with less focus on restriction of nutrients. Many institutions have a selective menu that allows the client certain choices; the adequacy of the diet varies based on the client’s selections. More recent developments in health care food service include use of “**room service**” similar to the hotel room service model; clients have complete freedom to choose what and when they will eat.

Consistency Modifications

Modifications in consistency may be needed for clients who have limited chewing or swallowing ability. See Chapter 39 and Appendix 20 for more information on consistency modifications and clients with neurologic changes that require these diets.

Clear liquid diets include some electrolytes and small amounts of energy from tea, broth, carbonated beverages, clear fruit juices, and gelatin. Milk and liquids prepared with milk are omitted, as are fruit juices that contain pulp. Fluids and electrolytes often are replaced intravenously until the diet can be advanced to a more nutritionally adequate one.

Little scientific evidence supports the use of clear liquid diets as transition diets after surgery. The average clear liquid diet contains only 500 to 600 kcal, 5 to 10 g of protein, minimum fat, 120 to 130 g of carbohydrate, and small amounts of sodium and potassium. It is inadequate in calories, fiber, and all other essential nutrients and should be used only for short periods. In addition, full liquid diets also are not recommended for a prolonged time. If needed, oral supplements may be used to provide more protein and calories and could be offered as liquids with which to take medications if appropriate.

Food Intake

Food served does not necessarily represent the actual intake of the client. Prevention of malnutrition in the health care setting requires observation and monitoring of the adequacy of client intake. This nutrient intake analysis is described in Chapter 4. If food intake is inadequate, measures should be taken to provide foods or supplements that may be better accepted or tolerated. Regardless of the type of diet prescribed, the food served and the amount actually eaten must be considered to obtain an accurate determination of the client’s energy and nutrient intake. Snacks and calorie-containing beverages consumed between meals also are considered in the overall intake. The RDN must maintain communication with nursing and food service personnel to determine adequacy of intake.

Acceptance and Psychologic Factors

Meals and between-meal snacks are often highlights of the day and are anticipated with pleasure by the client. Mealtime should be as positive an experience as possible. In whatever setting the client is eating, it should be comfortable for the client. Food intake is encouraged in a pleasant room with the client in a comfortable eating position in bed or sitting in a chair located away from unpleasant sights or odors. Eating with others often promotes better intake.

Arrangement of the tray should reflect consideration of the client’s needs. Dishes and utensils should be in a convenient location. Independence should be encouraged in those who require assistance in eating. The caregiver can accomplish this by asking clients to specify the sequence of foods to be eaten and having them participate in eating. Even visually impaired persons can eat unassisted if they are told where to find foods on the tray. For clients who require eating assistance it is important that food be served when a caregiver is ready to assist so the foods are at an optimal temperature. Occupational therapists are helpful for recommending special utensils (such as weighted spoons) and for developing a plan for eating independence.

Poor acceptance of foods and meals may be caused by unfamiliar foods, a change in eating schedule, improper food temperatures, the client’s medical condition, or the effects of medical therapy. Food acceptance is improved when personal selection of menus is encouraged.

Clients should be given the opportunity to share concerns regarding meals, which may improve acceptance and intake. The attitude of the caregiver is important for encouraging acceptance of a therapeutic diet. The nurse who understands that the diet contributes to the restoration of the client’s health communicates this conviction by actions, facial expressions, and conversation. Clients who understand that the diet is important to the success of their recovery usually accept it more willingly. When the client must adhere to a therapeutic dietary program indefinitely, a counseling approach helps him or her achieve nutritional goals (see Chapter 13). Because they have frequent contact with clients, nurses and nursing assistants play an important role in a client’s acceptance of nutrition care. Ensuring that the nursing staff is aware of the client’s nutrition care plan can greatly improve the probability of success.

Interventions: Nutrition Education and Counseling

Nutrition education is an important part of nutrition care provided to individuals and populations. The goal of nutrition education is to help the client acquire the knowledge and skills needed to make changes, including modifying behavior to facilitate sustained change. Nutrition education and dietary changes can result in many benefits, including management of the disease or symptoms, improved health status, enhanced quality of life, and decreased health care costs.

As the average length of hospital stays has decreased, the role of the inpatient dietitian in educating inpatients has changed to providing brief education or “survival skills.” This education includes the types of foods to limit, timing of meals, and portion sizes. Many clients now transfer to a rehabilitation facility to complete their recovery to lower the cost of care. RDNs are able to follow them for longer periods of time and are able to continue nutrition counseling started in the hospital. Follow-up outpatient counseling should be encouraged at discharge. See Chapter 12 for managing nutrition support and Chapter 13 for counseling.

Intervention: Coordination of Care

Nutrition care is part of **discharge planning**. Education, counseling, and mobilization of resources to provide home care and nutrition support are included in discharge procedures. Completing a discharge nutritional summary for the next caregiver is imperative for optimal care. Appropriate discharge documentation includes a summary of nutrition therapies and outcomes; pertinent information such as weights, laboratory values, and dietary intake; relevant drug-nutrient interactions; expected progress or prognosis; and recommendations for follow-up services. Types of therapy attempted and failed can be very useful information. The amount and type of instruction given, the client’s comprehension, and the expected degree of adherence to

the prescribed diet are included. An effective discharge plan increases the likelihood of a positive outcome for the client.

Regardless of the setting to which the client is discharged, effective coordination of care begins on day 1 of a hospital or nursing home stay and continues throughout the institutionalization. The client should be included in every step of the planning process whenever possible to ensure that decisions made by the health care team reflect the desires of the client.

When needed, the RDN refers the client to other caregivers, agencies, or programs for follow-up care or services. For example, use of the home-delivered meal program of the Older Americans Act Nutrition Program traditionally has served frail, homebound, older adults, yet studies show that older adults who have been discharged recently from the hospital may be at high nutritional risk but not referred to this service (Sahyoun et al, 2010; see Chapter 19). Thus the RDN plays an essential role in making the referral and coordinating the necessary follow-up.

NUTRITION FOR THE TERMINALLY ILL OR HOSPICE CLIENT

Maintenance of comfort and quality of life are most typically the goals of nutrition care for the terminally ill client. Dietary restrictions are rarely appropriate. Nutrition care should be mindful of strategies that facilitate symptom and pain control. Recognition of the various phases of dying—denial, anger, bargaining, depression, and acceptance—will help the health care professional understand the client's response to food and nutrition support.

The decision as to when life support should be terminated often involves the issue of whether to continue enteral or parenteral nutrition. With **advance directives**, the client can advise family and health care team members of individual preferences with regard to end-of-life issues. Food and hydration issues may be discussed, such as whether tube feeding should be initiated or discontinued, and under what circumstances. Nutrition support should be continued as long as the client is competent to make this choice (or as specified in the client's advance directives).

In advanced dementia, the inability to eat orally can lead to weight loss (see Chapter 19). One clear goal-oriented alternative to tube feeding may be the order for “comfort feeding only” to ensure an individualized eating plan (Palecek et al, 2010). **Palliative care** encourages the alleviation of physical symptoms, anxiety, and fear while attempting to maintain the client's ability to function independently.

Hospice home care programs allow terminally ill clients to stay at home and delay or avoid hospital admission. Quality of life is the critical component. Indeed, individuals have the right to request or refuse nutrition and hydration as medical treatment. RDN intervention may benefit the client and family as they adjust to issues related to the approaching death. Families who may be accustomed to a modified diet should be reassured if they are uncomfortable about easing dietary restrictions. Ongoing communication and explanations to the family are important and helpful. RDNs should work collaboratively to make recommendations on providing, withdrawing, or withholding nutrition and hydration in individual cases and serve as active members of institutional ethics committees. The RDN, as a member of the health care team, has a responsibility to promote use of advanced directives of the individual client and to identify their nutritional and hydration needs. Quality of life and other **Patient Reported Outcome Measures (PROMs)** are becoming increasingly important as a concrete approach to monitor PCC.

CLINICAL CASE STUDY

Mr. B, a 47-year-old white male, 6 ft 2 in tall and weighing 200 lb, is admitted to the hospital with chest pain. Three days after admission, at patient care rounds, it is discovered that Mr. B has gained 30 pounds over the last 2 years. Review of the health record reveals the following laboratory data: LDL is 240 mg/dL (desirable 130), HDL is 30 mg/dL (desirable 50), triglyceride is 350 mg/dL (desirable <200). Blood pressure is 120/85. Current medications: multivitamin/mineral daily. Cardiac catheterization is scheduled for tomorrow. Diet history reveals frequent consumption of high-fat foods. 24-hour recall: 3200 kcal and 150 g of fat.

Nutrition Diagnostic Statements

- Altered nutrition-related laboratory values related to undesirable food choices as evidenced by elevated LDL and low HDL, and diet history of frequent consumption of high-fat foods.
- Excessive fat and energy intake related to consumption of high-fat foods at all meals as evidenced by 24-hour recall of 3200 kcal and 150 g of fat.

Nutrition Care Questions

1. What other information do you need to develop a nutrition care plan?
2. Was nutrition screening completed in a timely manner? Discuss the implications of timing of screening versus implementing care.
3. Develop a chart note, using ADIME format, based on this information and the interview you conduct with the client.
4. What nutrition care goals would you develop for this client during his hospital stay?
5. What goals would you develop for this client after discharge? Discuss how the type of health care insurance coverage the client has might influence this plan.

HDL, High-density lipoprotein; *LDL*, low-density lipoprotein.

Food-Nutrient Delivery: Planning the Diet With Cultural Competence

Lorena Drago, MS, RDN, CDN, CDE

Martin M. Yadrick, MBI, MS, RDN, FAND

KEY TERMS

adequate intake (AI)	food insecurity	phytochemicals
daily reference value (DRV)	functional food	recommended dietary allowance (RDA)
daily value (DV)	health claim	reference daily intake (RDI)
Dietary Guidelines for Americans (DGA)	Healthy Eating Index (HEI)	semivegetarian
dietary reference intake (DRI)	Lactoovovegetarian	tolerable upper intake level (UL)
estimated average requirement (EAR)	Lactovegetarian	vegan
flexitarian	MyPlate Food Guidance System	vegetarian
food deserts	nutrition facts label	

An appropriate diet is adequate and balanced and considers the individual's characteristics, such as age and stage of development, taste preferences, and food habits. It also reflects the availability of food, storage and preparation facilities, socioeconomic conditions, cultural practices and family traditions, and cooking skills. An adequate and balanced diet meets all the nutritional needs of an individual for maintenance, repair, living processes, growth, and development. It includes energy and all nutrients in proper amounts and in proportion to each other. The presence or absence of one essential nutrient may affect the availability, absorption, metabolism, or dietary need for others. The recognition of nutrient interrelationships provides further support for the principle of maintaining food variety to provide the most complete diet.

Registered dietitian nutritionists (RDNs) and registered nutrition and dietetic technicians (NDTRs) translate food, nutrition, and health information into food choices and diet patterns for groups and individuals. With increasing knowledge of the relationship between diet and incidence of chronic disease among Americans, the importance of an appropriate diet cannot be overemphasized. In this era of vastly expanding scientific knowledge, food intake messages for health promotion and disease prevention change frequently.

DETERMINING NUTRIENT NEEDS

According to the Food and Nutrition Board (FNB) of the National Academies of Sciences, Engineering, and Medicine, choosing a variety of foods should provide adequate amounts of nutrients. A varied diet also may ensure that a person is consuming sufficient amounts of **functional food** constituents that, although not defined as nutrients, have biologic effects and may influence health and susceptibility to disease. Examples include foods containing dietary fiber and

carotenoids, as well as lesser known **phytochemicals** (components of plants that have protective or disease-preventive properties) such as isothiocyanates in Brussels sprouts or other cruciferous vegetables and lycopene in tomato products.

WORLDWIDE GUIDELINES

Numerous standards serve as guides for planning and evaluating diets and food supplies for individuals and population groups. The Food and Agriculture Organization (FAO) and the World Health Organization (WHO) of the United Nations have established international standards in many areas of food quality and safety, as well as dietary and nutrient recommendations. In the United States the FNB has led the development of nutrient recommendations since the 1940s. Since the mid-1990s, nutrient recommendations developed by the FNB have been used by the United States and Canada.

The U.S. Departments of Agriculture (USDA) and Health and Human Services (USDHHS) have a shared responsibility for issuing dietary recommendations, collecting and analyzing food composition data, and formulating regulations for nutrition information on food products. Health Canada is the agency responsible for Canadian dietary recommendations, nutritional health and well-being of Canadians, and evidenced-based nutrition policies and standards. Eating Well with Canada's Food Guide aims to improve health, meet nutrient needs, and reduce the risk of nutrient-related conditions and diseases. In South America, several countries such as Argentina, Brazil, Chile, Uruguay, and Venezuela released dietary guidelines in the late 1990s or early 2000s. Among 27 Latin American and Caribbean countries, 24 have established food-based dietary guidelines. In Latin America and the Caribbean, the dietary guidelines and food guides are changing from a focus solely on undernutrition to now include obesity. The

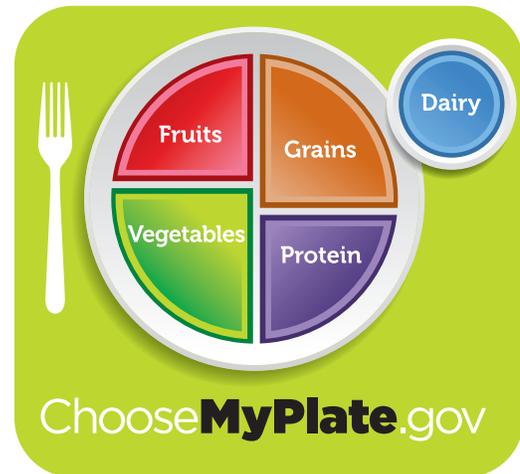

Mexican dietary guidelines were developed by a group of interdisciplinary experts in the fields of nutrition (including dietetics), food security, and public health convened by the National Academy of Medicine and the National Institute of Public Health to prevent the double burden of malnutrition and obesity and other chronic diseases related to food. The Mexican dietary and physical activity guidelines for the general population emphasize the enjoyment of eating in a family setting; eating whole grains; drinking water and *aguas frescas* (cold beverages made by blending fruit with water or by infusing fruits, seeds or grains, or flower petals with water) without sugar; and avoiding highly processed foods, sweetened beverages, and grain-based desserts. In El Salvador, the Nutrition Division of the Ministry of Health develops the Salvadoran Dietary Guidelines. The dietary guidelines recommend consuming a variety of fresh foods, fruits, vegetables, and avoiding fast foods, fried foods, canned foods, desserts, and sweetened beverages.

The Guatemalan Ministry of Public Health and Social Assistance, in coordination with the National Program of Chronic Noncommunicable Diseases of the Ministry of Public Health and Social Assistance with support from the Pan American Health Organization/WHO, the Nutrition Institute of Central America and Panama, and other institutions developed the Guatemalan Dietary Guidelines. The Guidelines promote a “protective diet,” which allows the population to make better decisions to avoid malnutrition while preventing obesity and chronic diseases, such as hypertension and diabetes, among others. The daily recommendations include physical activity and consumption of fruits, vegetables, and two tablespoons of beans with each tortilla as these are economical and healthy foods. To combat malnutrition and anemia, consumption of beef, chicken, liver, or fish is recommended at least twice per week. The Honduran Ministry of Health published the Honduran Dietary Guidelines in 2011 and revised them in 2013. Key messages include eating a variety of foods such as fruits and vegetables daily and beef, fish, or offal at least twice a week to promote growth and strengthen the body. The Dominican Republic Ministry of Public Health, with other public health collaborators, developed the dietary guidelines. The objectives of the dietary guidelines are to promote a healthy diet based on seven food groups to prevent diseases due to deficit or excess in the consumption of food; improve the feeding habits of the Dominican population through the promotion of a healthy and balanced diet; and encourage a healthy lifestyle through the routine practice of physical activity and healthy habits. The Colombian Institute of Family Welfare developed the Colombian Dietary Guidelines, emphasizing the consumption of a variety of food sources; daily intake of fruits, vegetables, and dairy; and physical activity. It encourages the consumption of legumes twice a week and eating organ meats once a week to prevent anemia. Sweetened beverages, “junk food,” processed and high-sodium foods, and animal sources of food are discouraged. The Bengoa Foundation for Food and Nutrition published the Venezuelan Dietary Guidelines. The core messages focus on eating a variety of foods in adequate amounts in a family setting with good food and good hygiene practices.

In Australia, the guidelines are available through the National Health and Medical Research Council of the Department of Health. In 1996 the WHO and FAO published guidelines for the development and use of food-based dietary guidelines (FAO/WHO, 1996). On the African continent, dietary guidelines have been developed in Benin, Kenya, Namibia, Nigeria, Seychelles, Sierra Leone, and South Africa. Asian countries, including Bangladesh, India, Indonesia, Malaysia, Nepal, Philippines, Singapore, and Thailand released dietary guidelines in the late 1990s and early 2000s.

Several countries have developed food-based dietary guidelines that are illustrated using images including a pyramid, a house, a

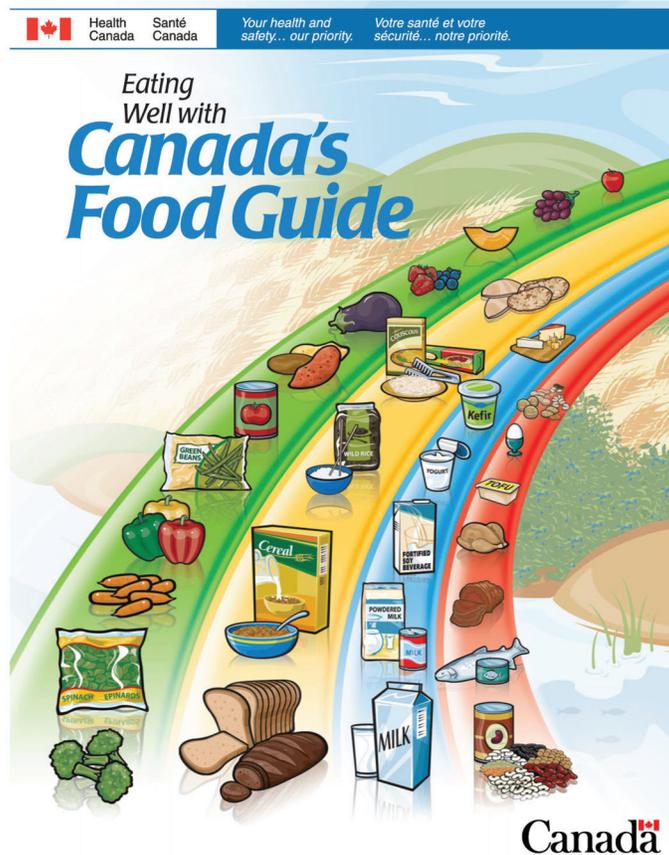

staircase, or a palm tree. In the United States the **MyPlate Food Guidance System**, shown in Fig. 10.1, replaced the previous MyPyramid diagram. For comparison, see Eating Well with Canada’s Food Guide as shown in *Clinical Insight: Nutrition Recommendations for Canadians* and Fig. 10.2. Mexico’s *El Plato del Bien Comer*, with its five plate sections including one for legumes, is shown in Fig. 10.3. The Healthy Colombian Family Plate *Plato Saludable de la Familia Colombiana* (Fig. 10.4) has a six-section plate that includes animal/vegetable protein, fruits and vegetables, grains and starchy vegetables, sweetened foods and fast foods, fats and oil, and dairy. There is an exercise icon to encourage regular physical activity. The Dominican Republic utilizes the mortar, a staple kitchen tool in the Dominican cuisine. Guatemala and Honduras use a pot containing the recommended food groups in proportion to how much they should be consumed. The Australian Guide for Healthy Eating uses a pie-shaped image with the five food groups represented proportionally in terms of recommended intakes (Fig. 10.5). There is a separate Australian Guide to Health Eating for Aboriginal and Torres Strait Islanders (Fig. 10.6). In Japan, the Ministry of Health, Labour and Welfare and the Ministry of Agriculture, Forestry and Fisheries jointly developed their Dietary Guidelines in 2000, and in 2005 published the “Japanese Food Guide Spinning Top” (with revisions in 2010) to encourage a well-balanced diet (Fig. 10.7). The Chinese Nutrition Society released the latest update to its dietary Pagoda in 2016. The 2016 dietary pagoda is a revision of the 2007 Food Pagoda. Compared with the 2007 version, the number of guidelines is reduced from ten to six (Fig. 10.8). Several other countries use images to illustrate their food-based dietary guidelines, including the

MyPlate Messages

- Find your healthy eating style and maintain it for a lifetime
- Make half your plate fruits and vegetables: vary your veggies, focus on whole fruits
- Make half your grains whole grains
- Move to low-fat or fat-free milk or yogurt
- Vary your protein routine
- Make small changes

Fig. 10.1 MyPlate showing the five essential food groups. (Courtesy the United States Department of Agriculture.) Retrieved from <http://www.choosemyplate.gov/>.

Canada

Recommended Number of Food Guide Servings per Day

Age in Years Sex	Children			Teens		Adults			
	2-3	4-8	9-13	14-18		19-50		51+	
	Girls and Boys			Females	Males	Females	Males	Females	Males
Vegetables and Fruit	4	5	6	7	8	7-8	8-10	7	7
Grain Products	3	4	6	6	7	6-7	8	6	7
Milk and Alternatives	2	2	3-4	3-4	3-4	2	2	3	3
Meat and Alternatives	1	1	1-2	2	3	2	3	2	3

What is One Food Guide Serving?
Look at the examples below.

<p>Fresh, frozen or canned vegetables 125 mL (½ cup)</p>	<p>Leafy vegetables Cooked: 125 mL (½ cup) Raw: 250 mL (1 cup)</p>	<p>Fresh, frozen or canned fruits 1 fruit or 125 mL (½ cup)</p>	<p>100% Juice 125 mL (½ cup)</p>		
<p>Bread 1 slice (35 g)</p>	<p>Bagel ½ bagel (45 g)</p>	<p>Flat breads ½ pita or ½ tortilla (35 g)</p>	<p>Cooked rice, bulgur or quinoa 125 mL (½ cup)</p>	<p>Cereal Cold: 30 g Hot: 175 mL (¾ cup)</p>	<p>Cooked pasta or couscous 125 mL (½ cup)</p>
<p>Milk or powdered milk (reconstituted) 250 mL (1 cup)</p>	<p>Canned milk (evaporated) 125 mL (½ cup)</p>	<p>Fortified soy beverage 250 mL (1 cup)</p>	<p>Yogurt 175 g (¾ cup)</p>	<p>Kefir 175 g (¾ cup)</p>	<p>Cheese 50 g (1½ oz.)</p>
<p>Cooked fish, shellfish, poultry, lean meat 75 g (2 ½ oz./125 mL (½ cup))</p>	<p>Cooked legumes 175 mL (¾ cup)</p>	<p>Tofu 150 g or 175 mL (¾ cup)</p>	<p>Eggs 2 eggs</p>	<p>Peanut or nut butters 30 mL (2 Tbsp)</p>	<p>Shelled nuts and seeds 60 mL (¾ cup)</p>

The chart above shows how many Food Guide Servings you need from each of the four food groups every day.

Having the amount and type of food recommended and following the tips in *Canada's Food Guide* will help:

- Meet your needs for vitamins, minerals and other nutrients.
- Reduce your risk of obesity, type 2 diabetes, heart disease, certain types of cancer and osteoporosis.
- Contribute to your overall health and vitality.

Oils and Fats

- Include a small amount – 30 to 45 mL (2 to 3 Tbsp) – of unsaturated fat each day. This includes oil used for cooking, salad dressings, margarine and mayonnaise.
- Use vegetable oils such as canola, olive and soybean.
- Choose soft margarines that are low in saturated and trans fats.
- Limit butter, hard margarine, lard and shortening.

Fig. 10.2 Eating Well with Canada's Food Guide. (Courtesy Health Canada. Data from Health Canada: Eating well with Canada's food guide, Her Majesty the Queen in Right of Canada, represented by the Minister of Health Canada, 2011.) Retrieved from https://www.canada.ca/content/dam/hc-sc/migration/hc-sc/fn-an/alt_formats/hpfb-dgpsa/pdf/food-guide-aliment/view_eatwell_vue_bienmang-eng.pdf.

Make each Food Guide Serving count... wherever you are – at home, at school, at work or when eating out!

- ▶ **Eat at least one dark green and one orange vegetable each day.**
 - Go for dark green vegetables such as broccoli, romaine lettuce and spinach.
 - Go for orange vegetables such as carrots, sweet potatoes and winter squash.
- ▶ **Choose vegetables and fruit prepared with little or no added fat, sugar or salt.**
 - Enjoy vegetables steamed, baked or stir-fried instead of deep-fried.
- ▶ **Have vegetables and fruit more often than juice.**

- ▶ **Make at least half of your grain products whole grain each day.**
 - Eat a variety of whole grains such as barley, brown rice, oats, quinoa and wild rice.
 - Enjoy whole grain breads, oatmeal or whole wheat pasta.
- ▶ **Choose grain products that are lower in fat, sugar or salt.**
 - Compare the Nutrition Facts table on labels to make wise choices.
 - Enjoy the true taste of grain products. When adding sauces or spreads, use small amounts.

- ▶ **Drink skim, 1%, or 2% milk each day.**
 - Have 500 mL (2 cups) of milk every day for adequate vitamin D.
 - Drink fortified soy beverages if you do not drink milk.
- ▶ **Select lower fat milk alternatives.**
 - Compare the Nutrition Facts table on yogurts or cheeses to make wise choices.

- ▶ **Have meat alternatives such as beans, lentils and tofu often.**
- ▶ **Eat at least two Food Guide Servings of fish each week.***
 - Choose fish such as char, herring, mackerel, salmon, sardines and trout.
- ▶ **Select lean meat and alternatives prepared with little or no added fat or salt.**
 - Trim the visible fat from meats. Remove the skin on poultry.
 - Use cooking methods such as roasting, baking or poaching that require little or no added fat.
 - If you eat luncheon meats, sausages or prepackaged meats, choose those lower in salt (sodium) and fat.

Enjoy a variety of foods from the four food groups.

Satisfy your thirst with water!
 Drink water regularly. It's a calorie-free way to quench your thirst. Drink more water in hot weather or when you are very active.

* Health Canada provides advice for limiting exposure to mercury from certain types of fish. Refer to www.healthcanada.gc.ca for the latest information.

Advice for different ages and stages...

Children

Following *Canada's Food Guide* helps children grow and thrive.

Young children have small appetites and need calories for growth and development.

- Serve small nutritious meals and snacks each day.
- Do not restrict nutritious foods because of their fat content. Offer a variety of foods from the four food groups.
- Most of all... be a good role model.

Women of childbearing age

All women who could become pregnant and those who are pregnant or breastfeeding need a multivitamin containing **folic acid** every day. Pregnant women need to ensure that their multivitamin also contains **iron**. A health care professional can help you find the multivitamin that's right for you.

Pregnant and breastfeeding women need more calories. Include an extra 2 to 3 Food Guide Servings each day.

Here are two examples:

- Have fruit and yogurt for a snack, or
- Have an extra slice of toast at breakfast and an extra glass of milk at supper.

Men and women over 50

The need for **vitamin D** increases after the age of 50.

In addition to following *Canada's Food Guide*, everyone over the age of 50 should take a daily vitamin D supplement of 10 µg (400 IU).

Eat well and be active today and every day!

The benefits of eating well and being active include:

- Better overall health.
- Lower risk of disease.
- A healthy body weight.
- Feeling and looking better.
- More energy.
- Stronger muscles and bones.

Be active

To be active every day is a step towards better health and a healthy body weight.

Canada's Physical Activity Guide recommends building 30 to 60 minutes of moderate physical activity into daily life for adults and at least 90 minutes a day for children and youth. You don't have to do it all at once. Add it up in periods of at least 10 minutes at a time for adults and five minutes at a time for children and youth.

Start slowly and build up.

Eat well

Another important step towards better health and a healthy body weight is to follow *Canada's Food Guide* by:

- Eating the recommended amount and type of food each day.
- Limiting foods and beverages high in calories, fat, sugar or salt (sodium) such as cakes and pastries, chocolate and candies, cookies and granola bars, doughnuts and muffins, ice cream and frozen desserts, french fries, potato chips, nachos and other salty snacks, alcohol, fruit flavoured drinks, soft drinks, sports and energy drinks, and sweetened hot or cold drinks.

Take a step today...

- ✓ Have breakfast every day. It may help control your hunger later in the day.
- ✓ Walk wherever you can – get off the bus early, use the stairs.
- ✓ Benefit from eating vegetables and fruit at all meals and as snacks.
- ✓ Spend less time being inactive such as watching TV or playing computer games.
- ✓ Request nutrition information about menu items when eating out to help you make healthier choices.
- ✓ Enjoy eating with family and friends!
- ✓ Take time to eat and savour every bite!

How do I count Food Guide Servings in a meal?

Here is an example:

Vegetable and beef stir-fry with rice, a glass of milk and an apple for dessert	
250 mL (1 cup) mixed broccoli, carrot and sweet red pepper	= 2 Vegetables and Fruit Food Guide Servings
75 g (2½ oz.) lean beef	= 1 Meat and Alternatives Food Guide Serving
250 mL (1 cup) brown rice	= 2 Grain Products Food Guide Servings
5 mL (1 tsp) canola oil	= part of your Oils and Fats intake for the day
250 mL (1 cup) 1% milk	= 1 Milk and Alternatives Food Guide Serving
1 apple	= 1 Vegetables and Fruit Food Guide Serving

Read the label

- Compare the Nutrition Facts table on food labels to choose products that contain less fat, saturated fat, trans fat, sugar and sodium.
- Keep in mind that the calories and nutrients listed are for the amount of food found at the top of the Nutrition Facts table.

Nutrition Facts	
Per 0 mL (0 g)	
Amount	% Daily Value
Calories 0	
Fat 0 g	0 %
Saturated 0 g	0 %
+ Trans 0 g	
Cholesterol 0 mg	
Sodium 0 mg	0 %
Carbohydrate 0 g	0 %
Fibre 0 g	0 %
Sugars 0 g	
Protein 0 g	
Vitamin A 0 %	Vitamin C 0 %
Calcium 0 %	Iron 0 %

Limit trans fat

When a Nutrition Facts table is not available, ask for nutrition information to choose foods lower in trans and saturated fats.

Netherlands (Fig. 10.9), France (Fig. 10.10), Greece (Fig. 10.11), Hungary (Fig. 10.12), Ireland (Fig. 10.13), Saudi Arabia (Fig. 10.14), Slovenia (Fig. 10.15), South Korea (Fig. 10.16), and the United Kingdom (Fig. 10.17). The dietary guidelines from Brazil and Venezuela include mention of the environment in which one eats, the time spent consuming a meal, and the importance of eating in a family setting (*Guia alimentar para a população Brasileira*, 2015). The Brazilian guidelines also offer advice on choosing fresh or freshly made foods at the grocery store and at restaurants and suggest that the consumer look objectively at food product advertisements.

Dietary Reference Intakes

American standards for nutrient requirements have been the **recommended dietary allowances (RDAs)** established by the FNB of the former Institute of Medicine (IOM), now the National Academy of Medicine.

They were first published in 1941 and most recently revised for certain nutrients in 2019. Each revision incorporates the most recent research findings. In 1993 the FNB developed a framework for the development of nutrient recommendations, called **dietary reference intakes (DRIs)**. Nutrition and health professionals always should use updated food composition databases and tables and inquire whether data used in computerized nutrient analysis programs have been revised to include the most up-to-date information. An interactive DRI

calculator is available at the USDA's website. This can be used to determine an individual's daily nutrient recommendations based on the DRI, including energy, macronutrients, vitamins, and minerals, as well as calculating body mass index (BMI).

DRI Components

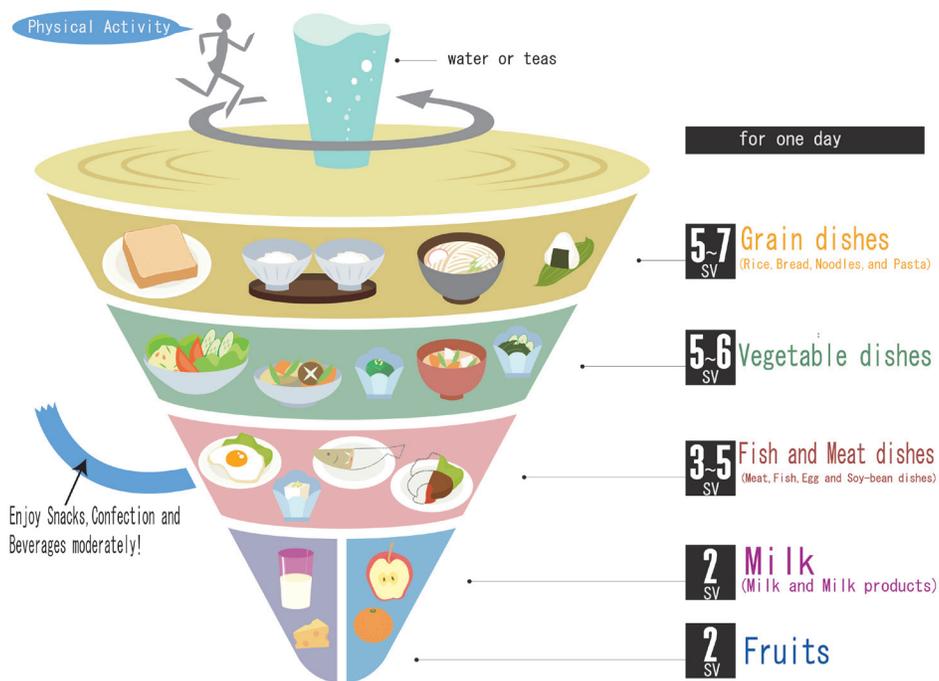

The DRI model expands the previous RDA and Canada's Recommended Nutrient Intakes (RNI), which focused only on levels of nutrients for healthy populations to prevent deficiency diseases. To respond to scientific advances in diet and health throughout the life cycle, the DRI model now includes four reference points: **adequate intake (AI)**, estimated average requirement (EAR), RDA, and tolerable upper intake level (UL), as well as acceptable macronutrient distribution ranges (AMDR).

The **AI** is an average daily intake level that is based on observed or experimentally determined approximations of nutrient intake by a group (or groups) of healthy people when sufficient scientific evidence is not available to calculate an RDA. Some key nutrients are expressed as an AI, including potassium (see Chapter 3). The **estimated average requirement (EAR)** is the average daily requirement of a nutrient for healthy individuals based on gender and stage of life. It is the amount of a nutrient with which approximately one-half of individuals would have their needs met and one-half would not. The EAR should be used for assessing the nutrient adequacy of populations but not for individuals.

The RDA presents the amount of a nutrient needed to meet the requirements of almost all (97% to 98%) of the healthy population of individuals for whom it was developed. An RDA for a nutrient should serve as an intake goal for individuals, not as a benchmark for adequacy of diets of populations. Finally the **tolerable upper intake level (UL)** was established for many nutrients to reduce the risk of adverse or toxic effects from consumption of nutrients in concentrated forms—either alone or combined with others (not in food)—or from enrichment and fortification. A UL is the highest level of daily nutrient intake that is unlikely to have any adverse health effects on almost all individuals in the general population. The DRIs for the macronutrients, vitamins, and minerals, including the ULs, are presented on the inside covers of this text. The AMDRs are ranges of intakes of macronutrients associated with reduced risk of chronic disease. The AMDRs for fat, carbohydrate, and protein are based on energy intake by age group. See [Table 10.1](#) and the DRI tables on the inside covers of this text.

Target Population

Each of the nutrient recommendation categories in the DRI system is used for specific purposes among individuals or populations. As noted previously, the EAR is used for evaluating the nutrient intake of populations. The AI and RDA can be used for individuals. Nutrient intakes between the RDA and the UL may further define intakes that may promote health or prevent disease in the individual.

Age and Gender Groups

Because nutrient needs are highly individualized depending on age, gender, and the reproductive status of females, the DRI framework has 10 age groupings, including age group categories for children, adolescents, men and women 51 to 70 years of age, and those older than 70 years of age. It separates three age group categories each for pregnancy and lactation—14 to 18 years, 19 to 30 years, and 31 to 50 years of age.

Reference Men and Women

The requirement for many nutrients is based on body weight, according to reference heights and weights that are specific to gender and stage of life. Reference height and weight information used in determining the DRIs was obtained from the Centers for Disease Control and Prevention (CDC)/National Center for Health Statistics (NCHS) growth charts. Although this does not necessarily imply that these weight-for-height values are ideal, at least they make it possible to define recommended allowances appropriate for the greatest number of people.

NUTRITIONAL STATUS OF AMERICANS

Food and Nutrient Intake Data

Information about the diet and nutritional status of Americans and the relationship between diet and health is collected primarily by the CDC via its NCHS and National Health and Nutrition Examination Survey (NHANES).

Unfortunately, gaps still exist between actual consumption and government recommendations in certain population subgroups. Nutrition-related health measurements indicate that overweight and obesity are increasing from lack of physical activity. Data from the combined NHANES and NHANES National Youth Fitness Survey showed that only about 25% of youth ages 12 to 15 engage in moderate to vigorous physical activity for more than 60 minutes daily. In males, this number decreased as weight increased ([NHANES, 2012](#)). Hypertension remains a major public health problem in middle-age and older adults and in non-Hispanic blacks in whom it increases the risk of stroke and coronary heart disease (see Chapter 32). Osteoporosis develops more often among non-Hispanic whites than non-Hispanic blacks (see Chapter 23). Concern about preventable conditions, along with an increased emphasis on sustainability, has led to many hospitals taking on the challenge for healthier food intake (see [Focus On: The “Healthy Food in Health Care” Pledge](#)).

TABLE 10.1 Acceptable Macronutrient Distribution Ranges

NUTRIENT	AMDR (PERCENTAGE OF DAILY ENERGY INTAKE)			AMDR SAMPLE DIET ADULT, 2000-KCAL/DAY DIET	
	1-3 Years	4-18 Years	>19 Years	%Reference*	g/Day
Protein [†]	5-20	10.30	10.35	10	50
Carbohydrate	45-65	45-65	45-65	60	300
Fat	30-40	25-35	20-35	30	67
α-Linolenic acid (*omega-3) [‡]	0.6-1.2	0.6-1.2	0.6-1.2	0.8	1.8
Linoleic acid (omega-6)	5-10	5-10	5-10	7	16
Added sugars [§]	≤25% of total calories			500	125

*Suggested maximum.

[†]Higher number in protein AMDR is set to complement AMDRs for carbohydrate and fat, not because it is a recommended upper limit in the range of calories from protein.

[‡]Up to 10% of the AMDR for α-linolenic acid can be consumed as EPA, DHA, or both (0.06%-0.12% of calories).

[§]Reference percentages chosen based on average DRI for protein for adult men and women, then calculated back to percentage of calories.

Carbohydrate and fat percentages chosen based on difference from protein and balanced with other federal dietary recommendations.

AMDR, Acceptable macronutrient distribution range; DHA, docosahexaenoic acid; DRI, dietary reference intakes; EPA, eicosapentaenoic acid. Modified from Food and Nutrition Board, Institute of Medicine: *Dietary reference intakes for energy, carbohydrate, fiber, fat, fatty acids, cholesterol, protein, and amino acids*, Washington, DC, 2002/2005: National Academies Press.

FOCUS ON

The “Healthy Food in Health Care” Pledge

Health care facilities across the nation have recognized that their systems of purchasing, producing, and distributing food may be misaligned with the U.S. dietary guidelines and have joined a movement to change their practices. One organization promoting this plan is called “Health Care Without Harm.” In 2009, The American Medical Association (AMA) approved a new policy resolution in support of practices and policies within health care systems that promote and model a healthy and ecologically sustainable food system. The resolution also calls on the AMA to work with health care and public health organizations to educate the health care community and the public about the importance of healthy and ecologically sustainable food systems. Hospitals are using the online pledge form to commit to these nine steps:

1. Work with local farmers, community-based organizations, and food suppliers to increase the availability of locally sourced food.
2. Encourage vendors and/or food management companies to supply food that is, among other attributes, produced without synthetic pesticides and hormones or antibiotics given to animals in the absence of diagnosed disease and food which supports farmer health and welfare and ecologically protective and restorative agriculture.
3. Increase offering of fruit and vegetables, nutritionally dense and minimally processed foods, and unrefined foods and reduce unhealthy (trans and saturated) fats and sweetened foods.
4. Implement a stepwise program to identify and adopt sustainable food procurement. Begin where fewer barriers exist and immediate steps can be taken. For example, the adoption of rBGH-free milk, fair trade coffee, or organic fresh produce in the cafeteria.
5. Communicate to group purchasing organizations an interest in foods that are identified as local and/or third-party certified.
6. Educate patients and community members about nutritious, socially just, and ecological sustainable healthy food practices and procedures.
7. Minimize or beneficially reuse food waste and support the use of food packaging and products which are ecologically protective.
8. Develop a program to promote and source from producers and processors that uphold the dignity of family, farmers, workers, and their communities and support sustainable and humane agriculture systems.
9. Report annually on implementation of this pledge.

Modified from *Health Care without Harm* (website): <https://noharm-uscanada.org/content/us-canada/healthy-food-health-care-pledge>.

CLINICAL INSIGHT

Nutrition Recommendations for Canadians

The revision to Canada’s Food Guide to Healthy Eating, released in 2007, developed age- and gender-specific food intake patterns. These suggested patterns include 4 to 7 servings of vegetables and fruits, 3 to 7 servings of grain products, 2 to 3 servings of milk or milk alternatives, and 1 to 3 servings of meat or meat alternatives. Canada’s Eating Well with Canada’s Food Guide contains four main food groupings presented in a rainbow shape.

Tips include the following:

- Eat at least one dark green and one orange vegetable each day.
- Make at least half of your grain products whole grain each day.
- Compare the Nutrition Facts table on food labels to choose products that contain less fat, saturated fat, trans fat, sugar, and sodium.
- Drink skim, 1% or 2% milk, or fortified soy beverages each day.
- Include a small amount—30-45 mL (2-3 tbsp)—of unsaturated fat each day.
- Eat at least two Food Guide Servings of fish each week.

It is recommended that adults accumulate at least 2½ hours of moderate to vigorous physical activity each week and that children and youth accumulate at least 60 minutes per day. The Canadian Food Guide recognizes the cultural, spiritual, and physical importance of traditional Aboriginal foods as well as the role of nontraditional foods in contemporary diets, with a First Nations, Inuit, and Métis guide available. The guide is available in 12 languages.

Data from Health Canada: *Eating Well with Canada’s Food Guide, Her Majesty the Queen in Right of Canada, represented by the Minister of Health Canada, 2011* (website): from <http://www.hc-sc.gc.ca/fn-an/food-guide-aliment/index-eng.php>.

Eating Well with Canada’s Food Guide – First Nations, Inuit, and Métis: from <http://hc-sc.gc.ca/fn-an/pubs/fnim-pnim/index-eng.php>.

Finally, in spite of available choices, many Americans experience **food insecurity**, meaning that they lack access to adequate and safe food for an active, healthy life. More than one in seven American households, including 12 million children, struggle to have enough to eat. In many lower socioeconomic neighborhoods, **food deserts** exist, where foods like fresh fruits and vegetables are not available at affordable prices. This is often accompanied by poor public transportation options. The Academy of Nutrition and Dietetics published a position paper on food insecurity in the United States in 2017.

Healthy Eating Index

The Center for Nutrition Policy and Promotion of the USDA releases the **Healthy Eating Index (HEI)** to measure how well people’s diets conform to recommended healthy eating patterns. The index provides

a picture of foods people are eating, the amount of variety in their diets, and compliance with specific recommendations in the **Dietary Guidelines for Americans (DGA)** (USDHHS, 2015). The HEI is designed to assess and monitor the dietary status of Americans by evaluating 12 components, each representing different aspects of a healthy diet. The HEI was last updated after the release of the 2015–2020 DGA. The dietary components used in HEI-2015 include nine related to adequacy: whole fruits, total fruits, whole grains, dairy, total protein foods, seafood and plant proteins, greens and beans, total vegetables, fatty acids, and four components for which moderation is recommended: refined grains, sodium, saturated fat, and added sugars (Krebs-Smith et al, 2018). One change since HEI-2010 is in the algorithm used to count legumes in the diet, which is now allocated to both the vegetable and the protein components.

NATIONAL GUIDELINES FOR DIET PLANNING

Eating can be one of life's greatest pleasures. People eat for enjoyment and to obtain energy and nutrients. Although many genetic, environmental, behavioral, and cultural factors affect health, diet is equally important for promoting health and preventing disease. Over the past several decades, attention has been focused increasingly on the relationship between nutrition and chronic diseases and conditions. Although this interest derives somewhat from the increasing percentage of older adults in the population as well as their longevity, it also is prompted by the desire to prevent premature deaths from diseases such as coronary heart disease, diabetes mellitus, and cancer. Approximately two-thirds of deaths in the United States are caused by chronic disease.

Current Dietary Guidance

In 1969 President Nixon convened the White House Conference on Nutrition and Health ([White House conference on food, nutrition and health, 1969](#)). Increased attention was being given to prevention of hunger and disease. The development of dietary guidelines in the United States is discussed in Chapter 8. Guidelines directed toward prevention of a particular disease, such as those from the National Cancer Institute; the American Diabetes Association; the American Heart Association; and the National Heart, Lung, and Blood Institute's cholesterol education guidelines, contain recommendations unique to particular conditions.

Implementing the Guidelines

The task of planning nutritious meals centers on including the essential nutrients in sufficient amounts as outlined in the most recent DRIs, in addition to appropriate amounts of energy, protein, carbohydrate (including fiber and sugars), fat (especially saturated and trans fats), cholesterol, and sodium. Suggestions are included to help people meet the specifics of the recommendations. When specific numeric recommendations differ, they are presented as ranges.

To help people select an eating pattern that achieves specific health promotion or disease prevention objectives, nutritionists should assist individuals in making food choices (e.g., to reduce saturated fat, to increase fiber). Although numerous federal agencies are involved in the issuance of dietary guidance, the USDA and USDHHS lead the effort. The DGA first were published in 1980 and are revised every 5 years; the 2015–2020 guidelines are included ([Box 10.1](#)). The DGA are designed to provide evidence-based nutrition information for people ages 2 and older to help them make healthy choices in their daily diet. The information in the DGA is used by the federal government to create educational materials for consumers and helps guide development of federal food and nutrition education programs (Dietary Guidelines 2015-2020: Introduction <https://health.gov/dietaryguidelines/2015/guidelines/introduction/dietary-guidelines-for-americans/>).

BOX 10.1 The 2015–2020 Dietary Guidelines for Americans

1. Follow a healthy eating pattern across the lifespan.
2. Focus on variety, nutrient density, and amount.
3. Limit calories from added sugars and saturated fats and reduce sodium intake.
4. Shift to healthier food and beverage choices.
5. Support healthy eating patterns for all.

Retrieved from <http://www.health.gov/dietaryguidelines/2015/guidelines/>.

FOOD AND NUTRIENT LABELING

To help consumers make choices between similar types of food products that can be incorporated into a healthy diet, the FDA established a voluntary system of providing selected nutrient information on food labels. The regulatory framework for nutrition information on food labels was revised and updated by the USDA (which regulates meat, poultry products, and eggs) and the FDA (which regulates all other foods) with enactment of the Nutrition Labeling and Education Act (NLEA) in 1990. The labels became mandatory in 1994. In 2016 the FDA announced the new nutrition facts label layout, designed to better educate consumers on the relationship between diet and chronic disease. Some of the changes include a larger type size for display of calories including declaration of actual amounts of Vitamin D, calcium, iron, and potassium (in addition to their percent daily value), and a better explanation of the meaning of daily value. The new labels also include a separate line for added sugars because many health experts recommend decreasing intake of sugars in favor of more nutrient-dense foods, as well as to help decrease overall caloric intake ([Fig. 10.18](#)). Compliance is currently set for January 1, 2020 for manufacturers with \$10 million or more in food sales, and January 1, 2021 for those with less than \$10 million in food sales.

Mandatory Nutrition Labeling

As a result of the NLEA, nutrition labels must appear on most foods, except products that provide few nutrients (such as coffee and spices), restaurant foods, and ready-to-eat foods prepared on site, such as supermarket bakery and deli items. Providing nutrition information on many raw foods is voluntary. However, the FDA and USDA have called for a voluntary point-of-purchase program in which nutrition information is available in most supermarkets. Nutrition information is provided through brochures or point-of-purchase posters for the 20 most popular fruits, vegetables, and fresh fish and the 45 major cuts of fresh meat and poultry. Several food

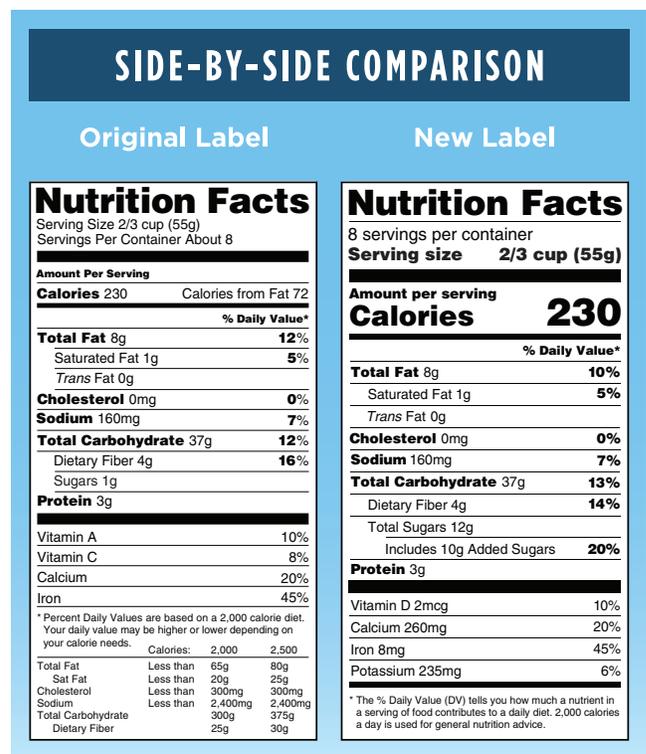

Fig. 10.18 Side-by-side comparison: original and new food label.

processors in the United States and elsewhere have tried implementing front-of-package labeling that employed a score, symbols, or color coding to reflect a product's overall nutrient content. Some of these systems, however, were confusing to consumers and have since been discontinued.

Nutrition information for foods purchased in restaurants is widely available at the point of purchase or from websites. FDA regulations require restaurant chains, retail food establishments, and vending machines with 20 or more locations to disclose calorie information on their menus or menu board (or on a sign or sticker on or adjacent to the vending machine). Additional nutrient information that must be made available upon request includes total calories, total fat, saturated fat, trans fat, cholesterol, sodium, total carbohydrates, fiber, sugars, and protein.

TABLE 10.2 Daily Value (Based on 2000 kcal Diet)

Nutrient	Amount
Total Fat	78 grams (g)
Saturated Fat	20 g
Cholesterol	300 milligrams (mg)
Sodium	2300 mg
Potassium	4700 mg
Total Carbohydrate	275 g
Added Sugars	50 g
Dietary Fiber	28 g
Protein	50 g
Vitamin A	900 micrograms (mcg) Retinol Activity Equivalents (RAE)
Vitamin C	90 mg
Calcium	1300 mg
Iron	18 mg
Vitamin D	20 mcg
Vitamin E	15 mg alpha-tocopherol
Vitamin K	120 mcg
Thiamin	1.2 mg
Riboflavin	1.3 mg
Niacin	16 mg Niacin Equivalents (NE)
Vitamin B ₆	1.7 mg
Folate	400 mcg Dietary Folate Equivalents (DFE)
Vitamin B ₁₂	2.4 mcg
Biotin	30 mcg
Pantothenic acid	5 mg
Choline	550 mg
Phosphorus	1250 mg
Iodine	150 mcg
Magnesium	420 mg
Zinc	11 mg
Selenium	55 mcg
Copper	0.9 mg
Manganese	2.3 mg
Chromium	35 mcg
Molybdenum	45 mcg
Chloride	2300 mg

From National Institutes of Health *Dietary Supplement Label Database: Labeling Daily Values*, retrieved from <https://www.dsid.nlm.nih.gov/dsid/dailyvalue.jsp>.

The new regulations also cover ready-to-eat unpackaged foods in delicatessens or supermarkets that meet the requirements above. If a food makes the claim of being organic, it also must meet certain criteria and labeling requirements. Use of the term *organic* is governed by USDA rather than FDA.

Standardized Serving Sizes on Food Labels

Serving sizes of products are set by the United States government based on reference amounts commonly consumed by Americans. For example, a serving of milk is 8 oz, and a serving of salad dressing is 2 tbsp. Standardized serving sizes make it easier for consumers to compare the nutrient contents of similar products (Fig. 10.18).

Nutrition Facts Label

The **nutrition facts label** on a food product provides information on its per-serving calories and calories from fat. The label must list the amount (in grams) of total fat, saturated fat, trans fat, cholesterol, sodium, total carbohydrate, dietary fiber, sugar, and protein. For most of these nutrients the label also shows the percentage of the **daily value (DV)** supplied by a serving, showing how a product fits into an overall diet by comparing its nutrient content with recommended intakes of those nutrients (Table 10.2). DVs are not recommended intakes for individuals; they are simply reference points to provide some perspective on daily nutrient needs and are based on a 2000-kcal diet. For example, individuals who consume diets supplying more or fewer calories can still use the DVs as a rough guide to ensure that they are getting adequate amounts of vitamin C, for example, but not too much saturated fat.

The DVs are listed for nutrients for which RDAs already exist (in which case they are known as **reference daily intakes [RDIs]**) (Table 10.3) and for which no RDAs exist (in which case they are known as **daily reference values [DRVs]**) [Table 10.4]). However, food

TABLE 10.3 Reference Daily Intakes

Nutrient	Amount
Vitamin A	900 mcg RAE
Vitamin C	90 mg
Thiamin	1.2 mg
Riboflavin	1.3 mg
Niacin	16 mg NE
Calcium	1300 mg
Iron	18 mg
Vitamin D	20 mcg
Vitamin E	15 mg alpha-tocopherol
Vitamin B ₆	1.7 mg
Folic acid	400 mcg DFE
Vitamin B ₁₂	2.4 mcg DFE
Phosphorus	1250 mg
Iodine	150 mcg
Magnesium	420 mg
Zinc	11 mg

TABLE 10.4 Daily Reference Values

Food Component	DRV	Calculation
Fat	78 g	35% of kcal
Saturated fat	20 g	10% of kcal
Cholesterol	300 mg	Same regardless of kcal
Carbohydrates (total)	275 g	55% of calories
Added Sugars	50 g	
Fiber	28 g	14 g per 1000 kcal
Protein	50 g	10% of kcal
Sodium	2300 mg	Same regardless of kcal
Potassium	3500 mg	Same regardless of kcal

DRV, Daily reference value.

NOTE: The DRVs were established for adults and children over 4 years old. The values for energy yielding nutrients below are based on 2000 calories per day.

labels use only the term *daily value*. RDIs provide a large margin of safety; in general, the RDI for a nutrient is greater than the RDA for a specific age group. As new DRIs are developed in various categories, labeling laws are updated. Box 10.2 provides tips for reading and understanding food labels.

Nutrient Content Claims

Nutrient content terms such as *reduced sodium*, *fat free*, *low-calorie*, and *healthy* must meet government definitions that apply to all foods (Box 10.3). For example, *lean* refers to a serving of meat, poultry, seafood, or game meat with less than 10 g of fat, less than 4 g of saturated fat, and less than 95 mg of cholesterol per serving or per 100 g. Extra lean meat or poultry contains less than 5 g of fat, less than 2 g of saturated fat, and the same cholesterol content as lean, per serving, or per 100 g of product.

BOX 10.2 Tips for Reading and Understanding Food Labels

Interpret the percent daily value (%DV).

- Nutrients with %DV of 5 or less are considered low or poor sources.
- Nutrients with %DV of 10 to 19 or less are considered moderate or “good sources.”
- Nutrients with %DV of 20 or more are considered high or “rich sources.”

Prioritize nutrient needs and compare %DV levels accordingly. For example, if a consumer wishes to lower osteoporosis risk versus limiting sodium, a packaged food containing 25%DV calcium and 15%DV sodium may be considered a sensible food selection.

Note the calories per serving and the servings per container. Consider how the energy value of a specific food fits into the total energy intake “equation.” Be conscious of the portion size that is consumed and “do the math” as to how many servings per container that portion would be.

Be aware of specific nutrient content claims. As shown in Box 10.3, there are many nutrient content claims, but only specific ones may relate to personal health priorities. For example, if there is a positive family history for heart disease, the “low fat” nutrient claim of 3 grams or less per serving may serve as a useful guide during food selection.

Review the ingredient list. Ingredients are listed in order of prominence. Pay particular attention to the top five items listed. Ingredients that contain sugar often end in *-ose*. The term *hydrogenated* signals that trans fats may be present. Sodium-containing additives also may be present in multiple forms.

BOX 10.3 Nutrient Content Claims

Free: *Free* means that a product contains no amount of, or only trivial or “physiologically inconsequential” amounts of, one or more of these components: fat, saturated fat, cholesterol, sodium, sugar, or calories. For example, *calorie-free* means the product contains fewer than 5 calories per serving, and *sugar-free* and *fat-free* both mean the product contains less than 0.5 g per serving. Synonyms for *free* include *without*, *no*, and *zero*. A synonym for fat-free milk is *skim*.

Low: *Low* can be used on foods that can be eaten frequently without exceeding dietary guidelines for one or more of these components: fat, saturated fat, cholesterol, sodium, and calories. Synonyms for low include *little*, *few*, *low source of*, and *contains a small amount of*.

- **Low fat:** 3 g or less per serving
- **Low saturated fat:** 1 g or less per serving
- **Low sodium:** 140 mg or less per serving
- **Very low sodium:** 35 mg or less per serving
- **Low cholesterol:** 20 mg or less and 2 g or less of saturated fat per serving
- **Low calorie:** 40 calories or less per serving

Lean and extra lean: *Lean* and *extra lean* can be used to describe the fat content of meat, poultry, seafood, and game meats.

- **Lean:** less than 10 g fat, 4.5 g or less saturated fat, and less than 95 mg cholesterol per serving and per 100 g
- **Extra lean:** less than 5 g fat, less than 2 g saturated fat, and less than 95 mg cholesterol per serving and per 100 g

Reduced: *Reduced* means that a nutritionally altered product contains at least 25% less of a nutrient or of calories than the regular, or reference, product. However, a *reduced* claim cannot be made on a product if its reference food already meets the requirement for a “low” claim.

Less: *Less* means that a food, whether altered or not, contains 25% less of a nutrient or of calories than the reference food. For example, pretzels that have 25% less fat than potato chips could carry a *less* claim. *Fewer* is an acceptable synonym.

Light: *Light* can mean two things:

- First, that a nutritionally altered product contains one-third fewer calories or half the fat of the reference food. If the food derives 50% or more of its calories from fat, the reduction must be 50% of the fat.
- Second, that the sodium content of a low-calorie, low-fat food has been reduced by 50%. In addition, *light in sodium* may be used on food in which the sodium content has been reduced by at least 50%.
- The term *light* still can be used to describe such properties as texture and color, as long as the label explains the intent (e.g., *light brown sugar* and *light and fluffy*).

High: *High* can be used if the food contains 20% or more of the daily value for a particular nutrient in a serving.

Good source: *Good source* means that one serving of a food contains 10% to 19% of the daily value for a particular nutrient.

More: *More* means that a serving of food, whether altered or not, contains a nutrient that is at least 10% of the daily value more than the reference food. The 10% of daily value also applies to *fortified*, *enriched*, *added*, *extra*, and *plus* claims, but in these cases the food must be altered.

Data adapted from Food and Drug Administration. Retrieved from <https://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfcfr/CFRSearch.cfm?fr=101.54> and <https://www.fda.gov/downloads/food/guidanceregulation/guidancedocumentsregulatoryinformation/ucm535370.pdf>.

Health Claims

A **health claim** is allowed only on appropriate food products that meet specified standards. The government requires that health claims be worded in ways that are not misleading (e.g., the claim cannot imply that the food product itself helps prevent disease). Health claims

cannot appear on foods that supply more than 20% of the DV for fat, saturated fat, cholesterol, and sodium. The following is an example of a health claim for dietary fiber and cancer: “Low-fat diets rich in fiber-containing grain products, fruits, and vegetables may reduce the risk of some types of cancer, a disease associated with many factors.” **Box 10.4**

lists health claims that manufacturers can use to describe food-disease relationships. In 2013 the FDA added a regulation that defines “gluten-free,” to clarify its voluntary use in food labeling and to help consumers with celiac disease to avoid foods containing gluten (see Chapters 25 and 27).

BOX 10.4 Health Claims for Diet–Disease Relationships

Calcium and Osteoporosis

- “Adequate calcium throughout life, as part of a well-balanced diet, may reduce the risk of osteoporosis.”

Calcium, Vitamin D, and Osteoporosis

- “Adequate calcium and vitamin D, as part of a well-balanced diet, along with physical activity, may reduce the risk of osteoporosis.”

Sodium and Hypertension

- “Diets low in sodium may reduce the risk of high blood pressure, a disease associated with many factors.”

Dietary Fat and Cancer

- “Development of cancer depends on many factors. A diet low in total fat may reduce the risk of some cancers.”

Dietary Saturated Fat and Cholesterol and Risk of Coronary Heart Disease

- “While many factors affect heart disease, diets low in saturated fat and cholesterol may reduce the risk of this disease.”

Fiber-Containing Grain Products, Fruits and Vegetables, and Cancer

- Low-fat diets rich in fiber-containing grain products, fruits, and vegetables may reduce the risk of some types of cancer, a disease associated with many factors.”

Fruits, Vegetables, and Grain Products That Contain Fiber, Particularly Soluble Fiber, and Risk of Coronary Heart Disease

- “Diets low in saturated fat and cholesterol and rich in fruits, vegetables, and grain products that contain some types of dietary fiber, particularly soluble fiber, may reduce the risk of heart disease, a disease associated with many factors.”

Fruits and Vegetables and Cancer

- “Low-fat diets rich in fruits and vegetables [*foods that are low in fat and may contain dietary fiber, vitamin A, or vitamin C*] may reduce the risk of some types of cancer, a disease associated with many factors. Broccoli is high in vitamins A and C, and it is a good source of dietary fiber.”

Folate and Neural Tube Defects

- “Healthful diets with adequate folate may reduce a woman’s risk of having a child with a brain or spinal cord defect.”

Dietary Noncariogenic Carbohydrate Sweeteners and Dental Caries

- Full claim: “Frequent between-meal consumption of foods high in sugars and starches promotes tooth decay. The sugar alcohols in [*name of food*] do not promote tooth decay”; Shortened claim on small packages only: “Does not promote tooth decay.”

Soluble Fiber from Certain Foods and Risk of Coronary Heart Disease

- “Soluble fiber from foods such as [*name of soluble fiber source, and, if desired, name of food product*], as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [*name of food product*] supplies ___ grams of the [*necessary daily dietary intake for the benefit*] soluble fiber from [*name of soluble fiber source*] necessary per day to have this effect.”

Soy Protein and Risk of Coronary Heart Disease

- “25 grams of soy protein a day, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [*name of food*] supplies ___ grams of soy protein.”
- “Diets low in saturated fat and cholesterol that include 25 grams of soy protein a day may reduce the risk of heart disease. One serving of [*name of food*] provides ___ grams of soy protein.”

Plant Sterol/Stanol Esters and Risk of Coronary Heart Disease

“Foods containing at least 0.65 gram per of vegetable oil sterol esters, eaten twice a day with meals for a daily total intake of at least 1.3 grams, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [*name of food*] supplies ___ grams of vegetable oil sterol esters.”

“Diets low in saturated fat and cholesterol that include two servings of foods that provide a daily total of at least 3.4 grams of plant stanol esters in two meals may reduce the risk of heart disease. A serving of [*name of food*] supplies ___ grams of plant stanol esters.”

FDA Modernization Act Health Claims

Whole Grain Foods and Risk of Heart Disease and Certain Cancers

- “Diets rich in whole grain foods and other plant foods and low in total fat, saturated fat, and cholesterol may reduce the risk of heart disease and some cancers.”

Potassium and the Risk of High Blood Pressure and Stroke

- “Diets containing foods that are a good source of potassium and that are low in sodium may reduce the risk of high blood pressure and stroke.”

Fluoridated Water and Reduced Risk of Dental Caries

- “Drinking fluoridated water may reduce the risk of [*dental caries or tooth decay*].”

Saturated Fat, Cholesterol, and Trans Fat, and Reduced Risk of Heart Disease

- “Diets low in saturated fat and cholesterol, and as low as possible in trans fat, may reduce the risk of heart disease.”

Substitution of Saturated Fat in the Diet with Unsaturated Fatty Acids and Reduced Risk of Heart Disease

- “Replacing saturated fat with similar amounts of unsaturated fats may reduce the risk of heart disease. To achieve this benefit, total daily calories should not increase.”

DIETARY PATTERNS AND COUNSELING TIPS

Vegetarian Diet Patterns

Vegetarian diets are popular. Those who choose them may be motivated by philosophic, religious, or ecologic concerns, or by a desire to have a healthier lifestyle. Considerable evidence attests to the health benefits of a vegetarian diet. For example, studies of Seventh-Day Adventists indicate that the diet helps lower rates of metabolic syndrome and cardiovascular disease (Rizzo et al, 2011).

Of the millions of Americans who call themselves **vegetarians**, many eliminate “red” meats but eat fish, poultry, and dairy products. A **lactovegetarian** does not eat meat, fish, poultry, or eggs but does consume milk, cheese, and other dairy products. A **lactoovovegetarian** also consumes eggs. A **vegan** does not eat any food of animal origin. The vegan diet is the only vegetarian diet that has any real risk of providing inadequate nutrition, but this risk can be avoided by careful planning (see Appendix 30). A type of **semivegetarian** is known as a **flexitarian**. Flexitarians generally adhere to a vegetarian diet for the purpose of good health and do not follow a specific ideology. They view an occasional meat meal as acceptable. A public health awareness campaign called Meatless Monday advocates that Americans have a vegetarian meal at least 1 day per week to help reduce the incidence of preventable chronic health conditions such as diabetes, obesity, and cardiovascular disease.

Vegetarian diets tend to be lower in iron than omnivorous diets, although the nonheme iron in fruits, vegetables, and unrefined cereals usually is accompanied either in the food or in the meal by large amounts of ascorbic acid that aids in iron assimilation. Vegetarians who consume no dairy products may have low calcium intakes, and vitamin D intakes may be inadequate among those in northern latitudes where there is less exposure to sunshine. The calcium in some vegetables is made unavailable for absorption by the presence of oxalates. Although phytates in unrefined cereals also can make calcium unavailable, this is not a problem for Western vegetarians, whose diets tend to be based more on fruits and vegetables than on the unrefined cereals of Middle Eastern cultures.

Long-term vegans may develop megaloblastic anemia because of a deficiency of vitamin B₁₂, found only in foods of animal origin. The high levels of folate in vegan diets may mask the neurologic damage of a vitamin B₁₂ deficiency. Vegans should have a reliable source of vitamin B₁₂ such as fortified breakfast cereals, fortified soy beverages, or a supplement. Although most vegetarians meet or exceed the requirements for protein, their diets tend to be lower in protein than those of omnivores. Lower protein intake usually results in lower saturated fat intake because many high-protein animal products are also rich in saturated fat (Academy of Nutrition and Dietetics, 2016).

Well-planned vegetarian diets are safe for infants, children, and adolescents and can meet all of their nutritional requirements for growth. They are also adequate for pregnant and lactating females. The key is that the diets be well planned. Vegetarians should pay special attention to ensure that they get adequate calcium, iron, zinc, and vitamins B₁₂ and D. Calculated combinations of complementary protein sources is not necessary, especially if protein sources are reasonably varied. Useful information on vegetarian meal planning is available at the Academy of Nutrition and Dietetics website.

CULTURAL ASPECTS OF DIETARY PLANNING

To plan diets for individuals or groups that are appropriate from a health and nutrition perspective, RDs and health providers must

use resources that are targeted to the specific client or group. Numerous population subgroups in the United States and throughout the world have specific cultural, ethnic, or religious beliefs and practices to consider. These groups have their own set of dietary practices, which are important when considering dietary planning (Diabetes Care and Education Dietetic Practice Group, 2010). The IOM report entitled *Unequal Treatment* recommended that all health care professionals receive training in cross-cultural communication to help reduce ethnic and racial disparities in health care. Cultural competence training improves the skills and attitudes of the clinician and can facilitate a dialogue that encourages the client to share more information during a session (Betancourt and Green, 2010).

Attitudes, rituals, and practices surrounding food are part of every culture in the world, and there are so many cultures that it defies enumeration. Many world cultures have influenced American cultures as a result of immigration and intermarriage. This makes planning a menu that embraces cultural diversity and is sensitive to the needs of a specific group of people a major challenge. It is tempting to simplify the role of culture by attempting to categorize dietary patterns by race, ethnicity, or religion. However, this type of generalizing can lead to inappropriate labeling and misunderstanding.

To illustrate this point, consider the case of Native Americans. There are more than 560 different federally recognized tribes in 35 states. The food and customs of the tribes in the Southwest are different from those of the Northwest. With traditional foods among Native Americans, the situation is complicated further by the fact that many tribes were removed from their traditional lands in the nineteenth century by the government and forced to accept the foods provided by the federal government. Another example of the complexity of diet and culture in the United States is that of African Americans. “Soul food” is commonly identified with African Americans from the South. Traditional food choices, likely borne out of hard times, limited choices, and creativity, may include greens such as collards, mustard, and kale prepared with pork; beans; field peas; yams; fried meats; grits; and cornbread. However, this by no means represents the diet of all African Americans. Similarly, the diet of Mexican Americans does not necessarily equal that of immigrants from Central and South America. Mexican cuisine is not homogenous. There are seven regions of Mexican cuisine, each with its distinctive culinary variations. Baby goat is commonly eaten in the Northern region, which also produces a wide variety of cheeses and wheat tortillas. The South Pacific Coast of Mexico includes Oaxaca, Guerrero, and Chiapas. Oaxaca is known for its seven mole varieties, and corn tortillas are the staple of this region.

When faced with planning a diet to meet the needs of an unfamiliar culture, it is important to avoid forming opinions that are based on inaccurate information or stereotyping (see Chapter 13). Some cultural food guides have even been developed for specific populations to help manage disease conditions.

Religion and Food

Dietary practices have been a component of religious practice for all of recorded history. Some religions forbid the eating of certain foods and beverages; others restrict foods and drinks during holy days. Specific dietary rituals may be assigned to members with designated authority or with special spiritual power (e.g., a *shohet*, certified to slaughter animals in accordance with Jewish law). Sometimes dietary rituals or restrictions are observed based on gender. Dietary and food preparation practices (e.g., halal and kosher meat preparation) can be associated with rituals of faith.

TABLE 10.5 Some Religious Dietary Practices

	Buddhist	Hindu	Jewish (Orthodox)	Muslim	Christian Roman Catholic	Christian Eastern Orthodox	Christian Mormon	Christian Seventh- Day Adventist
Beef	A	X						A
Pork	A	A	X	X				X
Meats, all	A	A	R	R	R	R		A
Eggs/dairy	O	O	R			R		O
Fish	A	R	R			R		A
Shellfish	A	R	X			O		X
Alcohol		A		X			X	X
Coffee/tea				A			X	X
Meat/dairy at same meal			X					
Leavened foods			R					
Ritual slaughter of meats			+	+				
Moderation	+			+				+
Fasting*	+	+	+	+	+	+	+	+

*Fasting varies from partial (abstention from certain foods or meals) to complete (no food or drink).

+, Practiced; A, avoided by the most devout; O, permitted, but may be avoided at some observances; R, some restrictions regarding types of foods or when a food may be eaten; X, prohibited or strongly discouraged.

Modified from Kittler PG et al: *Food and culture*, ed 7, Belmont, Calif, 2017, Wadsworth/Cengage Learning; Escott-Stump S: *Nutrition and diagnosis-related care*, ed 8, Baltimore, MD, 2015, Lippincott Williams & Wilkins.

Fasting is practiced by many religions. It has been identified as a mechanism that allows one to improve one's body, to earn approval, or to understand and appreciate the suffering of others. Attention to specific eating behaviors such as overeating, use of alcoholic or stimulant-containing beverages, and vegetarianism also are considered by some religions. Before planning menus for members of any religious group, clinicians must gain an understanding of the traditions or dietary practices (Table 10.5). In all cases, discussing the personal dietary preferences of an individual is imperative (Kittler et al, 2017).

Health Literacy

Health literacy is defined as the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions (Healthy People 2010, USDHHS). Approximately 80 million Americans have limited health literacy (Kutner, 2006). Low health literacy is associated with poorer health outcomes and poorer use of health care services. Poor health literacy affects all levels of the health care experience. It obstructs provider-patient communications and affects health outcome and patient self-management. Minority groups, older adults, poor persons, nonnative speakers of English, and those with less than a high school education have high rates of restricted health literacy.

The components of health literacy include (AHRQ):

1. Cultural and conceptual knowledge
 - a. Health beliefs, attitudes, and practices and the perceptions of illness, health risks, and benefits.
2. Oral Literacy
 - a. Listening and speaking
3. Print literacy
 - a. Reading and writing

4. Numeracy

- a. Use of numbers and math skills in everyday activities ([Strategies to Enhance Numeracy Skills, 2015](#)).

There is evidence to support the importance of health literacy for the management and treatment of diet-related diseases such as hypertension, diabetes, and cardiovascular disease. Health literacy is associated with glycemic management.

The goal of nutrition education and counseling is to promote healthy eating behaviors and provide individuals with knowledge and skills to make sound decisions conducive to health and well-being. RDNs provide verbal and visual information during the nutrition education and counseling sessions to increase understanding and help clients implement actionable goals. Restricted health literacy is a barrier to health behavior change (Academy of Nutrition and Dietetics).

Cultural Context

People from different cultural backgrounds determine how to define health, recognize illness, seek medical treatment, and relate to health care providers. The explanatory model of illness suggests that individuals develop conceptual models to explain illness. This includes beliefs about why the condition started, how long will it last, and how it should be treated. In a study by Lemley and Spies (2015), Mexican Americans believed that *susto*, a folk illness in which a person experiences an episode of fright, causes diabetes. Aloe vera (*sábila*), and prickly cactus (*nopal*) are some of the herbal remedies used to treat diabetes. Providers play an important role and must develop awareness and utilize available tools to provide cross-cultural counseling.

Models of Cultural Competence

The Campinha-Bacote model (1999) of cultural competence has five constructs that can be utilized by dietetic professionals to leverage

their knowledge and acquire cross-cultural communication skills to improve patient satisfaction and improve health outcomes. They are the following:

1. Awareness:

- Examine your own cultural background and your own personal beliefs and practices. How do your own perceptions improve or hinder the relationship with patients/clients?
- Ask your client: What are some of your food and health beliefs and practices?

2. Knowledge:

- Gain insight on the client's explanatory model of illness and dietary practices. Even when a cultural group shares common cultural traits, no group is homogenous and there are more variations within cultural groups than across cultural groups.
- **Ask your client:**
 - What do you think caused your health condition? (i.e., diabetes, high blood pressure.)
 - Do you think that diabetes is caused by eating too many processed foods?

3. Skill:

- Collect relevant cultural data to perform an assessment, evaluation, and counseling. Assess the client's therapeutic uses of foods.
 - **Ask your client:**
 - What is your preferred language?
 - Is there anything I should learn about your culture, beliefs, or religious practices that would help me take better care of you?
 - What do you call your illness and what do you think caused it?
 - Do you receive advice from traditional healers or others?
 - What kinds of foods do you eat to keep healthy?
 - What kinds of foods do you avoid when you are ill?
 - Do you avoid any foods for cultural or religious reasons?
 - How do you think you should manage or treat your condition? (i.e., high cholesterol, hypertension, arthritis, fatty liver, etc.)

4. Encounter:

- How many face-to-face encounters have you had with the cultural group? What skills, knowledge, and tools do you need to improve the outcome of this encounter? Acquaint yourself with your clients' traditional foods and dietary practices. Assess the acculturation of dietary practices.
- **Ask clients:**
 - What are your favorite foods?
 - Which foods do you dislike?
 - What foods do you commonly eat?
 - How often do you eat them?
 - Which foods do you eat on special occasions and holidays?
 - What new foods have you tried?
 - Which traditional foods do you no longer eat or eat infrequently?

- 5. **Desire:** Dietetic professionals seeking to become culturally competent should know that cultural competency is a continuously evolving process and the ability to effectively work with an individual, family, or community requires lifelong knowledge, adaptation, and flexibility.

Culturally Specific Education Tools

- Develop a food plan that is linguistically and culturally appropriate that incorporates traditional and newly acquired food choices.

- Provide food lists that includes foods from the patient's culture.
- Consider life experience of cultural groups prior to migrating to the United States, where there might have been exposure to other cultures and food influences.
- Consider the client's food insecurity and food availability that may hinder access to recommended nutrition recommendations.
- Translate educational materials into the client's preferred language
 - Translating education materials into the client's preferred language should take into consideration the client's literacy in his or her native language.
 - Consider the client's language variations. For example, Spanish has different variations in Latin America. When developing education materials, the best practice is to test the material to include the target audience dialect.

Oral Literacy

In order to have a successful patient–health care provider encounter, clients need to articulate health concerns, verbalize symptoms, explain medical history, and ask appropriate questions.

Patients need to understand medical diagnosis and treatment directions to be able to make appropriate health decisions. A person who does not fully comprehend diagnosis and treatment may be at risk of adverse events. Patients with limited health literacy are less likely to understand medical terminology and ask questions during a health care visit.

Oral Communication Tools

- Use living-room, nonmedical language. Use words that you would use to explain to non-health care providers. Below are some health and nutrition terms and suggested alternatives.

• Medical Conditions

- | | |
|--------------------|---------------------------|
| • Cardiac problems | Heart problems |
| • Diabetes | Blood sugar is elevated |
| • Heart failure | Heart is not pumping well |
| • Hyperlipidemia | Blood has too many fats |
| • Hypertension | High blood pressure |
| • Osteoporosis | Soft, breakable bones |

• Nutrition Concepts

- | | |
|-----------------------------|---|
| • Calorie | Amount of energy the body gets from food |
| • Carbohydrate | Provides energy/fuel to the body like fuel to a car |
| • Carbohydrate and diabetes | The part of foods that turns into sugar |
| • Protein | Building blocks needed for growth & repair |
| • Fat | Provides the body with energy and helps it use vitamins |

- **Use the patient's words:** If the patient says “tummy” or “belly” you may use abdomen and explain that abdomen is another word for tummy or belly.
- **Limit and repeat information:** Stick to three key points and repeat them
- **Use graphics:** Use pictures or food models to demonstrate important concepts
- **Use teach-back:** Confirm client understanding by asking them to tell you or show you. For example, “Tell me, what are you going to do at home?” or “Show me how are you going to use the nutrition facts label.” Remember: You are not testing the patient's knowledge; you are testing how well you explained the information.

Print Literacy

Clients' inability to complete nutritional assessments and questionnaires can affect the accuracy of their medical and nutritional history. Dietetic professionals rely on printed materials to educate and reinforce key concepts such as menu planning, nutrition facts labels, nutrient composition of foods, and food lists. A number of studies have shown moderate evidence that patients with low health literacy have difficulty taking medications as prescribed and had poor comprehension and poor interpretation of the nutrition label (Berkman, 2011). Reading food labels is not a good predictor of interpreting the information correctly. In a study that examined the use of the food label, only 60% of participants responded correctly when asked how many carbohydrates were in half a bagel (Rothman, 2006).

Written Communication Tools

Use the following tips when writing nutrition education materials (Goody and Drago, 2009):

- Write the most important information first, as patients with restricted health literacy may only read the first sentences.
- Keep paragraphs and sentences short because readers tend to skip information that appears difficult to read.
- Break complex information into chunks to enhance comprehension and retention.
- Use simple language and define medical terms. For example, an endocrinologist is a doctor who treats people with diabetes, and hemoglobin A1C is an average of blood sugar levels.
- Use definitive language. For example: A food diary *may* help you identify foods that you eat (passive). You *will* benefit from keeping a food diary (active).
- Write actionable content. Indicate what actions must be taken and break them down into steps. For example:
 - Eat whole grains such as whole wheat, brown rice.
 - Select cereals that have whole wheat and brown rice listed as the first ingredients on the food label.
- Provide benefits that the patient will gain when making changes. For example:
 - When you lower your blood sugar you will feel less thirsty and will be able to sleep better without making many trips to the bathroom.
- Provide tips to overcome barriers. For example:
 - Remember, small changes count: Even 10 minutes of activity is better than none. Walk for 10 minutes a day, three times a week during your lunch break.
- Add interactive content to increase retention.
- Have health professionals check for accuracy and have the target audience check for understanding.
- Use white space judiciously.
- Visit <https://healthfinder.gov> for examples to write and format health and nutrition education materials that are easy to read and understand and are actionable.

Use the following tips when selecting written education materials:

- Select material that is linguistically appropriate for the group that it is intended to reach. Hispanic subgroups speak different versions of Spanish. For example, the word *bocadillo* means “snack” in some Spanish speaking countries, but it means guava paste in Colombia. If you are writing a menu encouraging a snack and use the word *bocadillo*, it can have very different outcomes. Test the materials with the intended audience first.
- Select material that is culturally appropriate. A food exchange list that is translated into the patient's preferred language may lack many traditional foods.
- Ensure that printed materials are easy to understand. There are three commonly used readability formulas: Fry formula, SMOG, and Flesch Reading Ease. Search the Internet for “readability formulas.”

- Select materials that are written at a fifth or sixth grade level.
- Select materials that your patients understand: Word choice, organization of information, and formatting affect comprehension. These methods are available to test comprehension:
 - Agency for Healthcare Research and Quality's Patient Education Materials Assessment Tool (PEMAT) used to assess written and audiovisual materials.
 - Use the CDC Clear Communications Index to assess your health communications materials, including behavioral recommendations and risk information (<http://www.cdc.gov/ccindex>).
 - The Suitability Assessment of Materials (SAM) assesses the cultural appropriateness and how materials stimulate learning.

Include Engaging Content in your Reading Materials

Write or select materials that contain engaging content. Interactive material helps reaffirm information and increase retention. Consider adding interactive tools such as the following:

- Fill in the blanks
- Multiple choice
- True/false questions
- Short quizzes
 - Explain the reasons why answers were right or wrong.

Numeracy in Health and Nutrition

Numeracy is “the ability to access, use, interpret, and communicate mathematical information and ideas, to engage in and manage mathematical demands of a range of situations in adult life” (PIAAC, 2009). Numeracy skills are an important component of health literacy. Numeracy-related tasks are ubiquitous in health care and self-care management. Numeracy skills are needed to:

- Interpret test results (not being able to identify blood glucose within normal limits)
- Take medications appropriately and calculate dosages
- Read and interpret the nutrition label

Diabetes self-care involves tasks that require numeracy skills. These are:

Monitoring

- Taking medication including oral and injectables
- Interpreting nutrition food label
 - Using fractions, decimals, percentages, and proportions
- Multistep problem solving
 - Interpreting blood glucose readings
 - Calculating carbohydrate intake
- Approximately 25% of patients could not determine what glucose values were within normal range of 80 to 120 mg/dL.
- Approximately 56% of patients could not count carbohydrates in a prepackaged snacks.
- Approximately 59% of patients could not calculate insulin dose based on blood glucose reading and carbohydrate intake.

Measuring Numeracy Skills

There are several tests to measure numeracy skills that measure arithmetic skills and calculations without a health focus (Rothman, 2008):

- Wide Range Achievement Test (WRAT 3)
- Kauffman Test of Educational Achievement (K-TEA)
- Key Math
- Woodcock Johnson

The Diabetes Numeracy Test (DNT) is a scale to measure diabetes-related numeracy deficits. There are short and long versions.

Numeracy Skills Tools

- Use words and numbers to decrease misinterpretation. For example, instead of solely using words such as “rare” or “common”

include numerical terms. For example, this condition is rare—it affects 1 in 10,000 people.

- Do the math for your patients. For example, instead of saying “Losing 5% to 7% of weight has shown to lower blood sugar levels,” say “Losing 5% to 7% of weight (about 10 to 14 lbs for a person weighing 200 lbs) has shown to lower blood sugar levels.”
- Use visuals to explain nutrition concepts that require arithmetic calculations. Provide a conversion chart to help patients calculate basic arithmetic concepts.

- When helping clients use measuring cups:
 - 1 cup = ½ cup + ½ cup
 - 1 cup = 1/3 cup + 1/3 cup + 1/3 cup
 - 1 cup = ¼ cup + ¼ cup + ¼ cup + ¼ cup
- When helping clients interpret nutrition labels:
 - If a serving is ¾ cup, use: ½ cup + ¼ cup
 - If a serving is ½ cup, use: ¼ cup + ¼ cup

FOCUS ON

Nutrition Transition

The term *nutrition transition*, coined in the early 1990s, describes alterations in diet, body composition, and physical activity patterns in people in developing countries undergoing rapid urbanization and demographic, socioeconomic, and acculturative changes (Popkin, 2001; Shetty, 2013). The shifts in traditional ways, value systems, and behaviors experienced in emerging economies such as India, China, the Middle East, North Africa, and Latin America are associated with notable increases in nutrition-related chronic diseases, while infectious and nutrition related deficiency diseases persist. Consequently, these populations face a double burden of disease—the struggles of undernutrition coexist with the maladies of overnutrition within the same individual, family, or community (Schmidhuber and Shetty, 2005).

Rapid advancements in medicine, food production, and agricultural technologies, along with the liberalization of markets leading to changes in food distribution and retail, have proven to be a double-edged sword in these countries. On the one hand, enormous economic developments and health benefits

have accrued; on the other, myriad challenges marked by nutritional imbalances and chronic disease trajectories have risen (World Health Organization/Food and Agriculture Organization, 2013). Inequalities in income and access to quality food and health care exist. Inactive lifestyles and increased toxic burden exposure and processed food consumption at the expense of indigenous foods are important nutrition transition determinants. In addition, there is increased vulnerability of individuals because of epigenetic fetal programming changes (Barker, 2006).

Several holistic, sustainable nutrition intervention approaches using a food-based and community involvement focus are currently underway to address nutrition transition worldwide (Sunguya et al, 2014; Vorster et al, 2011). These initiatives are directed at achieving optimal and balanced nutrition for all using evidence-based interventions and timely policies (Garmendia et al, 2013).

THE INDIGENOUS FOOD SOVEREIGNTY MOVEMENT

A new movement to improve health and food access has taken off in indigenous communities across the world: “food sovereignty.” This movement is founded on the belief that these communities have the right to define their own food policy systems—including agriculture, labor, fishing, and land—according to their traditional and cultural understandings of their environment and unique needs.

The need to redefine food systems in these communities is serious. American Indian and Alaska Native (AI/AN) communities in the United States suffer from some of the most severe health disparities in the country. Childhood obesity rates in these communities often surpass 50%, and there was a 110% increase in diagnosed diabetes cases from 1990 to 2009 in AI/AN youth ages 15 to 19 years. AI/AN people are also twice as likely as the overall U.S. population to experience some manner of nutrition-related health problem.

Generations of failed federal food policy, lack of access to healthy food, and the need for better education are all significant contributors to this challenge in tribal communities. Federal programs such as those that distributed surplus commodity foods on reservations aligned with other policies designed to assimilate

AI/AN people and helped make many of these communities reliant on food with very little nutritional value. Food like fry bread have their roots in these programs. Access to markets with fresh foods is another serious challenge. Most reservation areas in the country reside in “food deserts” according to the USDA—meaning they do not have access to a grocery store every 10 miles within the community. The Navajo Nation alone, which spans over 27,000 square miles, only has 10 full time grocery stores.

AI/AN youth leaders, like Mariah Gladstone of the Blackfeet Nation, are leading many of these grassroots movements. Recognizing the need for cooking education, Mariah started *Indigikitchen*, an online cooking show aimed at teaching indigenous cooking methods with traditional ingredients to viewers. Youth leaders are also working in food sovereignty coalitions across the country to advocate for flexibility in federal food programs to invest in indigenous gardens and agriculture, and to promote indigenous cooking knowledge and ingredients in programs like Supplemental Nutrition Assistance Program Education (SNAP-Ed). For more information about *Indigikitchen*, visit <https://indigikitchen.com>. For more information on the food sovereignty movement and policy recommendations, visit the Indigenous Food and Agriculture Initiative at University of Arkansas School of Law at <http://indigenousfoodandag.com>.

Erik Stegman, Carry the Kettle First Nation (Nakoda), JD, MA, is the Executive Director of the Center for Native American Youth at the Aspen Institute.

CLINICAL CASE STUDY

George is a 65-year-old Navajo (Dine) male who lives in a traditional hogan. English is his second language. He lives in a food desert and eats a lot of canned foods and processed foods as well as foods his wife and other family grows and preserves. He does not drink milk but does consume other dairy products. He has a body mass index of 32 and a family history of heart disease. He has come to you for advice on increasing his calcium intake and decreasing his sodium intake because he thinks it will help his blood pressure.

Nutrition Diagnostic Statement

- Food and nutrition related knowledge deficit related to patient needs additional information about the relationship between calcium, sodium and blood pressure as evidenced by typical day intake containing highly processed foods.

Nutrition Care Questions

1. What type of dietary guidance would you offer George?
2. What type of dietary plan is realistic for him?
3. What are the cultural considerations for educating George about his diet?
4. How can food labeling information be used to help George meet his nutrition goals?

complementary medicine	integrative medicine	Tolerable Upper Limit (UL)
complementary and alternative medicine (CAM)		vis medicatrix naturae

COMPLEMENTARY AND INTEGRATIVE MEDICINE

Some people may be confused by the multiple names used to describe natural medicine approaches. **Holistic medicine**, from the Greek word *holos*, means “whole.” Holistic therapies are based on the theory that health is a vital dynamic state that is determined by the balance between physical, mental, and spiritual parameters. **Vis medicatrix naturae**, the healing force of nature, is the underlying precept of holistic medicine. The philosophy states that when a person lives according to the laws of nature, the body has the ability to self-heal or the overall health of the individual will improve. Examples would include the adoption of a whole foods, mostly unrefined diet, maintaining a level of physical activity, use of plant-based (herbal) medicines and dietary supplements, and meditation to reduce stress. This theory is primarily applied to conditions where diet and lifestyle influence health to a large degree such as cardiovascular disease, diabetes, and many inflammatory conditions. **Alternative medicine** refers to nonmainstream therapies used *in place* of conventional medicine. For example, the use of an herbal preparation instead of a drug. **Integrative medicine** and **complementary medicine** refer to holistic therapies used *in combination with* conventional medicine. Most people who use holistic or nonmainstream therapies also use conventional medicine (National Center for Complementary and Integrative Health [NCCIH], 2018; see Tables 11.1 and 11.2).

Functional medicine is another iteration of holistic medicine that has gained esteem in recent years. It shifts the disease-centered focus of conventional medical practice to a more individualized and patient-centered approach (IFM, 2018). The goal is to evaluate the whole person rather than individual symptoms or organs and to consider care in relation to both prevention and treatment of chronic disease. Functional medicine practitioners, including medical doctors, naturopathic doctors, chiropractors, nurse practitioners, and dietitians, acknowledge a web-like interconnectedness of internal physiologic factors within the body. Acting within their scope of practice, they use nutrition therapy, dietary supplements, lifestyle modifications, and physical manipulations as the foundation of medical care. Functional medicine providers assess for core imbalances, including dietary intake, hormones and neurotransmitters, markers of oxidative stress, environmental exposures, immune function, and psychological and spiritual health.

The Academy of Nutrition and Dietetics (AND) practice group, Dietitians in Integrative and Functional Medicine (DIFM), has developed a nutrition-oriented functional medicine radial for dietetics practitioners to assess clients using Integrative and Functional Medical Nutrition Therapy (IFMNT) (Noland, 2019). A functional nutrition assessment can overlap with the nutrition care process (NCP) and includes expanded categories in the clinical, biochemical, and physical domains (see Chapter 5 and Fig. 5.9).

USE OF COMPLEMENTARY AND INTEGRATIVE THERAPIES

According to the National Center for Complementary and Integrative Health (NCCIH), almost 53% of adults and 12% of children in the

Portions of this chapter were written by Cynthia A. Thomson, PhD, RDN, for the previous edition of this text.

TABLE 11.1 Common Holistic Therapies According to the National Center for Complementary and Integrative Health (NCCIH)

Complementary and Integrative Medical systems	Naturopathy, traditional Chinese medicine (also known as East Asian medicine), Ayurveda, and homeopathy
Mind/Body therapies	Meditation, prayer, art or music therapy, and cognitive behavior therapy
Biologically based therapies	Herbs, whole-foods diets, and nutrient supplementation
Manipulative therapies	Massage, chiropractic medicine, osteopathy, and yoga
Energy therapies	Qi gong, magnetic therapy, or reiki

National Center for Complementary and Integrative Health (NCCIH). Complementary, Alternative or Integrative Health: What's In a Name? <http://nccam.nih.gov/health/whatiscam>.

TABLE 11.2 Description of Commonly Used Complementary and Integrative Therapies

Naturopathy (Naturopathic Medicine)	<p>Naturopathy is a form of primary care medicine that uses the healing power of nature, <i>vis medicatrix naturae</i>, to restore and maintain optimum health.</p> <p>Guiding principles include the following:</p> <p><i>Primum non nocere</i>—First do no harm</p> <p><i>Tolle causam</i>—Treat the root cause of illness</p> <p><i>Docere</i>—Doctor as teacher</p> <p>Therapeutic methods and substances are used that work in harmony with a person's self-healing process, including diet and nutrient therapy, botanical medicine, psychotherapy, physical and manipulative therapy, minor surgery, prescription medicines, naturopathic obstetrics (natural childbirth), homeopathy, and acupuncture.</p> <p>Licensed in the United States to practice in 23 states and 2 territories.</p> <p>Training includes pathology, microbiology, histology, physical and clinical diagnosis, pharmacognosy (clinical training in botanical medicine), hydrotherapy, physiotherapy, therapeutic nutrition, and homeopathy.</p>
Chiropractic	<p>Chiropractic therapy embraces many of the same principles as naturopathy, particularly the belief that the body has the ability to heal itself and that the practitioner's role is to assist in that process. Like naturopathy, chiropractic care focuses on wellness and prevention and favors noninvasive treatments.</p> <p>Chiropractors do not prescribe drugs or perform surgery.</p> <p>The focus is on locating and removing interferences to the body's natural ability to maintain health, called subluxations (specifically musculoskeletal problems that lead to interference with the proper function of the nervous and musculoskeletal systems).</p> <p>Therapeutic approach is the manual manipulation of the body, such as spinal adjustment and massage and lifestyle recommendations, including physical exercises and stretching.</p> <p>Two fundamental precepts: (1) The structure and condition of the body influence how well the body functions, and (2) the mind-body relationship is important in maintaining health and in promoting healing.</p> <p>Licensed and regulated in all 50 states and in 30 countries.</p> <p>Must complete a 4-year program from a federally accredited college of chiropractic and, like other licensed practitioners, successfully pass an examination administered by a national certifying body.</p>
Homeopathy	<p>The root words of <i>homeopathy</i> are derived from the Greek <i>homios</i>, meaning <i>like</i> and <i>pathos</i>, meaning <i>suffering</i>. Homeopathy is a medical theory and practice advanced to counter the conventional medical practices of 200 years ago. It endeavors to help the body heal itself by treating like with like, commonly known as the "law of similars." The law of similars is based on the theory that, if a large amount of a substance causes symptoms in a healthy person, a smaller amount of the same substance can be used to treat an ill person.</p> <p>Samuel Hahnemann, an eighteenth-century German physician, is credited with founding homeopathy.</p> <p>The amounts of the remedies used in homeopathic medicines are extremely diluted. According to homeopathic principles, remedies are potentized and become more powerful through a shaking process called succussion.</p> <p>Homeopathic tinctures are made from a variety of source materials including botanicals, minerals, and animal tissues. Dosages are based on the following dilutions. A remedy becomes stronger the more it is diluted.</p> <p>X: 1 drop tincture in 10 drops water</p> <p>C: 1 drop tincture in 100 drops water</p> <p>M: 1 drop tincture in 1000 drops water</p> <p>The minimum-dose principle means that many homeopathic remedies are so dilute that no actual molecules of the healing substance can be detected by chemical tests.</p> <p>The goal of homeopathy is to select a remedy that will bring about a sense of well-being on all levels—physical, mental, and emotional—and that will alleviate physical symptoms and restore the patient to a state of wellness and creative energy.</p> <p>Although this form of medicine has a long history of use, clinical evidence on the efficacy of homeopathy is highly contradictory. In 2017, the FDA proposed new safety regulations for homeopathic medicines, specifically for those that contain potentially toxic substances or are used for life-threatening conditions. This is especially significant for those who are vulnerable (infants and children, the elderly, and immune compromised). Homeopathic treatments are highly individualized using thousands of remedy combinations which makes the practice difficult to study using randomized and blinded trials. This presents a research challenge that will not soon be overcome.</p>

TABLE 11.2 Description of Commonly Used Complementary and Integrative Therapies—cont'd

East Asian medicine	<p>Based on the concept that energy, also termed chi (qi) or life-force energy, is central to the functioning of the body. Chi is the intangible force that animates life and enlivens all activity. Wellness is a function of the balanced and harmonious flow of chi, whereas illness or disease results from disturbances in its flow. Wellness also requires preserving equilibrium between the contrasting states of yin and yang (the dual nature of all things). The underlying principle is preventive in nature, and the body is viewed as a reflection of the natural world.</p> <p>Four substances—blood, jing (essence, substance of all life), shen (spirit), and fluids (body fluids other than blood)—constitute the fundamentals.</p> <p>The nutritional modality has several components: food as a means of obtaining nutrition, food as a tonic or medicine, and the abstinence from food (fasting). Foods are classified according to taste (sour, bitter, sweet, spicy, and salty) and property (cool, cold, warm, hot, and plain) to regulate yin, yang, chi, and blood.</p> <p>The meridians are channels that carry chi and blood throughout the body. These are not channels per se, but rather they are invisible networks that act as energy circuits, unifying all parts of the body and connecting the inner and the outer body; organs are not viewed as anatomic concepts but as energetic fields.</p>
Acupuncture	<p>Acupuncture is the use of thin needles, inserted into points on the meridians, to stimulate the body's chi, or vital energy. Moxibustion, the application of heat using moxa, dried leaves from mugwort, along meridian acupuncture points for the purpose of affecting chi and blood so as to balance substances and organs, is related to acupuncture. This therapy is used to treat disharmony in the body, which leads to disease. Disharmony, or loss of balance, is caused by a weakening of the yin force in the body, which preserves and nurtures life, or a weakening of the yang force, which generates and activates life. The concept of yin and yang expresses the dual nature of all things, the opposing but complementary forces that are interdependent on each other and must exist in equilibrium.</p> <p>According to the National Certification Commission for Acupuncture and Oriental Medicine (NCCAOM), acupuncturists are licensed to practice in 46 states and the District of Columbia.</p>
Ayurveda	<p>Ayurveda is a 5000-year-old system of natural healing that originated in India.</p> <p><i>Ayur</i> means life and <i>Veda</i> means science of knowledge.</p> <p>Assessment and treatment are based on three fundamental forces that govern the internal and external environments and determine an individual's constitution and overall health:</p> <p>Vata (wind): energetic, creative, and adaptable. If out of balance, can be anxious, dry, thin, and have poor concentration.</p> <p>Pitta (fire): intense, driven, and strong. If out of balance, can be compulsive, irritable, inflamed, and have poor digestion.</p> <p>Kapha (earth): nurturing, methodical, and stable. When out of balance, can be sluggish, phlegmatic, and gain weight easily.</p> <p>Mental and physical health are achieved when these forces are in balance.</p> <p>Therapeutic modalities include diet, herbal and lifestyle recommendations, massage, and aromatherapy.</p>
Massage therapy/body work	<p>The philosophy behind massage therapy and body work is that there is a healing that occurs through the action of touching. Massage therapy became a profession in the United States in the 1940s and has grown in use over the last several decades. The key principles of body work are the importance of increasing blood circulation, moving lymphatic tissue to remove waste and release toxins, calming the spirit, enhancing physiologic functions of body systems, and improving musculoskeletal function. This therapy also has been widely used to reduce stress and increase energy.</p>

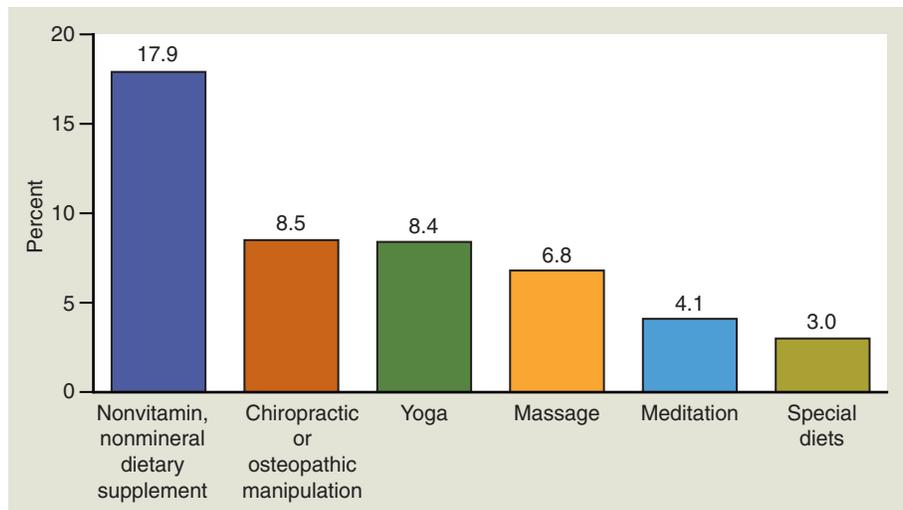

United States use nonmainstream health care approaches. Worldwide, the prevalence is 12% of the adult population in Canada, 26% in the United Kingdom, 56% in Malaysia, and 76% in Japan (Harris et al, 2012). Preferences in medical care are influenced by economic and sociocultural factors. In poor countries where access to modern medicine is limited, there is a heavy reliance on herbalists and traditional healers. In affluent countries, the decision to use natural therapies usually aligns with personal beliefs and preferences and is used commonly in addition to Western medicine (Harris et al, 2012).

The use of integrative therapies has been evaluated four times in the National Health Interview Survey (NHIS)—in 2002, 2007, 2012, and most recently 2017—with a data set limited to yoga, meditation, and chiropractic manipulation. In U.S. adults, the most popular integrative modalities include the use of nonvitamin, nonmineral supplements such as fish oil, glucosamine, probiotics, and melatonin (52%), chiropractic or osteopathic manipulation (10.3%), yoga (14.3%), and meditation (14.2%) (Peregoy et al, 2014; Falcì et al, 2016). The Council for Responsible Nutrition (CRN) conducts an annual survey of over 2000 adults in the United States and reports on the use of dietary supplement use. CRN reports the use of dietary supplements in 76% of the adult population. Discrepancies exist in exact numbers between the NHIS and CRN, however the prevalence

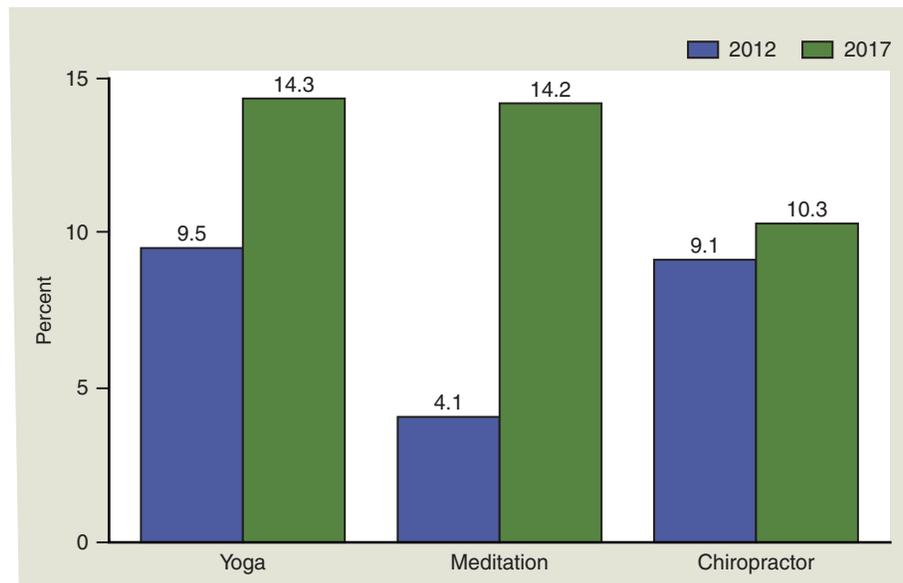

of use is significant (CRN, 2017). In children, the prevalence of use of integrative medicine approaches did not change significantly since 2007 except for an increase in use of yoga and a decrease in the use of nontraditional healers. Nonvitamin, nonmineral dietary supplements, chiropractic and osteopathic manipulations, and yoga were the most common modalities used. The most common reasons cited were for back, neck, and musculoskeletal pain; colds; anxiety; and stress.

Fig. 11.1 highlights the most common forms of integrative medicine used by adults in the United States.

A significant number of Americans use some form of integrative medicine with increases seen in yoga, meditation, homeopathic treatments, acupuncture, and naturopathy. Use has been shown to be greatest among those age 55 and older, living in the West and Northeast of the United States, female gender, and higher socioeconomic status and education level (CRN, 2017). By race or ethnicity, use of integrative approaches varies, with white adults (37.9%) and non-Hispanic other races (37.3%) having the highest use and Hispanic (22%) and black adults (19.3%) reporting lower rates of use (Clark et al, 2015). Among a survey of 5057 registered dietitians in the Academy of Nutrition and Dietetics (AND), the most common use of integrative approaches includes vitamin, mineral, and other dietary supplements

A

B

Fig. 11.1 A, Percentage of adults who used complementary health approaches in the past 12 months, by type of approach: United States, 2012. (Retrieved from <http://www.cdc.gov/nchs/data/databriefs/db146.pdf>.) **B**, Percentage increase by adults who used complementary approaches including yoga, meditation, and chiropractic care between 2012 and 2017 in the United States, 2018. (Retrieved from <https://www.cdc.gov/nchs/data/databriefs/db325-h.pdf>)

(such as probiotics and fatty acids) (55% to 75%), mind-body therapies (32%), herbs (22%), and detoxification (7%) (Augustine et al, 2016).

Integrative therapies are often considered when conventional medicine is not perceived as effective by the patient. Examples include chiropractic medicine for back pain, acupuncture for pain relief, and select dietary supplementation for conditions such as macular degeneration, depression, and digestive complaints. Integrative approaches are also commonly used when they are supported by significant evidence of efficacy. The NHIS survey also suggested that integrative medicine use increased when conventional treatments were too costly.

As a result of the increased interest in integrative therapies, the Office of Alternative Medicine of the National Institutes of Health (NIH) was created in 1992 to evaluate their effectiveness. This office became the twenty-seventh institute or center within the NIH in 1998,

when it was renamed the National Center for Complementary and Alternative Medicine (NCCAM). In 2015 the name was changed again to the **National Center for Complementary and Integrative Health (NCCIH)** because the use of complementary and integrative medicine in the United States is so common, it no longer warrants the term “alternative.” **Complementary and alternative medicine (CAM)** had been the most common term used to describe the use of holistic medicine, although this term may be falling out of favor and is being replaced by **complementary and integrative medicine (CIM)**. The NCCIH explores complementary and integrative healing practices scientifically using research, training, outreach, and integration (NCCIH, 2018). There continues to be an expansion of training opportunities and medical reimbursement for integrative therapies in the conventional medical system including the U.S. Department of Veterans Affairs (VA), and many nursing and medical curricula include training in integrative medicine.

In 2011 the Bravewell Collaborative, a philanthropic organization that works to improve health care, published results from a national survey on the use of integrative medicine among 29 major integrative medical centers and programs across the United States. Top conditions for which the centers reported the most success in treatment included chronic pain, gastrointestinal disorders, depression, anxiety, and stress. The most common interventions included nutrition, dietary supplements, yoga, meditation, acupuncture, massage, and pharmaceuticals (Horrigan et al, 2012). The Academic Consortium for Integrative Medicine and Health was formed in 1999 with the goal of “transforming the healthcare system and promoting integrative medicine and health for all.” Its members include over 70 academic health centers across the United States including Cleveland Clinic, Stanford, Duke, Georgetown, Harvard, Johns Hopkins, Tufts, Yale, UCLA, and a number of state universities. The Consortium provides mentoring and training and disseminates information about integrative approaches based on rigorous scientific research (Academic Consortium for Integrative Medicine and Health, 2018).

DIETARY SUPPLEMENTATION

More than half of all Americans are taking some form of dietary supplement, and many of them may not be well informed about what they are taking (Gahche et al, 2014). Historically, dietetics professionals focused their assessment, care plan, and counseling on diet or food-related recommendations. The demand for information about dietary supplements from dietetics professionals is high. The 2018 Position Paper of the AND on micronutrient supplementation calls on registered dietitian nutritionists and dietetic technicians to be reliable experts with information on nutrient supplementation by keeping up to date on issues associated with regulation, safety, and efficacy of dietary supplements (AND, 2018).

Defining Dietary Supplements

According to the Food and Drug Administration (FDA), a dietary supplement is a substance that is taken orally and is intended to add nutritional value to the diet (Food and Drug Administration, 2015). Dietary supplements can come in many forms, including teas, tablets, capsules, powders, and liquids. A complete description can be found in Box 11.1.

BOX 11.1 FDA Definition of a Dietary Supplement

Intended to be a supplement to the diet
 Intended to be taken by mouth; this excludes other routes of administration, such as intranasal, transdermal, and suppository
 Contains one or more dietary ingredients, including the following:
 Macronutrients (protein, carbohydrates, fats)
 Vitamins and minerals
 Herbs and botanicals
 “Other” dietary substances that are either grandfathered in or are approved as
 New dietary ingredients (NDIs), such as:
 Phytochemicals (such as curcumin from Turmeric)
 Bee pollen
 Probiotics
 Glandulars (products made from desiccated animal glands)
 Some hormones, including melatonin and DHEA
 Does not contain any unapproved ingredients, such as:
 Thyroid hormone, cortisol, estrogen, progesterone, or testosterone
 Pathogenic bacteria
 Human tissue

Herbal Medicine

Herbal medicine has been used since the beginning of time and has a written history of more than 5000 years. In many parts of the world, it is the primary source of medicine (AHG, 2019). Herbs and plants provide a large array of **phytochemicals** and **bioactive compounds** (plant-based chemicals and compounds) that have biologic activity within the human body. Although some of the phytochemicals have been identified and characterized, many of them have unknown actions and may interact with pharmaceutical drugs (Gurley, 2012). When herbs are used in combination with each other or in concentrated forms (such as in a capsule or tincture), the likelihood for a drug nutrient interaction (DNI) or side effect increases.

Botanical medicines are made up of a variety of plant parts including leaves, flowers, stems, bark, rhizomes, and roots. They are produced in a variety of forms and are used orally and topically, including teas, infusions, decoctions, extracts, and pills as shown in Box 11.2. Topical application of botanicals or nutrients such as salves and aroma therapy are not classified as **dietary supplements** under the current regulatory definition because they are not ingested. The **Commission E Monographs** on phytomedicines were developed in Germany in 1998 by an expert commission of scientists and health care professionals as references for practice of **phytotherapy**, the science of using plant-based medicines in an evidence-based way to prevent or treat illness. Other useful herbal references including the **American Botanical Council** and the **American Herbalists Guild** are listed at the end of the chapter.

Trends in the Dietary Supplement Industry

According to the National Health and Nutrition Examination Survey (NHANES) 1999-2010, the most common reasons people use dietary supplements are to improve or maintain health, supplement the diet, support bone health (in women), lower cholesterol, and improve immunity (Bailey et al, 2013; Gahche et al, 2014).

The industry has grown steadily for the past 30 years. Industry sales were more than \$43.5 billion in 2017 and sales are expected to continue to increase (Morton, 2018). The most popular supplements according to NHANES and the CRN include multivitamins and minerals (MVM), vitamin D, vitamin C, omega-3 fatty acids, lutein, probiotics, and protein powders. Among children, the most common dietary supplements include multivitamins, immune support supplements like vitamin C, omega-3 fatty acids, antacids, vitamin D, and melatonin (Quato et al, 2018). Herbal supplement sales increased 8.5% in 2017. Herbs that experienced the strongest growth in sales include turmeric (*Curcuma longa*), wheat grass (*Triticum aestivum*), barley grass (*Hordeum vulgare*), elderberry (*Sambucus nigra*), fenugreek (*Trigonella foenum-graecum*), echinacea (*Echinacea spp.*), and cranberry (*Vaccinium macrocarpon*), (Smith et al, 2018).

Multivitamin Efficacy

Most people take an MVM to increase nutrient levels in the diet or fill perceived gaps in nutrition. Dietary surveillance data from the National Center for Health Statistics (NCHS) and NHANES reveal that most adults and children in the United States are not meeting dietary guidelines and are underconsuming dark greens, orange vegetables, legumes, and whole grains (Bowman et al, 2018). Total nutrient intakes for vitamin D, vitamin E, calcium, vitamin A, vitamin C, and magnesium have been found to be significantly below the estimated average requirement (EAR), and less than 3% of the population is meeting the adequate intake (AI) for potassium (Drake and Frei, 2018).

Use of multivitamins and minerals has been shown to improve micronutrient status among adults and children (Bailey et al, 2012;

BOX 11.2 Botanical Formulations

Type	Form
Bulk Herbs	Sold loose to be used as teas, in cooking, and in capsules; rapidly lose potency; should be stored in opaque containers, away from heat and light.
Beverages	
Teas	Beverage weak in concentration; fresh or dried herbs are steeped in hot water and strained before drinking.
Infusions	More concentrated than teas; steep fresh or dried herbs for approximately 15 min to allow more of the active ingredients to be extracted than for teas. A cold infusion is made by steeping an herb over time in a cold liquid.
Decoctions	Most concentrated of the beverages, made by simmering the root, rhizome, bark, or berries for 30-60 min to extract the active ingredients.
Extracts	
	Herbs are extracted with an organic solvent to dissolve the active components; forms a concentrated form of the active ingredients. Standardized extracts concentrate a specific constituent(s) of an herb. Removal of the solvent creates a solid extract.
Tinctures	Extract in which the solvent is alcohol, glycerine, honey, or occasionally vinegar. Ratios are listed as herb:quantity of solvent. A 1:1 tincture is equal parts herb and solvent.
Glycerites	Extract in which the solvent is glycerol or a mixture of glycerol and water; more appropriate for children than an alcohol based tincture.
Salve	An infusion of herbs in oil and beeswax that is used topically. This preparation is not considered to be a dietary supplement under DSHEA.
Pill Forms	
	Pills should be taken with at least 8 oz of water to avoid leaving residue in the esophagus.
Capsules	Herbal material is enclosed in a hard shell made from animal-derived gelatin or plant-derived cellulose (vegetarian caps).
Tablets	Herbal material is mixed with filler material (excipients) to form the hard tablet; may be uncoated or coated with starches and polymers.
Lozenges	Also called <i>troches</i> ; method of preparation allows the active components to be readily released in the mouth when chewed or sucked.
Soft gels	Soft capsule used to encase liquid extracts such as fatty acids or vitamin E.
Essential oils	Fragrant, volatile plant oils; used for aromatherapy, bathing; concentrated form and not to be used internally unless specifically directed (such as enteric-coated peppermint oil capsules).

Blumberg et al, 2017). Unfortunately, increased nutrient intake has not translated into reduced risk of chronic disease in people without overt nutrient deficiencies. Research reviews by the NIH State of Science Panel and the U.S. Preventive Services Task Force have evaluated observational and randomized controlled trials (RCTs) of more than 400,000 people using single or paired vitamins or MVM and have not

found evidence that they reduce chronic disease or prevent early death with the exception of some forms of cancer and potentially cardiovascular disease, especially for long-term users of MVMs (Fortmann et al, 2013; Blumberg et al, 2018). Two trials, the Supplementation in Vitamins and Mineral Antioxidants Study (SU.VI.MAX) and the Physicians' Health Study II (PHS-II), found a small reduction in cancer incidence for men only after 12 ½ years (SU.VI.MAX) and 8 years (PHS-II) of supplementation (Fortmann et al, 2013; Gaziano et al, 2012). More recently, analysis of male physicians in the Physicians' Health Study I cohort who reported taking an MVM for more than 20 years showed a lower risk of cardiovascular events. In a nationally representative sample of women from NHANES, those who took an MVM for more than 3 years had lower cardiovascular mortality although the results were deemed nonsignificant when the results were fully adjusted for confounding variables (Rautiainen et al, 2016; Bailey et al, 2015). Trials looking at cognitive decline and all-cause mortality have not shown statistically significant incidence of harm or benefit (Fortmann et al, 2013). Chronic diseases are complex and usually have multifactorial causes. Studying the effect of an MVM on nutrient intake and overall health is a difficult undertaking. Almost all Americans are taking in supplemental forms of nutrients via fortified foods, which complicates efforts to quantify the impact of taking an MVM supplement. In observational trials, people take a variety of MVMs with differing compositions and potencies. People who self-select to take an MVM are usually healthier and have better diets, suggesting that MVMs may not be helpful for most well-nourished people. A few long-term RCTs evaluated the merits of MVMs, and the results have been population or gender specific and not generalizable to the entire U.S. population (Fortmann et al, 2013). MVMs may have efficacy based on assessment of individual needs, especially with the advent of nutrigenomics and personalized nutrition, but are not generally useful for all people. In those who do supplement with MVMs, there is little evidence for harm, however assessment should include a risk for exceeding upper limits on nutrients, especially when multiple supplements are taken at the same time (Blumberg et al, 2018).

Antioxidant Supplements

Oxidative stress is implicated in a variety of disease states, and many Americans take antioxidant supplements. A Cochrane review of 78 RCTs with 296,707 participants found that all-cause mortality was increased slightly with regular antioxidant use. The effect was strongest with beta carotene in smokers, and high-dose vitamin E and vitamin A. Vitamin C and selenium were not found to increase mortality but also did not improve longevity (Bjelakovic et al, 2012). Antioxidant supplements may be beneficial, however, for prevention of age-related macular degeneration (AMD). In the Age-Related Eye Disease Study (AREDS), high-dose vitamin C (500 mg), vitamin E (400 IU), beta carotene (15 mg), and zinc (80 mg) had a significant reduction in the risk of developing AMD after taking the antioxidant supplements for 6.3 years. The effects were still present after a 10-year follow-up (Chew et al, 2013). For the majority of people, it is probably best to get antioxidants and phytonutrients by eating a variety of plant-based foods, including fruits, vegetables, herbs, spices, nuts, seeds, legumes, and whole grains.

Potentially At-Risk Populations

Although dietary supplement use is most common among people who are least likely to have a nutrient deficiency, the AND has identified several populations and life cycle stages that potentially could benefit from dietary supplements (AND, 2018). Table 11.3 outlines potentially at-risk populations. Clinicians should be aware of these at-risk

TABLE 11.3 Populations Potentially at Risk for Nutrient Deficiencies

At-Risk Population or Life Cycle Stage	Nutrients of Concern that Could Potentially Be Corrected by Supplementation
Those living in poverty (especially children)	Iron, calcium, magnesium, folate, vitamins A, B ₆ , C, D, and E
Those taking oral contraceptives	Zinc, folic acid, B ₆ , and B ₁₂
Adolescent females	Iron and calcium
Pregnancy	Iron and folic acid
Older adults	B ₁₂ and vitamin D, multiple micronutrients
Those following calorie-restricted weight loss diets	Multiple nutrients
People with dark pigmented skin	Vitamin D
People with malabsorption (inflammatory bowel disease, gastric bypass)	Multiple nutrients
Those who avoid food groups due to allergy or preference including strict vegetarians and vegans	Multiple nutrients, iron, zinc, calcium, B ₁₂
Those with genetic predisposition to nutrient deficiencies (i.e., MTHFR or vitamin D receptor mutations)	Folate, B ₁₂ , vitamin D. Use of nutrigenomic testing is still an emerging science.
Those with advanced macular degeneration (AMD)	Vitamin C, vitamin E, zinc, copper, lutein, and zeaxanthin
Smokers	Vitamin C
Those with alcoholism	Folate and thiamin
People taking medications that deplete nutrients	Multiple nutrients

subgroups and complete a nutrition assessment to determine the need for supplementation on an individual basis if nutrition status cannot be improved by dietary changes alone.

DIETARY SUPPLEMENT REGULATION

Dietary supplements are regulated by two government agencies, the FDA, which oversees safety concerns, and the Federal Trade Commission (FTC), which oversees advertising, label, and health claims. Before 1994, dietary supplements existed in limbo under the general, but unspecified, regulation of the FDA. The **Dietary Supplement Health and Education Act of 1994 (DSHEA)** defined dietary supplements under the category of food and explicitly removed them from consideration as drugs or dietary additives. This was seen as a victory to the dietary supplement industry and consumers; they had become accustomed to open access in ability to manufacture and purchase dietary supplements without many restrictions.

Dietary supplement regulation set forth by DSHEA includes the following (NIH, 1994):

- **Generally recognized as safe (GRAS)** status to all supplements produced before October 15, 1994. This allows manufacturers to continue to sell all of the products that were on the market at the time DSHEA was passed. Any company that introduces a new dietary supplement must send notification and safety information to the FDA 75 days before selling the supplement.
- A supplement facts panel that defines how ingredients must be listed on the label. See Fig. 11.2 for an example of a dietary supplement label.
- Structure function claims vs. health claims: Supplement companies are no longer allowed to list disease states or make specific health claims on a dietary supplement label. A **structure function claim** allows for a description that includes a structure or function of the body or a stage of life. “Supports strong bones” is an allowable structure function claim; “Prevents osteoporosis” is not. The label must also include the disclaimer, “This statement has not been

Supplement Facts

† Daily Value not established.

Ingredients: Cod liver oil, gelatin, water, and glycerin.

Fig. 11.2 A dietary supplement facts label per Food and Drug Administration regulation as defined under the Dietary Supplement Health Education Act. (From <http://www.fda.gov/ucm/groups/fdagov-public/documents/image/ucm070717.gif>.)

evaluated by the Food and Drug Administration. This product is not intended to diagnose, treat, cure, or prevent any disease.” Opponents of DSHEA feel that structure function claims are too similar to drug claims and encourage dietary supplements to be used like drugs. By contrast, a **health claim** can mention a disease state as long as it has met the significant scientific agreement standard of the FDA and can exist on foods and dietary supplements.

For example, “soluble fiber from foods such as oat bran, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease.” The FDA has approved only a limited number of health claims.

- Disseminating product literature: Dietary supplement manufacturers and retailers are no longer able to display product information or technical data sheets next to products because they can mislead consumers and make dietary supplements appear to be drugs.
- Because a wide variety of dietary supplements are available, including some hormones and megadose vitamins, it is up to consumers to be educated about the dietary supplement they choose to consume. The NIH founded the Office of Dietary Supplements (ODS) in 1994 to fund research and disseminate credible information on dietary supplements to consumers. On this government website, consumers can find basic consumer information, technical data sheets about dietary supplements and herbs, and FDA warnings.
- Good manufacturing procedures (GMPs) were adopted in 2007 and went into full enforcement in 2010. According to the GMPs, manufacturers of dietary supplements must meet minimum standards for production and are subject to random audits. The GMPs regulate the design and construction of manufacturing plants, maintenance and cleaning procedures, manufacturing procedures, quality control procedures, testing of materials, handling of consumer complaints, and maintaining records (FDA, 2010).

Under DSHEA, dietary supplements are regulated only for safety and not for efficacy. Manufacturers are beholden to follow the regulatory laws governing dietary supplements; however, they do not have to send any premarket notification to the FDA except for structure function claims and safety documentation for **new dietary ingredients (NDIs)** that were not used before 1994. The FDA randomly inspects more than 300 dietary supplement manufacturers per year. According to the Natural Products Insider via information obtained through the Freedom of Information Act (FOIA), in fiscal year 2018, 75 inspections (~24% of inspections) resulted in GMP violations and companies were cited by the FDA. The most common noncompliance issues were failure to test products for identity, potency, and purity (Long, 2018). The FDA is increasing its auditing program every year. With repeated audits, many of the noncompliant companies will be forced to comply or shut down, which will help ensure increased safety in the industry. For now, health care providers should recommend dietary supplements only from reputable companies. The FDA does not publish data on which companies pass or do not pass inspections. This information can only be obtained via the FOIA or by looking on the FDA warning letters database under the company name.

Ensuring Dietary Supplement Safety

Under DSHEA, the FDA bears the burden of proving a supplement is unsafe. This can be a challenging task once a product is released onto the market. To date, only two dietary supplements have been banned by the FDA over safety issues, *Ephedra sinica* in 2004, and dimethylamylamine (DMAA) in 2013. Both have been linked to cardiovascular toxicity and death. The most common supplements with health and safety concerns are those used for weight loss, performance enhancement (ergogenic aids), and sexual dysfunction (FDA, 2018). These supplements have the highest risk of contamination and adulteration with unapproved dietary ingredients and pharmaceutical drugs, especially when purchased from obscure retailers and on the Internet. Internet sales of dietary supplements is one of the fastest-growing retail markets and is also the hardest to regulate. Consumers can often find banned supplements easily on the Internet. In a 2014 study, researchers found that when products are recalled or banned by the FDA, a significant number of them are still available online. Of 274 supplements

recalled between 2009 and 2012, 85% of the sports supplements, 67% of weight loss, and 20% of sexual enhancement products were still available and still contained the banned ingredient (Cohen et al, 2014).

In December 2006 the Dietary Supplement and Nonprescription Drug Consumer Protection Act was signed into law, requiring mandatory reporting by manufacturers and retailers of known serious **adverse events (AEs)** related to dietary supplement and over-the-counter (OTC) medications. Serious AEs include a life-threatening event, incapacitation, hospitalization, a birth defect, or death. These must be reported to the FDA MedWatch website and can be filed by an individual, a health care provider, or an industry representative. In addition, supplement manufacturers are required by law to have contact information on supplement bottles. AE reports are forwarded to the Center for Food Safety and Applied Nutrition, where they are further evaluated by qualified reviewers (FDA, 2013). Health care providers and consumers are not mandatory reporters under the law but are strongly encouraged to report AEs.

Between 2008 and 2011 the FDA and poison control centers received almost 13,000 AE reports related to dietary supplements. Of those, 71% were considered serious AEs. During that same time, the FDA logged 2.7 million adverse drug events, of which 63% were considered serious (Government Accountability Office, 2013). The 2013 Annual report of the American Poison Control Centers revealed 1692 deaths due to drugs and zero deaths due to dietary supplements. Less than 1% of Americans experience AEs related to dietary supplements and the majority are classified as minor (Brown, 2017). It is estimated that many AEs from taking supplements are not being reported or are not being reported correctly. Common barriers from consumers include downplaying the significance, not knowing where or how to report, and embarrassment. After nine years of tracking (2004 to 2013), the Centers for Disease Control and Prevention (CDC) released a report indicating that an estimated 23,000 emergency department visits per year could be attributed to dietary supplements. Among young adults ages 20 to 34, the most common supplements causing AEs were for weight loss and energy (ergogenic aids) and the most common symptoms were tachycardia, chest pain, and palpitations. For adults 65 and older, AEs were mostly attributed to choking on micronutrient pills. Twenty percent of dietary supplement related emergency visits were for unsupervised children who ingested dietary supplements (Geller et al, 2015). Health care providers who wish to stay abreast of alerts from the FDA can subscribe to the MedWatch email list on the FDA website. The ODS website is another resource for information about current warnings and recalls as well as consumer tips for buying and taking dietary supplements safely.

Botanical supplements are increasing in popularity, and some have the likelihood for producing AEs, especially when taken in combination products and in concentrated form. Most of the common herbs used in the United States do not pose a great risk for a **drug nutrient interaction (DNI)**. Of the herbs most commonly used, St. John's wort is the most problematic and has been shown to reduce efficacy of many drugs, including antiretrovirals for HIV, antirejection medications for organ transplants, oral contraceptives, cardiac medications, chemotherapy, and cholesterol medications. Two other herbs have been shown to have a high risk for DNI, including goldenseal (*Hydrastis canadensis*) and black pepper (*Piper nigrum*), although black pepper is only a problem in supplemental form and not in amounts commonly found in food (Gurley et al, 2012).

In recent years the ODS has worked collaboratively with several organizations and experts to develop a **Dietary Supplement Label Database** of dietary supplements used in the United States. Because the database provides specific information on the nutrient, herbal, or other constituents contained in a supplement, it allows clinicians to

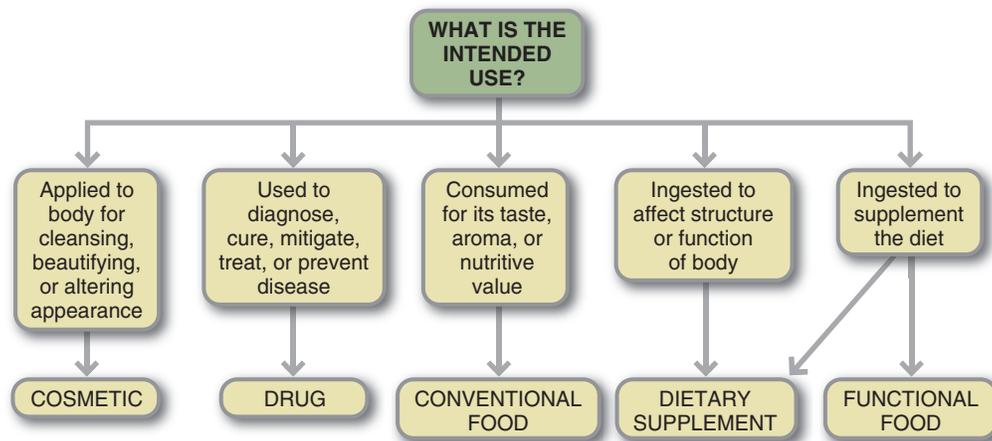

Fig. 11.3 Use of dietary supplementation in clinical practice requires use of a credible resource for evaluation and application. (From Thomson CA, Newton T: Dietary supplements: evaluation and application in clinical practice. *Topics Clin Nutr* 20(1):32, 2005. Reprinted with permission.)

assess more accurately the appropriate use of select supplements by their patients (Fig. 11.3). The database includes dietary supplement label information for more than 76,000 dietary supplement products, including the ingredients, daily values, and structure and function claims. The ODS offers Supplement Fact Sheets containing information about dietary supplements that is linked to PubMed, allowing clinicians and consumers to access to peer-reviewed information on use in human trials, AEs associated with use, and information regarding the mechanism of action. The Natural Medicines Comprehensive Database and Consumer Lab (subscriptions needed) offer similar information.

Third Party Certification

The FDA and FTC have primary jurisdiction for ensuring dietary supplements are safe and do not have misleading advertising. With approximately 85,000 products on the market, this is a daunting task. Because supplement manufacturers are audited randomly, it is not easy for consumers to know whether a company is truly following GMPs and their products are free from adulteration. Several private companies offer **third party certification** in the supplement industry. Consumer Lab is a well-known and affordable subscription-based company that randomly pulls supplements from store shelves to test them for potency, identity, and purity. Subscribers to the Consumer Lab website are able to access reports that reference specific brands. The U.S. Pharmacopeia (USP), the National Sanitation Foundation (NSF), and the Therapeutic Goods Association (TGA) each certify supplement companies for compliance with federal GMPs. Once verified, companies can display a stamp on their supplement labels that signifies the products have been third party certified. In addition, NSF offers a “Certified for Sport” certification for supplements that are used by competitive athletes to ensure they are not contaminated with illegal substances.

The **Codex Alimentarius Commission (Codex)** is an agency with international significance. It was created in 1963 by two U.N. organizations, the Food and Agriculture Organization and the World Health Organization, to protect the health of consumers and to ensure fair practices in international food trade. Codex participants work on the development of food standards, codes of practice, and guidelines for products such as dietary supplements. Codex standards and guidelines are developed by committees from 180 member countries, where they voluntarily review and provide comments on standards at several stages in the development process.

Quality Issues in Dietary Supplements

Not all dietary supplements are high quality. As discussed previously, many manufacturers are not in full compliance with DSHEA, which means many substandard and contaminated and adulterated products are on the market. Many of the popular brands in health food stores and major retail outlets are likely safe. Products bought off the Internet and from obscure retailers may be adulterated and/or may not meet label claims. What determines quality in a supplement must go beyond the safety issues to address the quantity, formulations, and quality of all ingredients used.

Quantity of Ingredients

Many MVMs contain **megadoses** of nutrients, which greatly exceed the RDA and may or may not be appropriate for each individual consumer. Some individuals may benefit from high doses of certain nutrients because of genetic variations in enzyme function or other pharmacologic effects of megadoses. Examples include increased need for folate with an MTHFR gene variant or reduction in triglycerides with megadoses of niacin (Ames et al, 2002; Boden et al, 2014).

It is important to assess for upper limits, especially when patients are taking multiple sources of nutrients. Most water-soluble vitamins do not have overt toxicity at high doses with the exception of niacin (flushing, prickly heat, and liver irritation in some people) and pyridoxine (reversible neuropathy). Fat-soluble vitamins can become toxic more quickly, such as vitamin A (hepatotoxicity and teratogenicity) and vitamin D (nephrolithiasis, calcification of soft tissue). Often vitamin A is listed in its provitamin form, beta carotene, which does not pose the same health risks as retinol at high doses.

Minerals can become toxic more easily than vitamins, so they often are not formulated using megadoses. In some cases, people may take a megadose of a mineral for a limited time, such as zinc for the common cold. To ensure patient safety, it is important to coordinate care with a physician when a patient is taking a megadose of a mineral. Although it is not a megadose, the FDA limits potassium content in dietary supplements to 99 mg because of the prevalence of chronic kidney disease. In patients with end stage kidney disease, high potassium levels can cause cardiac arrhythmia or arrest.

Formulations

Dietary supplements come in many formulations, including capsules, tablets, gels, chewables, liquids, and powders. The form a consumer selects has to do with convenience, preference, and affordability.

Supplement powders can be added easily to foods and beverages, but most have added sugars to increase palatability. Chewable and liquid supplements often are missing multiple nutrients to increase taste appeal, so it is important to assess the label to ensure it meets the patient's needs.

Tablets tend to be more compressed than capsules and require a fewer number of pills to achieve the optimal dosage. Capsules tend to be easier to swallow but less concentrated than tablets. Gelatin capsules may not be suitable for vegetarians. Some companies make vegetarian capsules out of vegetable cellulose to accommodate vegetarian consumers. Other nutrient forms that may not be suitable for vegetarian clients include cholecalciferol (often from fish oil or lambswool) and vitamin A/retinol (also usually from fish oil). Vegetarian formulations usually contain ergocalciferol and beta carotene as alternatives. Some manufacturers produce cholecalciferol from lichen and mushrooms, which are vegetarian sources.

Excipients

Excipients are extra ingredients added to dietary supplements to increase bulk, mask “off flavors,” add color, and improve compressibility and flow through machinery. To assess whether a dietary supplement is right for an individual, it is important to consider the quality of the excipients used. Some contain allergens and/or potentially unfavorable ingredients, such as wheat starch, lactose, hydrogenated oils, artificial colors. When choosing a dietary supplement, it is important to read the label for quantity and quality of active ingredients and excipients.

Vitamins

Most vitamins in dietary supplements are similar across brands with the exception of B₆ (pyridoxine), B₁₂ (cyanocobalamin), folate (folic acid), and vitamin E. Some formulations contain active, methylated, or phosphorylated forms of these nutrients such as in active B₆: pyridoxal 5'-phosphate, active B₁₂: methylcobalamin or adenosylcobalamin, and active folate: methyltetrahydrofolate. Individuals with genetic polymorphisms, nervous system disorders, increased oxidative stress, or impaired digestion may benefit from the increased bioavailability of these nutrients; however, research is limited on their widespread need and efficacy. In addition, the active forms tend to be more expensive (Head, 2006; Hendren, 2013). A review published in 2015 refutes the necessity of coenzyme forms of cobalamin, finding that all forms,

including cyanocobalamin are equally effective at treating B₁₂ deficiency (Obeid et al, 2015).

Vitamin E can be made synthetically or extracted naturally from soybean oil, sunflower oil, or other vegetable oils. Natural vitamin E (d-alpha tocopherol) is more expensive but has a greater bioavailability than synthetic vitamin E (dl-alpha tocopherol) (Landvik, 2004; AND, 2018). High-quality vitamin E products usually contain mixed tocopherols and tocotrienols in addition to the d-alpha tocopherol, which is thought to mimic more closely what one would get from eating a food source of vitamin E. Tocotrienols have been shown to possess potent antioxidant and antiinflammatory qualities, although dietary sources such as nuts, seeds, and plant-based oils may be superior to dietary supplements (Peh et al, 2016).

Minerals

Chelated minerals bound to an amino acid or a Krebs cycle intermediary are considered the most easily absorbed form of a mineral supplement, especially in specific populations such as older adults, preterm infants, people with low stomach acid, and those with compromised digestion including inflammatory bowel disease (IBD) and celiac disease but may not be better than other forms in healthy young people (Chermesh et al, 2006). Examples of chelated minerals include citrate, malate, bisglycinate, succinate, aspartate, and picolinate. Chelated minerals are less concentrated than ionic minerals and therefore more pills will often be needed to obtain the same dose. Chelated minerals can also be more expensive. Ionic mineral preparations such as carbonates and oxides should be taken with food, especially protein, to increase absorption (Straub, 2007).

ASSESSMENT OF DIETARY SUPPLEMENT USE IN PATIENTS

Health care professionals should be aware that patients often do not report their use of botanicals or other dietary supplements. Therefore practitioners must inquire specifically about the use of supplements by their patients. To facilitate disclosure, health care providers, including RDNs should approach patients in an open-minded, nonjudgmental manner. Key questions to ask are summarized in **Box 11.3**. Ideally,

BOX 11.3 Evaluating Dietary Supplement Use: The Patient–Health Care Provider Information Exchange

Ask

- What dietary supplements are you taking (type: vitamin, mineral, botanical, amino acid, fiber, including brand and dose)?
- Why are you taking these dietary supplements? Include review of patient's medical diagnosis and symptoms for reasons why they may be taking supplements (e.g., osteoarthritis, heart disease, high blood pressure, premenstrual syndrome [PMS], fatigue).
- How long have you been taking these dietary supplements?
- What dose or how much are you taking? For each, include supplement form and manufacturer.
- With what frequency are you taking each supplement?
- Where were the supplements purchased (e.g., health food store, Internet, health care provider)?
- Who recommended the supplement (e.g., media, physician, nurse, dietitian, integrative medicine practitioner, friend, family)?

Evaluate

- Dietary intake (including intake of fortified foods and beverages, and nutritional and sports bars)

- Health status and health history—include lifestyle habits (e.g., smoking, alcohol, physical activity level)
- Biochemical profile, laboratory data
- Prescribed and over-the-counter (OTC) medications
- Clinical response to supplements
- Adverse events, symptoms

Educate

- Scientific evidence of benefit and effectiveness
- Potential interaction with foods, nutrients, and medications or other dietary supplements
- Appropriate dose, brand, and chemical form; duration of supplementation; appropriate follow-up
- Quality of products, manufacturers, good manufacturing practices (U.S. Pharmacopeia [USP], Consumer Labs)
- Mechanism of action of the primary active ingredient
- Appropriate storage of the dietary supplement
- Administration instructions: With or without food? Potential food-supplement interactions?

BOX 11.3 Evaluating Dietary Supplement Use: The Patient–Health Care Provider Information Exchange—cont'd

- Awareness and reporting of any side effects or adverse events, symptoms
- Recommend necessary dietary changes to support needs. Food should come first.

Document

- List specific supplements and brand names of each supplement being taken.

- Record batch number from bottle in case of an adverse event.
- Record patient perception and expected level of compliance.
- Monitor efficacy and safety, including health outcomes and adverse effects.
- Record medication-supplement or supplement-supplement interactions.
- Plan for follow-up.

From Practice Paper of the American Dietetic Association: Dietary supplements, *J Am Diet Assoc* 105(3):466, 2005. Reprinted with permission.

BOX 11.4 Dietary Supplements that Affect Blood Clotting and Should Be Discontinued 10 to 14 Days Before Surgery or Certain Medical Tests

Ajoene, birch bark, cayenne, Chinese black tree fungus, cumin, evening primrose oil, feverfew, garlic, ginger, *Ginkgo biloba*, ginseng, grapeseed extract, milk thistle, omega-3 fatty acids, onion extract, St. John's wort, turmeric, vitamins C and E

Reference: American College of Surgeons. College of Education: *Medication and Surgery Before Your Operation* (website): <http://www.facs.org/patienteducation/medications.html>.

patients should be encouraged to bring all of their dietary supplements and medications into the clinic to be evaluated. In this way the health care provider can review doses (including those above the **tolerable upper limit [UL]**), forms, frequency of use, rationale for use, side effects, and the patient-perceived efficacy of each supplement (AND, 2018). This should be done on a regular basis. It is particularly important that dietary supplement use be reviewed before surgery because some dietary supplements and botanicals alter the rate of blood coagulation. **Box 11.4** provides specific recommendations regarding the discontinuation of dietary supplements before surgery to avoid complications associated with prolonged bleeding time. In addition, patients on blood-thinning medications may have to be monitored for a potential interaction with these supplements (American College of Surgeons, 2012).

For assessing patients for dietary supplement use using the NCP, potential diagnosis and intervention codes are shown in **Box 11.5**.

Recommendation and Sale of Dietary Supplements

Many health care professionals are uncomfortable recommending dietary supplements. Clinical guidelines for recommending and selling dietary supplements have been published previously by the Academy of Nutrition and Dietetics (Thompson et al, 2002). Dietitians and nutritionists who recommend dietary supplements must take the initiative to develop their knowledge, skills, and resources to provide accurate and safe recommendations. The AND has developed *The Academy Scope of Practice Decision Tool: A Self-Assessment Guide* for dietetics providers; it is available through the AND website. It can be used to assess competence and scope of practice as defined by training, place of employment, and state of residence. It is advisable to use this tool before beginning any new practice, including recommending or selling dietary supplements.

When recommending dietary supplements to clients, clinicians should use an evidence- or science-based approach and document thoroughly in the patient's medical chart. Documentation should

BOX 11.5 International Dietetics and Nutrition Terminology (IDNT) that Applies to the Documentation of Dietary Supplement Use Among Patients

Assessment Terminology: Food and Nutrient Intake, Medication and Complementary and Alternative Medicine Use and Knowledge, Beliefs and Attitudes

Diagnosis Terminology: Inadequate bioactive substance intake (NI-4.1), Excessive bioactive substance intake (NI-4.2), Increased nutrient needs (NI-5.1), Decreased nutrient needs (NI-5.4), Imbalance of nutrients (NI-5.5), Less than optimal intake of types of fats (NI-5.6.3), Less than optimal intake of types of proteins or amino acids (NI-5.7.3), Inadequate fiber intake (NI-5.8.6), Inadequate vitamin intake (specify) (NI-5.9.1), Excessive vitamin intake (specify) (NI-5.9.2)

Inadequate mineral intake (specify) (NI-5.10.1), Excessive mineral intake (specify) (NI-5.10.2), Predicted suboptimal nutrient intake (specify) (NI-5.11.1), Predicted excessive nutrient intake (specify) (NI-5.11.2), Impaired nutrient utilization (NC-2.1), Altered nutrition related laboratory values (specify) (NC-2.2), Food-medication interaction (NC-2.3), Predicted food-medication interaction (NC-2.4), Food and nutrition related knowledge deficit (NB-1.1), Un-supported beliefs and attitudes about food or nutrition related topics (NB-1.2), Limited adherence to nutrition related recommendations (NB-1.6)

Intervention Terminology: Vitamin and mineral supplements (specify) (ND-3.2), Bioactive substance management (specify) (ND-3.3), Nutrition related medication management: Nutrition related complementary/alternative medicine (ND-6.3), Nutrition education (specify) (E-1), Nutrition counseling (specify) (C-1), Collaboration and referral of nutrition care (RC-1)

include the supplement name, dosage, form, duration of use, and a short description of supporting evidence. Each provider is responsible to cross-check for contraindications and potential DNIs and document any risks in the patient's medical chart. See **Box 11.6** for guidelines for choosing dietary supplements and botanical products and **Box 11.7** for information about usage, dosage, and safety of some of the most commonly used dietary supplements.

Resources for Clinicians

As awareness of dietary supplement use expands within the health care community, the number of evidence-based resources available to clinicians is also growing considerably. Clinicians should have access to online and print resources that are updated at regular intervals. Resources that provide references to the original research are preferable. A list of evidence-based resources can be found at the end of the chapter. In addition, accessing available medical literature is advised, given that there are a growing number of studies being published in peer-reviewed literature.

BOX 11.6 Guidelines for Choosing Dietary Supplements and Botanical Products

- Ensure the supplement is appropriate for the individual patient based on state of health, dietary deficiency, and scientific evidence.
- Consider multiple sources of dietary supplements including fortified foods, bars, cereals, and beverages to ensure patients are not exceeding safe intake limits.
- Check for potential drug-nutrient interactions and be aware of side effects and contraindications. For example, fish oil can reduce blood clotting in high doses and antioxidant supplements can inhibit the effects of some chemotherapy drugs.
- Investigate the quality of the manufacturer to ensure a quality product. Look for companies that have third party certification (National Sanitation Foundation [NSF], U.S. Pharmacopeia [USP]), or well-known companies with a long-standing reputation for quality. Check Consumer Labs or the Food and Drug Administration (FDA) warning letters website for documented problems.
- Use the dietary supplement label to obtain important information, including the following:
 - Product identity (including scientific or botanical names), form, and dosage
 - Allergy information in case the patient has a dietary restriction. Excipients (inactive ingredients) are often the source of allergens or unwanted ingredients.
 - A lot number, which is helpful if problems arise because it allows the product to be tracked through each stage of the manufacturing process.
 - An expiration date
- After determining that a manufacturer and its product meet these standards, compare prices among products of similar quality. Prices can vary widely.

National Institutes of Health, Office of Dietary Supplements. *Dietary Supplements: What You Need to Know*. http://ods.od.nih.gov/HealthInformation/DS_WhatYouNeedToKnow.aspx. BOX 11.7 Popular Dietary Supplements and Their Efficacy

Supplement	Benefits	Dosage	Potential Contraindications	Quality Considerations
Vitamins				
Vitamin B ₆	Effective for hereditary sideroblastic anemia, pyridoxine-dependent seizures; Likely effective for hyperhomocysteinemia, age-related macular degeneration, hypertension, calcium oxalate kidney stones, pregnancy induced nausea and vomiting	Most supplemental doses are 5-50 mg/day. 25 mg every 8 hours for pregnancy induced nausea and vomiting. Doses up to 200 mg/day have been used for carpal tunnel, but close monitoring is recommended.	Doses up to 200 mg/day appear to be tolerated by most people, although high doses can cause hypotension and reversible neuropathy.	Available as pyridoxine and pyridoxal 5'-phosphate (coenzyme form).
Vitamin B ₁₂	Effective for pernicious anemia and B ₁₂ deficiency. Likely effective for hyperhomocysteinemia; possibly effective for age-related macular degeneration	Doses in supplements are often in megadoses due to lack of toxicity. Can be taken orally and injected. Common dosage range is 2.4-1000 mcg/day.	Most risk is associated with intravenous forms, not oral forms. People with pernicious anemia will not benefit from oral dosing.	Available as cyanocobalamin, methylcobalamin and adenosylcobalamin (coenzyme forms). Active form may be beneficial for those with genetic polymorphisms; however all forms of B ₁₂ have been found effective for correcting B ₁₂ deficiency.
Vitamin C	Effective for scurvy; likely effective for iron absorption enhancement; possibly effective for age-related macular degeneration, cancer prevention, common cold prevention and treatment, complex regional pain syndrome, hypertension, osteoarthritis, sunburn	Doses vary widely but usually range from 100-2000 mg/day. Use divided doses for enhanced absorption.	Safe at lower doses and in amounts found in foods. Higher doses can cause diarrhea and gastrointestinal cramping. Greater than 500 mg is contraindicated for those who have a history of calcium oxalate kidney stones.	Mineral ascorbates (buffered vitamin C) or Ester C® may be better tolerated (less gastrointestinal [GI] distress) than ascorbic acid for some people.

BOX 11.7 Popular Dietary Supplements and Their Efficacy—cont'd

Supplement	Benefits	Dosage	Potential Contraindications	Quality Considerations
Vitamin D	Effective for familial hypophosphatemia, hypoparathyroidism, osteomalacia, psoriasis, renal osteodystrophy, and rickets. Likely effective for corticosteroid induced osteoporosis, fall prevention in older adults, osteoporosis. Possibly effective for prevention of cancer, dental caries, multiple sclerosis, respiratory tract infections, rheumatoid arthritis, and obesity.	Dose is usually based on individual serum levels and can vary from person to person. Optimal serum level is considered to be 30-50 nmol/L. In research, doses range from 400 IU to 50,000 IU/day. The tolerable upper limit (UL) is 4000 IU (100 mcg)/day.	Exceeding the UL and elevated serum concentrations are associated with calcification of soft tissues (damage to the heart, blood vessels, and kidney), and increased risk for kidney stones. Risk may be increased in postmenopausal women who also take supplemental calcium. Best to coordinate care with primary care provider and monitor blood levels.	Cholecalciferol (D ₃) is the most common supplement and is usually sourced from fish or sheep (lanolin), lichen, or mushrooms. Ergocalciferol (D ₂) is suitable for vegetarians and vegans.
Vitamin E	Effective for vitamin E deficiency. Possibly effective for slowing cognitive decline in Alzheimer's disease, improving response to erythropoietin in hemodialysis, reducing cisplatin induced neurotoxicity and pain in rheumatoid arthritis, prevention of dementia, dysmenorrhea, premenstrual syndrome (PMS), Parkinson's disease, and radiation induced fibrosis and increasing muscle strength in older adults.	Most supplements are between 50 and 2000 IU. Most common dose is 200-400 IU/day.	Doses above 400 IU/day may increase risk for bleeding, prostate cancer, and have prooxidant effects.	D-alpha tocopherol is the natural form of vitamin E and dl-alpha tocopherol is the synthetic form. Natural forms with mixed tocopherols, specifically gamma tocopherol, may have cardioprotective effects. Supplemental Vitamin E has been linked with prostate cancer in the SELECT trial. This result was not found in other studies (Physicians' Health Study II [PHS II] and Women's Health Study (WHS)).
Folic acid/Folate	Effective for folate deficiency. Likely effective for hyperhomocysteinemia, methotrexate toxicity, and neural tube defects. Possibly effective for age-related macular degeneration, depression, hypertension.	Recommended dietary allowance (RDA) level is recommended in most people, although those with MTHFR variant or chronic conditions may need higher levels (200 mcg-5 mg/day has been used although 800 mcg-1000 mg is most common). Coordinate care with physician for megadose amounts. The Institute of Medicine (IOM) recommends adults limit their intake from supplements and fortification to 1000 mg/d	Excess folic acid (5 mg and above) can cause B ₁₂ deficiency. Folic acid supplements can also mask B ₁₂ deficiency. Caution with folic acid supplementation in those at risk for colon cancer.	Supplemental sources have greater bioavailability than folate in food. People with a MTHFR variant may have increased need for folate. The methylated form, methylenetetrahydrofolate is also used.
Minerals				
Calcium	Effective for dyspepsia, hyperkalemia, and renal failure (as a phosphate binder). Likely effective for osteoporosis, corticosteroid induced osteoporosis, hyperparathyroidism, and premenstrual syndrome. Possibly effective for reducing risk of colorectal cancer, hypercholesterolemia, hypertension, and prevention of weight gain.	500-1000 mg/day is a typical dose. Do not exceed the UL.	High doses can increase risk for kidney stones, cardiovascular disease (CVD), and constipation. CVD risk is greater in postmenopausal women who take supplemental calcium. Caution in patients with hyperparathyroidism.	Chelated forms such as citrate and malate are better absorbed than carbonate unless taken with a meal. Coadministration with vitamin K may be helpful to reduce risk of hypercalcemia except in those taking blood-thinning medications

Continued

BOX 11.7 Popular Dietary Supplements and Their Efficacy—cont'd

Supplement	Benefits	Dosage	Potential Contraindications	Quality Considerations
Chromium	Effective for chromium deficiency. Possibly effective for reducing blood sugar in diabetes, decreasing low-density lipoprotein (LDL) cholesterol, and triglycerides.	Studies have used 150-1000 mcg/day. Adequate intakes are thought to be 25-35 mcg/day for adults. No UL has been established.	Trivalent chromium is found in appropriate dietary supplements. Poor quality brands may contain hexavalent chromium, which is toxic and linked to cancer. Caution in those with diabetes, renal impairment. Higher doses may cause dermatitis and/or gastrointestinal irritation.	Chromium picolinate is the most common form and is thought to be well absorbed.
Iron	Effective for iron deficiency anemia and pregnancy induced anemia. Possibly effective for ACE inhibitor induced cough, cognitive function, restless leg syndrome, and heart failure	RDA is recommended unless blood work indicates increased need. Needs increase in pregnancy. Vegetarians may need higher levels because of decreased bioavailability from plant foods. 4-6 mg/kg/day or 60-120 mg/day for those with anemia. Some research shows intermittent doses (several times a week to weekly) can be effective for prevention of anemia in multiple populations.	Ensure the presence of iron deficiency anemia before supplementing with iron (also check ferritin level). Do not exceed the UL except with coordination of care with a physician. Excessive iron intake can cause nausea, constipation, and black stools and may increase the risk of heart disease.	Chelated iron (citrate, bisglycinate) and Feosol® (carbonyl iron) may be better tolerated and cause fewer gastrointestinal side effects.
Magnesium	Effective for constipation, dyspepsia, preeclampsia, and eclampsia. Possibly effective for asthma prevention, cancer associated neuropathic pain, chronic fatigue syndrome, chronic obstructive pulmonary disease (COPD), cluster headaches, osteoporosis, diabetes (improved blood glucose control), and vasospastic angina. IV forms are effective for cardiac arrhythmia, acute pre term labor and acute asthma attacks. Magnesium is often used in fibromyalgia and migraine headache, but the results are mixed.	Typical dose is 100-500 mg/day. Exceeding the UL from supplements (350 mg/day) is not recommended because of potential for diarrhea.	The most common side effects with high doses are diarrhea, bloating, and reduction in blood pressure. Serious side effects are a risk with IV magnesium, including hypotension, nausea, and ataxia.	Chelated forms such as citrate, bisglycinate, and amino acid chelate may be better absorbed and tolerated (less GI side effects) than oxide form.
Selenium	Possibly effective for autoimmune thyroiditis, dyslipidemia, prevention of HIV virus replication and increased immune cell count, reduced risk of cancer and cancer mortality with good selenium status. Used as an antioxidant supplement as a cofactor for selenocysteine and glutathione production.	Daily recommended intake is 55-70 mcg/day although most supplemental doses are in the 100-200 mcg range. Exceeding the UL of 400 mcg/day is not recommended.	Gastrointestinal symptoms, nausea, and vomiting are most common with high doses. Acute toxicity may impair liver, kidney, and cardiac function.	Brazil nuts are an excellent source of selenium. Selenium and vitamin E have a synergistic effect and are best taken together.

BOX 11.7 Popular Dietary Supplements and Their Efficacy—cont'd

Supplement	Benefits	Dosage	Potential Contraindications	Quality Considerations
Zinc	Likely effective for diarrhea and Wilson's disease. Possibly effective for acne, age-related macular degeneration, anemia, anorexia nervosa, attention deficit hyperactivity disorder, burns, common cold, dandruff, depression, diabetic foot ulcers, diaper rash, halitosis, gingivitis, herpes simplex virus, muscle cramps, radiation mucositis, osteoporosis, peptic ulcers, pressure ulcers, sickle cell disease, vitamin A deficiency, warts	Doses vary depending on condition. 15-45 mg/day range is common. Much higher doses sometimes given for wound healing short term. Coordination of care recommended.	Mostly nontoxic below the UL of 40 mg/day in adults. High zinc intake can deplete copper and can cause nausea, dermatitis, and copper deficient anemia.	Take zinc supplements with copper to prevent depletion of copper. Zinc lozenges have been used to prevent and treat the common cold.
Other Supplements				
Arginine	Possibly effective for angina, erectile dysfunction, hypertension, necrotizing enterocolitis (NEC), peripheral artery disease, post-surgery recovery, and preeclampsia.	Therapeutic dose range is thought to be from 400-6000 mg/day. There is no tolerable upper limit and higher doses (up to 30 g/day) have been used. Coordination of care recommended	High doses may increase bleeding in those on warfarin, may lower blood sugar and blood pressure. Caution in those with history of myocardial infarction or cancer	No special production or quality control issues with arginine. L- arginine is the active form.
Beta-glucans	Likely effective for hyperlipidemia. Possibly effective for allergic rhinitis (hay fever), cancer survival, and postoperative infection. Beta glucans can stimulate the immune response including upregulating natural killer cells and tumor necrosis factor.	3 g beta-glucan/day (from oats) per the FDA as a cholesterol lowering food. In supplements, 2-16 g/day is common dosing for hyperlipidemia.	Generally well tolerated with few side effects. May cause mild gastrointestinal symptoms in some. Can lower blood pressure and blood sugar	Found widely in plant-based foods, especially oats and mushrooms.
Coenzyme Q ₁₀ (Ubiquinone)	Possibly effective for mitochondrial encephalomyopathies, age-related macular degeneration, cardiovascular mortality, congestive heart failure, diabetic neuropathy, HIV/AIDS, hypertension, ischemic reperfusion injury, migraine headache, and Parkinson's disease.	Doses vary from 30-600 mg/day. The most common dosing is 100-200 mg/d in divided doses	Very few side effects reported other than mild nausea, headache, and skin itching. May decrease blood pressure. Caution with people on blood-thinning medications	Oil-based preparations may be better absorbed. Ubiquinol is the active form and may be more biologically active, although most people are able to convert ubiquinone to ubiquinol without problems.
Creatine	Possibly effective for athletic performance enhancement (muscle mass and muscle strength) and age-related muscle loss.	Usually taken as a loading dose of 20 grams per day for 4-7 days followed by a maintenance dose of 2-10 grams per day for up to 14 weeks in conjunction with strength training. Doses up to 30 g have been taken safely short term.	Considered safe for healthy people. Increased fluid needs when taking creatine. Caution with kidney disease especially if taking nonsteroidal antiinflammatory drugs (NSAIDs). Increased symptoms of anxiety and depression have been noted.	Usually sold as creatine monohydrate.

Continued

BOX 11.7 Popular Dietary Supplements and Their Efficacy—cont'd

Supplement	Benefits	Dosage	Potential Contraindications	Quality Considerations
DHEA Dehydroepiandrosterone	Possibly effective for aging skin and depression. Mixed results in studies on use in adrenal insufficiency, depression, chronic fatigue syndrome, fibromyalgia, HIV/AIDS, osteoporosis, physical performance, sexual dysfunction, weight loss. Most doctors treat with DHEA based on individual laboratory values.	Dose should be recommended by a physician and based on laboratory results. Doses range from 5-450 mg/day.	May increase estrogen and testosterone and risk for hormone imbalance and cancer. May increase acne, facial hair growth, and cause other hormonal side effects. Avoid with hormone blockers such as tamoxifen. Multiple contraindications.	7 Keto dehydroepiandrosterone (DHEA) is a metabolite of DHEA that is not converted into estrogen or testosterone and is thought to be a safer alternative to DHEA.
Fish oil	Effective for hypertriglyceridemia. Likely effective for cardiovascular disease. Possibly effective prevention of restenosis after angioplasty and coronary artery bypass grafts, attention deficit hyperactivity disorder, bipolar disorder, cachexia, dysmenorrhea, heart failure, hypertension, psoriasis, Raynaud's syndrome, rheumatoid arthritis, stroke. Conflicting evidence for depression, eczema, inflammatory bowel disease, autism.	1-4 g/day of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) combined. Up to 3 g/day is considered generally recognized as safe (GRAS) and the Food and Drug Administration (FDA) recommends not exceeding 2 g/d EPA/DHA from dietary supplements.	More than 3 g/day EPA/DHA may increase risk for bleeding, bruising, and elevation in blood sugar. Caution with people on blood-thinning medications and those with diabetes (may increase blood glucose above 3 grams EPA/DHA).	Molecular distilled fish oil is considered the best quality. For vegetarians, flaxseed oil may also be beneficial. Use cold pressed oil in dark bottles or refrigerate. The International Fish Oil Standards (IFOS) website lists brands that have passed strict international standards for purity.
Glucosamine	Possibly effective for mild to moderate osteoarthritis; conflicting or insufficient evidence to rate effectiveness for interstitial cystitis and temporomandibular (TMJ) disorders and postoperative recovery.	Typical dose for joint conditions is 1500 mg/day taken in 2-3 divided doses. Lower doses of 400-1000 mg/day have been used for other conditions.	Considered to be a safe supplement for most people. Most is sourced from shellfish, so may be an allergen in some. High doses can disrupt blood sugar metabolism in those with diabetes. Caution in those with renal dysfunction or in those taking warfarin.	Most research has been done on glucosamine sulfate form, although glucosamine hydrochloride has also been used with success. Glucosamine is often sold in combination with chondroitin for added benefit.
Glutamine	Possibly effective for use in burn patients, bone marrow transplants, burns, critical illness (trauma), AIDS wasting, and to improve nitrogen balance after surgery. Conflicting evidence for use with diarrhea (especially due to chemotherapy), oral mucositis, inflammatory bowel disease and short bowel syndrome.	5-30 g/day orally is a typical dose. Doses in IV or total parenteral nutrition (TPN) in the critically ill may be higher.	Considered safe. Many drugs deplete body stores of glutamine. Caution with higher doses in those with renal or liver impairment due to nitrogen content.	Take separately from food (especially protein) for maximal absorption.

BOX 11.7 Popular Dietary Supplements and Their Efficacy—cont'd

Supplement	Benefits	Dosage	Potential Contraindications	Quality Considerations
Melatonin	Likely effective for delayed sleep phase syndrome and sleep disorders, especially in the blind. Possibly effective for insomnia, benzodiazepine withdrawal, jet lag. High doses have been used to promote tumor regression in some forms of cancer.	500 mcg-5 mg/day have been used in research. 3-5 mg/day is the most common dose. 10-40 mg has been used for tumor regression—coordination of care with an oncologist is essential.	Generally regarded as safe for use up to 3 months and is even tolerated in neonates. Most common side effects are headache, nausea, and drowsiness. May lower blood pressure and disrupt hormone balance.	Usually taken 30 minutes before bed for sleep disorders.
Probiotics (lactobacillus acidophilus and bifidobacteria)	Likely effective for rotaviral diarrhea. Possibly effective for antibiotic associated diarrhea, atopic dermatitis (eczema), clostridium difficile diarrhea, chemotherapy induced diarrhea, constipation, Helicobacter pylori inflammation, infantile colic, irritable bowel syndrome, pouchitis, respiratory tract infections, travelers diarrhea, ulcerative colitis	Dosage varies and is measured in colony forming units (CFUs). Range is 1-450 billion CFU depending on the disease condition and therapeutic goal.	May be contraindicated in the immune suppressed, those with central line placement (especially saccharomyces boulardii), and in those on hemodialysis due to risk of sepsis. May cause diarrhea in high doses especially if the supplement contains prebiotics like inulin. May be contraindicated in premature infants with risk of bacteremia.	Refrigeration is important to preserve quality in most products; however, some products are shelf stable. Yeast-based probiotics (saccharomyces boulardii) are shelf stable.
Herbs				
Chamomile <i>Matricaria recutita</i> (German Chamomile)	Possibly effective for anxiety, colic, diarrhea, dyspepsia, and oral mucositis.	250-1100 mg/day in capsules or 1-4 cups/day as tea.	GRAS. Caution in those with allergy to ragweed or Asteraceae family.	Ensure correct plant is used. German chamomile (not Roman Chamomile) is the most common.
Cinnamon <i>Cinnamomum cassia</i>	Possibly effective for reducing fasting glucose in diabetes.	Typical dose is 120 mg-6 g/day in capsules or 1 tsp/day in food.	Generally safe. Caution in people with diabetes or blood sugar dysregulation or in those with impaired liver function. May enhance blood-thinning effects of warfarin.	Cassia cinnamon is more biologically active than Ceylon cinnamon for blood sugar regulation.
Cranberry <i>Vaccinium macrocarpon</i>	Possibly effective for urinary tract infection, (prevention and treatment). Preliminary evidence for reducing urinary odor and improving symptoms in benign prostatic hyperplasia (BPH).	As juice: 1 oz cranberry concentrate or 10 oz cranberry cocktail (sweetened). As capsules: 300-500 mg twice/day or 200 mg twice/day with 25% standardization of proanthocyanidins (PAC).	Generally safe. Caution with sugar in juice for diabetics, may increase calcium oxalate kidney stones.	Blueberries have similar constituents and may be similarly beneficial. Many supplements are standardized to contain a specific amount of PAC. This preparation may have a stronger effect.
<i>Echinacea angustifolia, pallida and purpurea</i>	Possibly effective for the common cold. Insufficient evidence for influenza, herpes simplex virus, human papilloma virus, and otitis media.	Can be taken as a capsule, tablet, tea, or tincture. Doses vary and are dependent on the variety used and preparation. 5 mL fresh juice or 20 drops in water every 2 hours, 4 mL 10 times per day for the first day of a cold then three times a day for the duration.	Caution in people with allergy to Asteraceae family (daisy, sunflower), and those on immunosuppressive medications.	Sometimes standardized to contain a specific amount of echinacoside or cichoric acid.

Continued

BOX 11.7 Popular Dietary Supplements and Their Efficacy—cont'd

Supplement	Benefits	Dosage	Potential Contraindications	Quality Considerations
Fenugreek <i>Trigonella foenum-graecum</i>	Possibly effective for improving blood sugar control in diabetes and dysmenorrhea. Conflicting evidence for promoting lactation, PCOS and hyperlipidemia.	Highly variable. 5-100 grams of ground seeds added to food although 2-5 grams 2-3 times per day is most common.	Long term studies lacking although the seeds are a staple some Asian cuisine. Therapeutic doses in children may be unsafe and not recommended for use during pregnancy (uterine stimulant). Few side effects noted. More than 100 grams may cause hypoglycemia. Avoid use with diabetes medications.	Ensure quality brand. In one case seeds were contaminated with E Coli and caused death. Generally recognized as safe (GRAS) as a food.
Garlic <i>Allium sativum</i>	Possibly effective for atherosclerosis, reducing blood sugar in diabetes, reducing blood lipids in hyperlipidemia, hypertension. Conflicting evidence for the common cold and cancer prevention.	2-5 g fresh garlic, 0.4-1.2 g dried powder, 2-5 mg oil, or 300-1000 mg extract to deliver 2-5 mg allicin (active constituent) per day. One clove fresh garlic has also been used.	Generally well tolerated. Higher doses may cause gastric irritation, body odor, and decreased blood pressure. Caution with those who are taking blood thinners and hypoglycemic drugs.	Comes in many forms in supplements. Those that preserve allicin content may be more effective. Aged extracts have shown benefits as well because of the multitude of sulfur compounds present.
Green tea <i>Camellia sinensis</i>	Likely effective for hyperlipidemia. Possibly effective for coronary artery disease, hypotension, Parkinson's disease. Conflicting evidence for cancer prevention, cardiovascular disease, and for weight loss.	Epigallocatechin (EGCG) epicatechin gallate, and epicatechin levels vary when taken as tea. 3 cups daily is a common dosage. Standardized extracts (60%-97% polyphenols) of 200-500 mg/day are common for a variety of conditions. 10% topical cream for skin aging and acne.	Well tolerated in most people. Most side effects come from the caffeine content (nervousness, anxiety, sleeplessness, and increased blood pressure). Use with caution in patients with psychiatric or cardiovascular conditions.	Decaffeinated versions are available to eliminate caffeine side effects.
Kava Kava <i>Piper methysticum</i>	Possibly effective for anxiety; insufficient evidence for benzodiazepine withdrawal, stress reduction, insomnia, and menopausal anxiety.	60-400 mg standardized extract per day.	Typical therapeutic doses are tolerated by most. Significant evidence of liver injury. Caution in people with liver disease. Chronic use can cause dry, scaly skin and photosensitivity.	Often standardized to contain 30%-70% kavalactones. May be best to start at lower doses and titrate up.
Milk thistle <i>Silybum marianum</i>	Although it is commonly used to reduce inflammation and fibrosis in liver disease, it is possibly effective for lowering fasting glucose in diabetes, and for dyspepsia. There is conflicting and insufficient evidence for alcohol related liver disease, amanita mushroom poisoning, cirrhosis, and hepatitis induced liver damage.	160-1200 mg/day based on condition treated. Take as divided doses. 140 mg standardized extract taken three times per day is a common dose.	Low toxicity risk. Can cause a mild laxative effect if taken in large amounts. Rare risk of allergic reaction. May lower blood sugar. May mildly inhibit CYP 3A4, 2C19, and 2D6 cytochrome enzymes.	Often standardized to contain 70%-80% silymarin. Tea preparation is not recommended because of poor water solubility. Whole, ground milk thistle seeds can be added to food.
Red Yeast Rice (RYR) <i>Monascus purpureus</i>	Likely effective for hyperlipidemia. Possibly effective for CVD and diabetes and HIV/AIDS related dyslipidemia. Preliminary evidence for use in nonalcoholic fatty liver disease (NAFLD).	The most common dose is 600- 2400 mg/day. It is estimated that average intake of naturally occurring RYR in Asia is 14-55 g/day.	Limited data on adverse events. Side effects appear to be similar to those with low-dose statin medications (headache, gastrointestinal discomfort, and muscle pain). May increase liver enzymes.	Contains naturally occurring lovastatin (Monacolin K). Dosing is difficult because of natural variations in products. It is illegal in the United States to standardize Monacolin K levels in supplements.

BOX 11.7 Popular Dietary Supplements and Their Efficacy—cont'd

Supplement	Benefits	Dosage	Potential Contraindications	Quality Considerations
St. John's Wort <i>Hypericum perforatum</i>	Likely effective for mild to moderate depression. Possibly effective for menopausal symptoms, somatization disorder. Conflicting or insufficient evidence for anxiety, obsessive compulsive disorder, premenstrual syndrome, seasonal affective disorder. Can be used topically for wound healing.	Typical dose is 300-450 mg three times per day. Coordination of care with a physician is important.	Has the most drug nutrient interactions of any common herb. Inhibits CYP 3A4, 2C19, and 2C9 cytochrome enzymes and the P-glycoprotein (P-gp) transporter. Reduces the effectiveness of immunosuppressive, antiretroviral, cardiovascular, and oral contraceptive medications among others. Can cause photosensitivity.	Typically standardized at 0.3% hypericin.
Turmeric <i>Curcuma longa</i>	Possibly effective for allergic rhinitis, depression, hyperlipidemia, NAFLD, ulcerative colitis, and osteoarthritis. Conflicting evidence for Alzheimer's disease, colorectal cancer, Crohn's disease, irritable bowel syndrome, rheumatoid arthritis, and ulcerative colitis.	500 mg-2 g curcumin per day depending on disease condition. Higher doses taken in divided doses.	Safe in amounts eaten in food. Higher doses can lower blood pressure and blood sugar and increase risk of bleeding. Caution in those with liver and gall bladder diseases and in those taking blood-thinning medications.	May be best absorbed when taken with food, especially a meal that contains fat. Curcumin supplements bound to phosphatidyl choline (Meriva) may be better absorbed.

CLINICAL CASE STUDY

Ellen is a 60-year-old white female who was referred from her primary care provider for evaluation of her dietary supplements. Medical history includes hypertension, hypercholesterolemia, osteopenia, mild depression, and memory problems. Two years ago, she had angioplasty (PTCA) with a stent placement in her coronary artery. Ellen is a retired school teacher, married, and has two grown children. Her neighbor works in a supplement store and recommended some herbs and supplements to address Ellen's health concerns.

At the initial consult Ellen reports she is taking the following supplements: calcium carbonate 1200 mg/d, garlic (*Allium sativum*) 500 mg/d, *Ginkgo biloba* 240 mg/d, and St. John's wort (*Hypericum perforatum*) 900 mg/d. Her prescription medications include warfarin, simvastatin, sertraline, and atenolol.

Height: 64" Weight: 165 lbs BMI: 28.4

Blood pressure readings: 134/92, 140/95 "This is higher than it usually is" Ellen reports.

Recent labs:

Total cholesterol: 284 mg/dL

High-density lipoprotein (HDL): 36 mg/dL

Low-density lipoprotein (LDL): 140 mg/dL

Prothrombin times (INR) has been inconsistent lately.

Typical dietary intake includes the following:

Breakfast: Total cereal with milk and calcium fortified orange juice

Lunch: Frozen entrée—beef and broccoli with rice and a Diet Coke

Snack: Strawberry yogurt and pretzels, coffee with milk

Dinner: Meatloaf, mashed potatoes with gravy and carrots. Glass of red wine.

Dessert: Chocolate ice cream, coffee with milk

Nutrition Diagnostic Statements

- Predicted food medication interaction (NC-2.4) related to a food and nutrition knowledge deficit about DNI's as evidenced by taking St. John's Wort with sertraline and the potential for serotonin syndrome.
- Altered nutrition related laboratory value (NC-2.2) related to knowledge deficit about DNI's, as evidenced by taking ginkgo and garlic with warfarin and inconsistent INRs

Nutrition Care Questions

1. Using the Office of Dietary Supplements Fact Sheets (ODS website), identify what each dietary supplement Ellen is taking is used for and if it has good evidence to support use.
2. List any potential drug nutrient interactions (DNIs) Ellen may have with her current concomitant use of medications and dietary supplements.
3. Looking at Ellen's lab tests, is there any evidence she may be having a DNI?
4. Does Ellen need to be taking a calcium supplement? Are there any potential risks with taking 1200 mg/day with a positive history of cardiovascular disease (CVD)?

 total nutrient admixture (3-in-1)
 transitional feeding

Nutrition support is the delivery of formulated enteral or parenteral nutrients for the purpose of maintaining or restoring nutritional status. **Enteral nutrition (EN)** refers to nutrition provided through the gastrointestinal tract (GIT) via a **catheter** or a tube or stoma that delivers nutrients distal to the oral cavity. **Parenteral nutrition (PN)** is the provision of nutrients intravenously.

RATIONALE AND CRITERIA FOR APPROPRIATE NUTRITION SUPPORT

When patients cannot or will not eat enough to support their nutritional needs for more than a few days, nutrition support should be considered as part of the integrated care plan. Using the GIT (EN vs. using PN alone) helps preserve the intestinal mucosal barrier function and integrity. In critically ill patients, feeding the GIT has been shown to attenuate the catabolic response and preserve immunologic function (McClave et al, 2016). Research shows less septic morbidity, fewer infectious complications, and significant cost savings in critically ill adult patients who received EN vs. PN. There is limited evidence that EN vs. PN affects hospital length of stay (LOS), but an impact on mortality has not been demonstrated (Academy of Nutrition and Dietetics [AND] and Evidence Analysis Library [EAL], 2012). A 2014 study

found no significant difference in 30-day mortality in critically ill adults who received nutrition support by the parenteral or the enteral route (Harvey et al, 2014). Another more recent study of ventilated adults with shock noted that early isocaloric EN did not reduce mortality or the risk of secondary infections but was associated with a greater risk of digestive complications compared with early isocaloric PN (Reignier et al, 2018). Conversely, a recent meta-analysis and systematic review noted that EN compared with PN had no overall effect on mortality but resulted in fewer infectious complications and shorter intensive care unit LOS (Elke et al, 2016).

A variety of diseases and conditions may result in the need for nutrition support (Table 12.1). PN should be used in patients who are or will become malnourished and who do not have sufficient gastrointestinal function to be able to restore or maintain optimal nutritional status (McClave et al, 2016). EN should be considered when an individual has a functional GIT and is unable or unwilling to consume sufficient nutrients to meet estimated nutritional needs. Fig. 12.1 presents an algorithm for selecting appropriate routes for EN and PN. Although these guidelines provide ideas, the choice of the most optimal method of nutrition support can be challenging. For example, the small bowel feeding access for EN may not be available in every health care setting. In such a case, PN may be the only realistic option for provision of nutrition support. PN may be used temporarily until adequate gastrointestinal function to support EN or oral intake returns, or PN may be used to supplement EN or oral intake to meet needs effectively for energy, protein, and other key nutrients. “Transitional

Sections of this chapter were written by Janice L. Raymond, MS, RDN, CSG for the previous edition of this text.

TABLE 12.1 Conditions That May Require Nutrition Support

Recommended Route of Feeding	Condition	Typical Disorders
Enteral nutrition	Inability to eat	Neurologic disorders (dysphagia) Facial trauma Oral or esophageal trauma Congenital anomalies Respiratory failure (on a ventilator) Traumatic brain injury Comatose state GI surgery (e.g., esophagectomy)
	Inability to eat enough	Hypermetabolic states such as with burns Cancer Heart failure Congenital heart disease Impaired intake after orofacial surgery or injury Anorexia nervosa Failure to thrive Cystic fibrosis
Parenteral nutrition	Impaired digestion, absorption, metabolism	Severe gastroparesis Inborn errors of metabolism Crohn's disease Short bowel syndrome with minimum resection Pancreatitis
	Gastrointestinal incompetency	Short bowel syndrome—major resection Severe acute pancreatitis with intolerance to enteral feeding Severe inflammatory bowel disease Small bowel ischemia Intestinal atresia Severe liver failure Persistent postoperative ileus Intractable vomiting/diarrhea refractory to medical management Distal high-output fistulas Severe GI bleeding
	Critical illness with poor enteral tolerance or accessibility	Multi-organ system failure Major trauma or burns Bone marrow transplantation Acute respiratory failure with ventilator dependency and gastrointestinal malfunction Severe wasting in renal failure with dialysis Small bowel transplantation, immediate after surgery

GI, Gastrointestinal.

McClave SA et al: Guidelines for the provision and assessment of nutrition support therapy in the adult critically ill patient, *J Parenter Enteral Nutr*; 40:159-211, 2016.

Feeding,” described later in the chapter, refers to the provision of nutrition support via two or more methods, until nutrition adequacy is reached via oral intake alone.

Although specific nutrition support regimens may be standardized for specific disease states or courses of therapy, each patient presents a unique challenge. Nutrition support frequently must be adapted to address unanticipated developments or complications. An optimal treatment plan requires interdisciplinary collaboration that is aligned closely with the comprehensive plan of patient care. In rare cases, nutrition support may be warranted but physically impossible to implement. In other situations, nutrition support may be possible but not warranted because it presents an unacceptable risk or is not indicated because of the prognosis or the patient’s right to self-determination.

In all cases, it is important to prevent errors in ordering, delivering, and monitoring of nutrition support to prevent undesirable risks or outcomes (**sentinel events**) such as an unexpected death, serious physical injury with loss of limb or function, or psychological injury (Joint Commission, 2017). A **computerized provider order entry (CPOE)** system allows prescribers to enter an order directly into a computer, often aided by decision-support technology to help facilitate accuracy and clinical effectiveness.

ENTERAL NUTRITION

Enteral implies using the GIT, usually via a feeding tube with the tip in the stomach or small bowel. The location of nutrient administration and type of enteral access device are selected after the patient is determined to be a candidate for EN. (The process for determining whether an individual is a candidate for EN is described later.) Enteral access selection depends on the (1) anticipated length of time enteral feeding will be required, (2) degree of risk for aspiration or tube displacement, (3) patient’s clinical status, (4) adequacy of digestion and absorption, (5) patient’s anatomy (e.g., after previous surgical resection or in extreme obesity), and (6) whether future surgical intervention is planned.

Feeding tubes may be referred to by their **French size**, which is a measure of the outer tube diameter. One French unit is 0.33 mm. A French size of 5 to 12 typically is considered “small bore,” and a French size of more than 14 is considered “large bore.”

ENTERAL NUTRITION ACCESS

Short-Term Enteral Nutrition Support

Nasogastric Access

Nasogastric tubes (NGTs) are used most commonly to access the GIT, for gastric decompression (i.e., draining the fluid normally secreted by the stomach when the normal emptying process is slowed), medication delivery, and/or feeding. They are appropriate only for those patients who require short-term (no more than 3 to 4 weeks) EN. Typically, the tube is inserted at the bedside by a nurse or physician (or a registered dietitian with appropriate clinical privileges) and passed through the nose into the stomach (Fig. 12.2). Polyurethane or silicone tubes of various diameters, lengths, and design features may be used, depending on formula characteristics and feeding requirements. These tubes are soft, flexible, and often well tolerated by patients. Tube placement is verified by aspirating gastric contents in combination with auscultation of air insufflation into the stomach or by radiographic confirmation of the tube tip location. The American Society for Parenteral and Enteral Nutrition (ASPEN) Enteral Nutrition Practice Recommendations offer detailed information on this process (Bankhead et al, 2009).

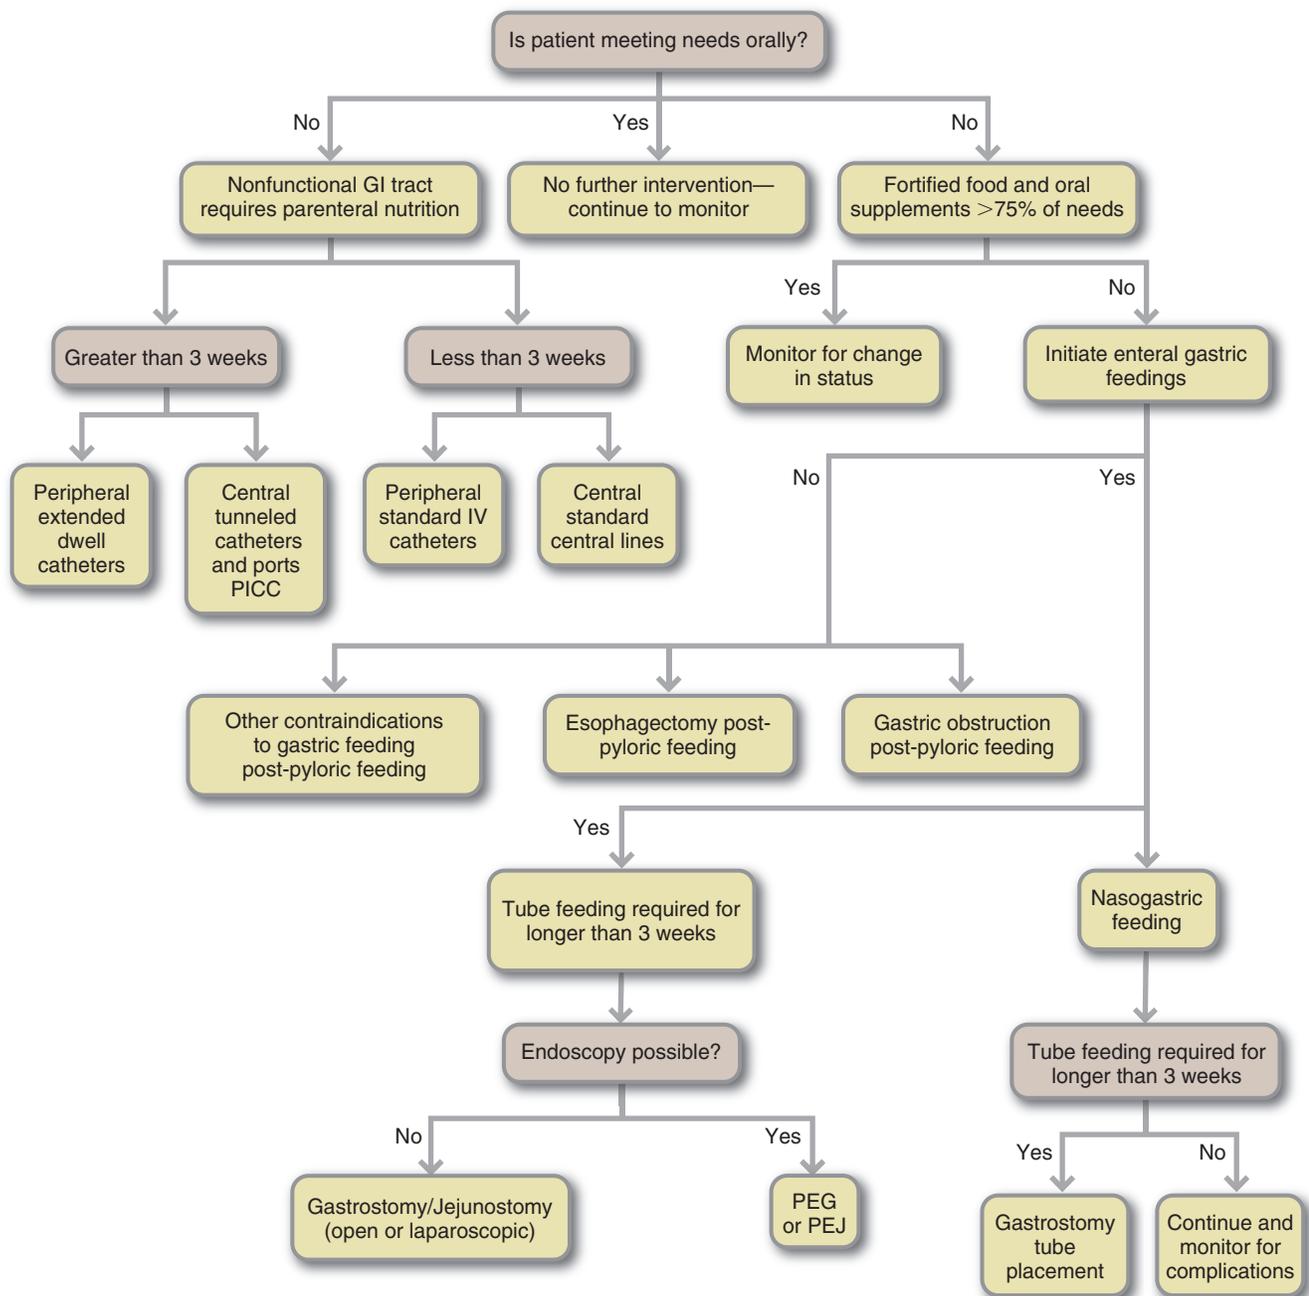

Fig. 12.1 Algorithm for route selection for nutrition support.

NGT feedings are provided by bolus administration or by intermittent or continuous infusions (see *Administration* later in this chapter). Patients with normal gastrointestinal function are often fed via this route, which takes advantage of normal digestive, hormonal, and bactericidal processes in the stomach. Rarely, complications occur (Box 12.1).

Gastric Versus Small-Bowel Access

Placement of a feeding tube into the stomach may be more straightforward and less time consuming than placing a tube into the small bowel. However, ease of access is only one consideration. Critically ill patients, including those who have undergone surgery, or suffered a head injury or major intraabdominal trauma, may not tolerate gastric feeding (see Chapter 37).

Signs and symptoms of intolerance to gastric feeding include, but are not limited to, the following:

- Abdominal distention and discomfort
- Vomiting
- Persistent diarrhea

Some clinicians believe that intragastric feeding increases the risk of aspiration pneumonia; the data on this subject are not totally clear (Bankhead et al, 2009; McClave et al, 2016).

Nasoduodenal or Nasojejunal Access

Patients who do not tolerate gastric feedings and require relatively short-term EN support may benefit from placement of a **nasoduodenal tube (NDT)** or a **nasojejunal tube (NJT)**, described by the point at which the tube tip terminates. These tubes may be placed with

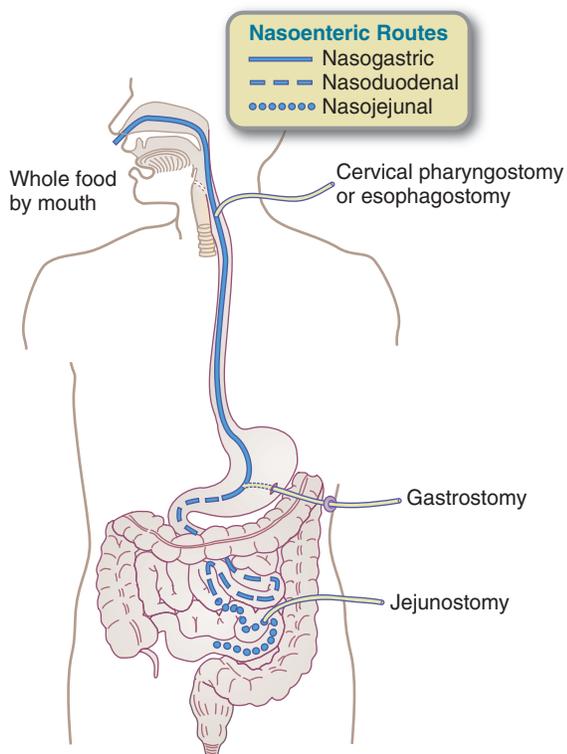

Fig. 12.2 Diagram of enteral tube placement.

BOX 12.1 Potential Complications of Nasoenteric Tubes

- Esophageal strictures
- Gastroesophageal reflux resulting in aspiration pneumonia
- Tracheoesophageal fistula
- Incorrect position of the tube leading to pulmonary injury
- Mucosal damage at the insertion site
- Nasal irritation and erosion
- Pharyngeal or vocal cord paralysis
- Rhinorrhea, sinusitis, otitis media
- Ruptured gastroesophageal varices in hepatic disease
- Ulcerations or perforations of the upper gastrointestinal tract and airway

Adapted from McClave SA et al: Guidelines for the provision and assessment of nutrition support therapy in the adult critically ill patient, *J Parenter Enteral Nutr* 40:159-211, 2016; Cresci G: Enteral access. In Charney P, Malone A: *Pocket guide to enteral nutrition*, ed 2, Chicago, 2013, Academy of Nutrition and Dietetics, p 62.

endoscopic or fluoroscopic guidance (Fig. 12.3, A); using a computer guidance system (Fig. 12.3, B); or intraoperatively as part of a surgical procedure.

Some practitioners may place a feeding tube intragastrically with the goal of migration into the duodenum by peristalsis; this process is unlikely to result in desired location of the feeding tube tip and inevitably delays initiation of appropriate EN. Spontaneous migration never achieves jejunal tip placement.

Long-Term Enteral Access

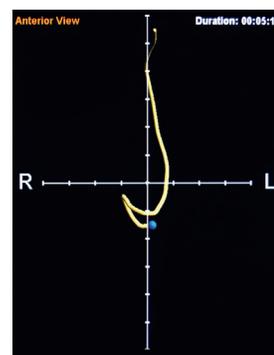

Gastrostomy or Jejunostomy

When EN is required for more than 3 to 4 weeks, placement of a surgically or endoscopically guided gastrostomy or jejunostomy feeding

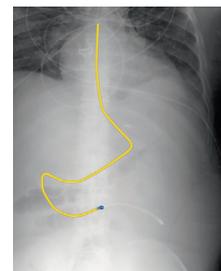

CORTRAK[®]
Enteral Access System

A

B

C

Fig. 12.3 Computerized Cortrak tube feeding placement system. **A**, CORTRAK System; **B**, CORTRAK anterior view compared with abdominal radiograph; **C**, 3-dimensional graphic representation of a CORTRAK feeding tube in post-pyloric position. (Used with permission from CORPAK MedSystems.)

tube should be considered to maximize patient comfort (Fig. 12.4) and minimize nasal and upper GIT irritation (see Box 12.1). This tube may be placed during a required surgical or endoscopic procedure to maximize efficiency and cost effectiveness.

Percutaneous endoscopic gastrostomy (PEG) or **percutaneous endoscopic jejunostomy (PEJ)** is a nonsurgical technique for placing

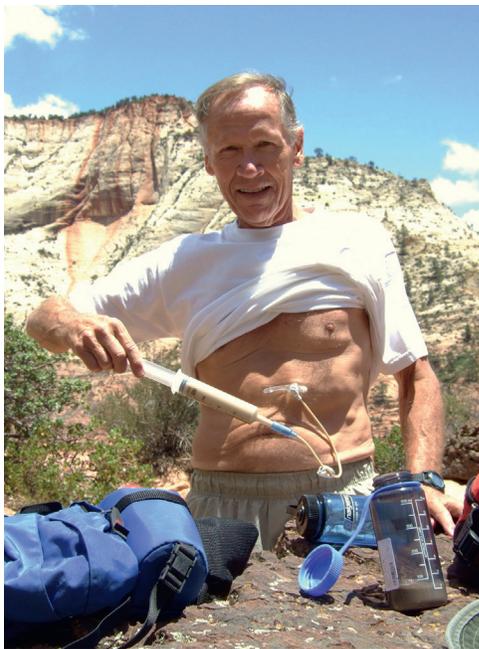

Fig. 12.4 A man with a gastrostomy tube out hiking. (From Oley Foundation, Albany, NY: www.oley.org.)

a tube directly into the stomach through the abdominal wall, using an endoscope and local anesthesia. The tube is guided from the mouth into the stomach or the jejunum and brought out through the abdominal wall. The short procedure time and limited anesthesia requirements have contributed to making it a very common method for long-term feeding tube placement.

Tubes placed by PEG (note the PEG is the procedure, not the tube, although clinicians commonly refer to “PEGs” as the tube) are generally large bore (French size), facilitating administration of medications and reducing the incidence of clogging. These tubes may be connected to a short piece of tubing used to infuse a bolus feeding or connect to a bag of formula. Some tubes placed by PEG are flush to the skin, or “low profile.” These tubes, also known as “buttons,” are a good choice for children, and for adults with dementia, both of whom may be likely to pull out a tube that protrudes from the skin. Active individuals, and those who prefer a sleeker profile under clothing, also may opt for this type of tube. Fig. 12.5 shows a component from a skin level balloon G-tube kit, designed to improve patient comfort and increase the length of time the G-tube may remain in place. To prevent the accidental parenteral infusion (into the blood) of enteral formula, a universal connector that is incompatible with IV equipment has been developed. Fig. 12.5 shows a silicone G-tube with a purple connector, which is incompatible with a Luer lock syringe or an IV connection. This innovation, recently made the industry standard, is designed to reduce the risk of accidental connection or infusion.

A tube placed by PEG may be converted to a **gastrojejunostomy** using fluoroscopy or endoscopy by threading a small-bore tube through the larger tube into the jejunum.

Other Minimally Invasive Techniques

High-resolution video cameras have made percutaneous radiologic and laparoscopic gastrostomy and jejunostomy enteral access an option for patients in whom endoscopic procedures are contraindicated. Using fluoroscopy, a radiologic technique, a feeding tube may be guided into the stomach or the jejunum and then brought

Fig. 12.5 Baxter Clinimix Compounding System. (Image provided by Baxter Healthcare Corporation. CLINIMIX is a trademark of Baxter International Inc.)

through the abdominal wall to provide access for enteral feedings. Laparoscopic or fluoroscopic techniques offer alternative options for enteral access.

Gastrojejunal dual tubes, used for early postoperative feeding, are available for endoscopic or surgical placement. These tubes are designed for patients who may require prolonged **gastrointestinal decompression** (removal of the contents of the stomach through a nasogastric tube). The **multiple lumen tube** includes one lumen for decompression and one for feeding into the small bowel.

Formula Content and Selection

Many enteral formulations, marketed for a wide variety of clinical conditions and indications, are currently available (Escuro and Hummel, 2016):

- Enteral formulas are classified as (1) standard, (2) elemental or semi-elemental, (3) specialty or disease-specific, (4) blenderized, and (5) modular. A variety of formulas are available in each of these categories. Health care organizations, including hospitals and long-term care organizations, typically develop a formulary of products to be used within the facility. Selection of an enteral formula for a specific patient should involve consideration of the patient’s nutrient needs, GIT function, and clinical status.

In the past, **osmolality** was considered key to EN tolerance, and belief was widespread that EN formulas should be the same osmolality as body fluids (290 mOsm/kg). However, studies in the mid-1980s showed that patients tolerate feedings across a wide range of osmolality, and clinical experience of many clinicians has reinforced those study results.

Cost of a formula and its availability after discharge from the hospital or other facility may be barriers for clinicians, patients, families, and facility administrators.

Formulas may be classified based on protein or overall macronutrient composition. The nutrition needs of most patients may be met with a standard or **polymeric enteral formula** (McClave et al, 2016). These formulas contain intact macronutrients (1 to 2 kcal/mL), are

lactose free, and frequently may be used as an oral supplement and an enteral feeding. The higher nutrient density (1.5 to 2 kcal/mL) formulas are useful when fluid restriction is required (cardiopulmonary, renal, and/or hepatic dysfunction), and for patients with intolerance to a higher feeding volume. Products intended to supplement oral diets may be used for EN in some cases; these products are flavored and may contain simple sugars to enhance palatability (see Appendix 15).

The manufacture and labeling of enteral formulas are regulated by the Food and Drug Administration (FDA), which classifies enteral formulas as medical foods (a subclassification of foods for special dietary use). As such, these products are exempt from specific nutrition labeling requirements in the Code of Federal Regulations. The products must be labeled as “intended to be used under medical supervision” (FDA, 2014).

Manufacturers are not obligated to register enteral products with the FDA or obtain FDA approval before placing them on the market. Many EN formulas lack rigorous scientific evidence to support their specific composition, and their marketing materials are not subject to the rigorous standards used for prescription drugs. Evaluation of the efficacy of EN products and the statements made in marketing materials and by company representatives requires the attention of qualified registered dietitian nutritionists (RDNs). RDNs should evaluate claims of pharmacologic effects and other specific benefits using clinical evidence before choosing a specific product for a formulary or for a specific patient (Box 12.2).

Blenderized (Homemade) Tube Feedings

Tube feedings made from common ingredients such as eggs, sugar, and wine have been used since the 1500s. Blenderized tube feedings (BTFs) were commonly used in the United States throughout the first half of the twentieth century (Vassilyadi et al, 2013). Clinicians often are concerned about nutritional adequacy, food safety, and the additional burden preparation of BTF places on the caregivers. Advantages of BTF may include cost effectiveness (because commercial formulas may not be covered by insurance), health benefits from using whole foods, and ability to tailor the formula exactly to patient needs. The social bond between the caregiver who prepares the feeding (possibly from foods served to the rest of the family) and the patient also is cited as a strong driver for BTF use. Hurt and colleagues found that more than 80% of a small sample of home EN patients at the Mayo Clinic in Rochester, MN, wanted to use BTF (Hurt et al, 2015). In the last several years, several commercially prepared BTF have appeared on the market, such as Liquid Hope™ and Real Food Blends™. Compleat® has been marketed by Nestle for a number of years, and Abbott Nutrition will soon market a BTF.

BOX 12.2 Factors to Consider When Choosing an Enteral Formula

Ability of the formula to meet the patient’s nutrient requirements
 Caloric and protein density of the formula (i.e., kcal/mL, g protein/mL, mL fluid/L)
 Gastrointestinal function
 Sodium, potassium, magnesium, and phosphorus content of the formula, especially for patients with cardiopulmonary, renal, or hepatic failure
 Form and amount of protein, fat, carbohydrate, and fiber in the formula relative to the patient’s digestive and absorptive capacity
 Cost effectiveness of formula
 Patient compliance
 Cost-to-benefit ratio

Homemade BTFs are contraindicated for patients who are immunocompromised and should be hung for no more than 2 hours. All BTF may be contraindicated for infusion through tubes smaller than 10 French, for continuous feeding (unless the recommended formula hang time is followed), if a fluid restriction of less than 900 mL/day is required, in cases of multiple food allergies, and if a jejunostomy tube (JT) is used (Novak et al, 2009). Some state regulations prohibit use of BTF in long-term care facilities (see *New Directions: Pured by Gastrostomy Tube—the PBGT Diet*).

NEW DIRECTIONS

Pured by Gastrostomy Tube—the PBGT Diet

The Pured by Gastrostomy (G) Tube (PBGT) Diet is a specialized, nutritionally balanced blended food feeding given by G-tube. It was originally designed to decrease or eliminate symptoms of retching and gagging which can be a complication of a Nissen Fundoplication surgery. In addition to improving tolerance of bolus feeds for individuals who are volume sensitive, the PBGT diet is also used by families seeking an alternative to commercial formulas. The goals of the PBGT diet are to:

- Decrease frequency of gastrostomy tube feedings and transition from drip feedings
- Meet all nutritional and fluid requirements
- Improve weight gain, growth, and overall nutritional status
- Encourage increased opportunities for oral intake
- Improve and sustain quality of life for individuals and their families

The PBGT diet is different from the usual blended tube feeding in that it is calculated and formulated by a registered dietitian nutritionist (RDN) to provide an individual with complete nutrition through small, calorie-dense gastrostomy tube boluses, thereby eliminating the need and cost for a feeding pump. In addition to the easier preparation of the PBGT, special attention is also given to the variety of foods, nutrient content, cost, and ease of the 5- to 10-minute bolus administration (Pentiuk et al, 2011).

The use of Stage 2 infant foods promotes consistency in the viscosity of the diet, provides availability and affordability, and eliminates the need for an expensive blender. They can be premeasured and individually sealed in containers that can be easily used in formula rooms within hospitals if allowed by hospital policy. Families can be educated on the easy preparation method and proper storage, along with additional fluid and vitamin and mineral supplementation guidelines (O’Flaherty et al, 2011; O’Flaherty, 2015).

Therese O’Flaherty MS, RDN, CSP, LD

Protein

The amount of protein in available commercial enteral formulas varies from 6% to 37% of total kilocalories. The protein typically is derived from casein, whey, or soy protein isolate. Standard formulas provide intact protein; elemental formulas contain di- and tripeptides and amino acids, which are absorbed more easily. Specialized formulas (that are marketed for hepatic or severe renal failure or for cases of multiple, severe allergies) usually include crystalline amino acids.

Specific amino acids may be added to some enteral formulas. Branched chain amino acids have been used in formulas for patients with severe hepatic disease, and arginine has been added to formulas marketed for critically ill patients. Strong evidence to support these additions is not available. (See Chapter 37 for further discussion.)

Carbohydrate

Carbohydrate content in enteral formulas varies from 30% to 85% of kilocalories. Corn syrup solids typically are used in standard formulas.

Sucrose is added to flavored formulas that are meant for oral consumption. Hydrolyzed formulas contain carbohydrate from cornstarch or maltodextrin.

Carbohydrate or fiber that cannot be processed by human digestive enzymes is added frequently to enteral formulas. Fibers are classified as water soluble (pectins and gums) or water insoluble (cellulose or hemicellulose). The effectiveness of different fibers added to enteral formulas in treating GIT symptoms of critically ill patients is controversial. The Adult Critical Illness guidelines, in the Evidence Analysis Library of the Academy of Nutrition and Dietetics (AND and EAL, 2012), suggests that the RDN “consider using soluble fiber to prevent and/or manage diarrhea.”

Fructooligosaccharides (FOS), which are prebiotics, have been added to enteral formulas, often in combination with a source of dietary fiber, for more than 15 years. More recently inulin, another fermentable oligosaccharide, has been added to some enteral formulas. Both FOS and inulin are associated with fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs), which are poorly absorbed short-chain carbohydrates (Escuro and Hummell, 2016).

FOS have been shown to stimulate the production of beneficial bifidobacteria, and when combined with dietary fiber may produce beneficial changes in colonic pH, fecal microbiota, and short-chain fatty acid concentrations. Animal models provide evidence that FOS may help to achieve colonization resistance against *Clostridium difficile*. Use of formulas with a high FODMAPs content may exacerbate and play a role in diarrhea, especially in individuals who receive antibiotics that affect the intestinal microbiome (Escuro and Hummell, 2016).

The Society of Critical Care Medicine (SCCM)/ASPEN guidelines suggest that “mixed-fiber formula not be used routinely” in adult critically ill patients “to promote regularity or prevent diarrhea” and also “to consider a fermentable soluble fiber additive (FOS, inulin) for routine use in all stable MICU/SICU patients placed on standard enteral formulations if there is evidence of diarrhea” (McClave et al, 2016).

All commercially available enteral formulas are lactose free, because lactase insufficiency may be encountered in acutely ill patients. (Atkinson and Worthley, 2003).

Lipid

Lipid content of enteral formulas varies from 1.5% to 55% of the total kilocalories. In standard formulas, lipid as (typically) canola, soybean, and/or safflower oil provides between 15% and 30% of the total kilocalories. Elemental formulas contain minimal amounts of fat, typically in the form of medium-chain triglycerides (MCTs) rather than long-chain triglycerides (LCTs).

Most of the lipid in standard enteral formulas is in the form of LCTs and MCTs. Some formulas contain “structured lipids,” which are a mix of LCTs and MCTs and contain properties of both. Most of the LCTs found in structured lipids are omega-3 fatty acids (such as eicosapentaenoic acid and docosahexanoic acid); these omega-3 fatty acids may have antiinflammatory effects (see Chapter 7).

MCTs do not require bile salts or pancreatic lipase for digestion and are absorbed directly into the portal circulation. The percentage of fat as MCT in enteral formulas varies from 0% to 85%. About 2% to 4% of daily energy intake from linoleic and linolenic acid is necessary to prevent **essential fatty acid deficiency (EFAD)**. MCTs do not provide linoleic or linolenic acids; the clinician must ensure that patients who receive high MCT enteral formulas receive linoleic and linolenic acids from other sources.

Vitamins, Minerals, and Electrolytes

Most, but not all, available formulas provide the dietary reference intakes (DRIs) for vitamins and minerals in a volume that may be administered to most patients. Because the DRIs are intended for healthy populations, not specifically for individuals (whether healthy or acutely or chronically ill), it is difficult to know for certain whether the vitamin and mineral provision from these formulas is adequate. Formulas intended for patients with renal or hepatic failure are intentionally low in vitamins A, D, and E; sodium; and potassium. Conversely, disease-specific formulas often are supplemented with antioxidant vitamins and minerals and marketed to suggest that these additions improve immune function or accelerate wound healing. Definitive studies demonstrating these effects are not available.

Electrolyte content of enteral formulas is typically modest compared with the oral diet. Patients who experience large electrolyte losses (e.g., because of diarrhea, fistula, emesis) likely will require electrolyte supplementation. Salt must be added to home-prepared BTFs in order to provide an adequate sodium intake.

Fluid

Adult fluid needs often are estimated at 1 mL of water per kilocalorie consumed, or 30 to 35 mL/kg of usual body weight. Patients fed exclusively by EN, especially if it is a concentrated formula, may receive insufficient fluid (water) to meet their needs. Insufficient fluid intake and administration of a high-fiber product can lead to undesirable consequences, including inadequate urine output, constipation, and formation of a fiber bezoar (a hard ball of fiber that may develop within the human stomach). All sources of fluid, including feeding tube flushes, medications, and intravenous fluids, should be considered when assessing a patient’s fluid intake relative to individual needs.

Standard (1 kcal/mL) formulas contain about 85% water by volume; concentrated (2 kcal/mL) formulas contain only about 70% water by volume. Additional water (as flushes and for additional hydration) are often necessary to meet fluid needs and help assure tube patency.

Administration

EN may be administered as a bolus, or as an intermittent or continuous feeding. Administration method selection should accommodate the patient’s clinical status, living situation, and quality-of-life considerations. One method may serve as a transition to another method as the patient’s status changes.

In a **closed enteral system**, the container or bag is prefilled with sterile liquid formula by the manufacturer and is “ready to feed” after connecting to the patient’s feeding access. In an **open enteral system**, the contents of formula cans or packages are poured into a separate, empty container or bag and then connected to the feeding access.

Hang time is the length of time an enteral formula hanging at room temperature is considered safe for delivery to the patient. Most facilities allow a 4-hour hang time for a product in an open system and 24 to 48 hours for products in closed system (manufacturer’s directions should always be followed).

Bolus

Syringe **bolus enteral feedings** can be suitable for patients with adequate gastric emptying who are clinically stable (see Fig. 12.4). Administered over 5 to 20 minutes, these feedings are more convenient and less expensive than pump or gravity bolus feedings and should be encouraged when tolerated. A 60-mL syringe may be used to infuse the formula. If bloating or abdominal discomfort develops, the patient

should wait 10 to 15 minutes before infusing the remainder of formula allocated for that feeding. Patients with normal gastric function generally tolerate 500 mL or more of formula per feeding; therefore, three or four bolus feedings per day typically provide their daily nutritional requirements. Some individuals, especially if elderly, may not tolerate larger boluses and require smaller, more frequent feedings. Formula at room temperature is better tolerated than cold formula; however, food safety must be the primary consideration. Follow label directions for storing partially used cans of formula.

Intermittent and Cyclic

Quality-of-life issues are often the reason for the initiation of **intermittent enteral feedings**. Cyclic regimens allow mobile patients an improved quality of life by offering time “off the pump” and more autonomy. They are initiated to allow time for treatments, therapies, and activities. Intermittent feedings can be given by pump or gravity drip. Gravity feeding is accomplished by pouring formula into a feeding bag that is equipped with a roller clamp. The clamp is adjusted to the desired drips per minute. A typical daily feeding schedule is four to six feedings, each administered over 20 to 60 minutes. Formula administration is initiated at 100 to 150 mL per feeding and increased incrementally as tolerated. Patients who most often succeed with this regimen are motivated, organized, alert, and mobile. Cyclic feeding also allows for time away from tube feeding. This feeding regimen is a good choice for patients who are receiving physical therapy or participate in other activities that require mobility. A typical daily feeding schedule is 90 to 150 mL per hour of formula administered over 18 to 20 hours. This regimen, often started at night, can be used to transition to an oral diet.

Continuous

Continuous infusion of EN requires a pump. This method is appropriate for patients who do not tolerate the volume of infusion used with the bolus, cyclical, or intermittent methods. Patients with compromised gastrointestinal function because of disease, surgery, cancer therapy, or other physiologic impediments are candidates for continuous feedings. Patients with a feeding tube tip in the small intestine should be fed only by continuous or cyclic infusion. (Use of bolus or gravity feeding in these patients is strongly discouraged, although anecdotal verbal reports of use of both have been shared by some providers.) The feeding rate goal, in milliliters per hour, is set by dividing the total daily volume by the number of hours per day of administration. Full strength feeding is started at one quarter to one half of the hourly goal rate and advanced every 8 to 12 hours to the final volume. Dilution of formulas is not necessary and can lead to underfeeding. High osmolality formulas may require more time to achieve tolerance and should be advanced conservatively.

One possible drawback to continuous feedings occurs if the patient requires medication that must be administered on an empty stomach. For example, when administering phenytoin (Dilantin) it is recommended that tube feedings be stopped before and after administration. The times vary by situation and medication.

Enteral pumps for home use are small and easy to handle. Many pumps run for up to 8 hours on battery power, with a “plug-in” option, allowing flexibility and mobility for the patient. Pump sets typically include bags and tubing compatible with proper pump operation. Feeding bags should be labeled in accordance with the ASPEN Enteral Nutrition Practice Guidelines and should include the name of the formula and its concentration, the date and time the bag was filled, and the initials of the health care provider who hung the feeding.

Monitoring and Evaluation

Monitoring for Complications

Box 12.3 provides a comprehensive list of complications associated with EN. Many complications can be prevented or managed with careful patient monitoring.

Aspiration, a common concern for patients receiving EN, is a controversial topic. Many experts believe that aspiration of throat contents and saliva is as much as or more important than aspiration of formula. To minimize the risk of aspiration, patients should be positioned with their heads and shoulders above their chests during and immediately after feeding (Bankhead et al, 2009; McClave et al, 2016).

Significant disagreement exists about the value of **gastric residual volumes (GRV)** as an indicator of EN tolerance. GRV procedures are not standardized and checking GRV does not protect patients from aspiration. GRV does not have to be checked regularly in patients who are stable on a feeding regimen and those who have a long history on tube feedings. In critically ill tube-fed patients the best methods for reducing the risk of aspiration include elevation of the head of the bed,

BOX 12.3 Complications of Enteral Nutrition

Access

- Leakage from ostomy/stoma site
- Pressure necrosis/ulceration/stenosis
- Tissue erosion
- Tube displacement/migration
- Tube obstruction/occlusion

Administration

- Microbial contamination
- Enteral misconnections or misplacement of tube, causing infection, aspiration pneumonia, peritonitis, pulmonary or venous infusion
- Regurgitation
- Inadequate delivery for one or more reasons

Gastrointestinal

- Constipation
- Delayed gastric emptying/elevated gastric residual volume
- Diarrhea
 - Osmotic diarrhea, especially if sorbitol is present in liquid drug preparations
 - Secretory
- Distention/bloating/cramping
- Formula choice/rate of administration
- Intolerance of nutrient components
- Maldigestion/malabsorption
- Nausea/vomiting

Metabolic

- Drug-nutrient interactions
- Glucose intolerance/hyperglycemia/hypoglycemia
- Dehydration/overhydration
- Hypernatremia/hyponatremia
- Hyperkalemia/hypokalemia
- Hyperphosphatemia/hypophosphatemia
- Micronutrient deficiencies (notably thiamin)
- Refeeding syndrome

Data from Russell M: Complications of enteral feedings. In Charney P, Malone A (eds): *Pocket guide to enteral nutrition*, ed 2, Chicago, 2013, Academy of Nutrition and Dietetics, p 170.

continuous subglottic suctioning, and oral decontamination (Bankhead et al, 2009; McClave et al, 2016).

In the presence of gastroparesis, doses of a promotility drug (like metoclopramide) may increase gastrointestinal transit, improve EN delivery, and improve feeding tolerance (McClave et al, 2016).

Diarrhea is a common EN complication, often related to the antibiotic therapy, colonic bacterial overgrowth, and gastrointestinal motility disorders associated with acute and critical illness. Hyperosmolar medications such as magnesium-containing antacids, sorbitol-containing elixirs, and electrolyte supplements also contribute to diarrhea. Adjustment of medications or administration methods may reduce or eliminate the diarrhea. FOS, pectin, guar gum, bulking agents, and antidiarrheal medications also can be beneficial. (Use care to avoid clogging the feeding tube when using bulking agents or pectin.) A predigested formula is rarely the best “first line” option, because the formula is typically not the cause of the diarrhea.

Constipation is a concern with EN, particularly among bed-bound patients who receive long-term feedings. Fiber-containing formulas or stool-bulking medication may be helpful; daily provision of adequate fluid is important. Narcotic pain relievers slow GIT activity; iron supplements can cause constipation. Diarrhea may coexist with constipation because liquid stool can pass a fecal impaction.

Monitoring for Tolerance and Nutrient Intake Goals

Monitoring the patient’s *actual* (not prescribed) intake and tolerance is necessary to ensure that all nutrition goals are achieved and maintained. Monitoring of metabolic and gastrointestinal tolerance, hydration status, weight, and lean body mass is extremely important (Box 12.4). Practice guidelines, institutional protocols, and standardized ordering procedures should be developed and used to ensure optimal, safe monitoring of EN (McClave et al, 2016).

Time is often lost from the prescribed feeding schedule because of issues such as NPO (nothing by mouth) status for medical procedures, clogged tubes, dislodged or misplaced tubes, and perceived or actual gastrointestinal intolerance. The result of “held” feedings is always inadequate nutrition with the risk of onset, or worsening, of malnutrition. Adjustment in the tube feeding regimen must be made. For example, if

tube feedings are being turned off for 2 hours every afternoon for physical therapy, the feeding rate on the feeding should be increased and the feeding time decreased to accommodate the therapy schedule.

PARENTERAL NUTRITION

PN provides nutrients directly into the bloodstream intravenously. PN is indicated when the patient or individual is unable to take adequate nutrients orally or enterally. PN may be used as an adjunct to oral or EN to meet nutrient needs (Mundi et al, 2017; Derenski et al, 2016). Alternatively, PN may be the sole source of nutrition during recovery from illness or injury or may be a life-sustaining therapy for patients who have lost the function of their intestine for nutrient absorption. As any type of nutrition support other than oral is invasive, it is important to evaluate ethical issues if the patient is terminal or has a short life expectancy (Schwartz et al, 2016).

Getting Started with Parenteral Nutrition

After the patient has been deemed to require nutrition support via the parenteral route, the clinician must choose between central and peripheral access. *Central access* refers to catheter tip placement in a large, high-blood-flow vein such as the superior vena cava; this is **central parenteral nutrition (CPN)**. **Peripheral parenteral nutrition (PPN)** refers to catheter tip placement in a small vein, typically in the hand or forearm.

The osmolarity of the PN solution dictates the location of the catheter; central catheter placement allows for the higher caloric PN formulation and therefore greater osmolarity (Table 12.2). The use of PPN is limited: it is short-term therapy and therefore has a minimum effect on nutritional status because the type and amount of fluids that can be provided peripherally are limited and most often do not fully meet nutrition requirements. Volume-sensitive patients such as those with cardiopulmonary, renal, or hepatic failure are not good candidates for PPN. PPN may be appropriate when used as a supplemental feeding or in transition to enteral or oral feeding, or as a temporary method to begin feeding when central access has not been initiated. Calculation of the osmolarity of a parenteral solution is important to ensure venous tolerance. **Osmolarity**, or mOsm/mL, is used to calculate IV fluids rather than osmolality, which is used for body fluids.

BOX 12.4 Monitoring the Patient Receiving Enteral Nutrition

Abdominal distention and discomfort
 Confirm proper tube placement and maintain head of bed >30 degrees (daily)
 Change feeding delivery container and tubing (daily)
 Fluid intake and output (daily)
 Gastric residual volume if appropriate (not for jejunal tubes)
 Signs and symptoms of edema or dehydration (daily)
 Stool frequency, volume, and consistency (daily)
 Weight (at least three times/wk)
 Nutritional intake adequacy (daily)
 Clinical status (daily)
 Nutrition focused physical exam (daily)
 Serum electrolytes, blood urea nitrogen, creatinine, (daily until stable, then two to three times/wk)
 Serum glucose, calcium, magnesium, phosphorus (daily until stable, then weekly)

Data from McClave SA et al: Guidelines for the provision and assessment of nutrition support therapy in the adult critically ill patient, *J Parenter Enteral Nutr* 40:159-211, 2016.

Shelton M: Monitoring and evaluation of enteral feedings. In Charney P, Malone A: *Pocket guide to enteral nutrition*, ed 2, Chicago, 2013, AND, p. 153.

TABLE 12.2 Osmolarity of Nutrients in PN Solutions

Nutrient	Osmolarity (mOsm/mL)	Sample Calculations
Dextrose 5%	0.25	500 mL = 125 mOsm
Dextrose 10%	0.505	500 mL = 252 mOsm
Dextrose 50%	2.52	500 mL = 1260 mOsm
Dextrose 70%	3.53	500 mL = 1765 mOsm
Amino acids 8.5%	0.81	1000 mL = 810 mOsm
Amino acids 10%	0.998	1000 mL = 998 mOsm
Lipids 10%	0.6	500 mL = 300 mOsm
Lipids 20%	0.7	500 mL = 350 mOsm
Electrolytes	Varies by additive	
Multitrace elements	0.36	5 mL = 1.8 mOsm
Multivitamin concentrate	4.11	10 mL = 41 mOsm

Data from RxKinetics: *Calculating Osmolarity of an IV Admixture* (website): http://www.rxkinetics.com/iv_osmolarity.html.

Access

Peripheral Access

PPN solutions should be hypoosmolar, that is, not more than 800 to 900 mOsm/kg to allow infusion through a peripheral, midline, or mid-clavicular intravenous catheter. Clear criteria must be identified to determine when it is appropriate to use PPN, as phlebitis is a common complication (Sugrue et al, 2018). Most often PPN is used as a “bridge” to either return to EN or CPN.

Short-Term Central Access

Catheters used for CPN ideally consist of a single lumen. If central access is needed for other reasons, such as hemodynamic monitoring, drawing blood samples, or giving medications, multiple-lumen catheters are available (Derenski et al, 2016). To reduce the risk of infection, the catheter lumen used to infuse CPN should be reserved for that purpose only. Catheters are inserted most commonly into the subclavian vein and advanced until the catheter tip is in the superior vena cava, using strict aseptic technique. Alternatively, an internal or external jugular vein catheter can be used with the same catheter tip placement. However, the motion of the neck makes this site much more difficult for maintaining the sterility of a dressing. Radiologic verification of the tip site is necessary before infusion of nutrients can begin. Strict infection control protocols should be used for catheter placement and maintenance. Fig. 12.6 shows alternative venous access sites for CPN; femoral placement is also possible.

A **peripherally inserted central catheter (PICC)** may be used for short- or moderate-term infusion in the hospital or in the home. This catheter is inserted into a vein in the antecubital area of the arm and threaded into the subclavian vein with the catheter tip placed in the superior vena cava. Trained nonphysicians can insert a PICC, whereas placement of a tunneled catheter is a surgical procedure. All catheters must have radiologic confirmation of the placement of the catheter tip before initiating any infusion.

Long-Term Central Access

A commonly used long-term catheter is a “tunneled” catheter. This single- or multiple-lumen catheter is placed in the cephalic, subclavian, or internal jugular vein and fed into the superior vena cava (Opilla, 2016). A subcutaneous tunnel is created so that the catheter exits the skin several inches from its venous entry site. This allows the patient to care for the catheter more easily as is necessary for long-term infusion. Another type of long-term catheter is a surgically implanted

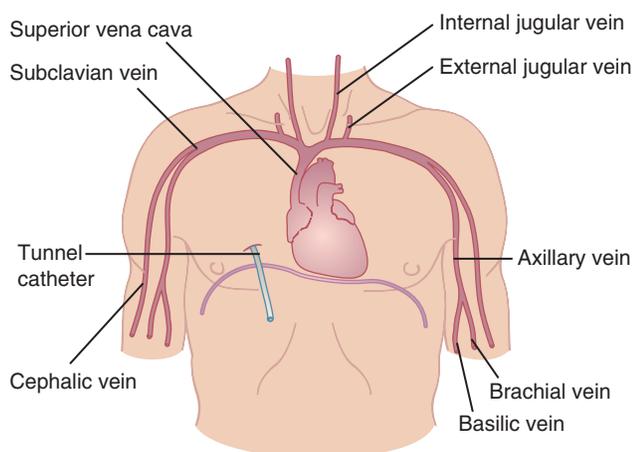

Fig. 12.6 Venous sites from which the superior vena cava may be accessed.

port under the skin where the catheter normally would exit at the end of the subcutaneous tunnel. A special needle must access the entrance port. Ports can be single or double; an individual port is equivalent to a lumen. Both tunneled catheters and PICCs can be used for extended therapy in the hospital or for home infusion therapy. Care of long-term catheters requires specialized handling and extensive patient education.

Parenteral Solutions

Protein

Commercially available standard PN solutions contain all essential amino acids and only some of the nonessential amino acids. Nonessential nitrogen is provided principally by the amino acids alanine and glycine, usually without aspartate, glutamate, cysteine, and taurine. Specialized solutions with adjusted amino acid content that contain taurine are available for infants, for whom taurine is thought to be conditionally essential.

The concentration of amino acids in PN solutions ranges from 3% to 20% by volume. Thus a 10% solution of amino acids supplies 100 g of protein per liter (1000 mL). The percentage of a solution usually is expressed as its final concentration after dilution with other nutrient solutions. The caloric content of amino acid solutions is approximately 4 kcal/g of protein provided. Protein needs are calculated based on the nutrition assessment data related to disease, injury, or clinical/nutrition status and range between 15% and 20% of total energy intake (Mueller et al, 2011).

Carbohydrates

Carbohydrates are supplied as dextrose monohydrate in concentrations ranging from 5% to 70% by volume. The dextrose monohydrate yields 3.4 calories per gram. As with amino acids, a 10% solution yields 100 g of carbohydrates per liter of solution.

Maximum rates of carbohydrate administration should not exceed 5 to 6 mg/kg/min, calculated over a 24-hour infusion period, in critically ill patients. When PN solutions provide 15% to 20% of total calories as protein, 20% to 30% of total calories as lipid, and the balance from carbohydrate (dextrose), infusion of dextrose should not exceed this amount. Excessive administration can lead to hyperglycemia, hepatic abnormalities, or increased ventilatory drive (see Chapter 33).

Lipids

Intravenous lipid emulsions (ILE) provide calories and the essential fatty acids (EFA), linoleic acid (LA) and alpha-linolenic acid (ALA) in PN to avoid EFAD (Derenski et al, 2016; Mundi et al, 2017)

Approximately 2% to 4% of calories from linoleic acid and 0.25% of calories from alpha-linolenic acid are required to prevent EFAD (Derenski et al, 2016; Gramlich et al, 2015). Administration should not exceed 2 g of ILE per kilogram of body weight per day, although recommendations of 1 to 1.5 g/kg are common. Triglyceride levels should be monitored and when triglycerides exceed 400 mg/dL, the ILE should be discontinued. All ILE should be administered through a 1.2-micron filter.

A 10% ILE contains 1.1 kcal/mL, whereas a 20% emulsion contains 2 kcal/mL. Providing 20% to 30% of total calories as lipid emulsion should result in a daily dosage of approximately 1 g of fat per kilogram of body weight. For critically ill patients who receive sedation in an ILE, these calories should be included in the nutrient intake calculations to avoid overfeeding or underfeeding (Drover et al, 2010). Diprivan (propofol) is an example of a sedation/anesthesia agent administered as an injectable infusion in a soybean oil-based ILE providing approximately 1.1 kcal/mL infused. In the hospital, lipid is infused for 24 hours when mixed with the dextrose and amino acids. Alternatively,

lipids can be provided separately by infusion via an infusion pump. For adult patients receiving **home parenteral nutrition (HPN)**, the PN most often is infused during 10 to 12 hours per day with the lipid as part of the PN solution. It may be infused as a daily component of the HPN or a few times per week (Kirby et al, 2017).

Selection of ILE should be based on individual patient requirements and ILE lipid content. The ILE currently available in the United States are composed of aqueous suspensions of soybean oil with egg yolk phospholipid as the emulsifier (Intralipid®, Fresenius Kabi [marketed by Baxter Healthcare in the United States]), and Nutrilipid® B. Braun), or a mixture of soybean, medium chain, olive, and fish oil (Smoflipid, Fresenius Kabi) or fish oil only (Omegaven, Fresenius Kabi). The ILE containing egg phospholipids should not be used when a patient has an egg allergy.

These ILE contain varying levels of omega-6 polyunsaturated fatty acids, omega-3 fatty acids, and monounsaturated fat. Until 2016, 100% soybean oil-based ILE were available in the United States. A multi-oil ILE, Smoflipid (Fresenius Kabi) has been used in Europe for many years with clinical studies in critical care and long-term HPN patients indicating that it is safe and well tolerated (Antébi et al, 2004; Klek et al, 2013) and is now used in the United States. Because of the multiple lipid types in the emulsion, the plasma fatty acid pattern demonstrated a rise in EPA- and DHA-derived lipid mediators and maintenance of an adequate vitamin E status (Puiggròs et al, 2009; Gramlich et al, 2015).

Omegaven (Fresenius Kabi) is a fish oil-based ILE now available in the United States. Proposed benefits of fish oil lipid emulsion, as well as those that contain MCTs, include decreased inflammatory effects and less immunosuppression (Manzanares et al, 2014; Driscoll, 2017).

Careful attention to the caloric load as well as the adequacy of EFA is important when these are used.

For the clinician, the choice of ILE must include risks and benefits of each formulation. As soybean oil is primarily proinflammatory omega-6 fatty acids, this is a consideration when higher amounts are administered to a patient, especially for a long-term HPN patient or critically ill patient. Additionally, when ILE is limited, as with lipid lowering techniques to prevent intestinal failure associated liver

disease, dextrose must be increased to assure adequate calories are provided. This can cause hyperglycemia. Therefore the use of an ILE with decreased levels of soybean oil and increased levels of fish oil can be advantageous (Gramlich et al, 2015; Klek et al, 2013).

Electrolytes, Vitamins, Trace Elements

General guidelines for daily requirements for electrolytes are given in Table 12.3, for vitamins in Table 12.4, and for trace elements in Table 12.5. Parenteral solutions also represent a significant portion of total daily fluid and electrolyte intake. Once a solution is prescribed and initiated, adjustments for proper fluid and electrolyte balance may be necessary, depending on the stability of the patient. The choice of the salt form of electrolytes (e.g., chloride, acetate) affects acid-base balance (Derenski et al, 2016).

Parenterally administered multivitamin and mineral preparations are designed to meet most patient's needs. These levels may be inadequate in some situations when additional individual supplementation is required (Vanek et al, 2012). Patients receiving PN as their sole source of nutrition should receive added multivitamins and trace

TABLE 12.3 Daily Electrolyte Requirements During Total Parenteral Nutrition—Adults

Electrolyte	Standard Intake/Day
Calcium	10-15 mEq
Magnesium	8-20 mEq
Phosphate	20-40 mmol
Sodium	1-2 mEq/kg + replacement
Potassium	1-2 mEq/kg
Acetate	As needed to maintain acid-base balance
Chloride	As needed to maintain acid-base balance

TABLE 12.5 Daily Trace Element Supplementation for Adult Parenteral Formulations

Trace Element	Intake
Chromium	10-15 mcg
Copper	0.3-0.5 mg
Manganese	60-100 mcg
Zinc	2.5-5.0 mg
Selenium	20-60 mcg

elements daily and be monitored closely, especially those who are critically ill. Patients receiving PN short-term or peripherally should also receive daily multivitamins and trace elements. If PN is provided, there is no reason to leave out these important additives. Monitoring of manganese and chromium status is recommended for patients receiving PN for longer than 6 months (Buchman et al, 2009). In most cases, manganese is not needed as a daily infusion as it is provided in adequate amounts as a contaminant in glass vials. Similarly, chromium is usually not needed daily.

In certain cases, additional multivitamins may be required to treat a specific deficiency such as thiamine infusion in patients with refeeding syndrome or a deficiency due to poor intake. Recognizing the importance of providing specific nutrients may obviate the development of a more complex problem.

Iron is not normally part of parenteral infusions because it is not compatible with lipids and may enhance certain bacterial growth. In addition, care must be taken to ensure that a patient can tolerate the separate iron infusion. When patients receive iron on an outpatient basis, the first dose should be done in a controlled setting (such as an outpatient infusion suite) to observe for any reactions that the patient may experience.

One of the challenges in PN in the last 5 years has been the occurrence of drug shortages that have affected micro- and macronutrients, including ILE, multivitamins, multitrace elements, and electrolytes including phosphorous. Patients in the hospital, at home, and in long-term care receiving not only PN but also other intravenous and injectable therapies have been affected. This problem is expected to be ongoing, and therefore clinicians should be aware of alternative products as well as methods to allocate safely products in short supply.

Fluid

Fluid needs for PN or EN are calculated similarly. Maximum volumes of CPN rarely exceed 3 L, with typical prescriptions of 1.5 to 3 L daily. In critically ill patients, volumes of prescribed CPN should be coordinated closely with their overall care plan (Mundi et al, 2017). The administration of other medical therapies requiring fluid administration, such as intravenous medications and blood products, necessitates careful monitoring. Patients with cardiopulmonary, renal, and hepatic failure are especially sensitive to fluid administration. For HPN, higher volumes may be best provided in separate infusions. For example, if additional fluid is required because of high output by the patient, then a liter bag of intravenous fluid containing minimal electrolytes may be infused during a short time during the day if the PN is infused overnight. See Appendix 16 on calculating PN prescriptions.

Compounding Methods

PN prescriptions historically have required preparation or compounding by competent pharmacy personnel under laminar airflow hoods

using aseptic techniques. Hospitals may have their own compounding pharmacy or may purchase PN solutions that have been compounded outside the hospital in a central location and then returned to the hospital for distribution to individual patients. A third method of providing PN solutions is to use multichamber bag technology, whereby solutions are manufactured in a quality-controlled environment using good manufacturing processes. PN solutions of two chamber bags contain amino acids (with or without electrolytes) and dextrose and are available in multiple formulas with varying amounts of dextrose and amino acids, making them suitable for CPN or PPN infusion. Some multichamber bag formulas may contain lipids in a third chamber; however, these are not currently available in the United States but are available in Europe and Canada. They contain conservative amounts of electrolytes or may be electrolyte free. These products have a shelf life of 2 years and do not have to be refrigerated unless the product covering has been opened to reveal the infusion bag. They do not contain vitamins or trace elements that can be added to the solutions; therefore, the clinician must add vitamins/minerals to the patient's treatment plan to avoid any deficiencies. Institutions frequently use standardized solutions, which are compounded in batches, thus saving labor and lowering costs; however, flexibility for individualized compounding should be available when warranted (Ayers et al, 2014).

Prescriptions for PN are compounded in two general ways. One method combines all components except the fat emulsion, which is infused separately. The second method combines the lipid emulsion with the dextrose and amino acid solution and is referred to as a **total nutrient admixture** or **3-in-1** solution. The PN Safe Practices Guidelines provide clinicians with information on many techniques and procedures that enhance safety and prevent mistakes in the preparation of PN (Boullata et al, 2014).

A number of medications, including antibiotics, vasopressors, narcotics, diuretics, and many other commonly administered drugs, can be compounded with PN solutions. In practice this occurs infrequently because it requires specialized knowledge of physical compatibility or incompatibility of the solution contents. The most common drug additives are insulin for persistent hyperglycemia and histamine-2 antagonists to avoid gastroduodenal stress ulceration. One other consideration is that the PN usually is ordered 24 hours before its administration, and patient status may have changed.

Administration

The methods used to administer PN are addressed after the goal infusion rate has been established. For critically ill and hospitalized patients, a 24-hour infusion rate is used. However, for patients transitioning to a long term or lifetime of receiving PN, infusion rate should be decreased to a 10- to 12-hour cycle per day to complete activities of daily living and improve quality of life (Kirby et al, 2017). Nevertheless, general considerations as listed in Box 12.5 can be applied to almost any protocol.

Continuous Infusion

Parenteral solutions usually are initiated below the goal infusion rate via a volumetric pump and then increased incrementally over a 2- or 3-day period to attain the goal infusion rate. Some clinicians start PN based on the amount of dextrose, with initial prescriptions containing 100 to 200 g daily and advancing over a 2- or 3-day period to a final goal. With high dextrose concentrations, abrupt cessation of CPN should be avoided, particularly if the patient's glucose tolerance is abnormal. If CPN is to be stopped, it is prudent to taper the rate of infusion in an unstable patient to prevent **rebound hypoglycemia**, low blood sugar levels resulting from abrupt cessation. For most stable patients this is not necessary.

BOX 12.5 Nutrition Care Process for Enteral and Parenteral Nutrition

Assessment

1. Clinical status, including medications
2. Fluid requirement
3. Route of administration
4. Energy (kcal) requirement
5. Protein requirement
6. Carbohydrate/lipid considerations
7. Micronutrient considerations
8. Formula selection or PN solution considerations
 - A. Concentration (osmolarity)
 - B. Protein content
 - C. Carbohydrate/lipid content
 - D. Micronutrient content
 - E. Special formula considerations
9. Calculations
 - A. Energy: use kcal/mL formula
 - B. Protein: use g/1000 mL
 - C. Fat and micronutrient considerations: units/1000 mL
 - D. Fluid considerations: extra water, IV fluids (including medications)

Nutrition Diagnosis

1. Identify the problems affecting oral nutritional intake.
2. Identify problems related to access or administration of tube feedings.
3. Write PES statements. These may include inadequate or excess infusion of enteral or parenteral nutrition, or other nutrition diagnoses.

Intervention

1. Each problem should have an intervention and a way to evaluate it.
2. Recommend method and how to begin feedings.
3. Recommend how to advance feedings.
4. Determine how fluids will be given in adequate amounts.
5. Calculate final feeding prescription.

Monitoring and Evaluation

1. Describe clinical signs and symptoms to monitor for feeding tolerance.
2. List laboratory values and other measurements to be monitored.
3. Determine how feeding outcomes will be evaluated.

IV, Intravenous; PES, problem, etiology, and signs and symptoms; PN, parenteral nutrition.

Cyclic Infusion

Individuals who require PN at home benefit from a cyclic infusion; this entails infusion of PN for 8- to 12-hour periods, usually at night. This allows the person to have a free period of 12 to 16 hours each day, which may improve quality of life. The goal cycle for infusion time is established incrementally when a higher rate of infusion or a more concentrated solution is required. Cycled infusions should not be attempted if glucose intolerance or fluid tolerance is a problem. The pumps used for home infusion of PN are small and convenient, allowing mobility during daytime infusions. Administration time may be decreased because of patient ambulation and bathing, tests or other treatments, intravenous administration of medications, or other therapies.

Monitoring and Evaluation

As with enteral feeding, routine monitoring of PN is necessary more frequently for the patient receiving PN in the hospital (Mundi et al, 2017). For patients receiving HPN, initial monitoring is done on a weekly basis or less frequently as the patient becomes more stable on PN. Monitoring is done not only to evaluate response to therapy but also to ensure compliance with the treatment plan (Kirby et al, 2017).

COMPLICATIONS

Infection

The primary complication associated with PN is infection (Box 12.6). Therefore strict adherence to protocols and monitoring for signs of infection such as chills, fever, tachycardia, sudden hyperglycemia, or elevated white blood cell count are necessary. Monitoring of metabolic tolerance is also critical. Electrolytes, acid-base balance, glucose tolerance, renal function, and cardiopulmonary and **hemodynamic stability** (maintenance of adequate blood pressure) can be affected by PN and should be monitored carefully. Table 12.6 lists parameters that should be monitored routinely.

The CPN catheter site is a potential source for introduction of microorganisms into a major vein. Protocols to prevent infection vary and should follow Centers for Disease Control and Prevention guidelines (O'Grady et al, 2011). Catheter care and prevention of catheter-related bloodstream infections are of utmost importance in the hospital and alternate settings. These infections not only are costly but also may be life-threatening. Catheter care is dictated by the site of the catheter and the setting in which the patient receives care.

REFEEDING SYNDROME

Patients who require enteral or PN therapies may have been eating poorly before initiating therapy because of the disease process and may be moderately to severely malnourished. Aggressive administration of nutrition, particularly via the intravenous route, can precipitate **refeeding syndrome** with severe, potentially lethal electrolyte fluctuations involving metabolic, hemodynamic, and neuromuscular problems. Refeeding syndrome occurs when energy substrates, particularly carbohydrate, are introduced into the plasma of anabolic patients.

Proliferation of new tissue requires increased amounts of glucose, potassium, phosphorus, magnesium, and other nutrients essential for tissue growth. If intracellular electrolytes are not supplied in sufficient quantity to keep up with tissue growth, low serum levels of potassium, phosphorus, and magnesium develop. Low levels of these electrolytes are the hallmark of refeeding syndrome, especially hypophosphatemia (Skipper, 2012). Carbohydrate metabolism by cells also causes a shift of electrolytes to the intracellular space as glucose moves into cells for oxidation. Rapid infusion of carbohydrate stimulates insulin release, which reduces salt and water excretion and increases the chance of cardiac and pulmonary complications from fluid overload.

Patients starting on PN who have received minimal nutrition for a significant period should be monitored closely for electrolyte fluctuation and fluid overload. A review of baseline laboratory values, including glucose, magnesium, potassium, and phosphorus should be completed and any abnormalities corrected before initiating nutrition support, particularly PN. Conservative amounts of carbohydrate and

BOX 12.6 Parenteral Nutrition Complications**Mechanical Complications**

Air embolism
 Arteriovenous fistula
 Brachial plexus injury
 Catheter fragment embolism
 Catheter misplacement
 Cardiac perforation
 Central vein thrombophlebitis
 Endocarditis
 Hemothorax
 Hydromediastinum
 Hydrothorax
 Pneumothorax or tension pneumothorax
 Subcutaneous emphysema
 Subclavian artery injury
 Subclavian hematoma
 Thoracic duct injury

Infection and Sepsis

Catheter entrance site
 Catheter seeding from bloodborne or distant infection
 Contamination during insertion
 Long-term catheter placement
 Solution contamination

Metabolic Complications

Dehydration from osmotic diuresis
 Electrolyte imbalance
 Essential fatty acid deficiency
 Hyperosmolar, nonketotic, hyperglycemic coma
 Hyperammonemia
 Hypercalcemia
 Hyperchloremic metabolic acidosis
 Hyperlipidemia
 Hyperphosphatemia
 Hypocalcemia
 Hypomagnesemia
 Hypophosphatemia
 Rebound hypoglycemia on sudden cessation of PN in patient with unstable glucose levels
 Uremia
 Trace mineral deficiencies

Gastrointestinal Complications

Cholestasis
 Gastrointestinal villous atrophy
 Hepatic abnormalities

Adapted from McClave SA et al: Guidelines for the provision and assessment of nutrition support therapy in the adult critically ill patient, *J Parenter Enteral Nutr* 33:277, 2009.

adequate amounts of intracellular electrolytes should be provided. The initial PN formulation usually should contain 25% to 50% of goal dextrose concentration and be increased slowly to avoid the consequences of hypophosphatemia, hypokalemia, and hypomagnesemia. PN compatibilities must be assessed when very low levels of dextrose are provided with higher levels of amino acids and electrolytes. The syndrome also occurs in enterally fed patients, but less often because of the effects of the digestive process.

TABLE 12.6 Inpatient Parenteral Nutrition Monitoring (Critical/Acute Care)

Variable to be Monitored	SUGGESTED FREQUENCY	
	Initial Period*	Later Period*
Weight	Daily	Weekly
Serum electrolytes	Daily	1-2/wk
Blood urea nitrogen	3/wk	Weekly
Serum total calcium or ionized Ca ⁺ , inorganic phosphorus, magnesium	3/wk	Weekly
Serum glucose	Daily	3/wk
Serum triglycerides	Weekly	Weekly
Liver function enzymes	3/wk	Weekly
Hemoglobin, hematocrit	Weekly	Weekly
Platelets	Weekly	Weekly
WBC count	As indicated	As indicated
Clinical status	Daily	Daily
Catheter site	Daily	Daily
Temperature	Daily	Daily
I&O	Daily	Daily

*Initial period is that period in which a full glucose intake is being achieved. Later period implies that the patient had achieved a steady metabolic state. In the presence of metabolic instability, the more intensive monitoring outlined under initial period should be followed. I&O, Intake and output; WBC, white blood cell.

I&O refers to all fluids going into the patient: oral, intravenous, medication; and all fluid coming out: urine, surgical drains, exudates. McClave SA et al: Guidelines for the provision and assessment of nutrition support therapy in the adult critically ill patient, *J Parenter Enteral Nutr* 33:277, 2009.

In managing the nutrition care process, refeeding syndrome is an undesirable outcome that requires monitoring and evaluation. Most often, the nutrition diagnosis may be “excessive carbohydrate intake” or “excessive infusion from enteral or parenteral nutrition” in the undernourished patient. Thus in the early phase of refeeding, nutrient prescriptions should be moderate in carbohydrate and supplemented with phosphorus, potassium, and magnesium.

TRANSITIONAL FEEDING

All nutrition support care plans strive to use the GIT when possible, either with EN or by a total or partial return to oral intake. Therefore patient care plans frequently involve **transitional feeding**, moving from one type of feeding to another, with several feeding methods used simultaneously while continuously administering estimated nutrient requirements. This requires careful monitoring of patient tolerance and quantification of intake from parenteral, enteral, and oral routes. Most experts advise that initial oral diets be low in simple carbohydrates and fat, as well as lactose free. These provisions make digestion easier and minimize the possibility of osmotic diarrhea. Attention to individual tolerance and food preferences also helps maximize intake. During the transition stage from HPN to **home enteral nutrition (HEN)** or an oral diet, careful attention should be paid to assuring multivitamin and mineral adequacy. This may require laboratory assessment of micronutrients if a deficiency is suspected.

Parenteral to Enteral Feeding

To begin the transition from PN to EN, introduce a minimal amount of enteral feeding at a low rate of 30 to 40 mL/hr to establish gastrointestinal tolerance. When there is severe gastrointestinal compromise, predigested formula to initiate enteral feedings may be better tolerated. Once formula has been given during a period of hours, the parenteral rate can be decreased to keep the nutrient levels at the same prescribed amount. As the enteral rate is increased by 25 to 30 mL/hr increments every 8 to 24 hours, the parenteral prescription is reduced accordingly. Once the patient is tolerating about 75% of nutrient needs by the enteral route, the PN solution can be discontinued. This process ideally takes 2 to 3 days; however, it may become more complicated depending on the degree of gastrointestinal function. At times the weaning process may not be practical, and PN can be stopped sooner, depending on overall treatment decisions and likelihood for tolerance of enteral feeding.

Parenteral to Oral Feeding

The transition from parenteral to oral feeding ideally is accomplished by monitoring oral intake and concomitantly decreasing the PN to maintain a stable nutrient intake. Approximately 75% of nutrient needs should be met consistently by oral intake before the PN is discontinued. The process is less predictable than the transition to enteral feeding. Variations include the patient's appetite, motivation, and general well-being. It is important to continue monitoring the patient for adequate oral intake once PN has been stopped and to initiate alternate nutrition support if necessary. Generally, patients are transitioned from clear liquids to a diet that is low in fiber and fat and is lactose free. It takes several days for the GIT to regain function; during that time, the diet should be composed of easily digested foods.

Special nutrient needs can be employed, especially when transitioning a patient with gastrointestinal disorders such as short bowel syndrome. Specialized nutrients, optimized drug therapy, and nutrition counseling should be comprehensive to improve outcome. Some PN patients may not be able to discontinue PN fully but may be able to use PN less than 7 days per week, necessitating careful attention to nutrient intake. A skilled RDN can coordinate diet and PN needs for this type of patient.

Enteral to Oral Feeding

A stepwise decrease also is used to transition from EN to oral feeding. It is effective to move from continuous feeding to a 12- and then an 8-hour formula administration cycle during the night; this reestablishes hunger and satiety cues for oral intake during daytime. In practice, oral diets often are attempted after inadvertent or deliberate removal of a nasogastric tube. This type of interrupted transition should be monitored closely for adequate oral intake. Patients receiving EN who desire to eat and for whom it is not contraindicated can be encouraged to do so. A transition from liquids to easy-to-digest foods may be necessary during a period of days. Patients who cannot meet their needs by the oral route can be maintained by a combination of EN and oral intake.

Oral Supplements

The most common types of oral supplements are commercial formulas meant primarily to augment the intake of solid foods. They commonly provide 250 to 360 kcal/8 oz or 240-mL portion and approximately 8 to 14 g of intact protein. Some products have 360 or 500 or as much as 575 kcal in a can. There are different types of products for different disease states, but many of these are brought to market with little to no scientific evidence to support their efficacy.

Fat sources are often LCTs, although some supplements contain MCTs. More concentrated and thus more nutrient-dense formulas are

also available. A variety of flavors, consistencies, and modifications of nutrients are appropriate for various disease states. Some oral supplements provide a nutritionally complete diet if taken in sufficient volume.

The form of carbohydrate is a key factor to patient acceptance and tolerance. Supplements with appreciable amounts of simple carbohydrate taste sweeter and have higher osmolalities, which may contribute to gastrointestinal intolerance. Individual taste preferences vary widely, and normal taste is altered by certain drug therapies, especially chemotherapy. Concentrated formulas or large volumes can contribute to taste fatigue and early satiety. Thus oral nutrient intake and the intake of prescribed supplements should be monitored.

Oral supplements that contain hydrolyzed protein and free amino acids such as those developed for patients with renal, liver, and malabsorptive diseases tend to be mildly to markedly unpalatable, and acceptance by the patient depends on motivation. Formulas for renal and liver disease may lack sufficient vitamins and minerals and are not nutritionally complete and therefore useful only to the specific population.

Although commercially available modular supplements are used most commonly for convenience, modules of protein, carbohydrate, or fat or commonly available food items can produce highly palatable additions to a diet. As examples, liquid or powdered milk, yogurt, tofu, or protein powders can be used to enrich cereals, casseroles, soups, or milk shakes. Thickening agents are now used to add variety, texture, and esthetics to pureed foods, which are used when swallowing ability is limited (see Chapter 39). Imagination and individual tailoring can increase oral intake, avoiding the necessity for more complex forms of nutrition support.

NUTRITION SUPPORT IN LONG-TERM AND HOME CARE

Long-Term Care

Long-term care (LTC) usually refers to a skilled nursing facility but includes subacute care for rehabilitation. Health care provided in this environment focuses on quality of life, self-determination, and management of acute and chronic disease. Indications for EN and PN are generally the same for older patients as for younger adults and vary according to the age, gender, disease state, and most importantly, the care goals of the individual. PN is often provided to these facilities by offsite pharmacies that specialize in LTC. These providers may employ dietitians and specially trained nurses to assist the facilities with education and training.

Oral supplements have gained widespread use in LTC over the last two decades, again for convenience. However, they appear to have detrimental effects, and real food always should be attempted first. A major goal in LTC is the elimination of canned nutrition supplements because they are seen as a detriment to eating real food. (See Chapter 19 for a discussion of the dining standards for LTC).

Advance directives are legal documents that residents use to state their preferences about aspects of care, including those regarding the use of nutrition support. These directives may be written in any setting, including acute or home care but are especially useful in LTC to guide interventions on behalf of LTC residents when they are no longer able to make decisions (Schwartz et al, 2016)

Differentiation between the effects of advanced age and malnutrition is an assessment challenge for dietitians working in LTC (see Chapter 19). This is an area of active research, as is the influence that nutrition support has on the quality of life among LTC residents. Studies generally show that use of nutrition support in older adults is

beneficial only in specific situations and especially when used in conjunction with physical activity. Patients who are actively pursuing physical therapy are good candidates for nutrition support. However, when there is a terminal illness or condition, starting nutrition support may have no advantage and can prolong suffering. Tube feeding has not been shown beneficial in people with dementia who's decreased intake is part of the disease process. Dietitians should be strong patient advocates in end-of-life decisions. RDNs should be involved in writing and implementing the policies in their institutions.

Home Care

Home enteral nutrition (HEN) or home parenteral nutrition (HPN) support usually entails the provision of nutrients or formulas, supplies, equipment, and professional clinical services. Resources and technology for safe and effective management of long-term enteral or parenteral therapy are widely available for the home care setting. Although home nutrition support has been available for more than 30 years, few outcome data have been generated. Because mandatory reporting requirements do not exist in the United States for patients receiving home nutrition support, the exact number of patients receiving this support is unknown.

The elements needed to implement home nutrition successfully include identification of appropriate candidates and a feasible home environment with responsive caregivers, a choice of a suitable nutrition support regimen, training of the patient and family, and a plan for medical and nutritional follow-up by the physician as well as by the home infusion provider (Box 12.7). These objectives are best achieved through the coordinated efforts of an interdisciplinary team (see *Clinical Insight: Home Tube Feeding—Key Considerations*).

Patients receiving HEN may receive supplies only, or formula and supplies with or without clinical oversight by the provider. Many enteral patients receive services from a **durable medical equipment (DME) provider** that may or may not provide clinical services. A home infusion provider provides intravenous therapies, including home PN, intravenous antibiotics, and other therapies. Home nursing agencies may be associated with a DME company or a home infusion agency to provide nursing services to home EN or PN patients. Often the patient's reimbursement source for home therapy plays a major role in determining the type of home infusion provider. In fact, reimbursement is a key component of a patient's ability to receive home therapy of any kind and should be evaluated early in the care plan so that appropriate decisions can be made before discharge or initiating a therapy.

Companies that provide home infusion services for EN or PN can be private or affiliated with acute care facilities. Criteria for selecting a home care company to provide nutrition support should be based on

BOX 12.7 Considerations When Deciding on Home Nutrition Support

- Sanitation of the home environment to preserve the patient's health and reduce risk of infection
- Potential for improvement in quality of life and nutritional status
- The financial and time commitment needed by patient or family; potential loss of income outside the home in some cases
- Ability to understand the techniques for administration of the product and safe use of all equipment and supplies
- Any physical limitations that prevent the implementation of HEN or HPN therapy
- Capacity for patient or caregiver to contact medical services when needed

HEN, Home enteral nutrition; HPN, home parenteral nutrition.

CLINICAL INSIGHT

Home Tube Feeding—Key Considerations

What Is the Best Kind of Tube?

In general, nasal tubes should be avoided because they are more difficult to manage, clog easily, are easily dislodged, and over time can cause tissue irritation and even erosion. Percutaneous endoscopic gastrostomy (PEG) tubes are now the most common and preferred method for home tube feedings. They can be either low profile (flat to the abdomen), button-type tubes, or they can have a short piece of tubing attached through the abdomen and into the stomach. The button tubes require some manual dexterity to access and can be difficult to use for patients who are very obese. Percutaneous endoscopic jejunostomy (PEJ) tubes are best for patients who require post-pyloric feedings as a result of intolerance of gastric feeding, but PEJ feedings require a pump, which severely limits mobility of the patient.

What Is the Best Method of Administration?

Bolus feeding is the easiest administration method and generally should be tried first. It should be started slowly at half of an 8-oz can four to six times a day. If bolus feeding is not tolerated, gravity feeding is a second option. It does require a bag and pole but can be accomplished fairly quickly and requires less manual dexterity than bolus feeding.

Pump feeding is sometimes necessary when a patient requires small amounts of formula delivered slowly. Although it is well tolerated, it has major implications for a patient at home because even the simplest pump is often viewed as "high tech." Its use greatly limits mobility, and, like any piece of equipment, it can break and interrupt feeding schedules.

What Is the Best Way to Educate the Patient and Caregiver?

- Directions should be written in common measurements such as cups, tablespoons, and cans rather than milliliters.
- The enteral nutrition regimen should be as simple as possible; use whole cans of formula rather than partial cans.
- Additives to the feedings should be minimized to avoid confusion and clogging of the feeding tubes.
- Provide clear directions for gradually increasing to the goal feeding rate.
- Provide clear directions for water flushing of the tube and for additional water requirements to prevent dehydration.
- Discuss common problems that may come up and provide guidance for resolving them.
- Make sure that the patient or caregiver can demonstrate understanding of the feeding process by either explaining it or by doing it.

the company's ability to provide ongoing monitoring, patient education, and coordination of care. However, in today's world hospital or patient insurance contracts often dictate the PEN provider. When a patient is receiving home EN or PN, it is important to determine whether the provider has an RDN on staff or access to the services of an RDN. The RDN is uniquely qualified not only to provide oversight and monitoring for the patient while receiving EN or PN but also to provide the appropriate nutrition counseling and food suggestions when the patient transitions between therapies.

Ethical Issues

Whether to provide or withhold nutrition support is often a central issue in end-of-life decision making. For patients who are terminally ill or in a persistent vegetative state, nutrition support can extend life to the point that issues of quality of life and the patient's right to self-determination come into play. Often surrogate decision makers are

involved in treatment decisions. The nutrition support clinician has a responsibility to know whether documentation, such as a living will regarding the patient's wishes for nutrition support, is in the medical record and whether counseling and support resources for legal and ethical aspects of patient care are available to patients and their significant others.

CLINICAL CASE STUDY

A 24-year-old has newly diagnosed type 1 diabetes mellitus and Crohn's disease. She recently had surgery for removal of one third of her ileum. She is 75% of her usual weight, which is 125 lb; she is 65 inches tall. She requires specialized nutrition support for several months until her body adapts to the shortened bowel.

Nutrition Diagnostic Statements

- Involuntary weight loss related to poor intake, surgery, and pain during flare-up of Crohn's disease as evidenced by 25% weight loss.
- Inadequate oral food and beverage intake related to recent ileal resection as evidenced by 75% of usual weight and need for artificial nutrition.

Nutrition Care Questions

1. What immediate nutrition support method would be recommended?
2. What long-term nutrition support plan is likely to be designed?
3. What specialty products, if any, may be beneficial?
4. What parameters would you monitor to determine tolerance and response to the nutrition plan?

Nutrition in the Life Cycle

The importance of nutrition throughout the life cycle cannot be refuted. However, the significance of nutrition during specific times of growth, development, and aging is becoming increasingly appreciated.

Health professionals have recognized for quite some time the effects of proper nutrition during pregnancy on the health of the infant and mother, even after her childbearing years. However, looking at “nutrition in the womb” encompasses not only maternal health history and nutrition but also paternal nutrition and the health of sperm before conception. “Fetal origins” have far more lifelong effects on the new life than originally thought.

Establishing good dietary habits during childhood lessens the possibility of inappropriate eating behavior later in life. Although the influence of proper nutrition on morbidity and mortality usually remains unacknowledged until adulthood, dietary practices aimed at preventing the degenerative diseases that develop later in life should be instituted in childhood.

During early adulthood many changes begin that lead to the development of chronic disease, the so-called diseases of aging, years later. Many of these changes can be accelerated or slowed over the years, depending on the genetic makeup of the individual, quality of the nutritional intake, the health of the gut, and the function of the immune system.

With the rapid growth of the population of older adults has evolved a need to expand the limited nutrition data currently available for these individuals. Although it is known that energy needs decrease with aging, little is known about whether requirements for specific nutrients increase or decrease. Identifying the unique nutritional differences among the various stages of aging is becoming even more important.

Education and Counseling: Behavioral Change

reframing
self-efficacy
self-management
social cognitive theory (SCT)
social-ecological model
stages of change
surface structure
theory of planned behavior (TPB)
transtheoretical model (TTM)

Key factors in changing dietary behaviors are the person's awareness that a change is needed and the motivation to change. Within the nutrition care process, nutrition education and nutrition counseling both provide information and motivation, but they do differ. **Nutrition education** can be individualized or delivered in a group setting; it is usually more preventive than therapeutic, and there is a transmission of knowledge. **Nutrition counseling** is most often used during medical nutrition therapy, one-on-one. In the one-on-one setting, the nutritionist sets up a transient support system to prepare the client to handle social and personal demands more effectively while identifying favorable conditions for change. The goal of both nutrition education and nutrition counseling is to help individuals make meaningful changes in their dietary behaviors.

BEHAVIOR CHANGE

Although there are differences between education and counseling as intervention techniques, the distinctions are not as important as the shared and desired outcome—behavior change. **Behavior change** requires a focus on the broad range of activities and approaches that affect the individual choosing food and beverages in their community and home environment. **Behavior modification** implies the use of techniques to alter a person's response to environmental cues through positive and negative reinforcement, and reduction of maladaptive behaviors. In the context of nutrition,

both education and counseling can assist the individual in achieving short-term or long-term behavioral goals to improve health outcomes.

Factors Affecting the Ability to Change

Multiple factors affect a person's ability or desire to change, the educator's ability to teach new information and skills, and the counselor's ability to stimulate and support progressive changes.

The **Social-Ecological Model** (McLeroy et al, 1988; Fig. 13.1) illustrates the different levels of influence that affect change: personal, interpersonal, institutional, community, and policy levels. This multi-level, comprehensive model is often used to guide health promotion and disease prevention programs. The 2015–2020 Dietary Guidelines for Americans support the use of the Social-Ecological Model for pursuing changes in diet and physical activity behaviors (U.S. Department of Health and Human Services and U.S. Department of Agriculture, 2015).

Financial constraints; perceived lack of time; situational expectations; lack of preparation, knowledge, and skills; low motivation; and inadequate family or social support are some of the personal and interpersonal factors that may be barriers for obtaining and maintaining an adequate diet (Munt et al, 2017). With a population that is culturally diverse, it is imperative to appreciate the differences in understanding, beliefs, and values that may influence the ability to change.

Physical and emotional factors may also make it hard to change, especially for some populations. Older adults need education and counseling programs that address their former positive or negative experiences with food and eating behaviors, their financial and food security situations along with their willingness to use food assistance programs, transportation issues, physical changes that affect food access and intake, and social

Sections of this chapter were written by Linda Snetselaar, PhD, RDN for the previous edition of this text.

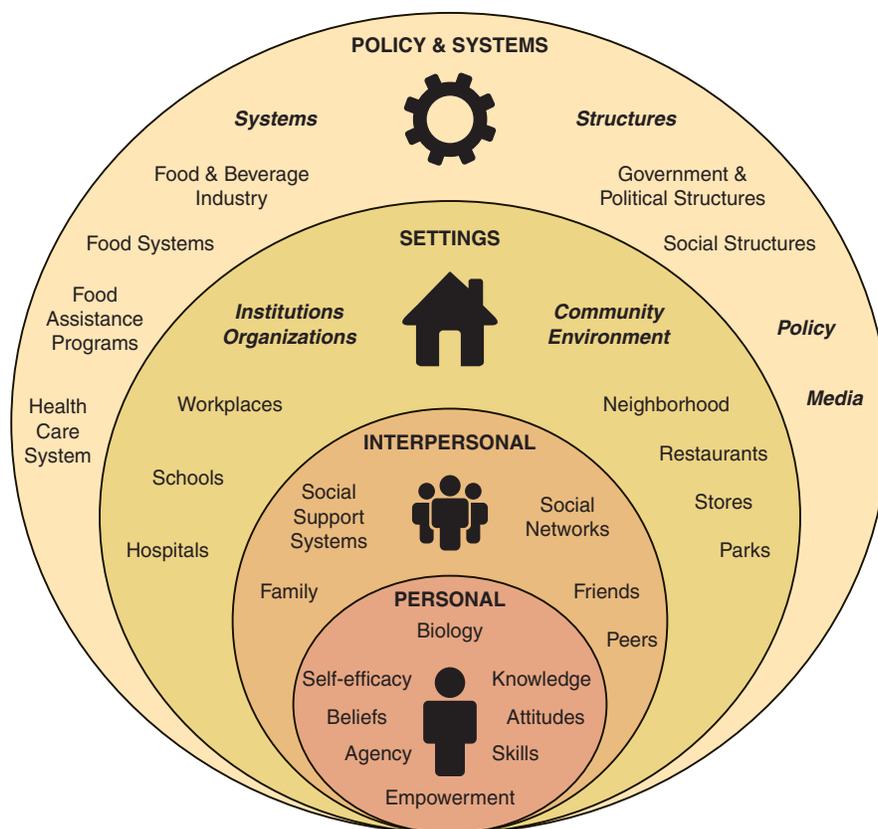

Fig. 13.1 The Social-Ecological Model. Behavior change can be influenced at the personal, interpersonal, institutional, community, and policy levels. (Adapted from: Conducting Effective SNAP-Ed Evaluations: A Step-by-Step Guide. In Contento IR. Nutrition Education: Linking research, theory, and practice [2nd ed.], 2011.)

influences (Oemichen et al, 2016). For families, time restraints, child-parent interplay, sibling dynamics, stressful everyday life, and a low priority for diet within the arena of parental concerns may also hinder changes in food intake (Norman et al, 2015). For children, barriers to sound eating choices include food marketing, taste preferences, food insecurity, and the availability of competing foods of low nutritional quality (Ogle et al, 2017; Nicklas et al, 2013). Across all ages, culture affects not only what foods are eaten and how, but also perceptions about education, counseling, health, and health care.

MODELS FOR BEHAVIOR CHANGE

Changing behavior is the ultimate goal for nutrition counseling and education. Providing a pamphlet or a list of foods can reinforce information, but it usually is not enough to change eating behavior. Behavioral science has provided valuable insight into the many different factors that influence what someone eats and has helped identify several mediators of people's eating behavior on which to intervene. Health professionals, including registered dietitian nutritionists, can support individuals in deciding what and when to change by using a variety of health behavior theories. Some of the theories for behavior change most commonly used are listed in Table 13.1, with examples described in the following paragraphs.

Health Belief Model

The **health belief model (HBM)** focuses on a disease or condition and factors that may influence behavior related to that disease (Rosenstock, 1974; James et al, 2012). These factors include perceived threat and severity

from the disease, as well as cues to action from the environment and perceived benefits, barriers, and self-efficacy related to engaging in preventive or disease management behaviors. The HBM has been used most with behaviors related to diabetes and osteoporosis, focusing on barriers to and benefits of changing behaviors (Babatunde et al, 2011; Plawecki and Chapman-Novakofski, 2013). The clinician may ask what they perceive could be the outcome if they had osteoporosis, as this information may be part of the decisional balance to change an eating behavior.

Social Cognitive Theory

Social cognitive theory (SCT) explains the reciprocal interaction among personal, behavioral, and environmental factors (Bandura, 1977, 1986). This means a person's behavior is modeled by the environment, and conversely, the person has the ability to shape their environment to achieve behavioral goals. Because it is one of the most comprehensive theories, SCT is particularly useful to understand complex behaviors, such as eating. Some of the most relevant SCT concepts to counseling include self-efficacy, self-regulation through goal setting, and relapse prevention by means of positive reinforcement (Matwiejczyk et al, 2018; Vilaro et al, 2016). Behavior modeling is especially important to emphasize when counseling parents with young children (Yee et al, 2017). The nutrition counselor may assess the client's self-efficacy and guide them to set realistic goals and to develop the skills needed to change their eating behavior.

Theory of Planned Behavior

The **theory of planned behavior (TPB)** is an extension of the theory of reasoned action, conceived in the 1960s to describe intentions as

TABLE 13.1 Overview of Behavior Theories Used in Nutrition Education and Counseling

Health Belief Model (HBM)	<p>Perceived susceptibility: Clients beliefs regarding the chance that they may get a condition or disease</p> <p>Perceived severity: An individual's belief of how serious a condition and its consequences are</p> <p>Perceived benefits: An individual's belief in the positive effects of the advised action in reducing the risk or the seriousness of a condition</p> <p>Perceived barriers: An individual's belief about the tangible and psychological costs of the advised action</p> <p>Self-efficacy: Clients believe they are capable of performing the desired action</p> <p>Cues to action: Strategies to activate one's readiness to change a behavior</p>
Social Cognitive Theory (SCT)	<p>Personal factors: Outcome expectations, self-efficacy, reinforcements, impediments, goals and intentions, relapse prevention</p> <p>Behavioral factors: Knowledge and skills, self-regulation and control, and goal setting</p> <p>Environmental factors: Include imposed, selected, and created environments</p>
Theory of Planned Behavior (TPB)	<p>Subjective norms: The people who may influence the patient</p> <p>Attitudes: What the patient thinks about the behavior</p> <p>Perceived control: How much control the patient has to change things that affect the behavior</p> <p>Behavioral intention: Whether the patient plans to perform the behavior</p>
Transtheoretical Model (TTM), or Stages of Change Model	<p>Precontemplation: The individual has not thought about making a change.</p> <p>Contemplation: The individual has thought about making a change but has done no more than think about it.</p> <p>Preparation: The individual has taken some steps to begin to make the desired change.</p> <p>Action: The individual has made the change and continues it for less than 6 months.</p> <p>Maintenance: The individual has continued the behavior for longer than 6 months.</p> <p>Termination: The individual no longer thinks about the change; it has become a habit.</p>

precursors of behavior at a given time and place. The original theory was expanded to account for the ability of people to exert control over their behavior. The theory was intended to explain all behaviors over which people have the ability to exert self-control. (Ajzen, 1991; Fishbein and Ajzen, 2010). Intentions are predicted by attitudes, subjective norms (important others), and perceived control (self-efficacy). This theory is most successful when a discrete behavior is targeted (e.g., vegetable intake), but has also been used for healthy diet consumption (Sheats et al, 2013).

Transtheoretical Model of Change

The **transtheoretical model (TTM)**, or **stages of change** model, has been used for many years to alter addictive behaviors, and is often described as “tailored education.” TTM describes behavior change as a process in which individuals progress through a series of six distinct stages of change, as shown in Fig. 13.2 (Prochaska and Norcross, 2001), whereby they move from experiential to behavioral processes of change. The value of the TTM is in determining the individual's current stage, then using change processes matched to that stage (Mochari-Greenberger et al, 2010).

MODELS FOR COUNSELING STRATEGIES

Cognitive behavioral therapy (CBT) focuses on identifying and changing erroneous perceptions of the self, environment, and behavioral consequences. CBT will often identify behaviors and thoughts that have a negative impact on desired behavioral goals and apply strategies to change those behaviors and thoughts (Beck, 2005). CBT counselors can help clients explore troubling themes, strengthen their coping skills, and focus on their well-being (Dobson and Dobson, 2017).

CBT is often used for obesity interventions, eating disorders, and chronic disease management when depression also exists, such as in heart failure and diabetes. CBT is also used in a range of psychological and psychiatric disorders (Freedland et al, 2015; Tovote et al, 2015).

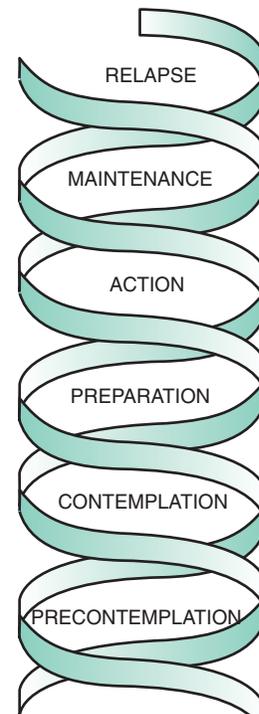

Fig. 13.2 A model of the stages of change. In changing, a person progresses up these steps to maintenance. If relapse occurs, the client gets back on the steps at some point and works up them again.

Acceptance and commitment therapy (ACT) helps to enhance mindfulness by focusing on thoughts and feelings related to valued behavior. Rather than trying to change thoughts or feelings as in CBT, ACT strives to create a new internal network that is flexible, compassionate, accepting, and reflective of one's life values (Hayes et al, 1999). ACT has

been used in counseling for overweight and obesity (Järvelä-Reijonen et al, 2018) and self-management of diabetes (Shayeghian, 2016) as well as for programs addressing chronic pain (Graham et al, 2016).

Motivational interviewing (MI) is a counseling style that allows the client to identify behavioral goals by encouraging a conversation about ambivalence to change (Miller and Rollnick, 2012). It has been used in a variety of conditions to guide clients to identify discrepancies between how they would like to behave and how they are behaving, and ultimately to promote their motivation to change toward improving dietary outcomes (Spahn et al, 2010). The following are key principles of MI (Miller and Rollnick, 2012):

Partnership

In MI, information is transmitted from one expert to another. This implies a paradigm shift from traditional counseling where the client is the recipient of information prescribed by an expert. The nutrition counselor practicing MI assumes the role of a learner by actively listening to the client's language about change and allowing them to openly and safely share the beliefs, values, and expectations that affect their ability to change. Acknowledging the client's autonomy and inherent knowledge of themselves are at the center of the MI interpersonal dynamics.

Acceptance

Practicing MI requires unconditional acceptance of the client's humanity. This is achieved by recognizing the client's inherent worth, by conveying empathy and offering affirmation, and by providing autonomy support. The nutrition counselor demonstrates **empathy** by displaying an understanding of the client's perspective rather than a judgmental attitude, affirms the client's efforts and resources, and supports client's chosen path to change.

Client: I want to lose weight, but with three children, two jobs, and a degree to finish, I just don't have time.

Nutrition Counselor: That is a lot to handle. If this is not the best time, I understand. If and when you want my help, I am ready to listen and help as I can.

Compassion

The nutrition counselor practicing MI deliberately focuses on advancing the client's well-being and best interests concerning their dietary choices. This means prioritizing the client's expressed needs and values over the provision of authoritative guidance.

Client: I need to get a meal out fast for my family or they are out the door.

Nutrition Counselor: It is hard to get that meal out quickly and have it be healthy. Can we look at some quick meals that are also healthy?

Evocation

Practicing MI means inviting new perspectives without imposing them. Perceptions can be shifted, and the client is the most valuable resource in finding solutions to problems. The role of the nutrition counselor is to help with this process by encouraging the evocation of dietary experiences and the resources developed as a result of those. As the client reviews situations in their lives and barriers to dietary changes, the nutrition counselor will hear ambivalence—on the one hand, the client wants to make changes; on the other hand, the client questions the feasibility or importance of changing. Identifying the advantages and disadvantages of modifying a behavior, or developing **discrepancy**, is a crucial process in making changes.

Client: I want to follow the new eating pattern, but I just can't afford it.

Nutrition Counselor: Let's look at your diet record and find some healthy, low-cost options.

When an atmosphere of acceptance is established, this pondering process represents an opportunity to express empathy and affirm internalized motivation to change. For example, clients who are wary of describing why they are not ready to change may become much more open to change if they perceive openness to their resistive behaviors. When it becomes okay to discuss resistance, the rationale for its original existence may seem less relevant.

Client: I just feel that my level of enthusiasm for making these changes is low. It all seems like too much effort.

Nutrition Counselor: I appreciate your concerns. Many people feel frustrated when they try to make dietary changes. Tell me more about your concerns and feelings.

Belief in one's own capability to change, or **self-efficacy**, is an important motivator. The client is responsible for choosing and carrying out personal change. The nutrition counselor can respect the client's autonomy and support self-efficacy by offering to practice behaviors or activities to develop skills while the counselor is available to help.

Client: I just don't know what to buy once I get to the grocery store. I end up with hamburgers and potato chips.

Nutrition Counselor: Let's think of one day's meals right now. Then we can make a grocery list from that.

MODELS FOR EDUCATIONAL PROGRAM DEVELOPMENT

The **PRECEDE-PROCEED model** is a participatory health program planning model that has been used in a variety of health topics and communities to systematically plan and evaluate behavior change programs. PRECEDE consists of four planning phases represented in its acronym for Predisposing, Reinforcing, Enabling, Constructs in Education/Ecological Diagnosis and Evaluation. This reflects the needs assessment and participatory planning of the educational program. PROCEED's acronym stands for Policy, Regulatory, and Organizational Constructs in Educational and Environmental Development and provides a framework for program implementation and evaluation (Green et al, 1980). This model has been applied to develop a number of nutrition education programs (Walsh et al, 2014; Kattelmann et al, 2014).

The Behavior Change Wheel (BCW) is a new method to develop interventions to change eating behavior that consists of three steps—define the behavior and understand its determinants (i.e., ability, opportunity, and motivation); identify intervention options suitable to address behavioral determinants (e.g., education, persuasion, skill-building, modeling); and devise content and implementation strategy (i.e., educational techniques and mode of delivery). It also considers policy categories to leverage for the program implementation (Atkins and Michie, 2015).

SKILLS AND ATTRIBUTES OF THE NUTRITION EDUCATOR OR COUNSELOR

Cultural Competency

The ability to productively engage clients from different cultural backgrounds is a distinctive mark of effective nutrition educators and counselors (Bruening et al, 2015). Culture is the framework through which people perceive and interact with the world. Thus, understanding cultural expressions on eating choices is fundamental to providing meaningful guidance. Cultural identity comprises a combination of

permanent (e.g., age, ethnicity/race, language, sexual orientation), modifiable (e.g., educational status, socioeconomic status, occupation, religion, geographic residence, food choices), and contextual (e.g., historical, social, political forces) factors. Refer to Chapter 10: Planning the Diet with Cultural Competency.

Educating or counseling with **cultural competency** requires acknowledging both surface and deep structure factors affecting eating choices. **Surface structure** refers to attributes that are easily observable, such as food preferences, traditions, and language. Surface structures allow first-hand contact; however, they are often sources of stereotypes and can create communication interference. For instance, language is often the primary surface structure issue that is addressed. Although knowing several languages is an asset, many rely on interpreters. Relying on unofficial interpreters, such as family or friends, is rarely a good choice because of a lack of familiarity with nutrition and health concepts. Using professional interpreters is also not without limitations in that the educator needs to understand not only the client but also the interpreter. The educator should maintain contact with the client and explain the role of the interpreter (**Box 13.1**). Using common terms, avoiding slang and words with multiple meanings, is a practice recommended when working with clients who have limited language skills. Always speak directly to the client, even when using an interpreter, and watch the client for nonverbal responses during the translation. Movements such as gestures, facial expressions, and postures are often the cause of confusion and misinterpretations in intercultural communication. Rules regarding eye contact are usually complex and vary according to attributes such as gender, physical distance, and social status (see *Clinical Insight: Body Language and Communication Skills*).

Deep structure culture includes psychosocial factors that are not readily apparent, such as beliefs, values, attitudes, norms, and stressors affecting eating choices, as well as the personal and interpersonal context of the intervention. Because culture is complex, shape-shifting, and ultimately inseparable from its social and economic context, it is impossible to consider it as an isolated or static phenomenon. Any understanding of a particular cultural context is always incompletely true, always somewhat out of date and partial (*Gregg et al, 2006*). The culturally competent nutrition practitioner facilitates the consideration of individual- or group-specific deep structure factors in all steps of the nutrition care process. The following are principles common to the several proposed models of cultural competency:

Cultural Awareness

Culturally competent nutrition practitioners assess their own surface and deep structure cultural makeup to identify personal and professional assumptions, beliefs, and attitudes that may affect their ability to effectively connect with the client (*Campinha-Bacote, 2002; Jongen et al, 2018; Wright and Lundy, 2014*). Heightening awareness of personal biases and becoming comfortable with cultural differences (see *Clinical Insight: The Counselor Looks Within*) allows the counselor to be more effective in understanding what the client may need to move forward.

BOX 13.1 Federal Regulations for Translation and Interpreting in Medical Settings

As part of the regulations for nondiscrimination administered by the Department of Health and Human Services, additional provisions were added to Section 1557 of the Affordable Care Act in 2016 concerning support for those with limited English proficiency. Reasonable language assistance is required in the form of an interpreter or translator. However, video remote interpreting may be allowed. In addition, acceptance of language assistance from the client is not required.

CLINICAL INSIGHT

The Counselor Looks Within

Before entering a counseling relationship and after reflecting on the session, nutritionists should look inward and consider any factors that affect their own thinking and how they might affect the client. The nutritionist should reflect on ethical issues, such as the autonomy of the client, and **beneficence** (good) versus **maleficence** (harm). An example may be when a client decides not to set goals for blood glucose levels and not to learn the amounts of carbohydrates in foods (autonomy). These choices serve as barriers to the benefit the counselor would make in teaching these **self-management** tools (beneficence) and the need for nonmaleficence (do no harm). Whenever clients decide a behavior change is not right for them, the counselor's role is not to force the issue but to encourage its future consideration.

Client's Perspective

Culturally competent communication considers deep structure issues, such as the role of the individual within a group, and why certain foods are prepared and preferred (*Broyles et al, 2011*). The culturally competent nutrition practitioner explores how clients perceive their own nutritional status, including their understanding of the causes and consequences; previous use of integrative remedies, care, and information sources; the level of cognitive or emotional attachment to integrative treatments; and the expectations around the impending dietary treatment. It is also important to prompt clients to describe how their nutritional issue affects and is affected by their social environment, as potential barriers or facilitators to change.

Informed Negotiation

Developing a culturally relevant intervention plan is a collaborative effort between the client and the practitioner. It requires summarizing deep structure attributes that influence the client's eating choices, communicating the rationale behind proposed evidence-based nutrition prescriptions, and reaching consensus for a meaningful integration of both. **Cognitive dissonance** may arise when the client expresses opinions, worldviews, or values different from the ones held by the nutrition educator or counselor. Acknowledging opposing views, instead of debating them, can help maintain open and productive communication. The client may show hesitation or lack of confidence to adopt certain dietary prescriptions or express a desire for retaining traditional or nonevidence-based practices. Allowing the client to actively participate in setting their own nutritional goals can increase ownership and accountability, convey respect for the client's values, and increase the level of trust.

Empathy and Rapport

Cultural awareness and understanding of the client's perspectives about their nutritional status is necessary for the nutrition practitioner to gain empathy and establish rapport with the client. In turn, this can improve the quality of the communication, setting the conditions for the negotiation of a sound action plan (*Diaz Rios and Chapman-Novakofski, 2018*).

Learning the skills to elicit the client's individual beliefs and interpretations and to negotiate conflicting beliefs is important to proper care, regardless of the social or cultural backgrounds of the client (*Constantinou et al, 2018*). When developing culturally sensitive interventions, the PRECEDE-PROCEED model can provide the framework to guide appreciation for the target audience's surface and deep cultural structures (*Cuy Castellanos et al, 2013; DePue et al, 2010*).

CLINICAL INSIGHT**Body Language and Communication Skills**

Active listening forms the basis for effective nutrition counseling. There are two aspects to effective listening: nonverbal and verbal. Nonverbal listening skills consist of varied eye contact, attentive body language, a respectful but close space, adequate silence, and encouragers. Eye contact is direct yet varied. Lack of eye contact implies that the counselor is too busy to spend time with the client. When the counselor leans forward slightly and has a relaxed posture and avoids fidgeting and gesturing, the client will be more at ease. Silence can give the client time to think and provide time for the counselor to contemplate what the client has said. Shaking one's head in agreement can be a positive encourager, leading to more conversation. Moving forward slightly toward the client is an encourager that allows for more positive interaction.

Asking Questions

Information gathering is an instrumental quality of effective counselors and educators as they consistently ask open-ended questions that prompt fruitful discussions. Data questions can provide valuable information but rarely lead to effective discussion (e.g., “What did you eat?”), and knowledge questions can sometimes elicit a defensive response depending on the context in which they are asked (e.g., “Can you tell me what you know about sodium?”).

Open-ended questions allow the client to express a wider range of ideas, whereas closed questions (e.g., data questions or yes/no questions) can help in targeting concepts and eliminating tangential discussions. For the person who is not ready to change, targeted discussions around difficult topics can help focus the session. The nutritionist asks questions that must be answered by explaining and discussing, not by one-word answers. This is particularly important for someone who is not ready to change because it opens the discussion to discover problem areas that keep the client from being ready. The following statements and questions are examples that create an atmosphere for discussion:

- “We are here to talk about your dietary change experiences to this point. Could you start at the beginning and tell me how it has been for you?”
- “What are some things you would like to discuss about your dietary changes so far? What do you like about them? What don't you like about them?”

Framing the optimal discussion question is not easy and requires the counselor to be self-reflective on which questions were successful. Teaching counseling skills has included simulated patient–counselor scenarios with a standardized patient (Tada et al, 2018); a tool has been developed to evaluate these skills called the Feedback on Counseling Using Simulation (FOCUS) (Henry and Smith, 2010). Verbal and nonverbal communication is important; for the latter, maintaining an appropriate facial expression and using affirmative gestures are important (Collins et al, 2011).

Building Rapport

The ability to build rapport is one of the most useful skills in counseling and education. However, it can also be a challenging skill to develop. A client who appears hostile, unusually quiet, or dismissive may have more success with someone with a similar background or experience. In those cases, working with a peer educator may be most effective. The **peer educator** should ideally share similarities with the target clientele in terms of age or ethnicity, and have primary experience in the nutrition topic (e.g., breastfeeding) (Jain, 2014; Perez-Escamilla et al, 2008). Peer educators are usually

Fig. 13.3 This nutrition counselor is effectively using verbal and nonverbal communication skills, including eye contact and leaning in, to build rapport with a client. From www.istockphoto.com.

community health workers or paraprofessionals. The Expanded Food and Nutrition Education Program (EFNEP) has demonstrated the effectiveness and cost efficiency of peer educators (Baral et al, 2013). In perinatal and Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) clinics, breastfeeding peer counselors are often highly effective in helping new mothers with their questions and concerns (Bartholomew et al, 2017).

Reflective Listening

Nutrition counselors not only listen but also try to tag the feelings that surface as a client is describing difficulties with an eating pattern. Listening is not simply hearing the words spoken by the client and paraphrasing them back. Fig. 13.3 shows a nutrition counselor listening reflectively to a client.

Reflective listening involves a guess at what the person feels and is phrased as a statement, not a question. By stating a feeling, the nutrition counselor communicates understanding. The following are three examples of listening reflectively:

Client: I really do try, but I am retired and my husband always wants to eat out. How can I stay on the right path when that happens?

Nutrition Counselor: You feel frustrated because you want to make dietary changes, but at the same time you want to be spontaneous with your husband. Is this correct? (*reflective listening; TPB, subjective norms; HBM, barriers; SCT, personal factors*)

Client: I feel like I let you down every time I come in to see you. We always discuss plans and I never follow them. I almost hate to come in.

Nutrition Counselor: You are feeling like giving up. You haven't been able to modify your diet, and it is difficult for you to come into our visits when you haven't met the goals we set. Is this how you are feeling? (*reflective listening*) Can you think of a specific time when you feel that you had an opportunity to achieve your plan, but didn't? (*HBM, barriers*)

Client: Some days I just give up. It is on those days that I just eat whatever I want and I can't make good decisions about what to eat.

Nutrition Counselor: You just lose the desire to try to eat well on some days and that is very depressing for you. Do I have that right? (*rephrasing*) Are those days when something in particular has happened?" (*HBM, barriers*)

Affirming

Counselors often understand the idea of supporting a client's efforts to follow a new eating style but do not put those thoughts into words. When

the counselor affirms someone, there is alignment and normalization of the client's issues. In **alignment** the counselor expresses understanding about the difficult times. **Normalization** means telling clients they are within reason and that it is normal to have such reactions and feelings. The following statements indicate affirmation:

- “I know that it is hard for you to tell me this. But thank you.”
- “You have had amazing competing priorities. I feel that you have done extremely well, given your circumstances.”
- “Many people I talk with express the same problems. I can understand why you are having difficulty.”

Summarizing

The nutrition counselor periodically summarizes the content of what the client has said by covering all the key points. Simple and straightforward statements are most effective, even if they involve negative feelings. If conflicting ideas arise, the counselor can use the strategy exemplified by the statement, “On the one hand you want to change, but you still feel attached to the way you have been eating.” This helps the client recognize the ambivalence in thinking that often prevents behavior change.

ASSESSMENT RESULTS: CHOOSING FOCUS AREAS

Health and Nutrition Literacy

Low **health literacy** is common among older adults, minorities, and those who are medically underserved or have a low socioeconomic status (*Health Resources and Services Administration, 2017*). Health literacy is the degree to which an individual has the capacity to obtain, communicate, process, and understand basic health information and services needed to make appropriate health decisions (Patient Protection and Affordable Care Act of 2010, Title V). The problem of low health literacy can lead to poor management of chronic health conditions, as well as low adherence to recommendations. Useful resources available from the Agency on Healthcare Research and Quality (AHRQ) are *Rapid Estimate of Adult Health Literacy in Medicine (REALM)* and *Short Assessment of Health Literacy for Spanish Adults (SAHLSA-50)* (AHRQ, 2016). Additional nutrition-targeted evaluation measures include the Newest Vital Sign which focuses on a nutrition facts label (Rowlands et al, 2013) and the Nutrition Literacy Assessment Instrument, which evaluates several components including understanding of nutrition and health, macronutrients, household food measurement, food labels and numeracy, and food groups (Gibbs and Chapman-Novakofski, 2013). Although there are some areas of overlap when discussing nutrition literacy and food literacy, specific guidelines or definitions are lacking (Velardo, 2015). Often, relying on the client's educational attainment provides some guidance about capacity to understand directions, information, or skills, but asking the clients to repeat explanations in their own words can also help the nutrition educator evaluate the client's level of understanding.

Assessing Readiness to Change

One purpose of assessment is to identify the client's stage of change and to provide appropriate help in facilitating change. The assessment should be completed in the first visit if possible. If the conversation extends beyond the designated time for the session, the assessment steps should be completed at the next session. The nutritional assessment requires gathering the appropriate anthropometric, biochemical, clinical, dietary, and socioeconomic data relating to the client's condition. The nutritional diagnosis then focuses on any problems related to food or nutrient intake.

Determining present eating habits provides ideas on how to change in the future. A reflective review of the client's eating

behavior will identify areas needing change, and help the client create goals that will have the most positive effect on health. For example, if the nutrition diagnoses include excessive fat intake (nutrient intake), inappropriate intake of food fats, excessive energy intake, inadequate potassium intake, food- and nutrition-related knowledge deficit (nutrition behavior), and impaired ability to prepare foods or meals, the counselor may need to focus on the last diagnosis before the others. If all other diagnoses are present except impaired ability to prepare foods or meals, the nutritionist may want to have a discussion about whether excessive fat intake, inappropriate intake of types of food fats, or excessive energy intake are related to knowledge deficit and which of them is more appealing or possible for the client to focus on first.

Once the nutrition diagnosis is selected for intervention, it is important to assess readiness for change. Using a ruler that allows the client to select their level of intention to change is one method of allowing client participation in the discussion. The counselor asks the client, “On a scale of 1 to 10, how ready are you right now to make any new changes to eat less fat? (1 = not ready to change; 10 = very ready to change).” The dietitian nutritionist may use this method with each nutrition diagnosis to help the client decide where to focus first.

Three possibilities for readiness exist: (1) not ready to change; (2) unsure about change; (3) ready to change. These three concepts of readiness have condensed the six distinct stages of change described in this chapter to assist the counselor in determining the level of client readiness. There are many concepts to remember, and readiness to change may fluctuate during the course of the discussion. The counselor must be ready to move back and forth between the phase-specific strategies. If the client seems confused, detached, or resistant during the discussion, the counselor should return and ask about readiness to change. If readiness has lessened, tailoring the intervention is necessary. Not every counseling session has to end with the client's agreement to change; even the decision to think about change can be a useful conclusion.

COUNSELING APPROACHES AFTER THE ASSESSMENT

Not-Ready-To-Change Counseling Sessions

In approaching the “not-ready-to-change” stage of intervention, there are three goals: (1) facilitate the client's ability to consider change, (2) identify and reduce the client's resistance and barriers to change, and (3) identify behavioral steps toward change that are tailored to each client's needs. At this stage, identifying barriers (HBM), the influence of subjective norms and attitudes (TPB), or personal and environmental factors (SCT) that may have negative influences on the intention to change can be helpful. To achieve these goals, several communication skills are important to master: asking open-ended questions, listening reflectively, affirming the patient's statements, summarizing the patient's statements, and eliciting self-motivational statements.

The four communication strategies (asking open-ended questions, listening reflectively, affirming, and summarizing) are important when eliciting self-motivational statements. The goals are for the client to realize that a problem exists, develop concern, and acknowledge the positive steps in the future that can be taken to correct the problem. These realizations set the stage for later efforts at dietary change. Examples of questions to use in eliciting self-motivational feeling statements follow.

Problem Recognition

- “What things make you think that eating out is a problem?”
- “In what ways has following this eating pattern been a problem?”

Concern

- “How do you feel when you can’t follow your dietary recommendations?”
- “In what ways does not being able to follow your dietary recommendations concern you?”
- “What do you think will happen if you don’t make a change?”

Intention to Change

- “The fact that you’re here indicates that at least a part of you thinks it’s time to do something. What are the reasons you see for making a change?”
- “If you were 100% successful and things worked out exactly as you would like, what would be different?”
- “What things make you think that you should keep on eating the way you have been?” And in the opposite direction, “What makes you think it is time for a change?”

Optimism

- “What encourages you that you can change if you want to?”
- “What do you think would work for you if you decided to change?”

Clients in this “not-ready-to-change” category have already told the counselor they are not doing well at making changes. Usually if a tentative approach is used that asks permission to discuss the problem, the client will not refuse. One asks permission by saying, “Would you be willing to continue our discussion and talk about the possibility of change?” At this point, it is helpful to discuss thoughts and feelings about the current status of dietary change by asking open-ended questions:

- “Tell me why you picked _____ on the ruler.” (Refer to previous discussion on the use of a ruler.)
- “What would have to happen for you to move from a _____ to a _____ (referring to a number on the ruler)? How could I help get you there?”
- “If you did start to think about changing, what would be your main concern?”

To show real understanding about what clients are saying, it is beneficial to summarize the statements about their progress, difficulties, possible reasons for change, and what needs to be different to move forward. This paraphrasing allows clients to rethink their reasoning about readiness to change. The mental processing provides new ideas that can promote actual change.

Ending the Session

Counselors often expect the client to be ready to decide to make changes and set goals. However, it is important in this stage to realize that traditional goal setting will result in feelings of failure on both the part of the client and the nutritionist. If the client is not ready to change, respectful acknowledgment of this decision is important. The counselor might say, “I can understand why making a change right now would be very hard for you. The fact that you are able to indicate this as a problem is very important, and I respect your decision. Our lives do change, and, if you feel differently later on, I will always be available to talk with you. I know that, when the time is right for you to make a change, you will find a way to do it.” When the session ends, the counselor will let clients know that the issues will be revisited after they have had time to think. Expression of hope and confidence in the client’s ability to make changes in the future, when the time is right, will be beneficial. Arrangements for follow-up contact can be made at this time.

With a client who is not ready to change it is easy to become defensive and authoritarian. At this point, it is important to avoid pushing, persuading, confronting, coaxing, or telling the client what to do. It is

reassuring to a nutritionist to know that change at this level will often occur outside the office. The client is not expected to be ready to do something during the visit.

Unsure-About-Change Counseling Sessions

The only goal in the “unsure-about-change” session is to build readiness to change. This is the point at which changes in eating behavior can escalate. This “unsure” stage is a transition from not being ready to deal with a problem eating behavior to preparing to continue the change. It involves summarizing the client’s perceptions of the barriers to a healthy eating style and how they can be eliminated or circumvented to achieve change. Heightened self-efficacy may provide confidence that goals can be achieved. A restatement of the client’s self-motivational statements assists in setting the stage for success. The client’s ambivalence is discussed, listing the positive and negative aspects of change. The nutritionist can restate any statements that the client has made about intentions or plans to change or to do better in the future.

One crucial aspect of this stage is the process of discussing thoughts and feelings about current status. Use of open-ended questions encourages the client to discuss dietary change progress and difficulties. Change is promoted through discussions focused on possible reasons for change. The counselor might ask the question: “What would need to be different to move forward?”

This stage is characterized by feelings of ambivalence. The counselor encourages the client to explore ambivalence to change by thinking about “pros” and “cons.” Some questions to ask are:

- “What are some of the things you like about your current eating habits?”
- “What are some of the good things about making a new or additional change?”
- “What are some of the things that are not so good about making a new or additional change?”

By trying to look into the future, the nutrition counselor can help a client see new and often positive scenarios. As a change facilitator, the counselor helps to tip the balance away from being ambivalent about change toward considering change by guiding the client to talk about what life might be like after a change, anticipating the difficulties as well as the advantages. An example of an opening to generate discussion with the client might be: “I can see why you’re unsure about making new or additional changes in your eating habits. Imagine that you decided to change. What would that be like? What would you want to do?” The counselor then summarizes the client’s statements about the “pros” and “cons” of making a change and includes any statements about wanting, intending, or planning to change.

The next step is to negotiate a change. There are three parts to the **negotiation** process. The first is setting goals. Set broad goals at first and hold more specific nutritional goals until later. “How would you like things to be different from the way they are?” and “What is it that you would like to change?”

The second step in negotiation is to consider options. The counselor asks about alternative strategies and options and then asks the client to choose from among them. This is effective because, if the first strategy does not work, the client has other choices. The third step is to arrive at a plan, one that has been devised by the client. The counselor touches on the key points and the problems and then asks the client to write down the plan.

To end the session the counselor asks about the next step, allowing the client to describe what might occur next in the process of change. The following questions provide some ideas that might promote discussion:

- “Where do you think you will go from here?”
- “What do you plan to do between now and the next visit?”

Resistance Behaviors and Strategies to Modify Them

Resistance to change is the most consistent emotion or state when dealing with clients who have difficulty with dietary change. Examples of resistance behaviors on the part of the client include contesting the accuracy, expertise, or integrity of the nutrition counselor; or directly challenging the accuracy of the information provided (e.g., the accuracy of the nutrition content). The nutrition counselor may even be confronted with a hostile client. Resistance may also surface as interrupting, when the client breaks in during a conversation in a defensive manner. In this case the client may speak while the nutrition counselor is still talking without waiting for an appropriate pause or silence. In another, more obvious manner, the client may break in with words intended to cut off the nutrition counselor's discussion.

When clients express an unwillingness to recognize problems, cooperate, accept responsibility, or take advice, they may be denying a problem. Some clients blame other people for their problems (e.g., spouses or partners may blame each other for their inability to make dietary changes). Other clients may disagree with the nutrition counselor when a suggestion is offered, but they frequently provide no constructive alternative. The familiar "Yes, but . . ." explains what is wrong with the suggestion but offers no alternative solution.

Clients try to excuse their behavior. A client may say, "I want to do better, but my life is in a turmoil since my husband died 3 years ago." An excuse that was once acceptable is reused even when it is no longer a factor in the client's life.

Some clients make pessimistic statements about themselves or others. This is done to dismiss an inability to follow an eating pattern by excusing poor compliance as just a given resulting from past behaviors. Examples are "My partner will never help me" or "I have never been good at sticking with a goal. I'm sure I won't do well with it now."

In some cases, clients are reluctant to accept options that may have worked for others in the past. They express reservations about information or advice given. "I just don't think that will work for me." Some clients will express a lack of willingness to change or an intention not to change. They make it very clear that they want to stop the dietary regimen.

Often clients show evidence that they are not following the nutrition counselor's advice. Clues that this is happening include using a response that does not answer the question, providing no response to a question, or changing the direction of the conversation.

These types of behaviors can occur within a counseling session as clients move from one stage to another. They are not necessarily stage-specific, although most are connected with either the "not ready" or "unsure-about-change" stages. A variety of strategies are available to assist the nutrition counselor in dealing with these difficult counseling situations. These strategies include reflecting, double-sided reflection, shifting focus, agreeing with a twist, emphasizing personal choice, and reframing. Each of these options is described in the following paragraphs.

Reflecting. In reflecting, the counselor identifies the client's emotion or feeling and reflects it back. This allows the client to stop and reflect on what was said. An example of this type of counseling is, "You seem to be very frustrated by what your wife says about your food choices."

Double-Sided Reflection. In **double-sided reflection**, the counselor uses ideas that the client has expressed previously to show the discrepancy between the client's current words and the previous ones. For example:

Client: I am doing the best I can. (Previously this client stated that she sometimes just gives up and doesn't care about making dietary modifications.)

Nutrition Counselor: On the one hand you say you are doing your best, but on the other hand I recall that you said you just felt like giving up and didn't care about making dietary changes. Do you remember that? How was that point in time different than now?

Shifting Focus. Clients may hold onto an idea that they think is getting in the way of their progress. The counselor might question the feasibility of continuing to focus on this barrier to change when other barriers may be more appropriate targets. For example:

Client: I will never be able reduce my saturated fat intake as long as my grandchildren come to my house and want snacks.

Nutrition Counselor: Are you sure that this is really the problem? Is part of the problem that you like those same snacks?

Client: Oh, you are right. I love them.

Nutrition Counselor: Could you compromise? Could you ask your grandchildren which of this long list of low saturated fat snacks they like and then buy them?

Agreeing with a Twist. This strategy involves offering agreement, then moving the discussion in a different direction. The counselor agrees with a piece of what the client says but then offers another perspective on the problem. This allows the opportunity to agree with the statement and the feeling, but then to redirect the conversation onto a key topic. For example:

Client: I really like eating out, but I always eat too much, and my blood sugars go sky high.

Nutrition Counselor: Most people do like eating out. Now that you are retired it is easier to eat out than to cook. I can understand that. What can we do to make you feel great about eating out so that you can still follow your eating plan and keep your blood glucose values in the normal range?

Reframing. With **reframing** the counselor changes the client's interpretation of the basic data by offering a new perspective. The counselor repeats the basic observation that the client has provided and then offers a new hypothesis for interpreting the data. For example:

Client: I gave up trying to meet my dietary goals because I was having some difficulties when my partner died, and I have decided now that I just cannot meet those strict goals.

Nutrition Counselor: I remember how devastated you were when he died and how just cooking meals was an effort. Do you think that this happened as a kind of immediate response to his death and that you might have just decided that all of the goals were too strict at that time? (*Pause*)

Client: Well, you are probably right.

Nutrition Counselor: Could we look at where you are now and try to find things that will work for you now to help you in following the goals we have set?

These strategies help by offering tools to ensure that nutrition counseling is not ended without appropriate attempts to turn difficult counseling situations in a more positive direction.

Ending the Session. Counselors should emphasize that any future action belongs to the client, that the advice can be taken or disregarded. This emphasis on personal choice (autonomy) helps clients avoid feeling trapped or confined by the discussion. A sense of self-efficacy reflects the belief about being capable of influencing events and choices in life. These beliefs determine how individuals think, feel, and behave. If people doubt their capabilities, they will have weak commitments to their goals. Success breeds success, and failure breeds a sense of failure. Having resilience, positive role models, and effective coaching can make a significant difference.

Ready-To-Change Counseling Sessions

Setting goals. The major goal in the “ready-to-change” session is to collaborate with the client to set goals that include a plan of action. The nutrition counselor provides the client with the tools to use in meeting nutrition goals. This is the stage of change that is most often assumed when a counseling session begins. To erroneously assume this stage means that inappropriate counseling strategies set the stage for failure. Misaligned assumptions often result in lack of adherence on the part of the client and discouragement on the part of the nutritionist. Therefore it is important to discuss the clients thoughts and feelings about where they stand relative to the current change status. Use of open-ended questions helps the client confirm and justify the decision to make a change and in which area. The following questions may elicit information about feelings toward change:

- “Tell me why you picked _____ on the ruler.”
- “Why did you pick (nutrition diagnosis 1) instead of (other nutrition diagnoses)?”

In this stage, goal setting is extremely important. Here the counselor helps the client set a realistic and achievable short-term goal: “Let’s do things gradually. What is a reasonable first step? What might be your first goal?”

Action Plan. Following goal setting, an action plan is set to assist the client in mapping out the specifics of goal achievement. Identifying a network to support dietary change is important. What can others do to help?

Early identification of barriers to adherence is also important. If barriers are identified, plans can be formed to help eliminate these roadblocks to adherence.

Many clients fail to notice when their plan is working. Clients can be asked to summarize their plans and identify markers of success. The counselor then documents the plan for discussion at future sessions and ensures that the clients also have their plans in writing. The session should be closed with an encouraging statement and reflection about how the client identified this plan personally. Clients are experts about what influences their behavior. Compliment the client on carrying out the plan. Ways to express these ideas to clients are:

- “You are working very hard at this, and it’s clear that you’re the expert about what is best for you. You can do this!”
- “Keep in mind that change is gradual and takes time. If this plan doesn’t work, there will be other plans to try.”

The key point for this stage is to avoid telling the client what to do. Clinicians often want to provide advice. However, it is critical that the client express ideas of what will work best: “There are a number of things you could do, but what do you think will work best for you?” The next contact may be in person, online, or by phone.

Following up with clients by phone or a telemedicine portal have become popular counseling methods for many nutritionists. The dietitian nutritionist utilizing telemedicine services in their practice is required to follow certain regulations. The Academy of Nutrition and Dietetics (AND) has developed practice tips for the utilization of these services (AND, 2018). When behavior and counseling theories are combined with phone counseling, the results have been effective in managing weight, type 2 diabetes, and metabolic syndrome (Muñoz Obino et al, 2017). Telephone counseling in itself has been reported to be effective in achieving weight reduction (Schmittiel et al, 2017), and online programs and telehealth interventions have also been successful (Muñoz Obino et al, 2017; Kelly et al, 2016).

NEW DIRECTIONS

Counseling and Educating Online

More counselors and educators are turning to online connections with their clients and target audiences. Although the basics of counseling and education remain the same, there are additional issues to consider. If clients are recording food intake and physical activity through mobile technology or telemedicine, it is important to consider how often to monitor and provide feedback. While many best practices in nutrition education include the use of mobile technology, consideration should be given to whether a company will develop the website or app, and will the sites be maintained in a constantly changing technological world.

Telenutrition is defined by the Academy of Nutrition and Dietetics as “the interactive use, by a RDN [registered dietitian nutritionist], of electronic information and telecommunications technologies to implement the Nutrition Care Process . . .” (AND, 2018). A systematic review of apps for lifestyle improvements concluded that in eight of nine included studies, apps were effective for improving lifestyles (Lunde et al, 2018). Barriers to successful app use include the cost of apps, data entry burden, and loss of interest and discontinued use of apps (Sun et al, 2017). Clinicians should be aware of privacy and security aspects of telenutrition. Personal data should be encrypted, and all patient privacy policies upheld (Boulos et al, 2014). While the Food and Drug Administration (FDA) does regulate apps that are intended for use as an accessory to a regulated medical device (Glucometers), it does not regulate apps that function as an electronic or personal health record system (U.S. Department of Health and Human Services [USDHHS] and FDA, 2018).

EVALUATION OF EFFECTIVENESS

Counseling

Clinicians and educators need to evaluate their services. Just completing the process does not mean that outcomes will match the goals. When the AND Evidence Analysis Library Nutrition Counseling Workgroup conducted a review of literature related to behavior change theories and strategies used in nutrition counseling, they found the following (Spahn et al, 2010):

1. Strong evidence supports the use of CBT in facilitating modification of targeted dietary habits, weight, and cardiovascular and diabetes risk factors.
2. MI is a highly effective counseling strategy, particularly when combined with CBT.
3. Few studies have assessed the application of the TTM or SCT on nutrition-related behavior change.
4. Self-monitoring, meal replacements, and structured meal plans are effective; financial reward strategies are not.
5. Goal setting, problem solving, and social support are effective strategies.
6. Research is needed in more diverse populations to determine the most effective counseling techniques and strategies.

A systematic review of nutrition therapy by a registered dietitian nutritionist compared with dietary advice by others concluded that individualized nutrition therapy by a registered dietitian nutritionist led to greater effects on clinical outcomes such as hemoglobin A1C, body weight, and blood lipids (Møller et al, 2017). On the other hand, a systematic review comparing either dietary counseling or high energy supplements’ effects on dietary intake found dietary counseling alone less effective. Many other topics and populations can be found in the literature. Looking for systematic reviews and meta-analyses will help to stay current on what is working best.

Educational Programs

LOGIC Models are often used to evaluate a program's effectiveness. The simplest version includes inputs (resources or investments into a program), outputs (activities, services, and events) and outcomes (behavior change of individuals, groups, or communities), although some include multiple levels within these three broad categories (McLaughlin and Jordan, 1999). LOGIC Models have guided evaluation of national nutrition programs (Levine et al, 2012) as well as educational programs at the individual level, such as a video program to improve dietary habits of children (Beasley et al, 2012).

The three evaluation phases in the PRECEDE-PROCEED model are commonly applied to determine (1) program feasibility and whether it was implemented as intended (i.e., process evaluation); (2) program effectiveness at eliciting desired change in target behaviors (i.e., outcome evaluation); and (3) program contribution to changes in ecological and structural determinants of behavior (i.e., impact evaluation).

SUMMARY

Effective nutrition education and counseling requires skill development and practice. It is important to have an understanding of the individual and cultural needs of the client and knowledge of the variety of behavior change theories that can help clarify the client's behavior change process. Monitoring and evaluation of outcomes will ensure effectiveness of the interventions offered.

CLINICAL CASE STUDY

Mrs. Lee is originally from mainland China, and primarily speaks and reads in Mandarin Chinese. She has been living in Chicago for several years with her husband and daughter, and has numerous health problems, including high blood pressure, diabetes, and glaucoma. You have been asked to counsel her about making changes in her diet. Using an interpreter, you discover she is also having difficulty buying and preparing food and depends on her daughter for help. Because her vision is poor, she will not be able to use printed materials that you have in your office that have been translated into Chinese.

Nutrition Diagnostic Statement

- Impaired ability to prepare food and meals (NB-2.4) related to inability to see as evidenced by client report and history of glaucoma.

Nutrition Care Questions

1. What steps should you take to make her comfortable with this session?
2. Should you invite family members to attend the counseling session? Why or why not?
3. What tools might be useful to help Mrs. Lee understand portions or types of food that she should select?
4. Would a supermarket tour be useful? Why or why not?
5. What other types of information will be needed to help Mrs. Lee?

 developmental origins of health
 and disease (DOHaD)
 fetal alcohol syndrome (FAS)
 fetal origins of disease
 foremilk
 galactagogue
 geophagia
 gestational diabetes mellitus (GDM)
 gestational hypertension

gravida
 HELLP syndrome
 hindmilk
 hyperemesis gravidarum (HG)
 intrauterine fetal demise (IUFD)
 intrauterine growth restriction (IUGR)
 lactogenesis I
 lactogenesis II
 large for gestational age (LGA)
 let-down
 low birth weight (LBW)
 macrosomia
 mature milk
 Montgomery glands
 mother-led weaning

nausea and vomiting in pregnancy (NVP)
 neural tube defects (NTDs)
 oxytocin
 pagophagia
 perinatal mortality
 pica
 postpartum depression (PPD)
 preeclampsia
 prolactin
 ptyalism gravidarum
 small for gestational age (SGA)
 teratogen
 transitional milk

Optimal nutrition during pregnancy actually begins preconceptually. The placenta and developing fetus must receive all the necessary nutrients for growth and development from the mother. The old cliché that the “fetus is the perfect parasite” implies fetuses take all they require at the expense of the host. However, at some point nutritional deficiency can result in a preterm delivery. After birth, quality nutrition during lactation continues providing the nutritional building blocks for normal cerebral development and growth of all body organs in the neonate.

This time period—growing a new human being—sets the stage for the health of future generations. The quality and quantity of nourishment to the developing zygote, then fetus, then neonate, then adult emerge as one explanation for diseases that manifest in adulthood. This concept is known as **fetal origins of disease** or **developmental origins of health and disease (DOHaD)** (Guéant et al, 2013).

PRECONCEPTION AND FERTILITY

The focus on preconceptual nutrition and health is important for both women and men. Infertility affects 10% to 12% of U.S. couples of reproductive age, and extremes in body mass index (BMI) in either partner may be one cause. Women with a BMI less than 20 have an increased risk of anovulation. Men and women have increased rates of subfertility when overweight or obese, and fat distribution patterns may be important. Obesity appears to negatively affect the sperm (both concentration and motility), oocyte (development, quality, and ovulation), embryo, and the endometrium, including uterine receptivity (Catalano and Shankar, 2017). Elevated BMI negatively affects the fertility of both men and women in a dose-dependent manner. The

potential mechanisms that obesity negatively affects fertility are many and likely include direct effects and comorbidities, but also endocrine, genetic, epigenetic, hormonal, and inflammation factors (Craig et al, 2017; Broughton and Moley, 2017). Elevated serum cholesterol levels in both partners are associated with an increased time to pregnancy (Schisterman et al, 2014). Preconceptual control of diabetes of both parents improves birth outcomes (Kotelchuck and Lu, 2017). Weight loss (by reducing calories from fat and carbohydrates) and increased physical activity may be helpful, but the evidence is stronger for women than for men. However, the benefit of preconception weight loss is not yet established with clinical trials (Stephenson et al, 2018) and treatment results don't always match expectations. Although 5% weight loss often is cited to improve fertility, there is not a clear dose-response relationship, and the degree of weight loss is not a good surrogate for perinatal benefit (Legro, 2017). Conception during active weight loss can be harmful. Refer to the Postbariatric Surgery section later in this chapter. The use of weight loss drugs is not recommended. While weight loss should theoretically be the first line of therapy, eliminating tobacco and alcohol, increasing physical activity, and stress management may be more productive for improved conception (Luke, 2017).

As yet, there is no documented ideal diet for increased fertility but it may include components of heart healthy (Chavarro and Schaff, 2018) and Mediterranean diet patterns (Broughton and Moley, 2017), as well as the New Nordic diet pattern. Specific dietary changes have been shown to decrease ovulatory disorders and improve fertility and embryonic growth trajectory (Berti et al, 2017). Zinc deficiency negatively affects oocyte development in animal models (Hester et al, 2017). Iodine deficiency has been associated

with decreased fertility in women (Pearce, 2018). Vitamin D deficiency in men and women can be associated with infertility (Pludowski et al, 2013). For women, vitamin D deficiency may be associated with insulin resistance and metabolic syndrome in polycystic ovary syndrome (PCOS), as well as follicular development. For men, vitamin D deficiency is associated with lower testosterone levels and lower sperm quality. However, in both cases, neither causality nor ability to treat has yet been demonstrated and there is little evidence that supplementation is beneficial without evidence of deficiency (Chavarro and Schlaff, 2018). Calcium has been shown to be important in males for spermatogenesis, sperm motility, hyperactivation, and acrosome (area of the sperm that contains digestive enzymes to break down the outer layers of the ovum) reactions. Healthier sperm counts are associated with optimal dietary zinc, folic acid, and antioxidants, as well as avoidance of tobacco and alcohol (Gaur et al, 2010). Recommendations for improved male fertility include eating a diet higher in fiber, with a lower glycemic index (including high-fat dairy products and monounsaturated fats but reducing trans fats) and lower in animal protein. They may also see improvements by consuming a multivitamin daily, being moderately physically active, and obtaining iron from plant sources. However, there is also very preliminary evidence of decreased sperm quality among those consuming a self-described vegan diet (Orzylowska et al, 2016). Whether the effect can be attributed to low caloric intake, low intake of vitamin B₁₂ or zinc, an increased intake of isoflavones with high soy intake, an increased intake of pesticides, or other unidentified factors is not yet known and intervention trials have not been done. Oxidative stress is associated with impaired spermatogenesis. However, the evidence for taking supplemental antioxidants appears weak and inconsistent. The optimal types and dosages of the specific antioxidants are not yet known, and individuals also may exhibit variable responses (Mora-Esteves and Shin, 2013). On the other hand, supplementation is not likely to be harmful, assuming it is at levels of the recommended dietary allowance (RDA) or less. Whether supplements are as effective as a diet rich in antioxidants is unknown. Although studies exist to the contrary, the American Society for Reproductive Medicine states there is little evidence that herbal supplements improve fertility or affect infant gender (Practice Committee, 2017).

Preconception guidance is based on findings that many women enter pregnancy with suboptimal nutritional status, including obesity, and with low intakes of fiber, long-chain polyunsaturated fatty acids (LCPUFA), protein, zinc, iron, phosphorus, potassium, calcium, magnesium, vitamins A and D, folate, riboflavin, and choline (Monk et al, 2013; Rai et al, 2015). Even overweight and obese women can have low nutrient intakes and, in some studies, have been seen to be more nutritionally vulnerable than other pregnant women (Dubois et al, 2018). Although current public health recommendations primarily promote folic acid supplementation, many other nutrients are also important in the periconceptual period. Micronutrient supplementation can improve maternal status but may not improve child health outcomes if started after conception (Stephenson et al, 2018). How much before conception this supplementation is needed is unknown and likely varies by maternal nutrient status. Optimal nutrient intakes are associated with lower risk of growth-restricted babies (**low birth weight [LBW]** or **small for gestational age [SGA]**) or preterm births (Table 14.1). Thus a preconceptional multivitamin-multimineral supplement may confer more benefit than single supplements for a pregnant woman, or **gravid**, especially in the context of low background food intake.

Preconception educational programs for both parents are promoted, but evidence of effectiveness and benefit is inconsistent.

TABLE 14.1 Examples of Nutrients Likely Important in the Periconceptual Period: Preconception Through Organogenesis

System or Function	Nutrients
Brain and nervous system	Iron, zinc, iodine, LCPUFA, vitamins A, B ₆ , B ₁₂ , folic acid, copper, protein, selenium
Placental function and structure	Iron, LCPUFA, vitamins E, C, B ₁₂ , zinc, selenium, copper, omega-3 PUFA, folate
Inflammation and immune function	Vitamins A, D, zinc, fatty acids
Oxidative stress	Vitamins C, E, B ₆ , B ₁₂ , folic acid
Embryogenesis	Vitamins A, B ₆ , B ₁₂ , folic acid, zinc

Adapted from Cetin I et al: Role of micronutrients in the periconceptual period, *Hum Reprod Update* 16:80, 2010; Monk C et al: Research review: maternal prenatal distress and poor nutrition—mutually influencing risk factors affecting infant neurocognitive development, *J Child Psychol Psychiatry* 54:115, 2013; Ramakrishnan U et al: Effect of women's nutrition before and during early pregnancy on maternal and infant outcomes: a systematic review, *Paediatr Perinat Epidemiol* 26:285, 2012. LCPUFA, Long-chain polyunsaturated fatty acids; PUFA, polyunsaturated fatty acids.

There is also little evidence for which interventions are most effective (Goldstein et al, 2016). However, it appears that nutrition interventions may be more effective in promoting change than those targeting smoking and alcohol cessation (Temel et al, 2014). In addition, these programs are targeted at those planning pregnancies, not the general public, and likely won't resonate with many. Even if these programs could address the parents of the estimated 50% of pregnancies that are unplanned, the issues that can be addressed quickly (smoking, alcohol use, vitamin supplementation, caffeine, etc.) are limited. Because some preconceptional issues, including obesity and harmful dietary patterns, require long-term interventions, there are calls for a more public health or marketing approach to improve the health status of potential parents (Stephenson et al, 2018).

Toxins

Screening women for alcohol, tobacco (including e-cigarettes, vapors), and recreational drug use is critical and also may be important for occupational toxin exposure. Marijuana (*Cannabis sativa*) use is now legalized in some states. It does not appear to affect semen parameters but the prevalence of infertility increases among women reporting marijuana use (Practice Committee, 2017). Animal models have demonstrated an increase in birth defects (Hennessy, 2018) but human studies are confounded with polysubstance abuse and often ignore the timing of exposure (American College of Obstetricians and Gynecologists [ACOG], 2017a). In addition, the potency has increased over time. The chemicals cross the placenta and fetal cannabinoid receptors are active as early as 14 weeks. Marijuana use affects the central nervous system and animal models show it negatively affects fetal brain development. The prevalence of SGA babies and stillbirths both increase among those using marijuana and, if associated with cigarette smoking, may increase the risk of preterm birth (ACOG, 2017a; ACOG, 2018d). In vitro studies, using first trimester placental villous cells from terminated pregnancies transplanted to a nutrient medium, demonstrate poor placental growth and function, including lower taurine transport to the fetus, when the fetus is exposed to high amounts of alcohol in early pregnancy (Lui et al, 2014). Women may be at risk for entering pregnancy with toxic levels of mercury, and the

types of fish eaten should be discussed (see *Focus On: Omega-3 Fatty Acids in Pregnancy and Lactation*). The effect of maternal caffeine intake on infertility is often debated. No increased risk of miscarriage has been seen with caffeine consumption less than 200 mg/day, but

consumption of more than 500 mg/day is associated with decreased fertility (*Practice Committee, 2017*). Caffeine is not a **teratogen** (a substance that causes malformation in an embryo or fetus), and does not affect semen parameters (see Appendix 25).

FOCUS ON

Omega-3 Fatty Acids in Pregnancy and Lactation

Our ancestors likely consumed a diet with equal amounts of omega-3 and omega-6 fatty acids. American diets currently are estimated to contain much higher levels of omega-6 than omega-3 fatty acids. This dramatic change in the ratio is thought to affect overall disease prevalence as well as pregnancy outcome. However, there is no evidence that the absolute amounts of essential fatty acids (EFA) provided by any culture are inadequate for the placenta, fetus, or infant growth (*Lauritzen and Carlson, 2011*). Adequacy of EFA intake is highly individual based on dietary intake, food access, and food preferences.

Fatty acids are found in all cell membranes. The fetal brain contains equal amounts of omega-6 (arachidonic acid) and omega-3 (docosahexaenoic acid [DHA]). Arachidonic acid intake is seldom limited. The omega-3s, primarily eicosapentaenoic acid (EPA) and DHA, are important for fetal neurodevelopment, vasodilation, reduced inflammation, and thrombosis inhibition. Although EPA is thought to be beneficial, the separate effects have not yet been tested because purified EPA supplements are only recently available.

DHA is important for the growth and development of the fetal central nervous system and the retina. It may play a beneficial role in the fetal immune function and may help lower the risk of food allergy (*Larqué et al, 2012*). DHA may also be helpful regarding birth weight, as well as maternal depression. There is some evidence that supplementing all pregnant women with DHA may be a cost-effective way to lower the risk of early preterm delivery (*Shireman et al, 2016*). A recent Cochrane review found that increased overall intake of the omega-3 long-chain polyunsaturated fatty acids (LCPUFAs) (from food or supplements) reduced the risk of both preterm (< 37 weeks) and early preterm (< 34 weeks) births (*Middleton et al, 2018*). Cochrane also concluded that more research is needed to determine the long-term effects on mother and child; to determine the metabolic and neurodevelopment pathways; and to determine whether, and how, the outcomes vary by the different types of omega-3 fatty acids, as well as the effects of the timing, dosage, and characteristics of women.

DHA is selectively and preferentially transferred across the placenta (*Lauritzen and Carlson, 2011*). Fetal DHA accretion is highest in the last half of pregnancy, reaching 30 to 45 mg/day in the last trimester (*Koletzko et al, 2007*), primarily to the brain and adipose tissue, and in the first few months of life. DHA must be mobilized from maternal stores or the prenatal diet must include adequate amounts of preformed DHA. Transfer rates are highly variable and are lower among women with obesity, preeclampsia, hypertension, and diabetes (type 1, type 2, and gestational diabetes) (*Lauritzen and Carlson, 2011*). Women who smoke and have growth restricted fetuses also have lower transfer rates. It is thought that short interconceptual periods may cause a mother to enter a subsequent pregnancy depleted. The amount of DHA in the blood that optimizes maternal and infant outcomes, as well as the intake levels to achieve that level, is still unknown. An average daily intake of 200 mg DHA during pregnancy and lactation currently is recommended, but studies are underway testing

the benefit of larger amounts (*Carlson et al, 2017*). Current intakes are often far lower. Intakes of up to 1 g/day of DHA or 2.7 g/day of total omega-3 PUFAs appear safe (*Koletzko et al, 2007*). The main food source of DHA is fatty, cold-water fish, and a couple of meals per week of low-mercury fish during pregnancy provide adequate amounts of DHA. Those fish that are low in methylmercury but high in DHA include salmon, sardines, trout, herring, anchovies, and mackerel (not King mackerel). Caviar and brains (do not use where prion contamination is of concern) are also particularly high in DHA. Other foods also may be used, depending on local availability and acceptability of safe sources. Check the local food composition tables for options.

Vegetable sources of omega-3 fats (alpha-linolenic acid [ALA]) include flaxseeds and nuts, especially walnuts. The conversion rate to DHA is usually very low but improves during pregnancy (*Burdge et al, 2017*). However, biomagnification by the placenta doesn't appear to compensate for the absence of preformed EPA or DHA. DHA fortified eggs can be helpful, but other fortified foods contain very little DHA. Foods labeled as fortified with omega-3s likely contain ALA. In dietary supplements, algae source EPA and DHA is another useful vegetarian option.

Any pregnant woman allergic to fish should seek an algal source of supplemental DHA. It is currently unknown if EPA or other components (e.g., other fatty acids, vitamin D, iodine, and selenium) are also important (*Oken et al, 2013*). Fish oil supplements contain EPA and DHA, although better long-term outcomes are seen with fish consumption than with supplements. Caution is advised, though, with the fish liver oils (such as cod liver oil) because of high preformed vitamin A levels.

The breastfed infant obtains DHA through maternal milk when the mother eats sufficient quantities of foods containing DHA. If the exclusively breastfeeding mother is not consuming fish or DHA supplements, a DHA supplement can be given to the infant. For women who are unable, or choose not to breastfeed, most infant formulas in the United States are fortified with DHA.

There is no dietary reference intake (DRI) for either EPA or DHA in the United States. The benefit of maternal supplementation has not been proven as of yet and there are potential epigenetic effects that must also be considered. Maternal fish consumption is associated with better child neurodevelopment, at least in observational studies subject to confounding. Perhaps supplementation is merited only for those women with very low intakes of LCPUFAs and/or for premature infants who had insufficient time to accumulate enough.

Promoting a variety of safe seafood choices is preferable. Women have consumed less fish since the mercury advisories were issued (*McGuire et al, 2016*). They must be reassured that fish can be eaten safely as a good protein source as long as care is taken in choosing and preparing the fish (see *Box 14.7*). If at least some of the high DHA sources are chosen, pregnancy outcomes, as well as infant neurodevelopment and visual acuity, may improve. In addition, if women eat these fish during pregnancy, they are also likely to continue eating them postpartum, improving the maternal repletion and the child's DHA accretion that continues after birth.

Exposure of men and women to environmental chemicals, including pesticides, heavy metals, and organic solvents, is associated with an increased time to pregnancy. However, most studies are plagued with important confounders (age, smoking, alcohol use, parity, use of contraceptives, underlying disease) and causality cannot be determined. It is also unknown whether men and women have different susceptibility to the effects of environmental toxins. The strongest evidence of adverse effect is with pesticide and lead exposure. Pesticide

exposure affects semen quality and increases risk of sterility (*ACOG, 2013b; Table 14.2*).

A father's regular preconceptional smoking is associated with DNA damage to the sperm, but it is unclear whether male fertility is reduced (*Practice Committee, 2017*). Smoking also increases the risk that his child will have acute lymphoblastic leukemia, but the absolute risk is still very small, raising it from 27 per million births to 34 per million births (*Van der Zee et al, 2013*). Maternal smoking is associated with an increased rate

TABLE 14.2 Examples of Reproductive Health Effects of Prenatal Exposure to Environmental Contaminants

Chemicals	Exposure Sources and Pathways	Reproductive or Developmental Health Effects
Pesticides	Pesticides are applied in large quantities in agricultural, community, and household settings. In 2001 more than 1.2 billion pounds of pesticides were used in the United States. Pesticides can be ingested, inhaled, and absorbed by the skin. The pathways of pesticide exposure include food, water, air, dust, and soil.	Impaired cognitive development Impaired neurodevelopment Impaired fetal growth Increased susceptibility to testicular cancer Childhood cancer
Solvents	Examples include benzene, toluene, xylene, styrene, 1-bromopropane, 2-bromopropane, perchloroethylene, and trichloroethylene. Solvents include some of the highest production volume chemicals in the United States. They are used in plastics, resins, nylon, synthetic fibers, rubber, lubricants, dyes, detergents, drugs, pesticides, glues, paints, paint thinners, fingernail polish, lacquers, detergents, printing and leather tanning processes, insulation, fiberglass, food containers, carpet backing, and cleaning products. Solvents are a component of cigarette smoke. Exposure is primarily through breathing contaminated air.	Fetal loss Miscarriage
Toluene	Exposure occurs from breathing contaminated air at the workplace, in automobile exhaust, and in some consumer products, paints, paint thinners, fingernail polish, lacquers, and adhesives.	Decreased fetal and birth weight Congenital malformations
Phthalates	Phthalates are synthetically derived. They are used in a variety of consumer goods, such as medical devices, cleaning and building materials, personal care products, cosmetics, pharmaceuticals, food processing, and toys. Exposure occurs through ingestion, inhalation, and dermal absorption.	Reduced masculine play in boys Reduced anogenital distance Shortened gestational age Impaired neurodevelopment in girls
Lead	Occupational exposure occurs in battery manufacturing and recycling, smelting, car repair, welding, soldering, firearm cleaning and shooting, and stained glass ornament and jewelry production. Nonoccupational exposure occurs in older homes where lead-based paints were used, water pipes, imported ceramics and pottery, herbal remedies, traditional cosmetics, hair dyes, contaminated soil, toys, and costume jewelry.	Alterations in genomic methylation Intellectual impairment Increased likelihood of allergies
Mercury	Mercury from coal-fired power plants is the largest man-made source of mercury pollution in the United States. Primary human exposure is by consumption of contaminated seafood.	Reduced cognitive performance Impaired neurodevelopment
Polychlorinated biphenyls	Polychlorinated biphenyls were used as industrial insulators and lubricants. They were banned in the 1970s but are persistent in the aquatic and terrestrial food chains, resulting in exposure by ingestion.	Development of attention-deficit/hyperactivity disorder-associated behavior Increased body mass index Reduced IQ
Air pollutants	Common air pollutants include carbon monoxide, lead, ground-level ozone, particulate matter, nitrogen dioxide, and sulfur dioxide. Air pollution arises from a variety of sources, including motor vehicles, industrial production, energy (coal) production, wood burning, and small local sources such as dry cleaners.	Low birth weight Birth defects
Cigarette smoke	Cigarette smoke exposure includes active smoking, passive smoking, or both.	Miscarriage Intrauterine growth restriction Low birth weight Preterm delivery Decreased semen quality
Perchlorate	Perchlorate is used to produce rocket fuel, fireworks, flares, and explosives and also can be present in bleach and some fertilizers. Sources of exposure are contaminated drinking water, food, and other nonwater beverages. Infants also may be exposed through breastmilk.	Altered thyroid function
Perfluorochemicals	Perfluorochemicals are widely used man-made organofluorine compounds with many diverse industrial and consumer product applications. Examples are perfluorooctane sulfonate and perfluorooctanate, which are used in cookware products with nonstick surfaces and in packaging to provide grease, oil, and water resistance to plates, food containers, bags, and wraps that come into contact with food. They persist in the environment. Occupational exposure and general population exposure occur by inhalation, ingestion, and dermal contact.	Reduced birth weight

Continued

TABLE 14.2 Examples of Reproductive Health Effects of Prenatal Exposure to Environmental Contaminants—cont'd

Chemicals	Exposure Sources and Pathways	Reproductive or Developmental Health Effects
Polybrominated diphenyl ethers	These include flame retardant materials that persist and bioaccumulate in the environment. They are found in furniture, textiles, carpeting, electronics, and plastics that are mixed into but not bound to foam or plastic.	Impaired neurodevelopment Premature delivery Low birth weight Stillbirth
Bisphenol-A	Bisphenol-A is a chemical intermediate for polycarbonate plastic and resins. It is found in food, consumer products, and packaging. Exposure occurs through inhalation, ingestion, and dermal absorption.	Recurrent miscarriage Aggression and hyperactivity in female children
Formaldehyde	Formaldehyde is used in the production of wood adhesives, abrasive materials, and other industrial products and in clinical laboratories and embalming. It is found in some germicides, fungicides, insecticides, and personal care products. Routes of exposure are oral, dermal, and inhaled.	Spontaneous abortion Low birth weight
Antineoplastic drugs	This class of chemotherapy drugs presents an occupational exposure for nurses and other health care professionals.	Spontaneous abortion Low birth weight
Anesthetic gases	Anesthetic gases are administered by inhalation in health care settings and veterinary care. Occupational exposure is a risk for nurses, physicians, dentists, veterinarians, and other health care professionals who work in settings where anesthetic gases are used.	Congenital anomalies Spontaneous abortion
Ethylene oxide	Ethylene oxide is used to sterilize heat-sensitive medical items, surgical instruments, and other objects that come into contact with biologic tissues. Occupational exposure is a risk in some health care settings, particularly sterilization units. Exposure is through inhalation.	Spontaneous abortion and pregnancy loss Preterm and postterm birth

of miscarriage (Practice Committee, 2017). Habitual alcohol consumption may be associated with reduced semen quality and changes in testosterone and sex hormone-binding globulin levels. Although higher intakes are of more concern, even five drinks per week have been associated with a reduced sperm count and concentration, as well as a reduction in the percentage of spermatozoa with normal morphology (Jensen et al, 2014).

Obesity and Endocrine Conditions

Preconceptual obesity raises risk for men and women. In men, elevated BMI is associated with lower success with in vitro fertilization (IVF).

Maternal prepregnant obesity is correlated with lower rates of conception, higher rates of congenital anomalies, and lower live birth rates (Merhi et al, 2013). Obesity affects oocyte development, ovulation, embryo development, endometrial development, implantation, and pregnancy loss. Obesity in pregnancy and postpartum is correlated with lactation failure (Garcia et al, 2016). Those with known diabetes and hypothyroidism, as well as hypertension, should be in good control before conception. Although weight loss improves fertility for women, it has less effect on fertility in men (see *Focus On: Special Case of Obesity*).

FOCUS ON

Special Case of Obesity

The rates of obesity have increased dramatically in industrialized and, to a lesser extent, in developing countries (see Chapter 20). Among women with obesity, rates of conception are lower and **congenital anomalies** (neural tube defects [NTDs], cardiovascular anomalies, oral clefts, anorectal atresia, hydrocephaly, limb reductions, spina bifida) occur more frequently and are detected less often prenatally than in the general population. Rates of NTDs increase with the degree of obesity. For women with severe obesity, rates are more than triple that for women with normal weight. Supplementation with folic acid is not as protective for these women, but the benefit of supplementing with more than 400 mcg folic acid/day has not been studied.

Women with obesity have an exaggerated response to the normal physiologic changes of pregnancy. They have increased risk of cardiac dysfunction, proteinuria, sleep apnea, nonalcoholic liver disease, gestational diabetes, and preeclampsia (American College of Obstetricians and Gynecologists [ACOG], 2015d). Genetic, hormonal, and biochemical environments are altered, influencing fetal growth and

organ development. Women who enter pregnancy with a body mass index (BMI) greater than 30 have a higher risk of spontaneous abortion (SAB, i.e., miscarriage), **intrauterine fetal demise (IUFD)** or stillbirth, with the risk of many complications increasing linearly (Nelson et al, 2010). These women are more likely to have intra-partum, operative, and postoperative complications, including anemia and postpartum depression. Increased risks of maternal morbidity and mortality are associated with increasing degrees of obesity (Lisonkova et al, 2017). Women with obesity are less likely to initiate breastfeeding and more likely to experience lactation failure.

Normal fetal growth patterns are disrupted. Risk is increased for macrosomia, birth injury (shoulder dystocia, brachial plexus injury, fetal hypoxia), and childhood obesity, but there are also significant rates of growth-restricted babies and preterm deliveries. Infants of women with obesity are more likely to require admission to the neonatal intensive care unit (NICU). There is a linear association between maternal BMI and neonatal death and both neonatal morbidity and maternal complications are significantly higher when maternal BMI is at least 60 (Kim et al, 2017).

FOCUS ON

Special Case of Obesity—cont'd

Although excessive gestational weight gain is common among women who are overweight or obese, and this weight gain is associated with similar increased risks, the prepregnant BMI is usually thought to be the more important factor. Weight loss before pregnancy is recommended and women who have undergone bariatric surgery are less likely to develop gestational diabetes, hypertension, preeclampsia, or to have a macrosomic infant. Weight loss medications are not recommended because of safety concerns at conception (ACOG, 2015d). The optimal timing and extent of that weight loss is being examined.

How maternal obesity mediates poor maternal and fetal outcomes is not clear (Catalano and Shankar, 2017). There are likely genetic and fetal-maternal interactions. It was thought that exposure to hyperglycemia was the main predictor, but it is now recognized that other factors are also important, including hypertriglyceridemia, insulin and insulin resistance, androgens, leptin, increased blood pressure, inflammation, and oxidative stress. Both placental and fetal functioning are affected. Obesity and inflammation are causally linked to insulin resistance. How maternal inflammation affects developmental programming, leading to increased infant adiposity, is not known but there is some evidence that fetal inflammation exists also. Obesity, with low levels of adiponectin, is associated with increased fetal growth. The normal twofold to threefold increase in serum cholesterol and free fatty acid levels during pregnancy are exaggerated in women with obesity. Placentas of these women have altered elevated inflammation markers and lower steroid hormone levels, possibly in response to maternal hyperinsulinemia. These placentas contain higher lipid levels but modified uptake of the LCPUFAs. Triglycerides do not pass through the placenta easily, but there is increased placental transfer of metabolites and an increase in fetal fat deposits with obesity. Altered placental development or function, leading to altered amino acid transfer, contributes to a fetal hyperinsulinemic state. In addition, obesity is associated with tissue-specific changes in mitochondrial function and elevated oxidative stress. High lipid levels also may cause epigenetic changes in lipid sensing and metabolism genes. Obesity may also alter the regulation of appetite, satiety, and adipocyte maturation of the fetus. Iron status in the context of obesity is understudied (Vricella, 2017). These women may have

less plasma volume expansion, resulting in higher hemoglobin values. On the other hand, because of the increased inflammation associated with obesity, they potentially have higher hepcidin levels, lowering hemoglobin levels.

Babies that are exclusively breastfed are less likely to be obese later in life (Uwaezuoke et al, 2017). Both the nutrient and hormonal content of breastmilk is altered with maternal obesity. In addition, the infant microbiome is also altered because of the changes in human milk oligosaccharides. Developmental programming and interactions with the early diet are likely to both be important (Catalano and Shankar, 2017).

Babies born to obese mothers have permanently altered body weight-regulating mechanisms, including the hypothalamic response to leptin, regulation of appetite, and pancreatic beta-cell physiology. There are also changes in the adipose tissue. They are more likely to have obesity, hypertension, and diabetes as adults. In addition, these babies have increased risk of allergy and atopy, possibly through the intestinal dysbiosis and reduced microbial diversity. Maternal obesity also negatively affects maturation and development of the neonate's immune system but the roles of maternal nutrition and exposure to infections and/or their treatments are as yet unclear (Godfrey et al, 2017b). The role of both the maternal and newborn gut microbiome in fetal programming is unknown but may be important (Zhou and Xiao, 2018). Maternal obesity is associated with an increased risk of autism spectrum disorders, developmental delay, and attention-deficit/hyperactive disorder (ACOG, 2015d). Animal research has identified potential mechanisms, including concentrations of fatty acids and glucose, high concentrations of leptin and insulin, and inflammatory mediators interleukins and tumor necrosis factor that cross the placenta and influence neuroendocrine development, neuronal proliferation, and brain development (Godfrey et al, 2017b). Interactions with the environment and epigenetic effects are also likely important. However, the relative impact of maternal obesity, gestational weight gain, and dietary patterns is not yet clear (Catalano and Shankar, 2017).

It appears that both preconception and periconception times are critical. Improving metabolic function preconceptionally improves perinatal outcomes. Interpregnancy intervention to lower weight improves placental function and fetal development.

PCOS affects up to 10% of women of reproductive age but prevalence varies widely between populations (Bellver et al, 2018). Whether PCOS affects oocyte quality is unknown. The testosterone-estrogen balance is altered, resulting in insulin resistance and infertility. Some research suggests that 5% to 10% weight loss is preferred to the use of metformin for ovulation induction in patients with PCOS (Usadi and Legro, 2012; see Chapter 30). Both metabolic syndrome and PCOS are associated with lower fertility rates, along with increased pregnancy and neonatal risks, even when controlling for the obesity. These problems are likely the result of multiple mechanisms, including inflammation, some of which may overlap with the two conditions, and some of which have not yet been identified. Obesity is often a comorbidity that may amplify the effects of PCOS but it is not a diagnostic criterion (ACOG, 2018a). Weight loss for both metabolic syndrome and PCOS is recommended as a first course of treatment because obesity is, in itself, associated with decreased fertility. However, in the case of PCOS, weight loss will not address the underlying hyperandrogenemia and likely will not be helpful if the patient is not overweight or obese. Because 50% to 70% of people with PCOS have insulin resistance regardless of BMI, optimizing glucose control may be beneficial (Bellver et al, 2018). A male equivalent of PCOS may also

exist but the impact on reproductive function still needs investigation (Cannarella et al, 2018).

Optimal antioxidants appear to be helpful, as well as vitamin D and omega-3 PUFAs from fish, but the relative importance of supplements vs. diets rich in these components is not clear. Herbal and dietary supplements are promoted for PCOS treatment (see *Focus On: Herbal and Dietary Supplements*).

A healthy diet and exercise program helps parents prepare for an optimal pregnancy outcome, with the goal of achieving normal weight before conception. However, although preconceptional intervention is recommended, it is seldom achieved because half of pregnancies in the United States are unplanned. In addition, advances in **assisted reproductive technology (ART)** mean that “parents” may be egg or sperm donors or surrogate mothers. The preconceptional health of these “parents” is likely also important but the impact is unknown.

CONCEPTION

Conception involves a complex series of endocrine events in which a healthy sperm fertilizes a healthy ovum (egg) within 24 hours of ovulation. Conception does not guarantee successful pregnancy outcome.

FOCUS ON

Herbal and Dietary Supplements

Some herbal and dietary supplements are promoted for PCOS and/or metabolic syndrome treatment. However, for many, the supporting evidence is insufficiently reliable to rate their effectiveness. For others, there is concern even if the herbal supplements are thought to be effective, because of the potential negative effect on a pregnancy. Specifically, berberine is likely unsafe in pregnancy because it crosses the placenta and may harm the fetus. It may also stimulate uterine contractions. N-acetyl cysteine is also mentioned as useful in treating PCOS. However, it also crosses the placenta. Melatonin may inhibit ovulation but the critical dose is unknown and it is not recommended. Inositol (myo-inositol, D-chiro-inositol) appears to be safe for use in pregnancy. Its use with folic acid appears to lower triglycerides and/or testosterone and improve ovarian function, including ovulation rates in overweight women with PCOS, working as well as metformin (Jellin and Gregory, 2018). A combination of the two forms of inositol may be more effective than a single form. However, a Cochrane systematic review found no differences between inositol and placebo on BMI, waist-hip ratio, the number of people who ovulated, serum testosterone, triglycerides, cholesterol, fasting glucose, or fasting insulin (Monash University, 2018). Data is still limited and inositol use should be considered experimental. Dosage appears critical and there are potential adverse effects among non-obese women, so caution is advised (Noventa et al, 2016).

As in the general population, the use of herbal and dietary supplements for many conditions is common during pregnancy. For many herbs, the supporting

evidence is insufficiently reliable to rate their effectiveness or safety, especially in the first trimester. Common local herbs should be investigated carefully for their safety during pregnancy. Even those with the same names can have different effects. For example, German chamomile appears to be of little concern during pregnancy, while Roman chamomile appears to increase the risk for preterm delivery and LBW (Trabace et al, 2015) and may be an abortifacient (Jellin and Gregory, 2018). Many herbs may cause uterine contractions and/or bleeding and are contraindicated in pregnancy, including ingested aloe vera latex, cat's claw, cinnamon volatile oil, oregano tea, avocado leaf tea, rue, sage tea, damiana, and large amounts of parsley or celery seeds (Kennedy et al, 2016; Rivera et al, 2006).

Caution is advised with the use of all herbal and dietary supplements because safety, purity, and effectiveness cannot always be guaranteed due to the way they are regulated by the Food and Drug Administration (FDA). Interactions with prescribed medications can occur, affecting treatment decisions (Kennedy et al, 2016). Even some herbs considered helpful during pregnancy can have unexpected consequences. For example, raspberry leaf and blackberry leaf tea can cause hypoglycemia in patients with gestational diabetes (Cheang et al, 2016). Women should advise their health care provider about any medication use, including dietary and herbal supplements, and the risk vs. benefit should be carefully considered. See Natural Medicines Comprehensive Database for specific detailed information. Also see Chapter 11.

Occult loss rates are estimated to be 41% to 70%, depending on the timing and sensitivity of the pregnancy test (Kwak-Kim et al, 2010). Among clinically recognized pregnancies, the overall early pregnancy loss rate is 10% but varies widely by the age of the mother (ACOG, 2015e).

The Carnegie Stages are a system used to describe predictable embryonic changes and developmental milestones. As noted in Table 14.3, as well as in Table 14.1 and Box 14.1, optimal conditions, including the absence of hostile factors and optimal status of many nutrients, are thought to be critical preconceptually and during fetal organogenesis.

TABLE 14.3 The Carnegie Stages of Human Gestation Through 16 Weeks Postovulation

Carnegie Stage (time postovulation)	Structure Size	Highlighted Developmental Events with Selected Potential Nutrient Implications
Stage 1 Fertilization (1 day)	0.1-0.15 millimeters (mm); smaller than the size of a pencil point	Fertilization begins when the sperm penetrates the oocyte. This requires the sperm, which can survive up to 48 hours, to travel 10 hours up the female reproductive tract. Then the sperm must successfully penetrate the zona pellucida, a tough membrane surrounding the egg, a process that takes approximately 20 minutes. Once the fertilization is successful, the structure now becomes a zygote. This is the end of the fertilization process. Optimal amounts of folate are needed for cell division and formation of DNA.
Stage 2 First Cell Division (1.5-3 days)	0.1-0.2 mm	Zygote begins to divide. Division begins to occur approximately every 20 hours. When cell division generates a mass of approximately 16 cells, the zygote now becomes a morula, a mulberry shaped structure. The newly created morula leaves the fallopian tube and enters the uterine cavity 3-4 days after fertilization.
Stage 3 Early Blastocyst (4 days)	0.1-0.2 mm	The morula enters the uterus and cell division continues. A cavity (hole), known as a blastocoele, forms in the middle of the morula. Cells are flattening and compacting inside this cavity. The zona pellucida remains the same size as it was after fertilization, with the cavity in the center. The entire structure is now called a blastocyst. Two cell types are forming: embryoblasts, on the inside of the blastocoele, and trophoblasts, on the outside portion of the blastocoele.
Stage 4 Implantation Begins (5-6 days)	0.1-0.2 mm	Pressure from the blastocoele expanding in the middle of the blastocyst against the rigid wall of the zona pellucida creates a "hatching" of the blastocyst from this zona pellucida. Separation of the embryoblasts and trophoblasts is complete. The outer layer of trophoblast cells secretes an enzyme that erodes the epithelial lining of the uterus so the blastocyst can implant. Trophoblast cells also secrete hCG, which stimulates the corpus luteum (the yellow glandular mass in the ovary formed by an ovarian follicle that has matured and discharged its ovum) to continue progesterone production, important in maintaining the blood-rich uterine lining. Progesterone is also later produced by the placenta. Five days is the latest that an IVF embryo would be transferred. Consider vitamin D.

TABLE 14.3 The Carnegie Stages of Human Gestation Through 16 Weeks Postovulation—cont'd

Carnegie Stage (time postovulation)	Structure Size	Highlighted Developmental Events with Selected Potential Nutrient Implications
Stage 5 Implantation Complete (7-12 days)	0.1-0.2 mm	Trophoblast cells continue to destroy cells of the uterine lining, creating blood pools and stimulating new capillaries to grow. This begins the growth of the placenta. The blastocyst inner cell mass differentiates into the epiblast (top layer of cells, becoming the embryo and the amniotic cavity) and the hypoblast (lower layer of cells, becoming the yolk sac). Ectopic pregnancies are those that do not implant in the uterus at this time, eventually becoming a life-threatening problem.
Stage 6 Primitive Streak (13 days)	0.2 mm	Placental formation: Chorionic villi “fingers” form, anchoring the embryo to the uterus. Blood vessels begin appearing. Stalk formation: The embryo is attached to the developing placenta by a stalk, which later becomes part of the umbilical cord. Gastrulation: A narrow line of cells, called the <i>primitive streak</i> , appears on the surface of the two-layered embryonic disc. Cells migrate in, with bilateral symmetry, from the outer edges of the disc to the primitive streak and begin to form three layers: the ectoderm (top layer of the embryonic disc that will later form skin, hair, lenses of the eye, lining of the internal and external ear, nose, sinuses, mouth, anus, tooth enamel, pituitary and mammary glands, and all parts of the nervous system), the mesoderm (middle cell layer that will later form muscles, bones, lymphatic tissue, spleen, blood cells, heart, lungs, and reproductive and excretory systems), and the endoderm (inner cell layer that will later form the lining of the lungs, the tongue, the tonsils, the urethra and associated glands, the bladder, and the digestive tract). Consider vitamins A, E, C, copper, and DHA.
Stage 7 Neurulation (16 days)	0.4 mm	Gastrulation continues, forming the three-layered embryonic disc. Neural crest cells originate at the top of the neural tube and migrate extensively throughout the embryo, differentiating into many cell types, including neurons, glial cells, pigmented cells of the epidermis, epinephrine-producing cells of the adrenal glands, and various skeletal and connective tissues of the head. Fetal alcohol syndrome results from disruption of the migration of neural crest cells. Consider vitamins A, E, folic acid, choline, zinc, selenium, DHA, and antioxidants.
Stage 8 (17-19 days)	1-1.5 mm	The embryonic area is now shaped like a pear, with the head region broader than the tail. The ectoderm has thickened to form the neural plate. The edges rise, forming the concave neural groove. This groove is the precursor of the embryo’s nervous system, one of the first organs to develop. Blood cells are already developed and begin to form channels alongside the epithelial cells that are also forming. <i>Sonic hedgehog (Shh)</i> is one of three genes that are now secreted from the notochord (rod-shaped body composed of mesoderm cells). These genes encode for signaling molecules involved in patterning processes during embryogenesis, including the development of cerebral neurons, the separation of the single eye field into two bilateral fields, hair growth, and limb development. A repression of Shh by the notochord initiates pancreatic development. Consider vitamin B₁₂, omega-3 fatty acids, folate, cholesterol, and choline.
Stage 9 Appearance of Somites (19-21 days)	1.5-2.5 mm	Embryo looks like a peanut with a larger head end compared with the tail end. One to three pairs of somites (mesoderm tissue that looks like “bumps”) are now present, with every ridge, bump, and recess indicating cellular differentiation. The head fold rises on either side of the primitive streak. Endocardial (muscle) cells begin to fuse and form into the early embryo’s two heart tubes. Secondary blood vessels now appear in the chorion/placenta. Hematopoietic cells (forming blood cells) and endothelial cells (forming blood vessels) appear on the yolk sac simultaneously. Consider folic acid, copper, and iron.
Stage 10 (21-23 days)	1.5-3.0 mm	At this time, the embryo looks like an old fashioned key-hole with a big oval top, with an ear of corn in the bottom two thirds of the structure. Rapid cell growth elongates the embryo and expands the yolk sac. By the end of this stage, 4-12 somite pairs can exist. Cells that will become the eyes and ears appear. Neural folds begin to rise and fuse, “zippering” the neural tube closed. Failure of this closure results in a neural tube defect, including anencephaly and spina bifida, which varies in severity depending on location and extent of the area left open. The two endocardial tubes fuse into one. This heart tube takes on an S-shaped form and cardiac muscle contraction begins. Consider folate, B₆, B₁₂, choline, vitamin A, zinc, copper, and methionine.

Continued

TABLE 14.3 The Carnegie Stages of Human Gestation Through 16 Weeks Postovulation—cont'd

Carnegie Stage (time postovulation)	Structure Size	Highlighted Developmental Events with Selected Potential Nutrient Implications
Stage 11 (23-25 days)	2.5-3.0 mm	Embryo has a modified S-curve shape with a bulb-like tail and a stalk connecting to the developing placenta. Somites increase to 20 pairs, at which point the forebrain is completely closed. The primitive tubal heart is beating and peristalsis begins. Consider Vitamin A.
Stage 12 (25-27 days)	3-5 mm	Embryo now has a C-shape. Brain and spinal cord are the largest tissue in the embryo. Face is becoming apparent; eyes and ears are beginning to form. Heart valves and septa may become apparent. Blood system is developing. Blood cells follow the surface of the yolk sac (where they originated), then move along the central nervous system to the chorionic villi, part of the maternal blood system. Liver cells are beginning to form, before the rest of the digestive system. Upper limb buds appear. Consider vitamin A, folic acid, choline, methionine, and zinc.
Stage 13 (26-30 days)	4-6 mm; size of the head of a pencil eraser	More than 30 somite pairs are now evident, precursors of multiple organ systems. First thin surface layer of skin appears to cover the embryo. Back muscles and ribs begin to form. The digestive epithelium layer begins to differentiate, eventually developing into the liver, lung, stomach, and pancreas.
Stage 14 (31-35 days)	5-7 mm	Brain and head are growing rapidly, sections of the brain and spinal cord wall are becoming differentiated. The eye is developing and the nasal plate can be detected. The adenohypophyseal pouch, later developing into the anterior pituitary, is defined. The esophagus is forming and lung sacs appear. Ureteric buds and the metanephros, later developing into the kidney, appear. Upper limbs elongate and innervation begins. Consider LCPUFA (especially DHA and AA), protein, zinc, iron, choline, copper, iodine, vitamin A, and folate.
Stage 15 (35-38 days)	7-9 mm	Brain is still larger than the trunk. Maxillary and mandibular arches are more prominent. The stomodeum, the depression in the ectoderm that will develop into the mouth and oral cavity, appears. Retinal pigment may appear in the optic cup. Symmetric and separate nasal pits appear as depressions in the nasal disc. Future cerebral hemispheres are distinct. Blood flowing through the atrioventricular canal is now divided into left and right streams. Handplate, forearm, arm, and shoulder may now be discerned in the upper limb bud. Lower limb bud begins to develop and innervation begins.
Stage 16 (37-42 days)	9-11 mm	Hindbrain, responsible for heart regulation, breathing, and muscle movements, begins to develop. Future lower jaw is now visible. Nasal pits rotate to face ventrally as head widens. Cardiac tube begins to develop. Mammary gland tissue begins to mature. Mesentery, the tissue that attaches the intestines to the rear abdominal wall and supplies them with blood, nerves, and lymphatics, is now defined. Hands begin to develop. Thigh, leg, and foot areas can now be distinguished. Consider vitamin A.
Stage 17 (42-44 days)	10-13 mm	Jaw and facial muscles are developing. The nasofrontal groove becomes distinct. An olfactory bulb (sense of smell) forms in the brain. Teeth buds (without a clear cell arrangement) begin to form. Heart separates into four distinct chambers. The diaphragm forms and the pituitary gland, trachea, larynx, and bronchi begin to form. Intestines begin to develop within the umbilical cord, later migrating to the abdomen when there is space. Primitive germ cells arrive at the genital area, responding to genetic instructions on whether they develop into female or male genitals. Digital rays are apparent on feet and hands. Consider vitamin K.
Stage 18 (44-48 days)	11-14 mm	Body appears more like a cube. Eyelids begin to develop, eyes are pigmented. Nipples appear on the chest. Kidneys begin to produce urine. Ossification of the skeleton begins. Consider calcium, phosphorus, magnesium, vitamins A, D, and K. See Chapter 23.
Stage 19 (48-51 days)	13-18 mm	Semicircular canals are forming in the inner ear, enabling a sense of balance and body position. Gonads are forming. Knee and ankle locations are now apparent, joints are more distinct. Toes are nearly completely notched and toenails begin to appear. Bone cartilage begins to form a more solid structure. Muscles develop and strengthen.
Stage 20 (51-53 days)	15-20 mm	Spontaneous movement begins. Nose is fully formed. Anal membrane is perforated. Testes or ovaries, as well as toes, are distinguishable.
Stage 21 (53-54 days)	17-22 mm	Eyes are well developed but have not yet migrated forward from the side of the head. External ears have not yet migrated up. Tongue is developing. Intestines begin to recede into the abdominal cavity. Failure to recede may result in either <i>gastroschisis</i> or <i>omphalocele</i> .

TABLE 14.3 The Carnegie Stages of Human Gestation Through 16 Weeks Postovulation—cont'd

Carnegie Stage (time postovulation)	Structure Size	Highlighted Developmental Events with Selected Potential Nutrient Implications
Stage 22 (54-56 days)	19-24 mm	Development of multiple organs continues. Upper lip now fully formed. The brain can signal muscle movement. Limbs begin to ossify (replacing cartilage with bone), starting in the upper limbs. Consider the bone nutrients. See Chapter 23.
Stage 23 Embryonic Period Ends (56-60 days)	23-26 mm	Head is erect and round. External ear is completely developed. Retina is fully pigmented. Eyelids begin to unite and are half closed. Taste buds begin to form. Bones of the palate begin to fuse. Primary teeth are at cap state (cells are now arranged and look like a cap). Upper and lower limbs are well formed; fingers and toes no longer webbed. Intestines continue to migrate from the umbilical cord into the body cavity. Layers of rather flattened cells (precursors to the surface layer of skin) replace the thin ectoderm. Consider vitamins A, D, and K, calcium, phosphorus, magnesium, protein, and omega-3 fatty acids.
(61-68 days, approximately 10 weeks)	31-42 mm	Basic brain structure is complete and the brain mass is rapidly growing. Sockets for all 20 teeth are formed in the gum line. Face has human appearance. Vocal cords form and the fetus can make sounds. Fetus develops reflexes. Digestive tract muscles can function and practice contraction. Nutrient-extracting villi line the folded intestines. The liver begins to secrete bile (thick, brown-green liquid containing bile salts, bile pigments, cholesterol, and inorganic salts), which is stored in the gallbladder. The thyroid and pancreas are fully developed. The pancreas produces insulin. Genitalia are not yet fully formed. Fingernails begin growing. Skin is very sensitive. Consider folate, omega-3 fatty acids, vitamins D, A, choline, Bs, protein, zinc, iron, copper, magnesium, and iodine.
(12 weeks)	Length: crown-rump length 61 mm (almost 2.5 inches) Weight: 8-14 g (0.3-0.5 oz)	Fetus begins to move around as muscle and nervous systems continue to develop. Heartbeat can be detected. Sucking muscles develop, salivary glands begin to function. Sweat glands and body hair begin to grow. Scalp hair pattern is discernible. Fetus inhales and exhales amniotic fluid, essential for the development of the air sacs in the lungs. Spleen is fully functional, removing old red blood cells and producing antibodies.
(Approximately 14 Weeks)	Length: 80-104 mm (3.2-4.1 inches) Weight: 25 g (almost 1 oz)	Bones continue to form, muscles strengthen. Eyes face more forward and ears are near their final position. Torso is growing rapidly, increasing its proportion to the head. Limbs are well developed. Toenails begin to grow. Heart pumps 25 quarts of blood/day (by the time of delivery it will be 300 quarts/day). Breathing, swallowing, and sucking are all becoming more developed. Consider vitamin A, protein, and the bone nutrients. See Chapter 23.
(16 weeks)	Length: 109-117 mm (4.3-4.6 inches) Weight: 80 g (approximately 2.8 oz)	The placenta is now the size of the fetus. The umbilical cord system grows and thickens, with the blood providing nourishment to the fetus through considerable force. 7.5 oz (250 mL) of amniotic fluid surround the conceptus. Eyes and ears are in correct positions. Fetus can blink, ears stand out from head. Fingerprints and toe prints develop. Circulation is completely functional. Meconium, the product of cell loss, digestive secretions, and swallowed amniotic fluid, begins to accumulate in the intestines. Nerves are being coated with myelin, a fatty substance that speeds nerve cell transmission and insulates them for uninterrupted impulses. Consider omega-3 fatty acids, iron, vitamin A, and cholesterol.

BOX 14.1 Potential Risk Factors for Development of Birth Defects

Assisted reproductive technologies (ART)	Maternal medical conditions (diabetes, hypothyroidism, phenylketonuria)
Genetic alterations	Maternal medication or substance exposure (including but not restricted to isotretinoin, phenytoin, carbamazepine, triamterene, trimethoprim, warfarin, and radioactive iodine), illicit recreational substances, alcohol
Gene-environmental interactions, such as maternal smoking	Nutrient deficits during early pregnancy (iodine, vitamin B ₁₂ , vitamin D, vitamin A [also excess], vitamin K, copper, zinc, folic acid, choline)
Hypoxia during pregnancy	Obesity
Infection during pregnancy (bacterial, parasitic, viral)	Older mother or father
In utero exposure to toxins or heavy metals (lawn chemicals, formaldehyde, endocrine disruptors, agricultural products, pesticides, carbon monoxide, radiation, mercury, lead)	

PREGNANCY

Physiologic Changes of Pregnancy

Blood Volume and Composition

Blood volume expands by nearly 50% by the end of pregnancy, with wide variability among women. This increased blood volume results in decreased levels of hemoglobin, serum albumin, other serum proteins, and water-soluble vitamins, primarily after the end of the first trimester. In contrast, serum concentrations of fat-soluble vitamins and other lipid fractions such as triglycerides, cholesterol, and free fatty acids increase to ensure sufficient transport to the fetus. A compilation of laboratory values by trimester is available, and selected values are listed in [Table 14.4](#). However, wide individual variability makes determination of an inadequate intake or a deficient nutrient state difficult. Normal hematocrit and hemoglobin values change by trimester and cut-points increase with altitude and smoking status, as shown in [Table 14.5](#).

Cardiovascular and Pulmonary Function

Increased cardiac output accompanies pregnancy, and cardiac size increases by 12%. Blood pressure, primarily diastolic, decreases during the first two trimesters because of peripheral vasodilation but may return to prepregnancy values in the third trimester. Mild lower extremity edema is normal, resulting from the pressure of the expanding uterus on the inferior vena cava.

Maternal oxygen requirements increase and the threshold for carbon dioxide lowers, which can make the pregnant woman feel dyspneic. Compensation results from more efficient pulmonary gas exchange and larger chest diameter. In the third trimester, the

diaphragm is pushed upwards by the growing uterus, which may also contribute to maternal dyspnea.

Gastrointestinal Function

During pregnancy the function of the gastrointestinal (GI) tract changes in several ways that affect nutritional status. Gums may bleed more easily because of increased blood flow. In the first trimester nausea and vomiting may occur, followed by a return of appetite that may be ravenous (see Nausea and Vomiting, Hyperemesis Gravidarum, and Pylalism). Cravings for and aversions to foods are common (see Cravings, Aversions, and Pica). Increased progesterone concentration relaxes the uterine muscle to allow for fetal growth while also decreasing GI motility with increased reabsorption of water. This often results in constipation. However, early hormonal changes can also cause diarrhea (see Constipation, Hemorrhoids, and Diarrhea). A relaxed lower esophageal sphincter and pressure on the stomach from the growing uterus can cause regurgitation and gastric reflux (see Heartburn).

Gallbladder emptying becomes less efficient because of the effect of progesterone on muscle contractility. Constipation, dehydration, and a low-calorie diet are risk factors for gallstone development. During the second and third trimesters, the volume of the gallbladder doubles and its ability to empty efficiently is reduced. Bile composition also changes, becoming more sludge-like, increasing the intrinsic risk of gallstones.

Immune Function

Pregnancy has been thought of as a time of overall immunosuppression but there is little evidence to support that idea. Instead, it appears to be a time of immunotransformation. It is hypothesized that the slow, gradual release of paternal/fetal antigens may somehow induce

TABLE 14.4 Selected Reference Ranges for Nutrient Levels in Nonpregnant and Pregnant Women, by Trimester

Component	Nonpregnant Adult	First Trimester	Second Trimester	Third Trimester
Albumin, g/dL	4.1-5.3	3.1-5.1	2.6-4.5	2.3-4.2
Protein, total, g/dL	6.7-8.6	6.2-7.6	5.7-6.9	5.6-6.7
Cholesterol, total, mg/dL	< 200	141-210	176-299	219-349
Triglycerides, mg/dL	< 150	40-159	75-382	131-453
Vitamin A (retinol), mcg/dL	20-100	32-47	35-44	29-42
Vitamin B ₁₂ , pg/mL	279-966	118-438	130-656	99-526
Vitamin C, mg/dL	0.4-1.0	Not reported	Not reported	0.9-1.3
Vitamin D, 25 hydroxy, ng/mL	14-80	18-27	10-22	10-18
Vitamin E, mcg/mL	5-18	7-13	10-16	13-23
Folate, red blood cell, ng/mL	150-450	137-589	94-828	109-663
Calcium, total, mg/dL	8.7-10.2	8.8-10.6	8.2-9.0	8.2-9.7
Copper, mcg/dL	70-140	112-199	165-221	130-240
Ferritin, ng/mL	10-150	6-130	2-230	0-116
Hemoglobin, g/dL	12-15.8	11.6-13.9	9.7-14.8	9.5-15.0
Hematocrit, %	35.4-44.4	31.0-41.0	30.0-39.0	28.0-40.0
Magnesium, mg/dL	1.5-2.3	1.6-2.2	1.5-2.2	1.1-2.2
Selenium, mcg/L	63-160	116-146	75-145	71-133
Zinc, mcg/dL	75-120	57-88	51-80	50-77

TABLE 14.5 Maximum Hemoglobin and Hematocrit Values for Prenatal Anemia Diagnosis

Trimester	Hemoglobin Cutpoints at Sea Level	Hematocrit Cutpoints at Sea Level
First	< 11.0 g/dL	< 33.0%
Second	< 10.5	< 32.0
Third	< 11.0	< 33.0
Altitude adjustments: must be added to the above cutpoints for accurate diagnosis		
3000-3999 feet above sea level 1000 meters	+0.2 g/dL	+0.5%
4000-4999 feet	+0.3	+1.0
5000-5999 feet 1500 meters	+0.5	+1.5
6000-6999 feet 2000 meters	+0.7-+0.8	+2.0
7000-7999 feet	+1.0	+3.0
8000-8999 feet 2500 meters	+1.3	+4.0
9000-9999 feet 3000 meters	+1.6-+1.9	+5.0
10,000-11,000 feet	+2.0	+6.0
3500 meters	+2.7	+8.0
4000 meters	+3.5	+10.5
4500 meters	+4.5	+13.5
Cigarette smoking: may be added to the above cutpoints for accurate diagnosis		
0.5 to < 1.0 pack per day	+0.3 g/dL	+1.0 %
1.0 to < 2.0 packs per day	+0.5	+1.5
≥ 2.0 packs per day	+0.7	+2.0
All smokers	+0.3 g/dL	+1.0 %

tolerance rather than rejection, thus not requiring the same immunosuppression as is necessary for transplant recipients. Some humoral and cell-mediated immunologic functions do appear to be suppressed, likely to aid in the acceptance of the “foreign” fetus. However, other immunologic cells appear to be upregulated. The fetal immune system appears to affect the maternal response (Mor et al, 2011). The placenta is an effective barrier to many pathogens but also produces signals and regulates the immune response at both the implantation site and also systemically (Silasi et al, 2015) and, at least in the murine model, peripheral blood measures of immune function may not be appropriate windows on the maternal-fetal interface (Lewis et al, 2018).

Pregnancy has both proinflammatory and antiinflammatory periods (Mor et al, 2011). It is now known that the first trimester, as well as just

NEW DIRECTIONS

Immune Function and Brain Development

Maternal chronic low-grade inflammation, causing inflammation in the fetus, appears to affect fetal brain structure development, negatively affecting neurodevelopment (Miller and Georgieff, 2017). This inflammation may be caused by over- or undernutrition, but also maternal stress or anxiety. Fetal inflammation is directly toxic to the developing brain but also reduces the availability of nutrients essential for neural migration, neuronal growth, and differentiation.

In addition, it is now thought that immune molecules are important in regulating the development of the brain (Bilbo et al, 2018). Current research has been guided by the working hypothesis that prenatal inflammatory events, including a response to infection but also exposure to environmental toxins, can disrupt the normal expression of immune molecules in the brain called microglia during critical periods of development, increasing the risk of neurodevelopmental disorders, including autism spectrum disorder. Causality has not yet been determined and most of the current research is still with animal models. Whether and how dietary changes would affect this process is also still unknown.

before labor, are proinflammatory. The early proinflammatory response is necessary for optimal endometrial vascularity and is, therefore, associated with a successful pregnancy. The second and most of the third trimester are antiinflammatory states, when the mother and fetus are in relative equilibrium. Exposure to infections, toxins, and environmental pollution, as well as maternal psychological stress, all affect maternal immune function and inflammation in utero (Claycombe et al, 2015). When the inflammatory response is exaggerated, as in the case of obesity, the risk of negative consequences increases, including the risk of both preterm labor and preeclampsia. The exaggerated inflammatory response may also negatively affect fetal brain development (see *New Directions: Immune Function and Brain Development*). There are also likely negative epigenetic effects (Claycombe et al, 2015).

It is still not completely clear how the immune system and pregnancy affect each other but the interaction is critical for the survival of this mother and child and, possibly, for future pregnancies. Although nutrition is likely important in affecting the inflammatory response during pregnancy, the extent of the dietary influence (Vannuccini et al, 2016), the specific dietary patterns and components (Claycombe et al, 2015), and the importance of individual differences (Bjørke-Monsen et al, 2016) are all still unknown but are currently under investigation (see Chapter 7).

Metabolic Responses

The metabolism of macronutrients changes during pregnancy. This response varies between normal weight women and women with obesity (Table 14.6).

Renal Function

The glomerular filtration rate (GFR) increases by 50% during pregnancy, although the volume of urine excreted each day is not increased. Renal plasma flow increases because of the increased GFR with lower serum creatinine and blood urea nitrogen concentrations. Renal tubular resorption is less efficient than in the nonpregnant state, and glucosuria, because of increased GFR, may occur along with increased excretion of water-soluble vitamins and amino acids. Small amounts of glucosuria increase the risk for urinary tract infections.

Placenta and Uterine Environment

The fetus is not provided nutrients and oxygen through the placenta until after blood flow is established to the placenta through

TABLE 14.6 Metabolic Changes During Pregnancy for Women of Normal Weight and Obese

Component	Normal Weight	Obese
Fat deposition with gestational weight gain	Gestational fat gain is primarily accumulated centrally, both subcutaneous and visceral fat. Visceral accumulation may increase as pregnancy progresses.	Locations are similar, amount may be less
Lipid metabolism	50% to 80% increase in basal fat oxidation and in response to glucose, marked hyperlipidemia	Hyperlipidemia is exaggerated
Amino acid metabolism	Protein synthesis increases in the second (15%) and third (25%) trimesters	Unknown, but limited evidence suggests anabolic response may be impaired
Glucose metabolism, insulin resistance	Improved fasting glucose levels, glucose tolerance and insulin sensitivity in early pregnancy, then insulin sensitivity decreases 50% to 70% by third trimester	Early fasting glucose improves less if at all, more insulin resistance, which increases serum levels of all macronutrients

Adapted from Nelson SM et al: Maternal metabolism and obesity: modifiable determinants of pregnancy outcome, *Human Reprod Update* 16:255, 2010.

the uterine spiral arteries, around 10 weeks of gestation. Before that, nourishment is through secretions from both the fallopian tubes and the endometrial glands, also known as uterine glands. The fallopian tube secretions are initially high in simple carbohydrates but become more complex farther down the tubes (Burton, 2018). These secretions are modified in response to the presence of gametes (Avilés et al, 2010) and also after fertilization (Leese et al, 2008). They include many growth factors, cytokines, and antioxidants (Ménézo et al, 2015). Animal studies have shown that many nutrients, including amino acids, potassium, and lactate, are present in concentrations higher than in maternal plasma, while glucose, pyruvate, and total protein concentrations are lower. The nutrients enter the egg through endocytosis and, in both mice and rats, a maternal diet low in protein negatively affects the growth and development of the embryo, including the cardiovascular phenotype (Leese et al, 2008). The contents of the endometrial secretions, called “uterine milk,” are also not completely understood but are rich in glucose, lipids, glycoproteins, and growth factors (Burton, 2018). These secretions enter through the intervillous spaces of the placenta, going to the yolk sac and feeding the developing fetus. Whether maternal diet or obesity affects the contents of these secretions is unknown (Burton et al, 2016) but at least glycogen is stored in these glands (Jones et al, 2015). The uterine gland secretions impact uterine receptivity and blastocyst implantation (Kelleher et al, 2016). The growth factors in the secretions that stimulate placental growth may be triggered by the trophoblast itself (Burton, 2018).

Maternal nutritional status affects placental development, growth, nutrient transport, and endocrine capabilities (Burton et al, 2016). Some nutrients, including iron, iodine, zinc, folate, selenium, and vitamin A, are known to be critically important preconceptually. Optimal maternal status improves pregnancy outcomes and reduces the risk of preeclampsia, gestational diabetes mellitus (GDM), and preterm delivery possibly by improving placental functioning by reducing placental oxidative stress and inflammation (Richard et al, 2017). Other nutrients, including magnesium, appear to directly affect placental development. However, very little is known about the effects of nutritional status on the development of the placenta. Maternal BMI (both high and low), body composition, past nutritional status, current diet, fuel reserves, and epigenetics are all likely important (Burton, 2018).

Placental weight is not a useful proxy measure for placental function (Burton et al, 2016). The placenta grows throughout the pregnancy, including exponentially in the third trimester, but the growth appears to be tightly regulated (Myatt and Thornburg, 2018). Small placentas can adapt to increase nutrient transporters. However, when, how, and by how much the placenta adapts is not completely clear, nor is the reserve capacity. When the placental capacity to adapt is limited, or if the placental function is impaired, fetal development may be impaired, affecting long-term health (Burton et al, 2016). For example, the effect of GDM on placental anatomy is not fully understood but sex-specific alterations are evident that may affect nutrient transport (Castillo-Castrejon and Powell, 2017), including docosahexaenoic acid (DHA) (Léveillé et al, 2018). Whether there are independent effects of GDM and obesity is not yet clear. Obesity appears to affect the placental function in a sex-specific way, where males continue to grow and females adopt a more conservative strategy, ensuring survival (Myatt and Thornburg, 2018). High altitude also affects placental development and function (Burton et al, 2016) (Fig. 14.1).

Nutrients pass through the placenta by a variety of mechanisms. Maternal nutrient status would directly affect those transferred through diffusion or endocytosis/exocytosis. However, the transport of other nutrients can be upregulated through facilitated transport, exchange transport, and active transport (Fig. 14.2). Transport mechanisms have not yet been identified for all nutrients. In addition, the placenta can synthesize proteins for transport to the fetus and may also be a source of glucose, choline, and fatty acids (Burton et al, 2016; Nugent and Bale, 2015; Myatt and Thornburg, 2018).

The placenta is very active metabolically, consuming 80% of the oxygen it takes from maternal circulation at midgestation and 40% to 60% in late gestation (Zhang et al, 2015). It plays a dynamic role in optimizing the resource allocation between the mother and the fetus. It responds to maternal nutrient availability but paternal genes also play a role, promoting the growth of placental tissues. It is not clear if obesity alters specific nutrient transporters. The sex of the fetus/placenta is also critical and, in general, placental adaptation is greater with female offspring (Brett et al, 2014). How the mother and fetus signal each other is not yet clear. However, it is known that the fetus is not just a passive recipient of maternal nutrients but, instead, actually directs how much is transferred through the placenta, including trying to match the perceived nutrient availability. For example, there is a down-regulation of protein transfer in the case of **intrauterine growth restriction (IUGR)**. When an abnormal situation is identified and interventions are implemented, it is unknown whether these transport mechanisms adapt to the new environment or, once set, are relatively permanent.

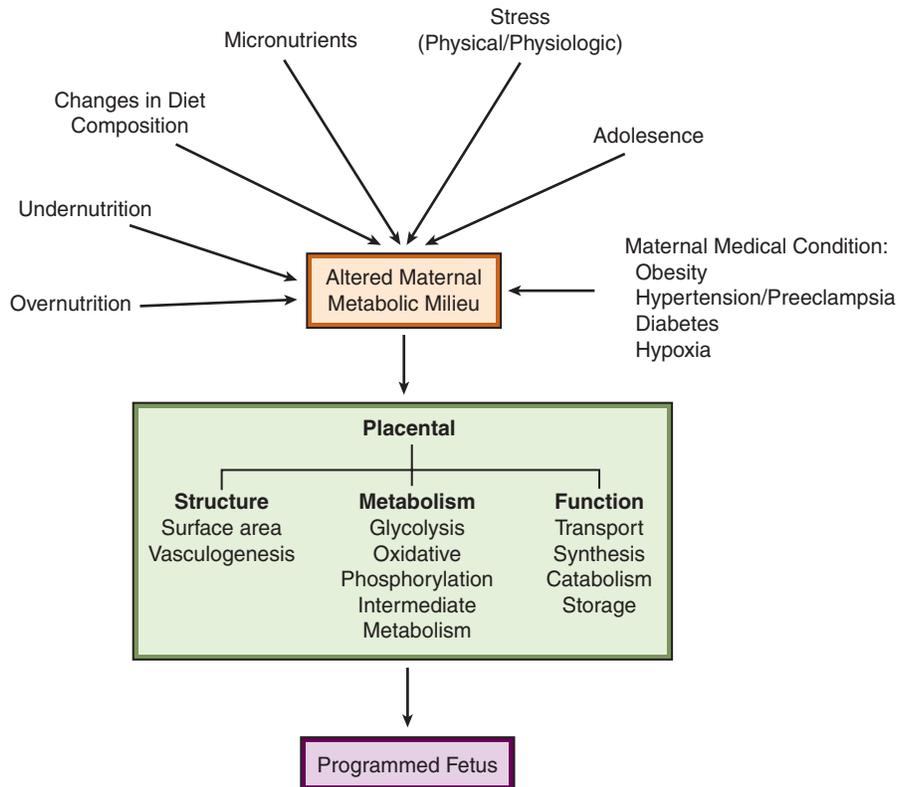

Fig. 14.1 Summary of potential stressors that can alter the placental structure and function, affecting the nutrient availability and therefore the programming of the fetus. (Adapted from Myatt L, Thornburg KL: Effects of Prenatal Nutrition and the Role of the Placenta in Health and Disease, *Methods Mol Biol* 1735: 19, 2018.)

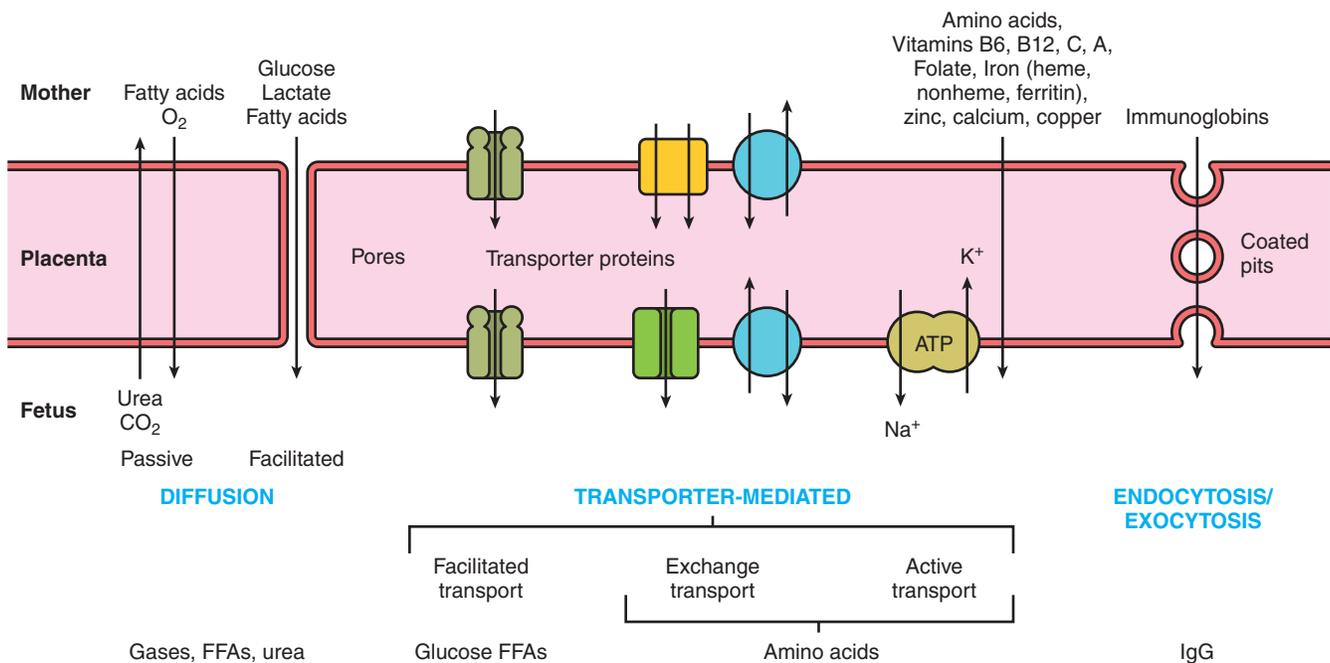

Fig. 14.2 Representation of the known processes by which materials cross the placental membrane. (Adapted from Burton GJ, Fowden AL, Thornburg KL: Placental Origins of Chronic Disease, *Physiol Rev* 96:1509, 2016; Cao C, Fleming MD: The placenta: the forgotten essential organ of iron transport, *Nutr Rev* 74:421, 2016; Grieger JA, Clifton VL: A review of the impact of dietary intakes in human pregnancy on infant birthweight, *Nutrients* 7:153, 2014; Myatt L, Thornburg KL: Effects of Prenatal Nutrition and the Role of the Placenta in Health and Disease, *Methods Mol Biol* 1735: 19, 2018; Nugent BM, Bale TL: The omniscient placenta: Metabolic and epigenetic regulation of fetal programming, *Front Neuroendocrinol* 39:28, 2015; Richard K, Holland O, Landers K et al: Review: Effects of maternal micronutrient supplementation on placental function, *Placenta* 54:38, 2017.)

The placenta produces several hormones responsible for regulating fetal growth and the development of maternal support tissues. It is the conduit for the exchange of nutrients, oxygen, and waste products. The placenta also provides a selective barrier, protecting the fetus from pathogens, teratogens, and other toxins (see [Clinical Insight: Consumption of Human Placenta](#)), but its defenses can be overwhelmed. In addition, it is now thought that the placenta may contain a unique microbiome, hypothesized to be important in the development of the fetal immune system, lowering the risk of allergies ([Prince et al, 2015](#)). It is also known now that the trophoblast invades the lymphatic system (as well as the spiral arteries and uterine veins) but whether access to the lymph triggers maternal immune tolerance is unknown ([Moser et al, 2018](#)).

Placental insults compromise the ability to nourish the fetus, regardless of how well-nourished the mother is. These insults can be the result of poor placentation from early pregnancy or small infarcts associated with preeclampsia and other hypertensive disorders. When the placenta has a reduced functional capacity for whatever reason, the result is often intrauterine growth restriction (IUGR). However, as mentioned before, the placenta also has the ability to respond to a poor environment. For example, women affected by the World War II Dutch famine in their first trimesters had larger placentas, resulting in normal weight infants ([Belkacemi et al, 2010](#)).

A less-than-optimal environment in utero can lead to a mismatch between available nutrients and the genetically determined fetal drive for growth. The goal is to support a healthy environment through a proper balance of nutrients and the avoidance of teratogens (see [Clinical Insight: High-Risk Pregnancies with Nutritional Components](#)).

CLINICAL INSIGHT

Consumption of Human Placenta

In many areas, women are now being offered their placentas after delivery. While some people want to save it for cultural reasons, many are now choosing to eat their placentas for many self-reported benefits. Placentophagy is promoted as a potential way to lower the risk of postpartum depression and improve infant bonding, as well as replace the iron and other nutrients lost during pregnancy and delivery. It is also promoted as a source of energy, a lactation promoter, an immune system booster, and as a way to decrease pain and bleeding after delivery ([Farr et al, 2018](#)).

Placentas do contain hormones that may be beneficial but the therapeutic effect has not been demonstrated ([Young et al, 2016b](#); [Young et al, 2018a](#); [Young et al, 2018b](#)). The placenta is a significant source of iron but normal consumption amounts are unlikely to make a significant difference in the postpartum iron status ([Gryder et al, 2017](#)). The placenta is a source of other nutrients as well, including selenium, protein, and cholesterol ([Chang et al, 2017](#)). However, there is wide variability between women ([Young et al, 2016a](#)).

The placenta is also a potential source of pathogens, toxins, and heavy metals, depending on prenatal exposure. Theoretically, maternal consumption could

trigger alloimmunization, exposing her to genetically different cells or tissues, triggering an immune response and, therefore, harming future pregnancies ([Farr et al, 2018](#)). A recent case report cited maternal ingestion of dried placenta as a likely source of Group B strep infection in a newborn, possibly increasing maternal intestinal and skin colonization, facilitating transfer to the infant. Dried placenta powder is not sterile and when stored over 6 months, has been a source of *Paenibacillus macerans*, bacteria that produce histamine in preserved foods, potentially causing foodborne chemical intoxication ([Johnson et al, 2018](#)).

The processing is not regulated by the Food and Drug Administration (FDA) and is not standardized. The placenta must be handled carefully, including being refrigerated soon after delivery. The consumption of placenta should be discouraged if the mother or baby has a viral infection ([Johnson et al, 2018](#)) or if the mother was exposed to heavy metals during pregnancy. It should not be eaten raw, including in a smoothie. If dried and encapsulated, it should be steamed first to lower the risk of pathogen transmission.

CLINICAL INSIGHT

High-Risk Pregnancies with Nutritional Components

Approximately 10% of all pregnancies are considered “high risk,” meaning there is a maternal preexisting complication or a situation that antedates pregnancy or presents in the current gestation that puts the mother or the fetus at risk for a poor outcome. Many of these may include nutritional concerns as well. Women who present with the following issues need increased medical surveillance and nutrition assessment to ensure the most favorable outcomes, controlled medical costs, and the fewest complications.

Anemias: microcytic or macrocytic

Cardiovascular issues: maternal cardiac structural defects, preexisting cardiovascular disease

Endocrine issues: polycystic ovary syndrome, thyroid disease, gestational diabetes, type 1 or 2 diabetes

Functional alterations: deafness, blindness, paralysis, paraplegia, quadriplegia

Gastrointestinal issues: food allergies, celiac disease, Crohn’s disease, ulcerative colitis, postbariatric surgery, gallstones

Hyperemesis gravidarum

Hypertension: preexisting, pregnancy-induced, preeclampsia

Infections: HIV and AIDS, malaria, dental disease, intestinal parasites

Maternal genetic diseases or intellectual developmental disability

Medical problems: lupus, myasthenia gravis, cystic fibrosis, pancreatitis, phenylketonuria, cancer, sickle cell disease

Multiple fetuses

Obesity: BMI ≥ 30

Pica

Psychiatric: eating disorders, depression, bipolar disorders, Munchausen syndrome, suicidal ideation, substance abuse

Respiratory issues: asthma, tuberculosis, adult respiratory distress disorder

Surgeries: cancers, gallbladder, appendectomy, trauma

Young age—teenagers

All nutrients are thought to be important, although some are better studied than others. Table 14.1 lists some potential functions. However, more complex interactions involving multiple functions are also likely critical. For example, multiple nutrients are involved in the creation of bone (see Chapter 23) and brain (Table 14.7). When either macro- or micronutrients are lacking, the timing of the deficit is important in predicting the impact of that insult (Monk et al, 2013). When critical periods are missed, the damage will be irreversible, even if the nutrient supply later appears adequate (Georgieff et al, 2015). Nutrients known to have critical or sensitive periods include protein, LCPUFAs, glucose, iron, zinc, copper, iodine, selenium, and vitamins B₆, B₁₂, A, K, folate, and choline. In the case of fetal neurodevelopment, the younger the brain, the more it is able to recover from an insult. However, the brain is not a homogenous organ and does not develop in a single trajectory, so the specific risks depend on the region of the brain as well as the timing, dose, and duration of the perturbation (Georgieff et al, 2015; Georgieff, 2017).

Effects of Nutritional Status on Pregnancy Outcome Fetal Growth and Development

In the early 1900s U.S. women with poor nutritional status had adverse pregnancy outcomes with hemorrhage at delivery, prolonged labor, and LBW infants, conditions still of concern today in many developing countries. Because of blockades during World War II, previously well-nourished Dutch populations were exposed to severe food restrictions for 6 months, with available rations as low as 500 kcals/day (Lumey et al, 2007). Higher rates of miscarriage (spontaneous abortion [SAB]), stillbirths, neonatal deaths, and congenital malformations were noted in offspring born to women who conceived during the famine. Surviving infants were smaller if exposed to famine late in gestation (Roseboom et al, 2011). Similar findings have been found in other countries as well. In addition, individuals may be at higher risk of undernutrition because of preexisting medical conditions or because of either physical or cultural limitations on food availability.

Even if a mother is not starving, the developing fetus may be unable to obtain optimal nutrients from someone who is compromised nutritionally, resulting in growth restriction. The causes of IUGR are many and include maternal, fetal, and placental factors (Box 14.2). Infants born with LBW (<2500 g), especially those with very LBW (<1500 g), are at higher risk for **perinatal mortality** (infant death occurring between 28 weeks of gestation and 4 weeks postpartum). Babies who are born with LBW may suffer from necrotizing enterocolitis, respiratory distress syndrome, intraventricular hemorrhage, cerebral palsy, or retinopathy of prematurity (see Chapter 41).

In addition to fetal growth restriction, any adverse maternal condition, including poor nutritional status, puts the fetus at risk for being delivered preterm. Prematurity leads to increased risk of neonatal morbidity and mortality, especially if the baby is also growth restricted. Preterm delivery rates are rising in developed countries and are higher in the United States than in Europe (Bloomfield, 2011). In the United States rates are highest among non-Hispanic black women, and it is unclear if early fetal developmental programming is playing a role. Preterm delivery rates are higher with ART, among both singletons and multiples, possibly explained in part by the underlying medical conditions that also increase infertility (ACOG, 2016a).

Although obesity does not predict optimal nutrition, it is somewhat protective for preterm delivery. However, prepregnant underweight, combined with low weight gain during pregnancy, has an additive effect on preterm delivery and LBW risk. Even for those women of normal weight, low weight gain doubles the risk of preterm delivery, while weight loss triples the risk (Bloomfield, 2011). Short interconceptional periods are associated with increased rates of preterm births. In a recent study, those women who were underweight, with an interconceptional period of less than 6 months, and who had inadequate weight gain had an increased risk of nearly 3.5 times, resulting in over 25% rate of preterm delivery (Lengyel et al, 2017).

TABLE 14.7 Key Nutrients for Fetal and Neonatal Brain Development

Nutrient	Function in Brain Development	Negative Effect of Deficiency
Long-chain polyunsaturated fatty acids, primarily DHA and AA	Cell membrane formation, myelin, synaptosomes, intracellular communication, signal transduction	Neurodevelopment, visual development
Protein	Neuronal and glial structural proteins, synaptic structures and numbers, neurotransmitter peptide production especially in cerebellum, hippocampus, and cerebral cortex	Overall central nervous system growth, neurodevelopment
Zinc	Cofactor in enzymes mediating protein and nucleic biochemistry, growth, gene expression, neurotransmitters, especially affecting cerebellum, limbic system, cerebral cortex, temporal lobe, frontal lobe	Attention, motor development delays, short-term memory, brain growth
Iron	Myelination, dendritogenesis, synaptogenesis, neurotransmission, especially in the hippocampus, striatum, frontal cortex	Global intelligence, general motor development, neurodevelopment, attention, memory, language, auditory recognition
Choline	Methylation, myelin, neurotransmitters, especially affecting hippocampus, septum, striatum, anterior neocortex, midposterior neocortex	Visual spatial and auditory memory in rodents (no information yet available for humans)
Copper	Iron transport, antioxidant activity, neurotransmitter synthesis, neuronal and glial energy metabolism, especially affecting cerebellum	Motor control, cognitive function
Iodine	Thyroid synthesis, neuronal synthesis, myelination	Cognitive function
Vitamin A	Structural development, antioxidant	Visual function
Folate	One-carbon metabolism	Neural tube development

BOX 14.2 Potential Causes of Intrauterine Growth Restriction (IUGR)

Maternal Factors

Medical conditions: chronic hypertension, preeclampsia (early in gestation), diabetes, systemic lupus erythematosus, chronic kidney disease, inflammatory bowel disease, severe lung disease, cancer, hyperemesis gravidarum

Infections: syphilis, toxoplasmosis, cytomegalovirus, rubella, hepatitis B, herpes simplex virus 1 or 2, HIV-1, *Helicobacter pylori*, malaria

Malnutrition: low prepregnant weight; small maternal size; poor weight gain (especially in the last half of pregnancy); obesity (especially if combined with weight loss); nutrient deficiencies, including protein, vitamins A, B's, C, folic acid, zinc, calcium, iron; recent history of pregnancy; high parity; multiple pregnancy; history of IUGR; active eating disorders

Social conditions: very young age; poverty; lack of food because of war, famine, natural disasters (earthquake, tsunami); physical or mental abuse; substance abuse (cigarettes, alcohol, heroin, cocaine); exposure

to teratogens; exposure to therapeutic medications (antimetabolites, warfarin, phenytoin)

Fetal Factors

Genetic: race, ethnicity, sex, genetic disorders

Parity: first baby often weighs less than subsequent siblings

Chromosomal anomalies: chromosomal deletions; trisomy 13, 18, 21

Congenital malformations: anencephaly, gastrointestinal atresia, Potter syndrome, pancreatic agenesis

Placental Factors

Placental insufficiency: reduced blood flow, impaired transfer of nutrients

Anatomic problems: multiple infarcts, aberrant cord insertions, umbilical vascular thrombosis and hemangiomas, premature placental separation, small placenta

Adapted from Alisi A et al: Intrauterine growth retardation and nonalcoholic fatty liver disease in children, *Int J Endocrinol* 2011;269853, 2011; Wu G et al: Biological mechanisms for nutritional regulation of maternal health and fetal development, *Paediatr Perinat Epidemiol* 26:4, 2012a.

Oxidative stress, metabolic stress, and inflammation may all be important factors in increasing risk of preterm delivery, and it appears that periconceptual malnutrition is more important than nutrition later in pregnancy. Those women who are still growing or who have eating disorders may have competition for nutrients. Supplementation with macronutrients may be helpful, but there are no preconceptional studies. Supplementation with LCPUFAs, protein, and vitamins E and C are not effective (ACOG, 2012). Although no ideal diet has been identified, one containing fruits, vegetables, whole grains, and fish has been observed to be associated with lower risk of preterm delivery. Probiotics might be helpful (Englund-Ögge et al, 2014) and smoking cessation is helpful (ACOG, 2012). Particular toxins may increase the risk of prematurity. One study found nearly double the risk of preterm delivery if women consumed more than four servings of diet soda per day (Bloomfield, 2011), although that finding has been disputed (La Vecchia, 2013). Licorice (*Glycyrrhiza glabra* root) blocks the enzyme that inactivates cortisol, and the effect on preterm delivery risk is dose-related. Similar results are seen when the mother is exposed to psychological stress (see *Clinical Insight: Stress during Pregnancy*). The role of paternal nutrition in preterm delivery risk is unexplored (Bloomfield, 2011).

The effect of poor maternal nutrition or exposure to toxins may follow the infant for decades. A very preterm, growth-restricted baby may suffer permanent brain damage. **Neural tube defects (NTDs)** may cause lifelong problems with mobility and bodily functions. Fetal alcohol syndrome (FAS) is a major cause of intellectual developmental disability. However, even those babies who are born with no apparent defects may suffer increased risk of chronic diseases because of a less-than-optimal prenatal environment. See Fig. 14.3 for a summary of the effects of maternal malnutrition.

Epigenetic Effects

Compromises in structural or cognitive potential may not be evident when an infant is born but may manifest later in life. A child with IUGR, often resulting from maternal hypertension or severe malnutrition or anemia, may have permanent mild neurodevelopmental cognitive abnormalities. Babies born preterm or growth restricted are more likely to have a higher risk of obesity, type 2 diabetes, hypertension, and cardiovascular disease (CVD) later in life (Simeoni et al, 2018). Those babies exposed to the Dutch famine early in gestation were at highest risk of CVD and had double the risk for schizophrenia, as well as an increased risk of stress sensitivity and breast cancer. Those

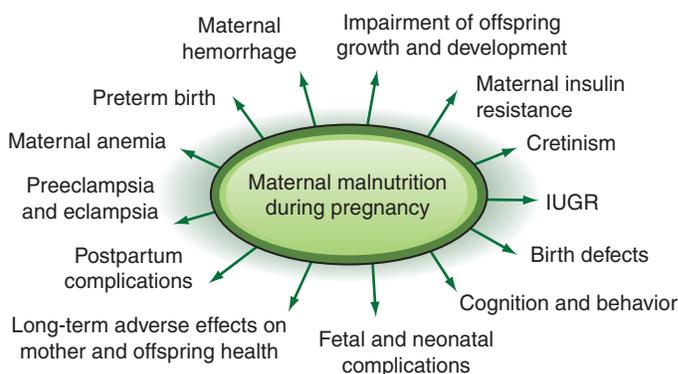

Fig. 14.3 Major negative effects of maternal malnutrition (both under- and overnutrition) on mother and infant.

exposed midpregnancy were three times more likely to develop microalbuminuria and decreased creatinine clearance, as well as having an increased risk for obstructive airway disease; growth restriction was common among those affected in the later trimesters (Roseboom et al, 2011; Matusiak et al, 2014).

Girls born preterm are more likely to deliver preterm with their own pregnancies and more likely to develop anorexia nervosa (Bloomfield, 2011). Immune function, learning ability, mental health, cancer, and aging are likely affected by LBW. Functional neural pathways controlling appetite and satiety likely develop in the third trimester, so preterm infants may experience disruptions in their development.

Those babies born **large for gestational age (LGA)** or exposed to maternal hyperglycemia or maternal obesity are at increased risk of chronic diseases, likely through multiple mechanisms (see *Focus On: Special Case of Obesity*).

Birth weight may not be the only predictor for the propensity for adult disease. Exposure to high folate during pregnancy is associated with insulin resistance and obesity in later life if combined with low vitamin B₁₂ levels, and increased rates of cancer are associated with supraphysiologic intakes of methyl donors (Milagro et al, 2013; see Chapter 6). Maternal and paternal nutritional imbalances are likely to increase the risk of metabolic syndrome (DelCurto et al, 2013).

Exposure to endocrine-disrupting chemicals (substances found in the environment that interfere with the synthesis, metabolism, or action

of the body's hormones) may modify gene expression and the effects, including increased risk of obesity, insulin resistance, and type 2 diabetes, may be nonlinear (i.e., low doses may be more harmful than high doses) (Barouki et al, 2012). In one study, mothers who ate an unbalanced high-protein diet (1 pound red meat/day, no carbohydrate) during late pregnancy produced offspring who experienced higher cortisol levels when exposed to stress as adults (Bloomfield, 2011).

This developmental plasticity can be helpful. However, when there is a mismatch between in utero programming and the later environment, the risk of chronic disease rises. A fetus may develop a “thrifty phenotype,” adapting to poor nutritional conditions by being more efficient in acquiring and conserving energy. However, when later exposed to an environment with higher availability, this “thrifty” adaptation may predispose the offspring to the diseases of affluence, including obesity and type 2 diabetes. In addition, harm may also be caused by overcompensation later with excessive catch-up growth. Altered organ structure, cell numbers, and metabolic functioning, including premature aging of tissues, all appear important (Burton et al, 2016).

Exposure of the embryo or fetus to specific maternal nutrients, as well as environmental contaminants, can turn the imprinting genes that control growth and development on or off, but the amounts, timing, and effects are still being investigated. Paternal nutrient imbalance and gene-environment interactions are also likely important (Barouki et al, 2012; DelCurto et al, 2013). Although the concept of the DOHaD originally focused on undernutrition, overnutrition also is being studied. Effects of macro- and micronutrients, as well as phytonutrients and hypoxia, are being examined, primarily through animal studies so far, and the ideal maternal and paternal diet for epigenetic effects has not yet been established (Vanhees et al, 2014). It appears that the epigenetic effect of preconceptual obesity is stronger for maternal than paternal obesity (Godfrey et al, 2017b). However, the paternal diet before conception does appear to affect the offspring epigenetically and there is evidence that the sperm epigenome is rapidly remodeled after weight loss following bariatric surgery (Block and El-Osta, 2017). Parental diet, body composition, metabolism, and stress exposure all appear important, but the effects are sex-specific. Mechanisms include epigenetic, cellular, physiologic, and metabolic changes (Fleming et al, 2018).

New research also is focusing on the grandchildren of people affected by the Dutch famine (Roseboom et al, 2011) to document the long-term epigenetic effects (Fig. 14.4). Preliminary results show that under- and overnutrition are important issues, but there are differences in response by sex, and the timing of the insult matters (Vanhees et al, 2014; Preston et al, 2018).

The preconceptional nutritional role in altering the epigenome is still being actively explored. Animal research shows components of a preconceptional diet may resolve toxicant epigenetic changes (Owen et al, 2013). Maternal and paternal weight and nutritional status, as well as that of previous generations, are likely important in affecting, and being affected by, genetic variations. Because of the increased appreciation for the periconceptional effects on the lifetime health of the offspring, there are calls for much better guidance and parental preparation before conception (Fleming et al, 2018) (see Chapter 6).

Nutrient Requirements During Pregnancy

Nutrition during pregnancy often is equated with weight gain because weight is most easily and consistently measured. However, maternal weight gain is not necessarily predictive of health outcomes, especially for heavier women. In general, although the mother needs to eat a little more when she is pregnant or breastfeeding, she needs to eat more carefully because most nutrient requirements increase more during pregnancy and lactation than do the calorie requirements (Fig. 14.5). The U.S. dietary reference intakes (DRIs) are found on the inside cover. Estimated requirements during pregnancy and lactation vary between countries (see additional information on the Evolve website for recommendations from WHO and 16 governments or regions worldwide) but there is a call to improve the consistency in the development of these values across cultures (National Academies of Sciences, Engineering, and Medicine, 2018). For most nutrients, there is little guidance by trimester or for pregnancies with more than one fetus.

Energy

Additional energy is required during pregnancy to support the metabolic demands of pregnancy and fetal growth. Metabolism increases by an average of 15% in the singleton pregnancy, but with wide variability especially in the third trimester. The DRI for energy increases by only 340 kcal/day during the second trimester and by 452 kcal/day in the third trimester. If maternal weight gain is within the desirable limits, the range of acceptable energy intakes varies widely, given large individual differences in energy output and basal metabolic rate. Modifying intakes to achieve recommended weight gain (see [Pregnancy Weight Gain Recommendations](#)) is more useful than calculating caloric requirements.

Exercise. Energy expended in voluntary physical activity is the largest variable in overall energy expenditure. Physical activity increases energy expenditure proportional to body weight. However, most pregnant women compensate for increased weight gain by slowing their

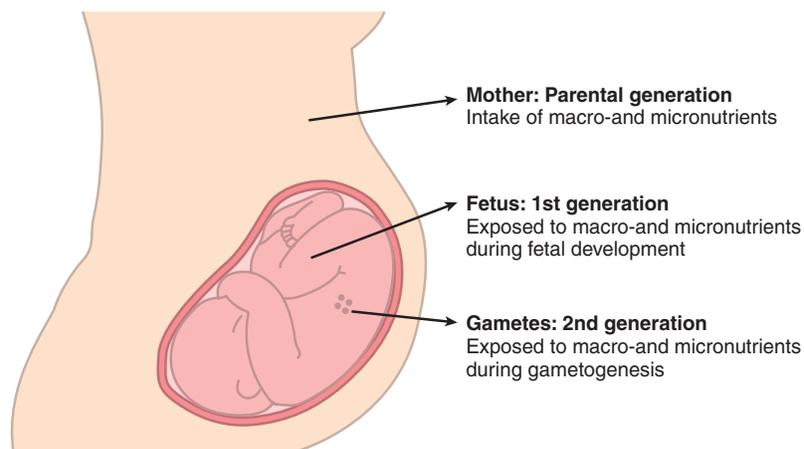

Fig. 14.4 Transgenerational inheritance of epigenetic modifications induced by exposure to macro- and micronutrients. (Adapted from Vanhees K, Vonhögen IG, van Schooten FJ et al: You are what you eat, and so are your children: the impact of micronutrients on the epigenetic programming of offspring, *Cell Mol Life Sci* 71:271, 2014.)

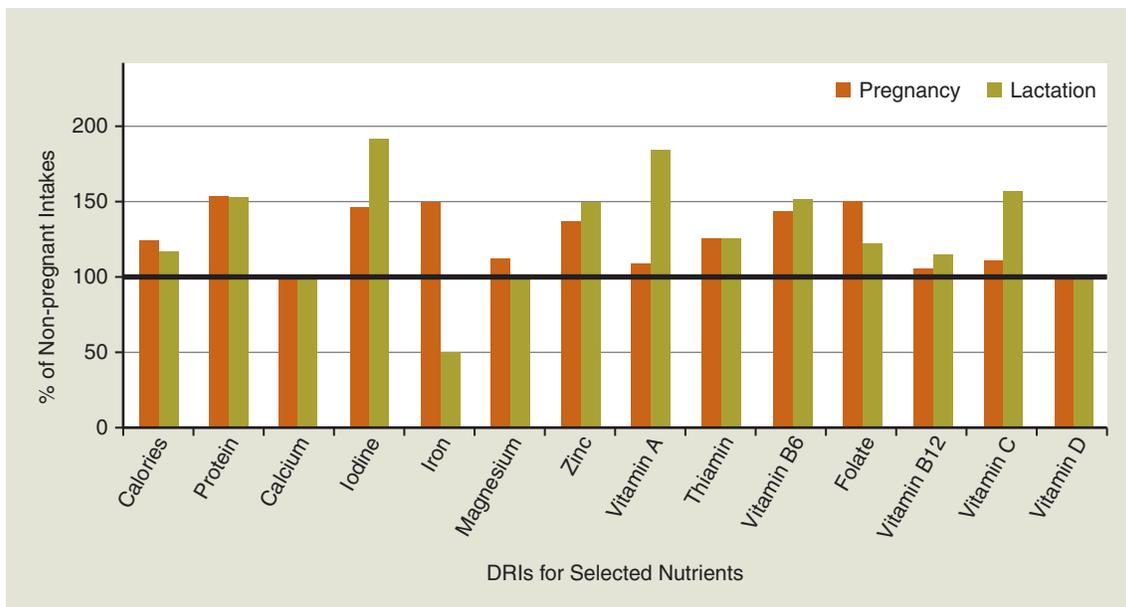

Fig. 14.5 Percent of nonpregnant DRIs for selected nutrients for pregnancy and lactation. Calculations are based on a 25-year-old woman (65 inches, 126 pounds prepregnant weight), pregnant with a singleton in the third trimester and lactation in the first 6 months.

work and movement pace. Therefore total daily energy expenditure may not be substantially greater than before pregnancy.

The ACOG recommends at least 20 to 30 minutes of moderate intensity exercise on most, if not all, days for pregnant women without contraindications (ACOG, 2015a). Short duration strenuous exercise appears un concerning, but the impact of long duration strenuous exercise on the fetus is unknown (Szymanski and Satin, 2012). Elite athletes may need to modify their exercise routines (Bø et al, 2018). Excessive exercise, combined with inadequate energy intake, may lead to suboptimal maternal weight gain and poor fetal growth. Therefore a pregnant woman should always discuss exercise with her health practitioner. Although there is limited evidence that exercise helps modify gestational weight gain, there is also no evidence of harm and in observational studies exercise has been associated with lower risk of gestational diabetes, pregnancy-induced hypertension, and preeclampsia (Seneviratne et al, 2015). The effect of maternal exercise on offspring susceptibility to chronic diseases is being explored in animal research but results are mixed and the type, timing, intensity, and dose of optimal exercise are all unknowns (Blaize et al, 2015). However, not all epigenetic effects may be positive. There is limited evidence that excessive paternal exercise is associated with an offspring's thrifty phenotype (Dhasarathy et al, 2017).

Protein

Additional protein is required to support the synthesis of maternal and fetal tissues. This demand increases throughout gestation and is maximized during the third trimester. Caution is advised when reading the DRI tables. The baseline protein RDA of 0.8 g/kg current body weight/day for pregnant women is 46 g only for someone with a prepregnant weight of 126 pounds. The protein calculation in the first half of pregnancy is the same as that for nonpregnant women but the required intake increases as weight increases. The RDA calculation increases in the second half of pregnancy to 1.1 gm/kg current body weight/day. This would be 71 g/day only for that same reference woman who is also gaining weight appropriately. For many women, the protein requirement

is higher. For each additional fetus, the Institute of Medicine (IOM) recommends an additional 50 g/day starting in the second trimester (Otten et al, 2006), but because protein is also used as an energy source, the total may be as much as 175 g/day for the normal-weight woman carrying a twin gestation who is consuming 3500 kcal/day (Goodnight and Newman, 2009).

The WHO uses slightly different calculations. They also calculate a baseline requirement using current body weight. However, the estimates of increased needs are presented as standard amounts/day for everyone. The 2007 recommendations are designed to support a total 13.8 kg weight gain. However, some researchers recommend the older (1985) and more conservative guidelines (Millward, 2012) (Table 14.8).

There is concern that nitrogen balance studies may underestimate protein needs, especially when considering that the increased requirements of specific amino acids may be disproportionately higher according to animal research (Elango and Ball, 2016). There is some call to increase protein requirements, including increasing the protein intake earlier in pregnancy. Recent research found optimal intake was 1.2 g/kg/day at 16 weeks and 1.52 g/kg/day at 36 weeks when estimated by indicator amino acid oxidation. However, the method is not universally accepted and further research is necessary. Protein deficiency during pregnancy has adverse consequences, including poor fetal growth. Protein also is involved in the synthesis of hormones and neurotransmitters. Limited intakes of protein and energy usually occur together, making it difficult to separate the effects of energy deficiency from those of protein deficiency. Although most women in the United States likely eat more than enough protein, there are some for whom particular attention must be paid, including those consuming a vegetarian diet, those who are still growing themselves, or those who are pregnant with multiples. The optimal balance of protein to total calories has yet to be determined and recommendations, as well as intakes, vary across cultures (Blumfield and Collins, 2014). Caution is advised when considering very high protein supplements. Intakes at the high end of the acceptable macronutrient distribution ranges (AMDR) (i.e., 30% to 35% of calories from protein) have been associated with an increased risk of poor fetal growth in some

TABLE 14.8 Protein Intake Recommendations

	Prepregnancy	First Trimester	Second Trimester	Third Trimester	Notes
U.S. DRIs	0.8 g/kg current body weight/day	0.8 g/kg current weight/day	1.1 g/kg current weight/day starting in the second half of pregnancy	1.1 g/kg current weight/day	
WHO, 2007	0.83 g/kg current body weight/day	Baseline + 0.7 g/day	Baseline + 9.6 g/day	Baseline + 31.2 g/day	
WHO, 1985	0.83 g/kg current body weight/day	Baseline + 1.2 g/day	Baseline + 6.1 g/day	Baseline + 10.7 g/day	Average increase 6 g/day above baseline requirements

Adapted from Millward DJ: Identifying recommended dietary allowances for protein and amino acids: a critique of the 2007 WHO/FAO/UNU report, *Br J Nutr* 108(Suppl 2):S3, 2012.

studies, although the mechanism is unclear. Current U.S. practice often targets protein intakes at 20% of total calories, possibly higher for multiples. WHO recommends 23% of calories come from protein (Millward, 2012). Supplementation, if necessary, should be done with food rather than with protein supplements. For example, someone consuming 2240 kcal from 6 cups/day of 2% milk, 8 oz of meat, six servings of starch, three vegetable servings, two fruit servings, and six fat servings gets 23% of calories from protein (128 g). If using skim milk, the total is 1970 kcal with 26% from protein.

Carbohydrates

The RDA for carbohydrates increases slightly, helping maintain appropriate blood glucose and prevent ketosis. Intakes may be greater in women consuming more calories, but careful carbohydrate choices are needed to include all the daily nutrients for pregnancy. Priority should be given to complex carbohydrates from whole grains, fruits, and vegetables rather than just simple sugars, including refined liquid sugars, whether natural (juices) or industrially produced (soda).

Fiber

Daily consumption of whole-grain breads and cereals, leafy green and yellow vegetables, and fresh and dried fruits should be encouraged to provide additional minerals, vitamins, and fiber. The DRI for fiber during pregnancy is 14 g/day/1000 kcal and, if met, will help a great deal in managing the constipation that often accompanies pregnancy.

Lipids

As with nonpregnant women, there is no DRI for total lipids during pregnancy. The amount of fat in the diet should depend on energy requirements for proper weight gain. However, recommendations for omega-6 polyunsaturated fatty acid (PUFA) (linoleic acid) and omega-3 PUFA (alpha-linolenic acid) increase slightly. Although not a DRI, the recommended intake of DHA is 200 mg/day and can be met by one to two portions of fish per week (Carlson et al, 2017) (see *Focus On: Omega-3 Fatty Acids in Pregnancy and Lactation*).

Vitamins

All vitamins and minerals are needed for optimal pregnancy outcome. In some instances requirements may be met through diet. For others a supplement, started preconceptionally, is often necessary. Many, but not all, vitamin and mineral recommendations increase with pregnancy, but the magnitude of the increase varies by nutrient (see the DRI tables on the inside cover and Fig. 14.5).

Folate. The RDA for dietary folate equivalents increases to support maternal erythropoiesis, DNA synthesis, and fetal and placental

growth. Low folate levels are associated with miscarriages, LBW, and preterm birth. Early maternal folate deficiency is associated with an increased incidence of congenital malformations, including NTDs, orofacial clefts, and congenital heart defects (Obeid et al, 2013). Approximately 3000 new cases of NTDs occur in the United States annually and over 300,000 babies are born worldwide with NTDs (CDC, 2018a), but prevalence varies widely, from 6.9/10,000 births in the Western Pacific to 21.9/10,000 births in the Middle East (ACOG, 2017b). Although spina bifida and anencephaly are the most common, other NTDs can also occur (Table 14.9). The neural tube closes by 28 days of gestation, before most women realize they are pregnant. In addition, more than half of all U.S. pregnancies are unplanned. Therefore the CDC recommends that all women of childbearing age, in anticipation of possible pregnancy, increase their intake of folic acid by 400 mcg/day, the synthetic version that is available in supplements and fortified foods, especially some breakfast cereals (CDC, 2018a). The U.S. Preventive Services Task Force (USPSTF) recommends 400 to 800 mcg/day of folic acid preconceptionally. Women who have had a previous NTD-affected pregnancy should consume 400 mcg/day when not planning to conceive and those planning pregnancy should consider 4000 mcg/day (4 mg/day) from 3 months before to 3 months after conception (ACOG, 2017b). Other situations that may merit the higher supplementation levels include women who have an NTD themselves, whose partner has an NTD, or whose partner has a previously affected child. These higher doses should be taken as a separate supplement and not as part of a multivitamin supplement to avoid excess intakes of other nutrients in the multivitamin. Although this level is recommended by many medical providers, there are calls to reevaluate these higher recommendations because of evidence that the lower doses may be equally effective in preventing recurrent NTDs (Dolin et al, 2018). Supplementation recommendations vary by country (Moussa et al, 2016) and may take the genetic susceptibility to low folate status into account (Colson et al, 2017) so local guidelines should be followed. Although the 800-mcg dose achieves recommended blood levels in 4 weeks, the 400-mcg dose requires 8 to 12 weeks to reach these levels (Berti et al, 2011). Also available is 5-methyltetrahydrofolate, the primary circulating form of folate. It is proposed to be better used, especially by those with polymorphisms (see Chapter 6), and without the detrimental rise in unmetabolized folic acid. However, its role in preventing NTDs or other birth defects is untested in clinical trials (Obeid et al, 2013). In addition, concern about unmetabolized folic acid may be unwarranted in some cases, as it was found to be undetectable if pregnant women took 400 mcg/day throughout the pregnancy, in addition to consuming 100 mcg/day from fortified grains, even among those with the C677T polymorphism

TABLE 14.9 Neural Tube Defects

Neural Tube Defect	Malformation
Cranial	
Anencephaly	Failure of fusion of cephalic portion of neural folds; absence of all or part of brain, skull, and skin
Encephalocele	Failure of complete skull formation; extrusion of brain tissue into membranous sac
Exencephaly	Failure of scalp and skull formation; exteriorization of abnormally formed brain
Iniencephaly	Defect of cervical and upper thoracic vertebrae; abnormally formed brain tissue and extreme retroflexion of upper spine
Spinal	
Craniorachischisis	Coexisting anencephaly and open neural tube defect, often in the cervical–thoracic region
Holorachischisis	Failure of fusion of vertebral arches; entire spinal cord exposed
Meningocele	Failure of fusion of caudal portion of neural tube; meninges exposed
Myelomeningocele	Failure of fusion of caudal portion of neural tube; meninges and neural tissue exposed
Myeloschisis	Failure of fusion of caudal portion of neural tube; flattened mass of neural tissue exposed
Spina bifida	Failure of fusion of caudal portion of neural tube, usually of 3-5 contiguous vertebrae; spinal cord or meninges, or both, exposed to amniotic fluid

Adapted from American College of Obstetricians and Gynecologists Committee on Practice Bulletins-Obstetrics: Practice Bulletin No. 187: Neural Tube Defects, *Obstet Gynecol* 130:e279, 2017b.

(Pentieva et al, 2016). The impact of higher doses of folic acid causing higher, and concerning, levels of unmetabolized folic acid is not well-established but is being studied (Plumprtre et al, 2015).

Red blood cell folate levels exceeding 906 nmol/L (400 ng/mL) have been associated with the fewest NTDs (Obeid et al, 2013), although the mechanism of folic acid is still unknown (ACOG, 2017b). Natural folate is less bioavailable and has not been shown to raise blood levels as well as the synthetic folic acid or to lower the risk of NTDs. Although theoretically natural folate could be effective, 6 to 12 cups of raw spinach (more than 2 cups cooked) daily is the bioequivalent level of natural folate that is found in one bowl of fortified breakfast cereal. Look for 100% of the daily value/serving.

Women who are obese or who smoke, consume alcohol moderately or heavily, or use recreational drugs are at risk for marginal folate status, as are those with malabsorption syndromes or genetic differences related to methylation and the metabolic use of dietary folate, including the estimated 11% of the U.S. population with the MTHFR 677 C to T variation (Caudill, 2010). European prevalence is estimated to be 10% to 22% (Obeid et al, 2013), but not all populations with the C677T polymorphism show higher rates of NTDs (ACOG, 2017b). Other polymorphisms are also being investigated for increased risk for NTDs. Although increased folate intake may be helpful in some situations, added riboflavin also may be beneficial (see Chapters 5 and 6).

Women using antiseizure medications must be monitored closely when starting folic acid because it can reduce their seizure control.

Enriched grain products in the United States are fortified with folic acid and are estimated to provide an average 200 mcg/day, with resulting higher blood folate levels and reduced (19% to 54%) NTD rates (Caudill, 2010). However, with the increased popularity of the low carbohydrate diets, estimated intake has been reduced recently and is associated with increased risk of NTDs (Desrosiers et al, 2018). Because NTD rates remain higher among the Hispanic population in the United States, fortification of corn masa flour is now approved by the FDA but implementation is voluntary and not widespread.

Over 70 countries now fortify grain products but this fortification is not universally practiced because of concerns about exposing the entire population to extra folic acid. Possible adverse effects of increased folic acid intake include masking of vitamin B₁₂ deficiency, tumor promotion, epigenetic hypermethylation, interference with antifolate treatments, and an increase in miscarriages and multiple births. Widespread problems have not been seen. However, high intakes of folic acid also have potential epigenetic effects, but data are fragmentary and sometimes conflicting. Caution is advised with the use of pharmacologic doses. For example, although some studies have seen no negative effects on DNA methylation at doses up to 4000 mcg/day (Crider et al, 2011), other studies have found that, in the context of low vitamin B₁₂ status, supplementing pregnant women with just 500 mcg/day was associated with an increased risk of diabetes among the women (Paul and Selhub, 2017) and of offspring adiposity and insulin resistance at age 6 (Yajnik et al, 2008).

On the other hand, adequate folic acid in the second trimester may decrease inflammation, and folate status is associated inversely with the severity of bacterial vaginosis, a documented risk factor for pre-term delivery (Dunlop et al, 2011). Murine studies have found that the negative effect of maternal exposure to bisphenol-A is effectively neutralized by maternal supplementation with folic acid, betaine, and choline (Guéant et al, 2013). Supplementation with methyl donors, such as folic acid, also may reduce the harmful effects of fumonisin (a mycotoxin produced by *Fusarium* molds that grow on agricultural commodities, especially corn, that has been associated with increased risk of NTDs) contamination. Spermatozoid folate deficiency among men exposed to dioxins may increase the risk of spina bifida in their offspring. Supplementation during early pregnancy (at least 800 mcg/day) may reduce the risk of autism spectrum disorders after prenatal exposure to pesticides (Schmidt et al, 2017).

While folic acid supplementation does not completely eliminate the risk of NTDs, up to 70% of NTDs could be prevented with the periconceptual use of 400 mcg folic acid/day (ACOG, 2017b). Optimal levels of other methyl donors (B₂, B₆, B₁₂, and choline) and inositol may also lower the risk of NTDs and improve birth weight. There is speculation that paternal folate deficiency might also explain part of the residual risk of NTDs (Guéant et al, 2013).

Vitamin B₆. Pyridoxine functions as a cofactor for many decarboxylase and transaminase enzymes, especially those involved in amino acid metabolism. Although this vitamin catalyzes a number of reactions involving neurotransmitter production, it is not known whether this function is involved in the relief of nausea and vomiting. Because meat, fish, and poultry are good dietary sources, deficiency is not common, and routine prenatal vitamins contain sufficient amounts (Hovdenak and Haram, 2012). Regarding nausea and vomiting, standard doses of 10-25 mg three to four times per day (ACOG, 2018b) have questionable efficacy but do not appear to be dangerous.

Vitamin B₁₂. Cobalamin is required for enzyme reactions and for generation of methionine and tetrahydrofolate. It is important in growth and development, including immune function (Wu et al, 2012a).

Vitamin B₁₂ is naturally found exclusively in foods of animal origin, so vegetarians, especially vegans, are at risk for dietary vitamin B₁₂ deficiency and should consume fortified foods or supplements. Also at risk are those people with malabsorption, including those with Crohn's disease involving the terminal ileum, women who have had gastric bypass surgery, and those using proton pump inhibitor medications (see Chapters 26 and 27). People taking metformin also may be at risk. Deficiencies in folate and vitamin B₁₂ have been related to depression in adults. Inadequate amounts of folate and B₁₂ may negatively affect infant cognitive and motor development as well as increase the risk of NTDs and inadequate fetal growth.

Choline. Choline is needed for structural integrity of cell membranes, cell signaling, and nerve impulse transmission and is a major source of methyl groups. Choline and folate are metabolically interrelated. Both support fetal brain development and lower risk of NTDs and orofacial clefts (Zeisel, 2013). Animal studies show choline is neuroprotective after prenatal alcohol exposure (Blusztajn et al, 2017). Maternal supplementation during the third trimester was recently seen in a small study to improve the offspring's information processing speed (Caudill et al, 2018). While 480 mg/day was helpful, 930 mg/day produced larger effects. Preliminary animal data shows prenatal supplementation with choline may be helpful in minimizing the harm caused by iron deficiency by helping restore some of the neural plasticity (Georgieff et al, 2015). Choline also appears to be important in placental functioning, including playing a role in the remodeling of the spiral arteries, and may affect maternal and fetal responses to stress. The DRI for choline increases slightly during pregnancy and there are calls for it to be reexamined and possibly raised (Caudill et al, 2018). Genetic variations and concurrent intakes of folate and methionine may affect requirements, and de novo synthesis may not meet fetal and maternal needs (Zeisel, 2013). Choline-rich foods include milk, meat, and egg yolks, and women not eating these foods may need supplementation (see Appendix 32). Many popular prenatal supplements do not contain choline or, if so, contain very little (25 to 50 mg) (Zeisel et al, 2018). Large supplemental doses may cause GI discomfort, but a small study using 750 mg during pregnancy did not identify adverse effects (Zeisel, 2013).

Vitamin C. The DRI for vitamin C increases during pregnancy and may be even higher for those who smoke, abuse alcohol or drugs, or regularly take aspirin. Daily consumption of good food sources should be encouraged. Low plasma levels are associated with preterm labor (Dror and Allen, 2012), possibly because of its antioxidant function or its role in collagen synthesis. However, supplemental vitamin C is not recommended for the prevention of premature rupture of membranes (PROM). Previously supplementation with vitamin C (1000 mg) along with vitamin E (400 IU) was promoted for the possible prevention of preeclampsia. However, it is not currently recommended (ACOG, 2013c) and actually may increase risk of gestational hypertension and PROM. Vitamin C is actively transported across the placenta, so there is also potential for excessive levels in the fetus (Dror and Allen, 2012).

Vitamin A. Vitamin A is critical during periods of rapid growth and important in cellular differentiation, ocular development, immune function, and lung development and maturity as well as gene expression (Wu et al, 2012a). Low vitamin A levels are associated with IUGR and increased risk of maternal and neonatal mortality, possibly due to the protective role of carotenoids against oxidative stress (Zielińska et al, 2017). Malformations are seen in animals exposed to deficiencies, but confirmation of human malformations has not been well-established. However, a recent case report demonstrated that vitamin A deficiency following bariatric surgery resulted in recurrent fetal and neonatal losses, with preterm delivery, pulmonary hypoplasia, and

microphthalmia in the surviving fetuses (Mackie et al, 2018). Among women positive for human immunodeficiency virus (HIV), improved vitamin A status is associated with improved birth weight, possibly by improving immunity (Hovdenak and Haram, 2012).

Excess preformed vitamin A is teratogenic, so high intake is of most concern in the first trimester. Supplementation is usually not necessary and is often limited to 5000 IU/day, although doses up to 10,000 IU/day are not associated with increased risk of malformations (Hovdenak and Haram, 2012). The acne medication isotretinoin is a vitamin A analog, and exposed fetuses are at extremely high risk for fetal anomalies and miscarriages. Women should stop its use for at least 1 month before conception. Other retinoids (tretinate, acitretin) would also be of concern (Harris et al, 2017). Beta-carotene is not associated with birth defects.

Although no cases have been seen, theoretically someone eating liver could consume as much preformed vitamin A as has been associated with fetal anomalies, so large amounts of liver, liver pâté, and liverwurst or braunschweiger are not recommended in the first trimester. Although guidance from some countries recommends avoiding liver throughout pregnancy because of its vitamin A content, ACOG does not. The vitamin A content of the livers from different animals varies considerably. Acute vitamin A poisoning has been documented with the livers from seals, whales, polar bears, and multiple species of saltwater fish, especially from the tropics (Dewailly et al, 2011). All of these livers should be avoided. Fish liver oils (halibut, shark, and cod) are also very high in vitamin A and should be avoided (McLaren and Kraemer, 2012). Livers from sheep and ox contain very high levels, as do all livers of animals fed feedstuffs fortified with vitamin A and all should be avoided (Scotter et al, 1992). Using data from the current U.S. Department of Agriculture (USDA) food composition tables, both veal and moose livers should be avoided. Livers from ringed seal and turkey should be very limited. Livers from other animals generally have lower vitamin A contents. Quantities eaten should be limited. Check your local food composition databases for details on the livers most commonly consumed in your area.

Vitamin D. According to the IOM, vitamin D requirements do not increase during pregnancy and intakes of 600 IU/day (15 mcg/day) are sufficient when considering bone health. The few dietary sources of vitamin D are salmon and other fatty fish, as well as some fortified breakfast cereals and mushrooms exposed to UV light, and seal and whale blubber and polar bear liver (Holick, 2017). Not all dairy products are fortified, but liquid milk is a good source, usually containing 100 IU/8 oz (see Appendix 38).

Vitamin D deficiency is recognized increasingly in dark-skinned and veiled women living in latitudes where sun exposure is low. Women who are at risk of entering pregnancy with low vitamin D levels also include those with BMI more than 30, those with fat malabsorption, and those with high use of sunblock, along with poor dietary intake. Screening for vitamin D status is advised for those women (ACOG, 2011).

Severe vitamin D deficiency is associated with congenital rickets and newborn fractures and also may manifest as seizures, although it is unknown if calcium insufficiency also plays a role (Brannon and Picciano, 2011). There is concern that low maternal vitamin D status may negatively affect fetal bone accrual. However, small studies have shown that although maternal supplementation can increase cord blood levels, there is no effect on fetal calcium, phosphorus, parathyroid hormone (PTH), or skeletal parameters (Kovacs, 2012). A recent study found no association between maternal vitamin D status and her offspring's bone mineral content at ages 9 to 10 years (Lawlor et al, 2013).

Vitamin D metabolism changes in pregnancy, with the conversion of 25(OH)D to 1,25(OH)₂D drastically increased (Hollis and Wagner, 2017). 1,25(OH)₂D levels are 2 to 3 times nonpregnant levels by 12 weeks of gestation and keep rising throughout the pregnancy, depending on 25(OH)D availability. These levels are not associated with hypercalciuria or hypercalcemia and appear to be driven by the pregnancy itself rather than by increasing vitamin D-binding protein levels. Mechanisms are still unknown but likely include an uncoupling of renal 1- α -hydroxylase from feedback control and upregulating it twofold to fivefold for reasons other than calcium homeostasis (Kovacs, 2012). It is assumed that high 1,25(OH)₂D values increase delivery of vitamin D to maternal tissues and may modulate innate and adaptive immunity, including possibly an immunomodulatory role in preventing fetal rejection. Vitamin D may be important in regulating gene expression and in promoting successful implantation so preconceptual levels, and therefore supplementation, may be important (Hollis and Wagner, 2017). It also may have a role in preventing preeclampsia, preterm delivery, gestational diabetes, bacterial vaginosis, and the need for cesarean delivery. In addition, it may be involved in the development of the infant's immune function and development of allergy as well as other developmental programming (Brannon and Picciano, 2011), including risk of type 1 diabetes (Kovacs, 2012). However, associations are inconclusive, often contradictory and confounded, and lack causality. Although supplementation raises maternal vitamin D levels, it has not been consistently associated with improved obstetric outcomes (Roth et al, 2017). However, a recent trial found that women who achieved blood concentrations of at least 40 ng/mL had at least a 60% lower risk of preterm delivery and that the risk reduction was 78% among non-white women (McDonnell et al, 2017). Optimal serum levels of 25(OH)D during pregnancy are not yet known but must be at least 20 ng/mL (50 nmol/L) for bone health (ACOG, 2011). Other experts suggest serum levels at least 32 ng/mL (80 nmol/L) is better for pregnancy and it has been proposed that optimal levels of 1,25(OH)₂D and, therefore, optimal fetal outcomes can be achieved only with blood levels of 40 ng/mL (100 nmol/L) (Hollis and Wagner, 2017). Others propose even higher levels (Heyden and Wimalawansa, 2018). On the other hand, increased risk of growth restriction at levels exceeding 70 nmol/L and child eczema at levels exceeding 75 nmol/L also have been reported (Brannon and Picciano, 2011). Research is active and ongoing and debate is vigorous. Vitamin D supplementation may be needed to reach desired serum concentrations, although there is insufficient evidence to recommend routine supplementation and WHO recommends against it (Roth et al, 2017). A dose of 1000 to 2000 IU/day of vitamin D appears safe (ACOG, 2011). Although some researchers have found no hypercalciuria with 4000 IU/day (the tolerable upper intake level [UL]), caution is advised. In those studies, only spot checks of urine were done, not 24-hour urine collections, and there was no long-term follow-up on kidney stone formation rates (Kovacs, 2012). Very high supplementation (≥ 1000 mcg = 40,000 IU/day) has been associated with hypercalcemia, and although vitamin D does not appear to be teratogenic in the doses usually given, some animal data suggest the need for concern (Roth, 2011). The potency of vitamin D supplements is variable and many contain less than the labeled amounts (LeBlanc et al, 2013).

Current data is inconsistent, with small, low quality studies. In an attempt to answer critical questions, many trials are planned or are currently ongoing. In addition to determining the optimal serum levels, the optimal timing of supplementation and the effect of different lifestyles, body types, baseline status, the role of the placenta, and genotypes (both maternal and fetal) are all currently unknown (Hollis and Wagner, 2017; Størdal et al, 2017).

Vitamin E. Vitamin E requirements do not increase. Although deficiency is speculated to cause miscarriage, preterm birth, preeclampsia,

and IUGR, vitamin E deficiency specifically has not yet been reported in human pregnancy. Vitamin E is an important lipophilic antioxidant, but supplementation of vitamin E (along with vitamin C) is not an effective strategy for preventing preeclampsia nor does it reduce risk of fetal or neonatal loss, SGA, or preterm delivery. Supplementation actually may be proinflammatory, preventing the switch from Th1 cytokines (proinflammatory) to Th2 cytokines (antiinflammatory) that is normal during pregnancy (Hovdenak and Haram, 2012; see Appendix 36 for food sources of vitamin E).

Vitamin K. Although vitamin K requirements do not increase during pregnancy, usual diets often do not provide sufficient vitamin K, as most food sources (e.g., dark leafy green vegetables) are not consumed in recommended amounts. Vitamin K has an important role in bone health as well as in coagulation homeostasis, so adequate amounts during pregnancy are vital (see Chapter 23). Vitamin K deficiency has been reported in women who have had hyperemesis gravidarum, Crohn's disease, or gastric bypass, and a case report describes a deficiency associated with intrahepatic cholestasis of pregnancy (Maldonado et al, 2017). See Appendix 37 for sources of vitamin K.

Minerals

Calcium. Hormonal factors strongly influence calcium metabolism in pregnancy. Human placental lactogen modestly increases the rate of maternal bone turnover. Although estrogen inhibits bone resorption, accretion and resorption increase. Maternal absorption of calcium across the gut doubles during pregnancy (Kovacs, 2016). PTH often drops in North American and European women consuming adequate calcium. In areas with lower calcium diets that are also rich in phytates, PTH levels stay the same or increase and more research is necessary on the limitations of maternal response when intakes are marginal or low (Olausson et al, 2012). These changes maintain maternal serum calcium levels and promote calcium retention to meet progressively increasing fetal skeletal demands for mineralization. Fetal hypercalcemia and subsequent endocrine adjustments ultimately stimulate the mineralization process. The placenta appears to protect the developing fetus unless there is maternal hypocalcemia with severe hypoparathyroidism (Kovacs, 2015).

The net effects of pregnancy and lactation on the maternal skeleton are not yet clear. Bone mineral is mobilized during pregnancy and replenished starting in later lactation. The degree of bone changes varies considerably by site and also between individuals. It appears that genetics, endocrine responses, and nutritional factors are all important. No prospective studies have examined whether there is increased risk of osteoporosis later in life attributed to pregnancy or lactation and retrospective studies are inconsistent. Higher intakes are associated with improved calcium balance when intakes are low, but some evidence suggests that supplementation may temporarily disrupt the process of adaptation to habitually low intakes (Olausson et al, 2012).

Approximately 30 g of calcium is accumulated during pregnancy, primarily in the fetal skeleton (25 g), but there is wide variation. The remainder is stored in the maternal skeleton, held in reserve for the calcium demands of lactation. Most fetal accretion occurs during the last half of pregnancy, increasing from 50 mg/day at 20 weeks of gestation to 330 mg/day at 35 weeks (Olausson et al, 2012). There is conflicting evidence regarding whether maternal calcium intake affects a child's long-term accretion.

In addition to its role in bone formation, low calcium intake is associated with increased risk of IUGR and preeclampsia (Hovdenak and Haram, 2012). Calcium also is involved in many other processes, including blood clotting, intracellular proteolysis, and nitric oxide synthesis, and it has a role in regulating uterine contractions (Wu et al, 2012a).

The requirement for calcium during pregnancy does not increase. However, many women enter pregnancy with low intakes and often

need encouragement to increase consumption of calcium-rich foods. Dairy products are the most common sources of dietary calcium.

Milk, including extra dry milk powder, can be incorporated into foods. One-third cup of dried skim milk is equivalent to 1 cup of fluid milk. Small amounts can be added to liquid milk while much more can be added to foods with stronger flavors. Although most of the dry milk sold in the United States is nonfat, powdered whole milk is also available in the ethnic food sections of grocery stores. Yogurt is often well accepted, and using plain nonfat yogurt with fruit and minimal added sugar can maximize nutrients without providing as many extra calories. Greek yogurt, although higher in protein, may contain less calcium than regular yogurt. Although cheese can be used, often the higher calories from fat become a limiting factor. Lactose intolerance can be managed (see Chapter 25).

Soy milks are fortified with calcium, but this often precipitates to the bottom of the container. It is difficult to reincorporate the sludge, with the milk containing only 31% of the labeled amount without shaking, 59% with shaking (Heaney and Rafferty, 2006). The fortificant should be calcium carbonate for best absorption. Other drinks, including enriched rice, coconut, and nut milks, are often low in protein, and caution is advised. Regarding vegetable sources of calcium, the concern is one of quantity and bioavailability (Table 14.10; see also Appendix 39).

Care should be taken when considering the use of calcium supplements. Among nonpregnant adults, bone building is better with dietary calcium than with supplements (Booth and Camacho, 2013). Overconsumption of calcium through food is not common. However, elevated serum calcium levels can result from excess antacid ingestion if the UL is exceeded (see Heartburn).

Copper. Diets of pregnant women are often marginal in copper, and requirements rise slightly in pregnancy. In addition to primary deficiency from genetic mutation (Menkes disease), secondary deficiency (from increased zinc or iron intake, the use of certain drugs, or a history of gastric bypass surgery) is also of concern. Copper deficiency alters embryo development and induced copper deficiency has been shown to be teratogenic. There is decreased activity of cuproenzymes, increased

oxidative stress, altered iron metabolism, abnormal protein cross-linking, decreased angiogenesis, and altered cell signaling (Uriu-Adams et al, 2010). Copper interacts with iron, affecting neurocognitive and neurobehavioral development. Although not commonly included in prenatal supplements, it is recommended that copper be supplemented when zinc and iron are given during pregnancy. Good sources of copper include organ meats, seafood, nuts, seeds, and whole grain products. Because of the relatively large amounts consumed, tea, milk, potatoes, and chicken are also important sources (Otten et al, 2006).

Fluoride. The role of fluoride in prenatal development is controversial, and fluoride requirements do not increase during pregnancy. Development of primary dentition begins at 10 to 12 weeks of gestation and the first four permanent molars and eight of the permanent incisors are forming during the final trimester. Thus 32 teeth are developing during gestation. Controversy involves the extent to which fluoride is transported across the placenta and its value in utero in the development of caries-resistant permanent teeth (see Chapter 24).

Most bottled water does not contain fluoride. Fluoride is often added to the municipal water supply in the United States to achieve the intake level recommended by CDC. In other countries, salt and milk are common vehicles for fortification. Fluoride levels exceeding the maximum contamination level of municipal water supplies are problematic for bones and teeth. These elevated levels also appear to be neurotoxic for the developing fetus (Barrett, 2017).

Iodine. Iodine is part of the thyroxine molecule, with a critical role in the metabolism of macronutrients as well as in fetal neuronal myelination and gene expression (Wu et al, 2012a). Because the thyroid hormone synthesis increases 50% during pregnancy, iodine requirements also increase (Stagnaro-Green and Pearce, 2012). Severe iodine deficiency is associated with increased risk of miscarriage, congenital anomalies, fetal goiter, and stillbirth, as well as prematurity, poor fetal growth, and decreased IQ. Infant cretinism, although rare in the United States, is a significant public health problem. Iodine deficiency is the most common cause of preventable intellectual developmental disability in the world (Leung et al, 2013).

TABLE 14.10 Comparison of Absorbable Calcium With 1 Cup Milk

Food	Calcium Content	Fractional Absorption	Estimated Absorbed Calcium	Amount Needed to Equal 1 c Milk
Milk	300 mg/c	32.1%	96.3 mg	1.0 cup
Beans, pinto	44.7 mg/0.5 c*	26.7	11.9	4.05 cups, cooked*
Beans, red	40.5 mg/0.5 c	24.4	9.9	4.85 cups
Beans, white	113 mg/0.5 c	21.8	24.7	1.95 cups
Bok choy	79 mg/0.5 c	53.8	42.5	1.15 cups
Broccoli	35 mg/0.5 c	61.3	21.5	2.25 cups
Cheddar cheese	303 mg/1.5 oz	32.1	97.2	1.5 oz
Chinese mustard greens	212 mg/0.5 c	40.2	85.3	0.55 cup
Chinese spinach	347 mg/0.5 c	8.36	29.0	1.65 cups
Kale	61 mg/0.5 c	49.3	30.1	1.6 cups
Spinach	115 mg/0.5 c	5.1	5.9	8.15 cups
Sweet potatoes	44 mg/0.5 c	22.2	9.8	4.9 cups
Tofu with calcium	258 mg/0.5 c	31.0	80.0	0.6 cup
Yogurt, regular	300 mg/c	32.1	96.3	1.0 cup

*All vegetables are cooked portions.

Adapted from Weaver CM et al: Choices for achieving adequate dietary calcium with a vegetarian diet, *Am J Clin Nutr* 70:543s, 1999.

Worldwide, many people are at risk for iodine deficiency caused by low intake of milk or by consuming produce grown in iodine-deficient soils, especially if eating locally and consuming goitrogens or exposed to perchlorate contamination. Fish and seafood are good sources. Iodine content varies between and within species. It is higher in white fish than oily fish and levels are highest at and just below the skin. Marine fish contain six times the amount found in fresh water fish. Other seafood is also a good source. Cooking losses are much higher with boiling than with frying or grilling (Bouga et al, 2018).

An estimated 70% of the world population has access to iodized salt (Pearce et al, 2013). Salt iodization is voluntary in the United States and Canada. Iodized salt rarely is used in processed foods, the primary source of dietary sodium, and must be labeled if used. Kosher salt and sea salt do not naturally contain iodine. Women should be encouraged to use iodized salt when cooking at home and to limit the intake of processed foods made with uniodized salt.

Median urinary iodine values in the United States have declined, mainly because of the reduction of iodine in dairy and bread products, such that 35% of U.S. women of childbearing age now have urinary iodine values suggesting mild iodine deficiency or insufficiency (Leung et al, 2013). Similar reductions have been seen in women in other developed countries as well (Pearce et al, 2013). A recent study estimated 21% to 44% of U.S. pregnant women in the third trimester may have inadequate iodine levels, using a new quantitative modeling tool (Lumen and George, 2017). Although the effects of severe iodine deficiency on fetal brain development are well established, the effects of milder deficits are not as clear. Results of supplementation studies are mixed regarding thyroid function and the neurodevelopment of children, but children of women with mild to moderate deficiency demonstrate better neurocognitive scores if mothers were supplemented starting very early in pregnancy, that is, by 4 to 6 weeks of gestation (Leung et al, 2013). Current research is studying the effect of iodine supplementation on obstetric outcomes and long-term child development. Because of the concern that a subset of the population may be at risk for mild deficiency, the American Thyroid Association recommends that women receive 150 mcg/day during pregnancy and lactation as potassium iodide, given the variability of iodine content in kelp and seaweed (Leung et al, 2013; ACOG, 2015b). A recent study in the United States found that 61% of prenatal vitamins contain iodine and that those that were available over the counter were more likely to contain it (71%) than those available by prescription (46%) (Lee et al, 2017). Iodine content ranged from 10 to 450 mcg according to product labels, but the majority (89%) contained at least 150 mcg. Another U.S. study found that adult multivitamins were more likely to contain iodine (74.2%) than those labeled prenatal vitamins (57.6%) (Patel et al, 2018). Although the adult multivitamins consistently used potassium iodide, that was only true for 73.5% of those labeled as prenatal vitamins. In addition, the accuracy of labeled content of multivitamins sold in the United States is also of concern.

High iodine levels are also of concern, potentially causing the same symptoms as low levels. There is concern about the safety of iodine supplementation in areas of iodine sufficiency, but the problems appear to be temporary (Pearce et al, 2013). There are individual differences in the ability to handle high iodine intakes but most healthy people adapt within a few days and produce normal levels of thyroid hormones (Hamby et al, 2018). However, the fetus and neonate are particularly sensitive to high iodine levels, especially the preterm infant, because the homeostatic mechanisms do not mature until 36 weeks of gestation (Pearce, 2018).

Problems have been seen with high intakes of seaweeds. The iodine content of seaweeds is variable and depends primarily on the species of seaweed but also the parts of the plant consumed, the growing

conditions, and the preparation methods (Roleda et al, 2018). Of most concern are the brown seaweeds, including kombu and kelp, because they are known to be the most efficient accumulators of iodine, followed by red seaweeds (Teas et al, 2004). Frequent consumption of these seaweeds could far exceed the UL (Desideri et al, 2016), even when cooking methods (iodine is water soluble) and bioavailability issues are taken into account (Roleda et al, 2018; Domínguez-González et al, 2017). Congenital hypothyroidism resulting from high prenatal intake of seaweeds has been documented (Nishiyama et al, 2004). Very high breastmilk iodine levels also have been seen among Korean women ingesting the customary brown seaweed soup postpartum, utilized for its nutrient content but also thought to facilitate maternal weight loss and enhance breast milk production (Hamby et al, 2018).

As a reminder, postpartum thyroiditis affects an estimated 5.4% of all women (Stagnaro-Green and Pearce, 2012). Thyroiditis can manifest as either hyper- or hypothyroidism, and both can affect breastmilk production.

Iron. The RDA for iron significantly increases in pregnancy. An estimated 42% of pregnant women worldwide have iron deficiency anemia with wide regional variability. Although prevalence is highest in developing countries, an estimated 33% of low-income pregnant women in the United States are anemic in the third trimester (Murray-Kolb, 2011).

Inadequate iron consumption may lead to poor hemoglobin production, followed by compromised delivery of oxygen, as well as iron, to the uterus, placenta, and developing fetus. The placenta contains multiple iron transporter proteins for both heme and nonheme iron but they are not yet fully described, especially for heme iron (Fisher and Nemeth, 2017). There is some evidence that ferritin can also be transported, as well as preliminary evidence that dietary heme iron is preferentially transported to the fetus (O'Brien and Ru, 2017). Iron transport is regulated, balancing maternal and fetal needs (Cao and Fleming, 2016). The fetus appears to drive placental iron transport, although it is unclear how the placenta senses the fetal demand. Fetal hepcidin, as we currently understand it, usually remains low, allowing high transfer rates of iron from the placenta to the fetus. However, there is speculation that elevated fetal hepcidin levels, as might be found in fetal inflammation, (i.e., chorioamnionitis), may inhibit the transfer of iron from the placenta to the fetus (Fisher and Nemeth, 2017). Supplementation may improve maternal status but doesn't necessarily improve cord levels because fetal transfer can be sustained until maternal anemia becomes too severe (hemoglobin < 9 g/dL or serum ferritin < 13.6 mcg/L) (Georgieff, 2017).

Iron deficiency anemia (IDA) is associated with IUGR (threefold increase in LBW), preterm delivery (twofold increased incidence), increased fetal and neonatal mortality, and if severe (hemoglobin < 9 g/dL), with complications during delivery (Auerbach, 2018). IDA also is associated with increased fetal cortisol production and oxidative damage to fetal erythrocytes (Hovdenak and Haram, 2012). Early iron deficiency affects fetal brain development and the regulation of brain function in multiple ways (see Table 14.7). Because erythropoiesis gets priority over the brain and other organs, fetal brain iron deficiency can occur before maternal IDA is identified and better functional measures are needed (Georgieff, 2017). Neonatal iron deficiency can result if the mother is extremely iron deficient, but maternal hypertension and therefore restricted blood flow, as well as maternal smoking and prematurity, also increase the risk. Infants of mothers with diabetes are also more likely to develop iron deficiency because of increased fetal demands with macrosomia and fetal hyperglycemia/hyperinsulinemia increasing fetal oxygen consumption, but also with hyperglycosylation of the placental transferrin receptors restricting iron transport to the fetus (Rao and Georgieff, 2012), all resulting in a 40% reduction in

brain iron concentration. These changes result in long-term neurobehavioral impairments affecting temperament, interactions with others, learning, and memory and also may result in genomic changes.

Maternal effects of IDA include fatigue, dyspnea, light-headedness, and poor exercise tolerance. Prenatal weight gain is likely to be low. The mother is at risk of increased blood loss with uterine atony during delivery, thus increasing her risk of needing a blood transfusion. Wound healing and immune function are impaired. She is more likely to suffer from postpartum depression, poor maternal/infant interaction, and impaired lactation. There is some evidence that negative alterations in cognition, emotions, quality of life, and behavior may occur before overt IDA is reached, but the degree of iron deficiency associated with negative consequences remains unknown. Treatment during pregnancy improves maternal iron status postpartum and also is associated with improved infant development (Murray-Kolb, 2011).

Plasma volume increases 50% from baseline, and normal erythrocyte volume increases by 20% to 30% in pregnancy. This marked increase in the maternal blood supply during pregnancy, as well as fetal needs, greatly increases the demand for iron. The estimated total requirement for pregnancy is 1190 mg, but with the cessation of menses, the average net deficit is 580 mg. Added to her normal requirements, a pregnant woman often needs to absorb 17 mg/day by the third trimester. Normal absorption is often 1 to 2 mg/day from a normal diet, and 3 to 5 mg/day if the diet contains high-iron foods (Lee and Okam, 2011). Absorption of both heme and nonheme iron increases during pregnancy. Hepcidin levels decrease in the second and third trimesters, thus increasing the available iron to the placenta and therefore, the fetus (Fisher and Nemeth, 2017). However, the mechanism that causes this decrease in maternal hepcidin is not yet known and it is also unknown how iron supplementation affects hepcidin levels during pregnancy. While hepcidin certainly affects the availability of nonheme iron, there is also some evidence that it impacts heme iron availability as well. Elevated maternal hepcidin levels, causing lower than optimal transfer of iron to the placenta, would be important in the case of inflammation. However, the normal inflammation of healthy pregnancies does not seem to increase hepcidin. Pregnancies with more intense inflammation may, however, cause hepcidin levels to increase and therefore, iron availability to drop. How important this is in the case of the inflammation associated with maternal obesity or excessive weight gain is currently unclear. The effect of supplementation on intestinal absorption is also unclear, as is the possible increased risk of higher exposure with increased intake (Brannon et al, 2017), as well as the role of unabsorbed iron on the microbiome. Most accretion occurs after the twentieth week of gestation, when maternal and fetal demands are greatest. Those at highest risk of IDA are women with inadequate iron stores, including those with short interconceptual periods, those with poor habitual intakes, those with impaired absorption including a history of bariatric surgery or chronic use of antacids, and those who have experienced red cell destruction from malaria or excessive blood loss from heavy menstrual flow or prior hookworm infections.

A first trimester serum ferritin level may be assessed and if less than 20 mcg/L, supplementation may be necessary (Lee and Okam, 2011). However, checking red blood cell indices on the complete blood count (CBC) (see Chapter 5) is often adequate. Hemoglobin and hematocrit values normally decrease in the second trimester (see Table 14.5). Not decreasing may be a sign of poor blood volume expansion, which is associated with increasing risk of a growth-restricted infant, preterm delivery, and stillbirth (Luke, 2015). Serum values should increase again in the third trimester for best outcomes, but often this rise is not seen and intervention is merited. If anemia does not improve with iron therapy (i.e., an increase of 1 g hemoglobin or 3% in hematocrit by 4 weeks [CDC, 1998]), it is advised to check vitamins B₆, B₁₂, and folate

status, although many other nutrients, including protein, cobalt, magnesium, selenium, zinc, copper, vitamins A and C, lipids, and carbohydrate, also may play a role (Lee and Okam, 2011; Mechanick et al, 2013; Wu et al, 2012a).

High iron status is also associated with poor fetal growth, preterm delivery, preeclampsia, gestational diabetes, and stillbirth. However, the mechanism(s) are unclear but may include the actual iron status (increased viscosity and therefore compromised blood flow and/or poor placental perfusion), relative zinc and copper deficiencies, oxidative stress with supplementation, altered gut microbiome, and/or poor plasma volume expansion itself (Brannon and Taylor, 2017; Fisher and Nemeth, 2017). Serum ferritin may also just be a proxy measure for inflammation, especially in the context of maternal obesity (Vricella, 2017). There are no good functional measures of replete vs. excess iron status (Brannon and Taylor, 2017), nor is there a good way to adjust serum ferritin or hepcidin for inflammation but there is evidence that the obesity-associated inflammation does not override the influence of low iron status on hepcidin signaling (O'Brien and Ru, 2017).

Because many women do not enter pregnancy with sufficient iron stores to cover the physiologic needs of pregnancy, iron supplementation (usually as a ferrous salt) often is prescribed, but the amount of elemental iron contained varies by the preparation (Office of Dietary Supplements [ODS], 2018). The iron in the supplement already is reduced (i.e., ferrous rather than ferric), so taking the supplement with water is effective and consuming it with juice is not necessary. As with all nonheme sources, supplements should not be taken with coffee, tea, or milk to optimize absorption. Iron supplements should be taken separately from the prenatal vitamins to minimize the competition with other minerals. Absorption is best if taken on an empty stomach, but tolerance is often worse. Multiple supplements should be taken separately from each other to maximize absorption, but diminishing absorption is seen with increasing dosage, so tolerance of side effects should be balanced against need. Enteric-coated and delayed-release preparations produce fewer side effects, but because they are not well absorbed they are not recommended. Intravenous iron can be used during pregnancy, even as a first line treatment, in the second and third trimesters (Auerbach, 2018).

Iron supplementation is controversial. CDC and WHO recommend routine early iron supplementation to lower the risk of maternal anemia, LBW, and preterm delivery (WHO, 2016b). The USPSTF states that while supplementation may improve maternal iron status, the evidence supporting routine supplementation to improve either maternal or infant clinical outcomes is inconclusive (Cantor et al, 2015). ACOG recommends screening everyone and supplementing those with documented IDA. However, for those at risk of chronic iron overload, including those with hemochromatosis and beta-thalassemia, iron supplementation may not be recommended. Iron supplements may cause oxidative damage and may exacerbate inflammation. Consequently, overtreatment of IDA is now thought to be associated with preterm delivery, IUGR, and GDM (Hovdenak and Haram, 2012; see Chapter 7 for other examples of oxidative damage). Intermittent supplementation (one to two times per week) may be effective (Kaiser and Campbell, 2014), possibly by minimizing the increase in hepcidin levels (Auerbach, 2018). Nonphysiologic intakes of iron, as would be achieved with supplementation, may increase the risk of infections, especially important for people living in unsanitary settings (Prentice et al, 2017). In areas where bacterial and protozoal infections, especially malaria, are of concern, food fortification providing smaller doses at a time may be safer than supplementation. In addition, iron supplements are extremely dangerous for small children. Doses as little as 36 mg elemental iron/kg body weight have been lethal (ODS, 2018), so mothers must be reminded to keep supplements out of the reach of children.

Because of the concerns with iron supplementation, including compliance, safety, and effectiveness, emphasizing dietary sources of iron is necessary. The best sources of iron are red meats, including wild meats, (see Appendix 43) because of their heme content, and many organ meats may contain even higher levels of iron. It is important to limit the amount of liver and liver products (pâté, liverwurst, braunschweiger) in the first trimester because of their high vitamin A contents.

Vegetable sources, containing only nonheme iron, are less well absorbed, and volume may become the limiting factor, especially late in pregnancy. Absorption can be enhanced by eating them with ascorbic acid or a little meat.

Women who follow vegetarian diets should pay particular attention to iron and try to prevent having their hematocrit drop so far that it cannot recover sufficiently. Followers of Jehovah's Witness also must pay close attention to their iron levels. Because they choose not to receive blood transfusions, these women should receive nutrition counseling on high-iron foods early in pregnancy, with reinforcement as the pregnancy continues.

Magnesium. Magnesium functions as an enzyme cofactor and activator. The full-term fetus accumulates 1 g of magnesium during gestation, and maternal deficiency may interfere with fetal growth and development, including possible teratogenesis (Hovdenak and Haram, 2012). Recommendations for magnesium increase slightly during pregnancy, but its role in preterm labor, preeclampsia, gestational diabetes, and poor fetal growth is not well understood (Dalton et al, 2016). Magnesium sulfate is sometimes used to treat women with preeclampsia, but whether supplementation of magnesium for any of these conditions is helpful when a woman is not deficient in magnesium is unknown. Maternal magnesium deficiency has been speculated to play a part in increased risk for sudden infant death syndrome (SIDS), but prospective supplementation trials have not been done. Moderate magnesium deficiency is associated with subtle renal deficits in offspring (Richard et al, 2017). Optimal magnesium levels may be beneficial in helping prevent leg cramps (see Edema and Leg Cramps). However, too few data are available to give supplementation recommendations (Hovdenak and Haram, 2012). See Appendix 43 for good dietary sources. Prolonged, high doses of magnesium supplements should be avoided (see Heartburn).

Phosphorus. Phosphorus is found in a variety of foods, and deficiency is rare if one is able to eat normally. Requirements do not rise with pregnancy. However, low phosphorus levels, indicative of “refeeding syndrome,” have been found in women experiencing severe vomiting or other situations resulting in starvation. Hypophosphatemia can be life threatening because phosphorus is important in energy metabolism as a component of adenosine triphosphate (ATP) and must be replenished promptly (see Chapter 12).

Selenium. Selenium functions as an antioxidant and is important for reproduction. Low selenium status is associated with recurrent miscarriages, preeclampsia, and IUGR. The DRI increases slightly during pregnancy, but there are no evidence-based recommendations for supplementation (Hovdenak and Haram, 2012). Excess selenium intake is also of concern, especially if women eat locally from areas where soil selenium contents are high. There are no known areas in the United States or Canada with recognized cases of selenosis. See Appendix 45.

Sodium. The hormonal milieu of pregnancy affects sodium metabolism. Increased maternal blood volume leads to increased glomerular filtration of sodium. Compensatory mechanisms maintain fluid and electrolyte balance.

Rigorous sodium restriction stresses the renin-angiotensin-aldosterone system. Although moderation in the use of salt and other sodium-rich

foods is appropriate for most people, aggressive restriction is usually unwarranted in pregnancy. For pregnant women with edema, the use of diuretics is not recommended but correcting high sodium intakes from the diet is warranted. Normal intakes are often much higher than the DRI, which does not increase during pregnancy. ACOG has previously recommended that sodium intake should not be restricted below 2300 mg/day, which is higher than the current DRI. (ACOG, 2013c). Use of iodized salt should be encouraged, but processed food consumption, the source of more than 75% of dietary sodium in the United States, should be limited because of the noniodized salt content.

Zinc. Zinc is critical for growth and development, and requirements rise during pregnancy. A zinc-deficient diet does not result in effective mobilization of zinc stored in the maternal skeletal muscle and bone. Therefore a compromised zinc status develops rapidly. Zinc is part of 100 enzymes related to the metabolism of macronutrients (Hovdenak and Haram, 2012). It provides a structural function in many tissues, including some proteins involved in gene expression. Deficiency is highly teratogenic, leading to congenital malformations, including anencephaly and possibly oral clefts. Even a mild zinc deficiency may lead to impaired fetal growth and brain development, as well as impaired immune function. Women with untreated low zinc levels associated with acrodermatitis enteropathica have increased risk of miscarriage, fetal growth restriction, hypertension, preeclampsia, preterm delivery, and intrapartum hemorrhage.

Zinc is widely available and good sources include red meat, seafood, whole grains, and some fortified breakfast cereals (see Appendix 47). Supplementation exceeding that found in prenatal vitamins usually is not required but may be necessary for women with GI disorders that affect absorption. Overt deficiency is rare in the United States, but rates are higher where the main staple foods are high in phytates (i.e., the unrefined cereals), and women following a vegetarian diet may experience low zinc bioavailability. High levels of iron supplementation may inhibit zinc absorption if both are taken without food (Kaiser and Campbell, 2014).

Pregnancy Weight Gain Recommendations

General Weight Gain Recommendations

With a singleton gestation, less than half of the total weight gain of a normal-weight pregnant woman resides in the fetus, placenta, and amniotic fluid. The remainder is in maternal reproductive tissues (breast tissues and uterus), interstitial fluid, blood volume, and maternal adipose tissue. Increased subcutaneous fat in the abdomen, back, and upper thigh serves as an energy reserve for pregnancy and lactation. The normal distribution of weight is illustrated in Fig. 14.6.

Recommended weight gains to support a healthy pregnancy vary by prepregnant BMI and are summarized in Table 14.11. Designed for

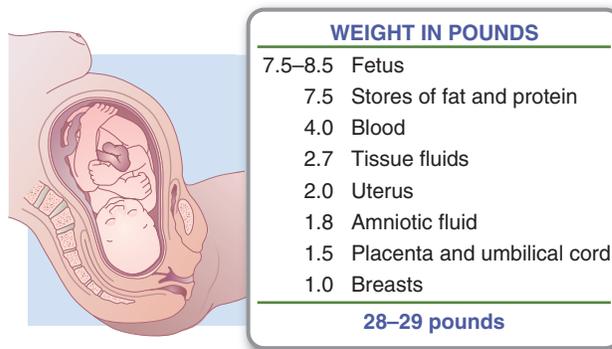

Fig. 14.6 Distribution of weight gain during pregnancy.

TABLE 14.11 U.S. Institute of Medicine (IOM) Prenatal Weight Gain Goals

Prepregnant Weight Category	Total Singleton Weight Gain	Rates of Gain in 2 nd and 3 rd Trimesters for Singletons* Mean/week (Range)	Total Twins Weight Gain (Provisional guidelines)
Underweight BMI < 18.5	28-40 lb [12.5-18 kg]	1 lb (1-1.3) [0.51 kg (0.44-0.58)]	Insufficient information available for guideline
Normal weight BMI 18.5-24.9	25-35 lb [11.5-16 kg]	1 lb (0.8-1) [0.42 kg (0.35-0.50)]	37-54 lb [17-25 kg]
Overweight BMI 25.0-29.9	15-25 lb [7-11.5 kg]	0.6 lb (0.5-0.7) [0.28 kg (0.23-0.33)]	31-50 lb [14-23 kg]
Obese BMI ≥ 30.0	11-20 lb [5-9 kg]	0.5 lb (0.4-0.6) [0.22 kg (0.17-0.27)]	25-42 lb [11-19 kg]

*Calculations assume a first trimester gain for singleton pregnancy of 1 to 3 kg (2.2 to 6.6 lb) for women who are underweight, normal weight, or overweight and 0.5 to 2 kg (1.1 to 4.4 lb) for those who are in the obese category.

Adapted from Rasmussen KM et al: Recommendations for weight gain during pregnancy in the context of the obesity epidemic, *Obstet Gynecol* 116:1191, 2010; Rasmussen KM, Yaktine AL: *Weight gain during pregnancy: reexamining the guidelines*, Washington, DC, 2009, IOM, NRC.

women living in healthy environments, the IOM weight gain guidelines balance the risk of adverse birth outcomes with the mother's risk of postpartum weight retention. Insufficient gain, especially if also associated with prepregnant underweight, is associated with increased risk of SGA babies and spontaneous preterm deliveries. Excessive gain often results in LGA babies, with increased risk during delivery. Excessive gain is also the strongest predictor of later maternal obesity. Outcomes are best when women gain within the recommended ranges. However, less than one third of pregnant women do so, and most (especially those who are overweight or obese) gain too much, although a significant proportion of underweight women gain too little (Siega-Riz and Gray, 2013). Women want advice on how much weight they should gain but a recent study found that 26% received no guidance from their health care provider (Deputy et al, 2018). Those that received advice tried to follow it, even if it was inappropriate, resulting in both inadequate and excessive gains among those studied.

Height and, ideally, prepregnant weight should be measured, not asked, to determine prepregnant BMI. Self-reported prepregnancy weight can be used if necessary but it is subject to error and is usually underreported (Headen et al, 2017). If prepregnant weight is unknown or unreliable, use the weight at the first visit, assuming she is early in pregnancy, as a good estimate of prepregnant weight. If she starts prenatal care late and has no idea of her prepregnant weight, estimate that she has had appropriate gain to that point. Later in pregnancy BMI is not a robust estimate of body fat because of the increase in total body water (Catalano and Shankar, 2017).

Women need guidance on target weight gains. One third of women try to keep the same weight or even lose weight during pregnancy (Rasmussen and Yaktine, 2009). Weight gain should be monitored as a way to evaluate progress and to intervene when necessary. The pattern of weight gain is also important. In an observational cohort, excessive first trimester weight gain was a stronger predictor of maternal weight retention, higher waist circumference, and higher blood pressure than was weight gain later in pregnancy (Walter et al, 2015). It is also associated with toddler obesity, in spite of having no effect on birthweight (Karachaliou et al, 2015). Higher rates of weight gain in the second trimester are associated with higher birth weight, especially among women whose prepregnant BMI is less than 26 (Rasmussen and Yaktine, 2009). Maternal weight gain plotted on the appropriate grid is an effective teaching tool. See Appendix 3 for all pregnancy weight gain grids, as well as tables (using pounds/inches and kilograms/centimeters)

to quickly choose the correct grid without needing to calculate the prepregnant BMI.

Weight loss during pregnancy should be discouraged. There are no intervention studies documenting benefit (Furber et al, 2013). As adipose tissue is mobilized, semivolatile organic compounds may be released (see *Clinical Insight: What's in That Fat When You Lose It* in Chapter 20). Because of the accelerated starvation characteristic of pregnancy, women are more likely to develop ketonemia and ketonuria after a 12- to 18-hour fast, with ketone levels higher than in nonpregnant women. Although the fetus has a limited ability to metabolize ketones, these compounds may adversely affect fetal brain development (Rasmussen and Yaktine, 2009). In addition, mobilized protein stores, increased free fatty acids, urinary nitrogen excretion, and lower plasma glucose, insulin, and gluconeogenic amino acids have been seen, resulting in increased risk of IUGR and preterm birth (Furber et al, 2013).

Prenatal weight gain guidelines vary somewhat worldwide (Scott et al, 2014). WHO has discussed, but not implemented, different weight gain guidelines based on ethnic differences in body composition and, therefore, different risks (Ma et al, 2016). The IOM guidelines are based on observational, not interventional, data. Thus some countries do not advocate either a particular weight gain or even routine weighing after determining the prepregnant BMI status. Although there are many small intervention studies, large trials are not yet available. It also must be noted that it is unclear whether maternal weight gain itself is a critical variable or whether it is a marker for nutritional status. Even so, tracking weight gain is useful and when variation from normal patterns is noted, more questions should be asked. While seeing the grid or hearing the actual weight may be stressful for some, many women find the visual tracking of their weight gain against the appropriate grid both effective and also reassuring. Just tracking weight gain without guidance or support is not beneficial.

Obesity Weight Gain Recommendations

Pregavid obesity is described as class I (BMI 30 to 34.9), class II (BMI 35 to 39.9), and class III (BMI at least 40). The IOM's weight gain recommendation of 11 to 20 pounds does not distinguish between these classes (Rasmussen and Yaktine, 2009). Optimal gestational weight gains for these groups are not yet known and research continues, with some evidence that lower gains, or even loss, can be managed successfully as individuals may balance intakes well enough to avoid

ketonemia. Overweight, and therefore overnutrition, is not the same as good quality nutrition and, in fact, obesity is associated with lower serum levels of carotenoids; vitamins C, D, B₆, K; folate; iron; and selenium (Saltzman and Karl, 2013; see also Chapter 20). Individual guidance and clinical judgment, including optimizing nutrient intakes and encouraging exercise, is necessary, and fetal growth must be monitored. Although weight gain targets may be too high for some women, evidence suggests that the risk of preterm delivery, IUGR, and perinatal mortality all increase if the weight gain is too restrictive. Epigenetic effects also must be considered. Inadequate weight gain and weight loss should not be encouraged (ACOG, 2015d). The United States, Canada, Australia, New Zealand, and Great Britain have similar, but not identical, guidelines regarding the management of obesity in pregnancy but all recommend that a nutrition consultation should be offered to all women who are overweight or obese before pregnancy (Vitner et al, 2019). No study has yet examined the pregnancy outcomes of low weight gain/weight loss resulting from insufficient food intake vs. that resulting from replacing foods containing excessive fats and sweets with those of higher nutrient, but lower caloric contents.

Postbariatric Surgery. The high prevalence of obesity has resulted in an increase in bariatric surgeries. Although prepregnancy weight loss may improve fertility, it has the potential to provide a suboptimal uterine environment for the developing fetus, and adequate nutrient supplementation is essential. Which nutrients are most likely to be deficient will be determined by the type of surgery and the nutritional status since that surgery (see Chapter 20), but commonly include protein, as well as vitamins D, folate, B₁₂, B₁, and A; iron; calcium; magnesium; copper; and zinc. Other deficiencies, although potentially severe, are more sporadic (Saltzman and Karl, 2013) but may include vitamins C, B₆, B₂, niacin, E, and K; selenium; and essential fatty acids (with biliopancreatic diversion). If anemia does not respond to treatment, vitamin B₁₂, folate, protein, copper, selenium, and zinc should be assessed (Mechanick et al, 2013). ACOG recommends women be evaluated for nutrient deficiencies and supplemented as needed (ACOG, 2015d).

The optimal timing of pregnancy following bariatric surgery is still unclear. Although 1 year has been commonly cited, ACOG now recommends delaying pregnancy for 18 months to avoid the period of rapid weight loss. However, a recent study is more conservative (Parent et al, 2017). They found that if pregnancy occurred within 2 years of surgery, the risk of prematurity increased (14% vs. 8.6%), as did the rates of neonatal intensive care unit (NICU) admission (15.2% vs. 11.3%), SGA prevalence (13% vs. 8.9%), and low APGAR scores (17.5% vs. 14.8%), compared with a matched cohort. They suggest that women should wait at least 3 years to conceive. An individualized approach has also been suggested, delaying pregnancy until the weight has been stable for 2 years and with all nutrient deficiencies treated prior to conception. However, many women don't follow this advice and are likely to be entering pregnancy with less than ideal nutrient status.

An optimum nutrient prescription and caloric requirement for pregnant women after bariatric surgery has not been determined and must be individualized. Protein intake recommendations following surgery are higher than normal (1.0 to 2.1 g/kg ideal body weight) but it is unknown what further increase is needed for pregnancy. Specific vitamin and mineral recommendations are also unknown. These women may have more difficulty eating enough if they have had a restrictive procedure and the gastric band may need to be adjusted. Those with bypass procedures may have malabsorptive problems and many women may develop food intolerances. In addition, women with a history of bariatric surgery may be less willing to gain enough weight after having invested so much in losing it, so guidance with reassurance and support may be necessary (see Chapter 20). Although the weight

gain guidelines are based on prepregnant BMI and are the same as for those without surgery, they are difficult to achieve for these women. Focus on high nutrient, low volume foods and minimize the intake of foods that don't help fetal growth or development.

These women need to be monitored carefully during pregnancy and their prenatal care may need to be modified. Practitioners should have a high degree of suspicion when hearing about discomforts. The gastric band can slip, causing an obstruction that can mimic hyperemesis but can result in fetal death (Jacquemyn and Meesters, 2014). This band migration can happen years after surgery, after uneventful pregnancies, and also after delivery. Roux-en-Y surgery has been shown to increase the risk of bowel obstruction. GI hemorrhage, anastomotic leaks, internal or ventral hernias, gastric rupture, peptic ulcers, cholelithiasis, and band erosion have all been seen. Those experiencing dumping syndrome (primarily after Roux-en-Y) may require glucose monitoring rather than trying to use the glucola to diagnose gestational diabetes. Glucose monitoring may also need to be modified. Because these women experience higher, shorter glucose peaks and lower lows, identification of a problem may be missed if the common 2-hour window is used (Bonis et al, 2016; Feichtinger et al, 2017).

Earlier research found little or no difference in pregnancy outcomes after bariatric surgery but studies were small, short term, and had inconsistent results. Newer studies are larger and have matched controls, enabling researchers to better characterize the additional risk for pregnancy after bariatric surgery, taking into account the elevated risk of continued obesity. Women who have had bariatric surgery often have successful pregnancy outcomes, with lower rates of gestational diabetes, hypertension, preeclampsia, macrosomia, and childhood obesity than seen among women with obesity who have not undergone bariatric surgery (Kassir et al, 2016). However, they also have higher risk of fetal growth restriction and preterm births (Kwong et al, 2018), including higher miscarriage and neonatal mortality rates after surgery (Kassir et al, 2016). If women have had Roux-en-Y or biliopancreatic diversion surgery, with or without the duodenal switch, they may also have higher risk of fetal malformations (Pelizzo et al, 2014), but there appears to be no consistent increase in the risk of malformations. Some have found an increased risk of NTDs and case reports describe the consequences of specific nutrient deficiencies, including vitamins K, B₁₂, and A.

The estimation of nutritional risk from bariatric surgery has risen over time, as evidenced by the increased number of nutrients being monitored, the testing frequency, and the level of routine supplementation recommended. Current guidelines (Parrott et al, 2017) are not specific to pregnancy (see Chapter 20). Studies regarding pregnancy following bariatric surgery are ongoing (Jans et al, 2016), including examining the effect of bariatric surgery on breastmilk composition, and better guidance is expected in the future. As with other dietary supplements, bariatric multivitamin-multimineral supplements are not standardized and some fit the profile of prenatal nutrient recommendations better than others do.

Multiple Births

The incidence of multiple births in the United States is rising because of the increased use of fertility drugs and ART, age at conception, and obesity rates among pregnant women (ACOG, 2016b). Multifetal gestations cause significant maternal physiologic adaptations beyond the usual pregnancy changes, including increased plasma volume, metabolic rate, and increased insulin resistance (Goodnight and Newman, 2009).

These infants have a greater risk of preterm delivery with accompanying IUGR or LBW than do singletons. Adequate maternal weight gain, especially early in pregnancy (before 20 weeks), has been shown to be particularly important for optimal growth and time in-utero

(Greenan et al, 2017). A common rule of thumb is to target a 24-pound gain by 24 weeks of gestation for twins (Goodnight and Newman, 2009) but intervention should begin in the first trimester. The IOM weight gain guidelines for twins are provisional (see Table 14.11 and Appendix 3) but are supported by more recent research (Hutcheon et al, 2018). The effect of chorionicity on optimal weight gain is unknown. For those pregnant with triplets or other higher-order multiples, there is limited information available, but best practice advice does exist. Target a gain of at least 36 pounds by 24 weeks of gestation for triplets (Stone and Kohari, 2015). Mean gestational weight gain for triplets is 45 to 51 pounds (20.5 to 23 kg) at 32 to 34 weeks. For quadruplets, it is 46 to 68 pounds (20.8 to 31 kg) at 31 to 32 weeks (Rasmussen and Yaktine, 2009) but better outcomes have been seen with higher gains (Luke et al, 2017; Luke, 2015).

The optimal nutrient requirements for twins and higher-order multiples are not yet known but are certainly higher than for singleton pregnancies. There are more fetuses and more placentas needing nourishment. In addition, the increased maternal weight may increase inflammation and therefore negatively affect the nutrient transport (Cao and O'Brien, 2013). It is assumed that at least the milk and meat food groups need to be doubled for twins, increasing as needed for optimal fetal growth, with even higher servings for the higher order multiples (Luke et al, 2017).

A summary of current nutritional plans for twins is summarized in Table 14.12 but may have to include iodine and choline as well; newer evidence cautions against high doses of vitamins C and E (see Hypertension and nutrient sections) (ACOG, 2013c). Because of a greater need for nutritional density in the diet, it is recommended that only 40% of calories come from carbohydrate, with 20% from protein, and 40% from fat (Goodnight and Newman, 2009). A woman pregnant with multiples has increased nutrient needs but decreased space. Counseling should focus on the consumption of very high nutrient foods. She must eat very frequently, possibly every hour, and must focus on foods that aid fetal growth each time she eats. Using fruits and vegetables as desserts rather than snacks often helps, as does suggesting that she eat before drinking liquids. Consumption of any foods that don't help fetal growth and development should be discouraged.

Adolescent Pregnancy

Public health initiatives have helped reduce the incidence of teen pregnancies overall, but it continues as a major problem in the United States among some minority groups (CDC, 2018c). Risk factors for poor outcome in pregnant adolescents are listed in Box 14.3.

Increased rates of LBW and preterm delivery are especially common among those who are very young and underweight, for whom there may be competition for nutrients between the mother and the fetus (see Chapter 17). Poor outcomes are also common in obese teens that become pregnant. Many teens enter pregnancy with suboptimal nutritional status, especially for iron, calcium, and folic acid. In one study, women in the United States who gave birth as teens were more likely to be overweight or obese as adults (Chang et al, 2013).

Improved dietary practices can be one of the most important factors for the pregnant teen. In counseling young mothers, the nutrition professional must be aware of the teen's psychosocial and literacy levels, her economic status and level of independence, as well as her cultural environment, all of which may influence her food choices.

Complications and Nutritional Implications

Many of the following complications follow from the normal hormonal changes during pregnancy. These changes cause the GI transit to slow so that more nutrients are available to the fetus. However, that causes more nausea and vomiting, constipation, and heartburn. Although

TABLE 14.12 Nutrient Recommendations for Women Pregnant with Twins

Nutrient	Twins	Comments
Calories	Underweight: 4000 kcal Normal: 3000-3500 kcal Overweight: 3250 kcal Obese: 2700-3000 kcal	Estimated needs are 40-45 kcal/kg. Monitor weight gain and modify calories to meet target weight goals.
Protein	Underweight: 200 g Normal: 175 g Overweight: 163 g Obese: 150 g	Target 20% of calories from protein. Choose concentrated sources as space becomes limiting.
Carbohydrate	Underweight: 400 g Normal: 350 g Overweight: 325 g Obese: 300 g	Encourage low glycemic choices.
Fat	Underweight: 178 g Normal: 156 g Overweight: 144 g Obese: 133 g	Encourage healthy fats.
Vitamin D	1000 IU/day or more as needed (1000 IU/day raises blood 5 mg/dL)	Assessment of maternal levels should be considered in first and early third trimesters to allow alterations in the supplemental dose, especially important if the mother is on bed rest.
Vitamin C	500-1000 mg/day	This is half of the UL of 1800-2000 mg/day. See more recent cautions.
Vitamin E	400 mg/day	This is half of the UL of 800-1000 mg/day. See more recent cautions.
Zinc	15 mg/day (T1); 30-45 mg/day (T2-3)	Diet alone may not be enough. Supplementation may be required.
Iron	30 mg/day as part of 1 multivitamin/day (T1), 2 multivitamins/day (T2 and T3)	Twin gestation requirement is likely double that of singletons. Higher intakes may be needed for treatment of anemia.
Folic acid	800-1000 mcg/day, 4 mg if with a history of NTD	
Calcium	1500 mg/day (T1); 2500-3000 mg (T2-3)	UL: 2500 mg/day, consider limiting if there is a history of kidney stones.
Magnesium	400 mg/day (T1); 800-1200 mg/day (T2-3)	
DHA + EPA	300-1000 mg/day	

Adapted from Goodnight W, Newman R: Optimal nutrition for improved twin pregnancy outcome, *Obstet Gynecol* 114:1121, 2009; Luke B: Nutrition for multiples, *Clin Obstet Gynecol* 58:585, 2015; Luke B, Eberlein T, Newman R: *When you're expecting twins, triplets, or quads*, ed 4, New York, 2017, Harper. DHA, Docosahexaenoic acid; EPA, eicosapentaenoic acid; NTD, neural tube defect; T, trimester; UL, tolerable upper limit.

BOX 14.3 Risk Factors for Poor Pregnancy Outcome in Teenagers

- Young maternal age
- Pregnancy less than 2 years after onset of menarche
- Poor nutrition and low prepregnancy weight
- Preexisting anemia
- Inappropriate weight gain (too low and too high)
- Obesity
- Sexually transmitted disease or infection
- Substance abuse: smoking, drinking, and drugs
- Poverty
- Lack of social support
- Low educational level
- Rapid repeat pregnancies
- Lack of access to age-appropriate prenatal care
- Late entry into the health system
- Unmarried status
- Unstable housing, shelter living, homelessness

normal, these complications can be uncomfortable and potentially dangerous but can be managed.

Constipation, Hemorrhoids, and Diarrhea

With the hormonal changes of pregnancy, women become constipated if they fail to consume adequate water and fiber. Women who receive iron supplements often complain of constipation. Those who are treated with ondansetron for nausea and vomiting often experience severe constipation. Compression of the pelvic floor by the fetus, as well as straining during stooling (Valsalva), increases the risk for hemorrhoids. Increased consumption of fluids and fiber-rich foods (see Appendix 27), including dried fruits (especially prunes), usually controls these problems. Some women also may require a bulking type of stool softener but laxatives containing stimulants are not recommended. Adding unprocessed wheat bran to foods is safe and effective.

Diarrhea may also be caused by a change in hormones early in pregnancy. It may also occur when a mother is starting labor. Infectious and other medical causes should be ruled out. See Chapter 27 for treatment options. Prevention of dehydration is important.

Cravings, Aversions, and Pica

Most women change their diets during their pregnancies as a result of medical advice, cultural beliefs, or changes in food preference and appetite. Food intake in pregnancy may be affected, both positively and negatively, by changes in hormone levels. There is limited research on pregnancy's effect on the various hormones related to appetite control. Taste preferences often change during pregnancy, likely due to the pregnancy hormones affecting both the taste buds and the central nervous system (Faas et al, 2010). Food avoidances may not reflect a mother's conscious choice but may include an adverse response to smell caused by an enhanced perception of aromas, a heightened gag response, getting ill while eating or smelling a particular food, or altered gastric comfort.

Cravings and Aversions. Cravings and aversions are powerful urges toward or away from foods, including foods about which women experience no unusual attitudes when not pregnant. In the United States the most commonly craved foods are sweets, fruits, and dairy products, or foods that can be eaten quickly. The most common aversions reported are to alcohol, coffee, meats, and the smell of frying.

However, cravings and aversions are not limited to any particular food or food groups, they often overlap, and cultural differences exist. For examples, see Table 14.13.

Pica. Consumption of nonfood substances or food items in non-physiologic amounts (**pica**) during pregnancy most often involves **geophagia** (consumption of dirt or clay), **amylophagia** (laundry starch, corn starch, or uncooked rice), or **pagophagia** (ice). Other substances include paper, burnt matches, stones or gravel, charcoal, rock salt, bleach, cigarette ashes, baby powder, baking soda, soap, tires, and coffee grounds. Although some of the common substances are of little concern, others are dangerous to the mother. The local poison control center can give guidance on which require immediate intervention.

Pica is common in pregnancy, and the incidence of pica in the United States is estimated to be 14% to 44%, with wide variability between groups (Scolari Childress and Myles, 2013). Pica is not limited to any one geographic area, race, culture, or social status, but there are cultural components related to the substances chosen and the acceptability of disclosure. Preferred substances often are imported from home countries, including soil or clay and blocks of magnesium carbonate.

The cause of pica is poorly understood. One theory suggests that pica relieves nausea and vomiting, although pica often appears later in pregnancy when nausea and vomiting are not so prevalent. One hypothesis is that it is due to a deficiency of an essential nutrient, most often iron, but zinc, calcium, and potassium also have been mentioned (Cardwell, 2013). Although it is hypothesized that the craving causes one to eat the nonfood substance that contains the missing nutrients, that is seldom the case. Pica also can be a craving for smell or texture as well as taste. IDA has been associated with the olfactory craving in pica (Hansen et al, 2017) and chewing ice has been shown to improve alertness and response times on a neuropsychological test for people who are anemic but not for others (Hunt et al, 2014). Taste perceptions often change, but whether that is associated with lower zinc levels is not known.

Malnutrition can be a consequence of pica when nonfood substances displace essential nutrients in the diet. Starch in excessive amounts contributes to obesity and can negatively affect glucose control. Large intakes of baking soda can raise blood pressure and extreme doses (1 box/day) have caused rhabdomyolysis and cardiomyopathy (Scolari Childress and Myles, 2013). Excessive intakes of baking powder can mimic preeclampsia. Substances may contain toxic compounds or heavy metals, parasites, or other pathogens. The absorption of iron or other minerals may be disrupted. Excessive geophagia can result in intestinal obstruction or perforation (Young, 2011).

Recommending stopping a pica often fails, either because of the strong physiologic drive or the cultural perception that not complying with the craving will cause harm to the fetus. Rather than insisting on cessation, resulting only in less willingness to admit the pica, a more productive approach is to offer a better alternative. For example, allowing the mother to continue to smell the wet dirt, but trading its consumption for a burned tortilla, toast, or jicama often is successful. Pica often is associated with IDA, but whether the pica is a result, a cause, or a marker of other concurrent deficiencies is unknown. However, treatment with very high iron foods often decreases the cravings and infusions of iron have resulted in a cessation of the pagophagia, as well as restless legs (Auerbach and Adamson, 2016).

Diabetes Mellitus

Gestational diabetes mellitus (GDM), carbohydrate intolerance with onset or recognition during pregnancy, encompasses two distinct groups—those who have unrecognized preexisting diabetes and those for whom the pregnancy precipitates the carbohydrate intolerance.

TABLE 14.13 Reported Cravings and Aversions by at Least 10% of Pregnant Women in Published Studies

Country	Cravings	Aversions
Ethiopia	Meat sauce, cheese, milk	Wheat, coffee, wheat bread, meat sauce
Tanzania	Meat, mangoes, yogurt, oranges	Rice, meat, fish, eggs
Nigeria	Cereals, vegetables, beans, yams, cassava, plantain, nonalcoholic beverages, fruits, meats, milk, fish	Alcohol, plantains, cassava, yams, fish, meat, milk, nonalcoholic beverages, beans, fruits, cereals
South Africa	Fruits, sour foods, sweets, cold drinks	Meat
Iraq	Meat, chicken, milk, eggs, fruits, milk	Melons, onions, leeks, radishes, spices
Saudi Arabia	Salty foods, sour foods, milk	Tea, coffee, cola, meat, spicy foods
Italy	Fruit, pasta	Meat, smoke, perfumes, coffee (taste, smell), white wine
England	Fruit and fruit juices, including citrus, sweets, chocolate, biscuits, ice cream, milk and milk products, vegetables, sweet meats, liquids, meats	Tea, coffee, highly flavored or spicy foods, including curries, meats, fish, eggs, smell of fried or fatty foods, cigarette smoke/tobacco, cocoa, vegetables
Ecuador	Fruit and fruit juices, meat, poultry, fish and seafood, eggs	Meat, poultry, fish, seafood, chicken and quail eggs, vegetables, white rice, wheat noodles, corn, barley
Jamaica	Water, ice, milk and milk drinks, fruit and fruit juices, vegetables, sweet drinks, meats, fish	Meat, rice, wheat dumplings, yams, milk, fruit and fruit juices, sweet drinks, fish
United States	Sweets, chocolate, fruit and fruit juice, citrus, pickles, ice cream, ice milk, pizza, beef, chips, spicy foods, raw vegetables, milk and other dairy, fish, ethnic foods, meat, grains, nuts and nut butters, salty foods, cookies, Italian sauce, breads/cereals	Meat, beef, fish, eggs, vegetables, ethnic foods, greasy foods, coffee, tea, legumes, alcohol, grains, sweets, fruits, cigarettes, Italian sauce, spicy foods

Adapted from: Patil CL, Abrams ET, Steinmetz AR, et al: Appetite sensations and nausea and vomiting in pregnancy: an overview of the explanations, *Ecol Food Nutr* 51:394, 2012.

Women with risk factors for type 2 diabetes (including but not limited to a history of GDM, known impaired glucose metabolism, and BMI ≥ 30) should be screened early in pregnancy using standard diagnostic criteria (ACOG, 2018c; American Diabetes Association [ADA], 2019; see Chapter 29). According to the ADA, those women identified with diabetes in the first trimester should be given a diagnosis of overt diabetes rather than GDM. Universal screening with a hemoglobin A1C at the first prenatal visit is common and will often identify these people.

Women identified by early screening, as well as those with known preexisting diabetes (either type 1 or 2), should be referred to a Certified Diabetes Educator (CDE) and/or a diabetes management team. Fetuses of mothers with poorly controlled diabetes at conception are at risk for multiple congenital anomalies. See Chapter 29 for management guidelines.

As pregnancy progresses and insulin resistance increases, GDM resulting from the pregnancy may appear. GDM rates in the United States are 5% to 6% of the prenatal population (National Institutes of Health [NIH], 2013), but the prevalence can be much greater in high-risk groups, including women with a high BMI, advanced maternal age, and personal and family history (first-degree relative with diabetes). Rates are higher among African American, Asian, Hispanic, Native American, and Pacific Islander women compared with non-Hispanic white women (ACOG, 2018c).

A diagnosis of GDM is associated with increased risk of gestational hypertension and of preeclampsia, as well as increased risk of type 2 diabetes and CVD later in life. Fetal implications include hyperinsulinemia, **macrosomia** (often defined as a baby weighing more than 4000 g), and, therefore, increased risk of delivery complications, including shoulder dystocia and cesarean delivery. The neonate is more likely to require admission to NICU and to experience respiratory distress syndrome and metabolic complications, including

hyperbilirubinemia and hypoglycemia. Infant iron levels may be lower because of overgrowth and therefore increased demand (Monk et al, 2013). Other nutrients also may be low. Fetal programming, with increased long-term risk of obesity and type 2 diabetes, is also of concern.

Although some practitioners believe that GDM may represent the early stages of type 2 diabetes, others feel that women should not be labeled at all with a GDM diagnosis. However, treatment for GDM is merited because it lowers the risk by 40% for gestational hypertensive disorders, reduces the risk of macrosomia, and therefore reduces the risk of shoulder dystocia from 3.5% to 1.5% (NIH, 2013).

The diagnostic criteria for GDM are controversial. Historically, the United States and other countries have used a two-step process, whereas the WHO has advocated a one-step approach. Table 14.14 summarizes selected current guidelines but other cutoffs and testing protocols also exist (Agarwal, 2015). Recently the International Association of the Diabetes and Pregnancy Study Groups (IADPSG) advocated for a universal one-step approach developed from the Hyperglycemia and Adverse Pregnancy Outcomes (HAPO) trials. All previous protocols were designed to identify women at risk of developing type 2 diabetes later in life while the HAPO study was the first to correlate glucose values with pregnancy outcomes. Because only one elevated value is diagnostic, using the more liberal IADPSG criteria results in a twofold to threefold increase in the number of people defined as having GDM, arriving at a national prevalence of 15% to 20% (NIH, 2013).

Because of the increased cost to the medical system and the patient, increased patient stress with likely increased interventions, combined with concern that treatment may not be as beneficial for those at the lower glucose levels, a NIH consensus committee concluded there is currently insufficient evidence to recommend changing to the IADPSG

TABLE 14.14 Screening and Diagnosis of Gestational Diabetes Mellitus (GDM) at 24 to 28 Weeks of Gestation: Blood Glucose Thresholds and Testing Protocols

Approach	Fasting mg/dL	1-hour mg/dL	2-hour mg/dL	3-hour mg/dL	Source
TWO STEP: universal screening; only those \geq cutoff need diagnostic test					
Screening: (nonfasting) 50 g glucose load, value \geq		130, 135, or 140			
Diagnosis: (fasting) 100 g load, 2 values \geq	95	180	155	140	Carpenter and Coustan
100 g load, 2 values \geq	105	190	165	145	National Diabetes Data Group
ONE STEP: universal testing					
Diagnosis: (fasting) 75 g load, 1 value \geq	92-125*	180	153-199*		World Health Organization (WHO)**
75 g load, 1 value \geq	92	180	153		International Association of the Diabetes and Pregnancy Study Groups

*Values above these cutpoints are considered diagnostic of diabetes mellitus in pregnancy rather than GDM, as is a random plasma value of \geq 200 mg/dL with diabetes symptoms.

**Considered diagnostic of GDM when found any time during the pregnancy.

Adapted from National Institutes of Health consensus development conference statement: diagnosing gestational diabetes mellitus, March 4-6, 2013, *Obstet Gynecol* 122:358, 2013; World Health Organization: WHO recommendation on the diagnosis of gestational diabetes in pregnancy, March 8, 2018 (website): <https://extranet.who.int/rhl/topics/preconception-pregnancy-childbirth-and-postpartum-care/antenatal-care/who-recommendation-diagnosis-gestational-diabetes-pregnancy-0>.

approach (NIH, 2013). Those concerns have now been studied and some practices have returned to using the two-step approach after finding no improvement in maternal or neonatal outcomes in spite of increased diagnoses and interventions (Pocobelli et al, 2018).

The ADA and ACOG recommend screening all pregnant women for GDM (unless already identified with diabetes) at 24 to 28 weeks of gestation (ACOG, 2018c; ADA, 2019). Only those with an abnormal result on the 1-hour screen receive the 3-hour diagnostic test. ACOG recommends that the choice of a screening cutpoint and the choice of diagnostic tests (using the Carpenter and Coustan criteria if testing serum or plasma, or the National Diabetes Data Group criteria if testing plasma), be guided by local community GDM prevalence rates (ACOG, 2018c). Although current practice requires two abnormal values for a diagnosis of GDM, further study is recommended to see if those with only one elevated value also benefit from treatment.

As with preexisting diabetes, those women with GDM should be followed carefully during pregnancy and managed by a diabetes team that includes a CDE. See Chapter 29 for diet and exercise recommendations, including target glucose values. Medications may be necessary to manage blood sugars. Insulin and some oral hypoglycemic agents (e.g., metformin and glyburide) can be used. Long-term use of metformin is associated with decreased vitamin B₁₂ levels, but its use only in late pregnancy has not been shown to be problematic for maintenance of normal B₁₂ levels (Gatford et al, 2013). There is intriguing preliminary evidence that myoinositol may be helpful in preventing or treating GDM and its use appears to be safe (Werner and Froehlich, 2016). However, its use in treating GDM is not endorsed by the Cochrane Review because of the limited data available (Brown et al, 2016). Inositol does not appear to lower the risk of an LGA baby and other clinically meaningful outcomes have not been reported. Optimal dose, frequency, and timing of supplementation are all currently unknown, as are the long-term effects. Its

preconceptional use, along with other micronutrients and probiotics, to help improve insulin sensitivity is currently being studied (Godfrey et al, 2017a).

Women with GDM should be screened for persistent diabetes at 4 to 12 weeks postpartum, usually with fasting and 2-hour (after a 75g glucose load) blood sugars, and at least every 3 years for diabetes or prediabetes, using nonpregnancy diagnostic criteria (ADA, 2019; see Chapter 29).

Eating Disorders

The rates of eating disorders during pregnancy are 1% for anorexia nervosa and slightly more for bulimia, with the prevalence likely underestimated (Cardwell, 2013) because of voluntary nondisclosure or because the medical practitioner is not assessing the risk (Leddy et al, 2009). Anorexia and bulimia are associated with increased risk of miscarriage, birth defects, hyperemesis, IUGR, and micronutrient deficiencies, as well as postpartum depression and impaired infant bonding. For those with binge eating, excessive weight gain, macrosomia, and increased cesarean rates are seen. Those that purge may have caries or fractured teeth severe enough that they cannot chew meat.

The effect of pregnancy on the individual with an eating disorder varies, but 70% may show improvement, especially with purging behaviors (Harris, 2010). However, pregnancy does not cure the eating disorder and symptoms often are exacerbated after delivery. In fact, in some cases the newborn is seen as “too fat,” to the point of restricting food, administering suppositories or enemas, or inducing vomiting. A team approach to treating the mom is helpful in those cases.

For the woman with an eating disorder, pregnancy may be particularly frightening because of the loss of control and disturbed body image. Anorexia can be diagnosed during pregnancy. Substance abuse, as well as the use of laxatives or diet pills, may be coping

mechanisms. Insulin has been used as a purging mechanism. Women may fear being weighed and may need reassurance that the nausea and vomiting of pregnancy is not necessarily a resurgence of purging. Fatigue, irritability, and depression may be due to starvation. These pregnant women should be treated with particular care, including focusing on healthy eating for optimal fetal growth and development (see Chapter 21).

Edema and Leg Cramps

Mild physiologic edema is usually present in the third trimester and should not be confused with the pathologic, generalized edema associated with preeclampsia. Normal edema in the lower extremities is caused by the pressure of the enlarging uterus on the vena cava, obstructing the return of blood flow to the heart. When a woman reclines on her side, the mechanical effect is removed, and extravascular fluid is mobilized and eventually eliminated by increased urine output. No dietary intervention is required, assuming her protein intake is adequate. If, however, her urine is dark and/or she has swelling in her hands, increased fluid intake is recommended and excessive salt consumption should be reduced.

Increased fluid intake also is recommended for leg cramps. Women should be advised to stretch with their toes pointing back toward their bodies rather than away from them. Massage and heat application may help treat the cramp. Optimal calcium intake may reduce the prevalence of leg cramps. The literature is conflicting about the benefit of magnesium supplementation for prevention or treatment of pregnancy-related leg cramps (Zhou et al, 2015). Caution is advised against large intakes of supplements.

Heartburn

Gastric esophageal reflux is common during the latter part of pregnancy and often occurs at night. The pressure of the enlarged uterus on the intestines and stomach, along with the relaxation of the esophageal sphincter due to hormonal changes, may result in regurgitation of stomach contents into the esophagus. Relief measures may include eating smaller meals, limiting fluids with meals, limiting caffeine, chocolate, mint, carbonated beverages, tomatoes, citrus, fat, and spicy foods, as well as chewing gum, walking, and staying upright for at least 3 hours after a meal, but interventions have not been evaluated for effectiveness (Kaiser and Campbell, 2014). Using more pillows at night also may help (see Chapter 26).

Although heartburn medicines can be used, they are not benign and use should be limited. Taking excessive calcium carbonate can cause life-threatening milk-alkali syndrome (hypercalcemia, renal sufficiency, and metabolic alkalosis). Hypercalcemia-induced pancreatitis has also been documented (Trezevant et al, 2017). The UL of 2500 mg of elemental calcium (food plus supplements) should be observed. If a couple of calcium carbonate tablets (two regular strength Tums contain 400 mg calcium; two ultrastrength tablets provide 800 mg) do not resolve the heartburn, switching to those containing magnesium may be beneficial. However, prolonged use of high-dose magnesium-containing antacids is associated with offspring kidney stones, hypotonia, and respiratory distress (Bustos et al, 2017). Antacids containing bicarbonate may cause maternal and fetal metabolic acidosis, as well as fluid overload and are not recommended in pregnancy. Proton pump inhibitors may reduce the bioavailability of many nutrients, including vitamins C, B₁₂, calcium, magnesium, and nonheme iron. The use of antacids also potentially can increase the risk of food allergies by impeding gastric protein digestion, but whether that translates into a higher risk of food allergy or asthma for the child is unclear. Some herbal medicines, including aloe vera juice, are promoted for treatment of heartburn. However, caution is advised

because animal research demonstrates some preparations of aloe contain latex which might induce abortion and/or stimulate menstruation (Zielinski et al, 2015).

Hypertension

Hypertension observed during pregnancy may be preexisting or observed for the first time. Elevated blood pressure that is first diagnosed in pregnancy may be relatively benign. However, a rise in blood pressure, accompanied by other changes listed in this chapter, can be a sign of **preeclampsia**, a progressive, systemic problem affecting 3% to 8% of pregnancies worldwide and the leading cause of maternal and neonatal morbidity and mortality (Myers, 2017). Although delivery resolves the problem for most, some women develop hypertension after delivery.

Chronic hypertension predates pregnancy and is associated with fetal growth restriction. Avoidance of severe hypertension is a goal, but the optimal blood pressure during pregnancy for someone with preexisting hypertension is unclear (see Chapter 32). Appropriate weight gain, a modified Dietary Approaches to Stop Hypertension (DASH) diet (see Appendix 17), and regular aerobic exercise for those without complications are recommended. Although excessive sodium should be reduced, ACOG has previously recommended that intake should not be less than 2300 mg/day (ACOG, 2013c). Calcium supplementation for those with low calcium intakes may be helpful. Some antihypertensive medications can be used during pregnancy but may need to be modified during breastfeeding.

Gestational hypertension is defined as elevated blood pressure that appears after 20 weeks of gestation, but without proteinuria or other findings. Some women (up to 50%) go on to develop preeclampsia, while others may have no risk except the elevated blood pressure (ACOG, 2019). They are treated the same as those with chronic hypertension and monitored for worsening of symptoms. Gestational hypertension may predict increased risk for future hypertension. Optimal periconceptual nutrition is important, including focus on folate, sodium, calcium, potassium, iron, copper, and zinc intakes (Tande et al, 2013).

Some women who develop hypertension during pregnancy go on to develop preeclampsia. Risk factors include women who are primiparous and obese, but other risk factors include a personal or family history of preeclampsia, chronic hypertension, diabetes (type 1, type 2, or GDM), chronic renal disease, history of thrombophilia, systemic lupus erythematosus, antiphospholipid antibody syndrome, obstructive sleep apnea, multifetal pregnancy, IVF (especially following oocyte donation [Myers, 2017]), and maternal age of at least 35 years (ACOG, 2019). However, the presence of these risk factors doesn't necessarily guarantee that an individual will develop preeclampsia. For example, while women who are obese are twice as likely to develop preeclampsia compared with women with a lower BMI, only one in ten women with obesity develop preeclampsia (Myers, 2017). In addition, most cases of preeclampsia occur in healthy, nulliparous women with no apparent risk factors (ACOG, 2019). Paternal factors also likely play a role. Risk increases with advanced paternal age, paternal obesity, and family history of early-onset CVD. Paternal genes also may be important—increased risk for preeclampsia is seen if the man has fathered a preeclamptic pregnancy or if he was born of a preeclamptic pregnancy (Dekker et al, 2011). Maternal smoking reduces the risk by 35% (ACOG, 2013c), but if preeclampsia occurs, the severity increases (Trogstad et al, 2011). Risk of recurrence in a subsequent pregnancy is 25% (Myers, 2017). Risk of preeclampsia is less likely in subsequent pregnancies with the same partner than when the mother is pregnant with a new partner.

Preeclampsia involves dysfunction of multiple organ systems. It is dynamic, progressive, and once evident, is not reversible. Delivery is needed because it is potentially fatal for mother and baby. Growth restriction is common and babies are often also premature in an effort to avoid the mother progressing to severe preeclampsia, eclampsia (new onset grand mal seizures), or **HELLP syndrome** (hemolysis, elevated liver enzymes, and low platelets), all of which have high rates of maternal morbidity and mortality (ACOG, 2019). Those women with superimposed preeclampsia onto chronic hypertension (13% to 40% of women) have much worse consequences (ACOG, 2013c). Women with preeclampsia that develops near term have double the risk of CVD later in life, but the risk of CVD is nearly 10-fold for those who must be delivered at less than 34 weeks of gestation because of preeclampsia (Roberts and Bell, 2013).

Preeclampsia has historically been defined by elevated blood pressure and proteinuria, but guidelines now recommend not waiting for the proteinuria to appear. **Box 14.4** summarizes diagnostic criteria designed to facilitate earlier diagnosis and therefore earlier treatment.

The causes of preeclampsia are under intense investigation. It appears to be a two-stage process, with a poorly perfused placenta (from failed remodeling of the maternal spiral arteries) being the root cause (ACOG, 2013c). Reduced perfusion and increased velocity of blood perfusing the intervillous spaces alters placental function and leads to maternal disease through oxidative and endoplasmic reticulum stress and inflammation, as well as modified endothelial function and angiogenesis. The second stage, called *maternal syndrome*, is a cascade of events, but what links the hypoxic placenta and the maternal syndrome is unclear and possibly involves oxidative stress. The hypertension and proteinuria are only a small part of the syndrome and

reduced perfusion of any organ in the body can lead to hemorrhage and necrosis. Not all women with inadequate placental perfusion develop preeclampsia. A woman's underlying disease (e.g., diabetes, hypertension), lifestyle (e.g., obesity, activity, sleep), genetics, and environmental conditions (e.g., air pollution) may affect the maternal response (Roberts and Bell, 2013). The inflammatory response is accentuated in preeclampsia. Predictive tests are being studied but are not ready for clinical use (ACOG, 2019). It is now thought that preeclampsia is actually a syndrome of many diseases with subsets of pathophysiology and varied contributions of maternal and placental factors (Roberts and Bell, 2013).

Prevention of preeclampsia has not yet been effective, although daily low-dose aspirin may be beneficial (ACOG, 2019). Although previously recommended, vitamin C and E supplements do not prevent occurrence of preeclampsia or adverse outcomes and may be associated with increased risk of gestational hypertension and LBW. Calcium supplementation may help reduce symptom severity if a mother's baseline calcium intake has been less than 600 mg/day (ACOG, 2013c). There is insufficient evidence to demonstrate effectiveness of fish oil, garlic, vitamin D or folic acid supplementation, nor of sodium restriction (ACOG, 2019). Avoiding excessive weight gain and tightly controlling diabetes may help. Protein and calorie restriction for women with obesity does not reduce the risk of either gestational hypertension or preeclampsia and may increase the risk of IUGR. Bed rest does not appear to reduce risk. Diuretics are not recommended. Moderate exercise (30 minutes/day) is recommended as during normal pregnancy, but it is unclear whether it can help reverse the endothelial dysfunction and prevent adverse pregnancy outcomes. Obesity, leptin, insulin, and free fatty acids appear to affect various stages of preeclampsia. Endothelial cell disorder from placental ischemia and hypoxia appear important. An imbalance of angiogenic factors, immune factors, inflammation, endothelin (a protein that constricts blood vessels), nitric oxide, oxidative and endoplasmic reticulum stress, the stress response gene hemeoxygenase and its catalytic product carbon monoxide, and the effect of statins are all being studied.

For those women with a history of preeclampsia, weight loss, increased physical activity, smoking cessation, and optimization of blood glucose levels and nutrient intakes preconceptionally are recommended. During pregnancy, helping women maintain a normal rate of weight gain, with optimal calcium intake and fruits and vegetables (antioxidants), may be beneficial. Encourage notifying the medical provider immediately if there is a sudden onset of face or hand swelling, persistent headaches, seeing spots or changes in eyesight, pain in the upper right quadrant or stomach, nausea and vomiting in the second half of pregnancy, rapid weight gain, or difficulty breathing.

Although delivery resolves the preeclampsia for most, a subset of women have a worsening of preeclampsia after delivery and others may first develop preeclampsia postpartum, including HELLP syndrome. Pain medications may have to be modified. Blood pressure may be labile for months but usually normalizes by 1 year postpartum. Postpartum hypertension may predict future chronic hypertension (ACOG, 2013c).

Nausea and Vomiting, Hyperemesis Gravidarum, and Pylalism

Morning sickness, **nausea and vomiting in pregnancy (NVP)**, affects 50% to 90% of all pregnant women during the first trimester and usually resolves by 20 to 22 weeks of gestation, although up to 10% of women suffer with it until delivery (Bustos et al, 2017). The cause of NVP is unclear but likely includes a genetic predisposition, combined with changes in human chorionic gonadotropin (hCG), estrogen, and progesterone levels. Recently an increase in the half-life of endokinin B,

BOX 14.4 Preeclampsia Diagnostic Criteria

Elevated blood pressure

Confirmed ≥ 160 or ≥ 110 for anyone (confirmed over a few minutes) or ≥ 140 or ≥ 90 after 20 weeks of gestation (confirmed over 4 hours) if previously normal

AND

Proteinuria

≥ 300 mg/24-hour urine collection, an extrapolated amount from a timed collection, protein/creatinine ratio ≥ 0.3 , or dipstick reading of 2+ if no other quantitative methods are available

OR

Elevated blood pressure

Confirmed ≥ 160 or ≥ 110 for anyone (confirmed over a few minutes) or ≥ 140 or ≥ 90 after 20 weeks of gestation (confirmed over 4 hours) if previously normal

AND

New onset of any of the following:

Thrombocytopenia: platelets $< 100,000$ /microliter

Renal insufficiency: serum creatinine > 1.1 mg/dL or doubling of serum creatinine concentration in absence of other renal disease

Impaired liver function: elevated liver transaminases to twice normal blood concentrations

Pulmonary edema

Cerebral or visual symptoms

Adapted from American College of Obstetricians and Gynecologists (ACOG): ACOG Practice Bulletin No. 202: Gestational Hypertension and Preeclampsia, *Obstet Gynecol* 133:e1, 2019.

a tachykinin produced by the placenta to increase blood flow, has also been proposed as a cause (Lowry and Woods, 2018) because it also stimulates the NK1R receptor in the brain, causing nausea and vomiting in some women. NVP may be mediated through the vestibuloocular reflex pathway and those with a history of motion sickness or migraines are at increased risk. Those pregnant with a female fetus, multiple fetuses, or a molar pregnancy (sperm fertilizes an empty egg, resulting in no embryo but a placenta that develops into an abnormal mass of cells) are more likely to suffer with either NVP or hyperemesis gravidarum, as are those with hyperthyroid disorders, GI disorders, preexisting diabetes, or a psychiatric illness. Maternal age more than 30 years and smoking are protective, but paternal smoking increases risk (Fejzo et al, 2012). NVP is associated with more favorable pregnancy outcomes, including fewer birth defects; reduced risk of miscarriage, preterm delivery, or stillbirth; and greater birth weight.

Treatment for NVP involves managing the symptoms. Motion, specific odors, loud noises, bright or flickering lights, and adverse climate conditions may trigger the nausea. Fortunately, most women with NVP are functional, able to work, do not lose weight, and are helped by simple dietary measures. Many dietary and lifestyle recommendations have not been evaluated in the literature (Kaiser and Campbell, 2014). Although the quality of the evidence is low, it appears that ginger preparations (tablets, syrup, capsules, or ginger biscuits) are more effective than placebos in reducing the severity of symptoms (O'Donnell et al, 2016), possibly by multiple mechanisms (Marx et al, 2017). However, while ginger reduces the nausea, it may not reduce the episodes of emesis and does not work for many people, especially those with hyperemesis (Dean and O'Hara, 2015). Ginger supplements can be offered as a first line therapy (250 mg capsules 4x/day) (ACOG, 2018b) but should not be used for women on anticoagulation therapy because of the increased risk of bleeding with platelet function inhibition (Bustos et al, 2017). Ginger has also been reported to increase symptoms for some, including heartburn and throat burning during vomiting (Dean and O'Hara, 2015). If the symptoms are already severe, ginger is unlikely to be helpful and therefore delays more effective treatment.

Acupressure of the P6 point of the wrist may have limited benefit but neither acupuncture nor electrical nerve stimulation appear to be effective (ACOG, 2018b). Noise reduction and hypnosis also can be helpful. If not tolerated, stopping the prenatal vitamins may help, but women should continue the supplemental folic acid if possible, and often taking the prenatal vitamins before bed or with food during the largest meal of the day is tolerated. Others recommend adding supplemental thiamin (at least 5 mg/day) to lower the risk of Wernicke's encephalopathy (Fejzo et al, 2016). Various anti-nausea medications are also available, with different modes of action and risk levels. Vitamin B₆, in combination with doxylamine, is often used (ACOG, 2018b). Whether the vitamin B₆ alone is effective as well as what form of the B₆ is best are both unclear but it appears that the metabolites pyridoxine and pyridoxal may function as prodrugs (Matok et al, 2014). Marijuana, while it is promoted by some to help with NVP, is not recommended (ACOG, 2018b). In fact, cannabinoid hyperemesis syndrome, potentially fatal, has been documented (Nourbakhsh et al, 2018).

Small, frequent snacks of carbohydrate foods, including crackers or dry cereal, reduce nausea for some, whereas protein foods may help others (Erick, 2014). Some women crave potato chips. Some do not tolerate odors and are bothered by hot foods, preferring foods that are cold or at room temperature. Smelling lemons may help block noxious odors. Avoiding hunger by eating more frequently often helps, as does separating dry foods from liquids. Avoiding highly spiced foods or bitter foods is helpful for some, but for others taste sensitivity decreases and strong flavors are craved. Women should avoid odors or situations

that trigger symptoms and should eat whatever reduces the nausea sensation. Unfortunately, there is no cure-all. However, reminding the mother that this is a good sign for the pregnancy (i.e., the body is responding as it should), and that it *will* end, often reassures her and lowers the worry and stress, thus helping with the nausea.

When early pregnancy is characterized by excessive vomiting (severity is often estimated by the PUQE score: pregnancy-unique quantification of emesis) and weight loss (often at least 5% prepregnant weight), usually with dehydration, electrolyte imbalances can occur. Here, "morning sickness" becomes **hyperemesis gravidarum (HG)**. The prevalence of HG is 0.3% to 3% of pregnancies (ACOG, 2018b) and is the most frequent cause of hospital admissions early in pregnancy, increasing both worry and the economic burden. Risk factors are the same as those with NVP. Recurrence rate in a subsequent pregnancy is 15% to 81% (Grooten et al, 2016), with higher estimates from surveys in which symptoms are reported rather than those just looking at hospital admissions. Early treatment of NVP, including even preemptive, is thought to help prevent progression to HG (ACOG, 2018b).

Fetal complications of HG vary but include poor fetal growth and preterm delivery. There is an increased risk of fetal loss with gestational malnutrition, as high as 37% spontaneous fetal loss rate among women with significant weight loss and Wernicke's encephalopathy (Chiossi et al, 2006). While documented congenital anomalies are rare, chondrodysplasia punctata resulting from maternal vitamin K deficiency has been documented (Erick, 2014). Research has shown these exposed children have a 3.28-fold increase in the odds of receiving a neurodevelopmental diagnosis, including attention or sensory disorders and speech, language, and learning delays, especially if the HG started before 5 weeks of gestation (Fejzo et al, 2015). Lower insulin sensitivity in children exposed to HG has also been seen (Abramowitz et al, 2017). Maternal complications include extreme fatigue, dehydration, and malnutrition. HG is associated with guilt and a loss of self, often with a sense of dying, as well as with social isolation. It is associated with increased depression and/or anxiety but the direction of the relationship is controversial and stigmatizing the mother is not helpful (Dean et al, 2018). Other complications may include splenic avulsion (spleen is torn from its normal location, resulting in an emergency situation due to excessive bleeding), esophageal rupture, diaphragmatic tears, pneumothorax, Valsalva retinopathy, hypocalcemia, liver dysfunction, acute renal failure, rhabdomyolysis, central pontine myelinolysis, and delirium, as well as maternal posttraumatic stress syndrome and high risk of pregnancy termination when management of HG fails (Erick, 2014; Fejzo et al, 2012; Dean et al, 2018; ACOG 2018b; Abramowitz et al, 2017). Maternal deaths associated with HG have been reported (Fejzo et al, 2016). Difficulty producing breastmilk and bonding also may have to be addressed.

Hospitalization for nutrition support and hydration usually is indicated for HG. Management goals include appropriate weight gain for pregnancy, correction of fluid and electrolyte deficits, avoidance of ketosis, control of HG symptoms, and achievement of nitrogen, vitamin, and mineral balance. Because pregnancy is a condition of accelerated starvation, refeeding syndrome is seen often, especially with the provision of simple dextrose-containing intravenous fluids. Phosphorus, magnesium, and potassium must be evaluated daily because low levels may result in cardiac irregularities and respiratory failure (see Chapter 12). Another potentially serious complication is Wernicke's encephalopathy, with at least 63 cases being reported worldwide (Di Gangi et al, 2012). It is thought to be caused by thiamin depletion and, because there is little storage in the body (Frank, 2015), a deficiency can develop in as little as 2 weeks of vomiting (Selitsky et al, 2006). There is no consensus on early diagnosis, treatment, or prevention. The classic triad of nystagmus and ophthalmoplegia, mental status changes, and ataxia has been found in

only 16% of known HG cases. Women in 60% of cases displayed ocular symptoms, 83% had cerebellar changes, and 52% had memory impairment (Di Gangi et al, 2012). Symptoms are often vague and nonspecific, including headaches, fatigue, abdominal discomfort, irritability, and inability to concentrate. If not treated quickly, Wernicke's encephalopathy can progress to Korsakoff syndrome, with chronic maternal memory impairment (Kloss et al, 2018). Thiamin blood levels are not useful for diagnosis. Instead, thiamin is given intravenously, and a presumptive diagnosis is made if the patient responds. ACOG recommends giving 100 mg IV thiamin with the initial rehydration fluid, followed by 100 mg/day for the next 2 to 3 days, followed by IV multivitamins (ACOG, 2018b). Correcting deficiencies of niacin and magnesium also may be helpful.

In HG, early enteral tube feeding does not consistently improve birthweight (Grooten et al, 2017). Women with severe emesis and retching have often dislodged tubes and are sometimes reluctant for replacement. During hospitalization, frequent nursing checks on tube placement add to sleep deprivation issues, which have not been fully appreciated (Erick, 2014). When enteral nutrition is not tolerated and oral intake is not sufficient, parenteral nutrition should be considered (see Chapter 11). Historically, problems with infections, as well as hyperglycemia, hepatic dysfunction, and respiratory compromise have all been seen (Worthington et al, 2017). However, with careful management, including avoiding overfeeding, adequate glucose control, and meticulous venous access care, these problems can be minimized or eliminated. Parenteral nutrition has safely been employed during pregnancy for HG, as well as GI disorders such as short bowel syndrome and Crohn's disease (Mogensen and Erick, 2017).

Women historically have been reassured that even with HG the fetus is protected, using adequate birth weight as evidence. However, given the results of the Dutch famine studies, it is known that birth weight does not necessarily predict long-term health and that there are consequences of early malnutrition, even if later resolved (Erick, 2014; Roseboom et al, 2011). HG merits early and aggressive attention and treatment.

Some women develop **ptyalism gravidarum**, or excess saliva. It often has an abrupt onset 2 to 3 weeks after conception and reported prevalence varies widely, from 0.08% in the United States to 35% in Turkey (Thaxter Nesbeth et al, 2016). Hormonal changes are thought to play a role but a new possible causal explanation is an increase in the half-life of endokinin B (Lowry and Woods, 2018). Salivary output can be substantial, up to 1.5 to 2.0 liters/day, and can be a source of lost electrolytes as well as dehydration (Thaxter Nesbeth et al, 2016) because the saliva is often spit into a cup or paper tissue. It may interfere with swallowing and cause distended cheek pouches and swollen salivary glands. Because the saliva is excessively thick and the tongue is often enlarged and coated, ptyalism often interferes with speech. It may increase the nausea and vomiting and often adversely affects the sense of taste. It interferes with sleep and is associated with increased depression. However, ptyalism does not appear dangerous for the fetus. Antihistamines may be helpful, as may chewing gum or sucking on hard candy, throat lozenges, lemon drops, or ice. Ptyalism ceases at delivery but may end after the first trimester for some people (Thaxter Nesbeth et al, 2016).

Oral Health

Good oral health is important throughout one's lifetime, including during pregnancy (see Chapter 24). Pregnant women can receive dental care while pregnant, with some qualifications. The National Maternal and Child Oral Health Resource Center provides guidance. Although periodontal infection is associated with preterm birth and LBW, treatment does not appear to lower that risk. However, optimal

maternal oral hygiene may lower the amount of *Streptococcus mutans* transmitted to the infant through sharing spoons or licking pacifiers, thus lowering or delaying the risk of childhood caries.

During pregnancy, increased inflammatory response to dental plaque causes gingivae to swell and bleed more easily. Rinsing with salt water (1 tsp salt in 1 cup warm water) can help soothe the irritation. Erosion of enamel may occur with increased exposure to gastric acid from vomiting or gastric reflux. Rinsing with a baking soda solution (1 tsp baking soda in 1 cup water) may help neutralize the acid (ACOG, 2013a) and tooth brushing should be avoided for at least an hour after vomiting to allow the enamel to reharden (Dragan et al, 2018).

Preexisting Medical Conditions

Many women begin pregnancy with preexisting conditions that can complicate the pregnancy and modify nutrient requirements and appropriate food sources, as well as the supplementation that is necessary. As an example, celiac disease adversely affects fertility for men and women, and the absorption of nutrients often is impaired (Freeman, 2010). Women with celiac disease have increased risk of miscarriages and preterm deliveries. Some prenatal supplements may contain gluten or wheat binders and should be avoided. Women with phenylketonuria (PKU) must be following the dietary restrictions months prior to conception to minimize damage to the fetal brain (see Chapter 42). Women with inflammatory bowel disease may have low serum vitamin B₁₂ levels if there is damage to the intestines. Women with HIV infection may have higher energy needs and the interaction of nutrients with medications may have to be considered. Immigrant women may suffer with active malaria, which invades the placenta, or GI parasites, which can both decrease nutrient intakes and increase nutrient losses. Women with preexisting depression are at risk for poor pregnancy outcome and postpartum depression, putting the mother and her newborn at risk if she is unable to function optimally.

Women also may develop conditions resulting from the pregnancy that need particular attention, including HG, gallstones, or intrahepatic cholestasis of pregnancy. They also may be involved in a motor vehicle accident or other trauma that requires special care or even time in an intensive care unit (ICU). In all cases, the needs of the mother and the fetus must remain paramount. Although guidance is available for some conditions (Crozier, 2017), strong evidence-based recommendations are lacking.

Food Safety during Pregnancy

Although a pregnant woman is no more likely to be exposed to pathogens than a nonpregnant woman, she and her fetus may be at higher risk of suffering negative consequences from foodborne illnesses. In addition, because metabolically active tissues may be more susceptible to the action of toxins, along with the potential long-term effects of fetal exposure to suboptimal conditions, a pregnant woman often has questions regarding the safety of common foods and nonnutritive substances. Those food safety issues of most concern vary between populations. **Box 14.5** summarizes general food safety guidelines.

However, caution is advised to not overestimate the risk of food contamination in pregnancy or the amount of control that an individual has in lowering that risk. It is critical to avoid the impression that a healthy baby is guaranteed if parents do everything right and that the mother is to blame if anything goes wrong. In addition, it is becoming increasingly apparent that maternal psychological stress is also harmful to the pregnancy (see *Clinical Insight: Stress During Pregnancy*).

BOX 14.5 General Food Safety Guidelines**Clean**

- Wash hands thoroughly with soap and water, especially before and after handling food, and after using the bathroom, changing diapers, or handling pets. Do not touch mucous membranes after handling meats.
- Wash cutting boards, dishes, utensils, and countertops with hot water and soap. Washing utensils, including cutting boards, in the dishwasher is preferable.
- Wash raw fruits and vegetables thoroughly under running water, even if the skin will not be eaten.
- Do not wash or rinse meat and poultry.

Separate to Avoid Cross Contamination

- Separate raw meat, poultry, and seafood from ready-to-eat foods when shopping, preparing, and storing foods.
- Use one cutting board for raw meat, poultry, and seafood and another one for fresh fruits and vegetables.
- Place cooked food on a clean plate. The unwashed plate that held raw meat, poultry, or seafood, may be contaminated.

Cook to Proper Temperature

- Cook foods thoroughly. Use a food thermometer to check the temperature. (Color is not a reliable indicator of meat doneness.) Examples include the following:
 - Beef, pork, veal, lamb, large cuts (steaks, roasts, and chops): 145° F + 3-minute rest
 - Fish: 145° F
 - Beef, pork, veal, lamb, ground meats: 160° F
 - Egg dishes: 160° F
 - Turkey, chicken, duck (whole animal, pieces, ground): 165° F

- Cook eggs until firm.
- Reheat leftovers to at least 165° F and sauces, gravies, and soups should be boiled.

Chill to Avoid the Danger Zone

- Refrigerator should register at 40° F or below and the freezer at 0° F. Check the temperature periodically with an appliance thermometer.
- Limit the time foods are in the danger zone, the range of temperatures at which bacteria can grow quickly, usually between 40° F and 140° F.
- Defrost (and marinate) foods in the refrigerator, not on the kitchen counter.
- Refrigerate or freeze perishables (foods that can spoil or become contaminated by bacteria if left unrefrigerated) promptly.
- Use ready-to-eat, perishable foods (dairy, meat, poultry, seafood, produce) as soon as possible.
- 2-hour rule: discard perishable foods left out at room temperature for more than 2 hours. If it is a hot day (more than 90° F), shorten the time to 1 hour.

Avoid High-Risk Foods

- Avoid unpasteurized milks, including goat milk, and foods made of unpasteurized milks. Even if soft cheeses are pasteurized, hard cheeses are safer.
- Avoid raw or undercooked meats, poultry, eggs, fish, or seafood.
- Avoid unpasteurized fruit or vegetable juices. Unpasteurized juice, including cider, must be boiled (full rolling boil) for at least 1 minute.
- Avoid raw or undercooked sprouts, including alfalfa, clover, mung bean, and radish. Cooked sprouts are lower risk.
- Do not open bulging cans.
- Boil home-canned foods for 20 minutes.
- Pay attention to national food recalls, as well as cautions issued locally. Pregnancy is not the time to gamble.

Adapted from Cox JT, Phelan ST: Food safety in pregnancy, part 1: putting risks into perspective, *Contemporary Ob/Gyn* 54:44, 2009a; United States Department of Health and Human Services (USDHHS): *Keep Food Safe: Check your Steps* (website): <https://www.foodsafety.gov/keep/basics/index.html>, 2018.

CLINICAL INSIGHT**Stress During Pregnancy**

Prenatal psychological stress is associated with shorter gestations and lower birth weights. Stress also appears to interact with poor nutrition to negatively affect fetal neurocognitive development, especially the hippocampus and memory functioning, using the same mechanisms as infectious stress (Monk et al, 2013).

All nutrients are important for neuronal and glial cell growth and development. Stress appears to alter the metabolism of many nutrients (protein, glucose, zinc, iron, chromium, choline, folate, vitamin D, B vitamins), but not others (LCPUFA, copper, iodine, vitamin A), and some nutrients (LCPUFA, protein, zinc, iron, choline) may have a role in the stress response (Monk et al, 2013; McCabe et al, 2017; Lindsay et al, 2019).

Distress can induce insulin resistance and proinflammatory cytokines, diverting amino acids to gluconeogenesis and energy production rather than protein production (Monk et al, 2013). Stress also raises the risk of hypertension, increasing uterine artery resistance and lowering nutrient delivery to the fetus. Risk of autism and schizophrenia may increase, but the timing of the insult may affect the response (Marques et al, 2013). Prenatal stress also affects placental development and placental response to fetal development in a sex-specific manner (Cao-Lei et al, 2017), as well as fetal programming, including affecting the production of genes that affect the ability to regulate stress as an adult (Georgieff et al, 2015).

Maternal and fetal immune systems communicate bidirectionally, and the fetal immune system (innate and adaptive) can be disrupted with maternal stress, as well as by exposure to toxins and malnutrition. This disruption may be sufficient to affect a child's response to vaccines but there is no consensus on the timeframe of vulnerability or on the mechanisms (Marques et al, 2013).

When studying infant neurocognitive development, psychological stress and nutritional status must be studied together to examine their bidirectional and synergistic effects, but the effects appear to differ with race and offspring sex (Lindsay et al, 2019). Maternal depression and anxiety, as well as maternal malnutrition, are associated with altered offspring brain anatomy, cognitive impairments, and neurodevelopmental disorders.

When studying intervention strategies, stress and nutrition also need to be studied together (Lindsay et al, 2019). High fat diets appear to be neuroprotective in the context of maternal stress exposure. The type of fat, specifically a low n3:n6 ratio, may be of concern, but the effect appears to vary by race and ethnicity. Prenatal supplementation with antioxidants or 1-carbon nutrients may lower the angiogenic effects of perinatal stress in the adult offspring, at least in the rodent model. Many nutrients, including choline, lutein, B₆, B₁₂, folate, methionine, and betaine, are being studied, but the beneficial effects appear to be sex-specific.

CLINICAL INSIGHT**Stress During Pregnancy—cont'd**

Current evidence is insufficient to recommend any specific diet or nutrient components to mitigate the effect of prenatal stress on neurodevelopmental outcomes in the offspring.

Often issues of psychological stress arise in the course of discussing food intake and weight gain. They would include, but are not limited to, catastrophic life events, verbal or physical abuse, unemployment, and food insecurity, as well as anxiety about the pregnancy itself. In addition, a history of adverse childhood experiences (ACEs) is also associated with lower birthweights and shorter

gestational age (Smith et al, 2016), as well as increased risk in the perinatal and postnatal periods (Madigan et al, 2017). Paternal stress and trauma appear to affect sperm development, negatively affecting offspring neurodevelopment (Chan et al, 2018). Whether or not any of these historic exposures to stress are mediated, or can be altered, by nutritional interventions is unknown. A referral to a mental health professional for evaluation and treatment is warranted and good support systems appear to be helpful (Madigan et al, 2017). See Chapter 30 for more information.

Alcohol

Abundant evidence from animal studies and human experience associates maternal alcohol consumption with teratogenicity, causing a variety of problems collectively known as Fetal Alcohol Spectrum Disorders (FASDs). **Fetal alcohol syndrome (FAS)**, the most involved of these conditions, is the leading cause of preventable birth defects, potentially affecting 5% to 10% of pregnancies worldwide (Harris et al, 2017) (see Chapter 43).

Use of any alcohol during pregnancy is associated with an increased rate of miscarriage, placenta abruption, LBW (five-fold increased risk with at least 1 drink/day), preterm delivery (twofold increased risk), and cognitive compromise (Cox and Phelan, 2009b). Epigenetic effects have also been documented (Gupta et al, 2016) and both maternal and paternal gene expression may affect a fetus' susceptibility to FAS. However, the effects on an individual are difficult to predict and even dizygotic twins can be affected differently (Sarman, 2018).

Poor nutrition can exacerbate the development of FAS. High blood alcohol concentrations can displace or reduce the transfer of nutrients across the placenta. While prenatal interventions to prevent or reverse alcohol's teratogenicity are being explored, including the use of antioxidants and other nutrients, results are not consistent and none are approved for clinical use (Gupta et al, 2016).

ACOG, the American Academy of Pediatrics (AAP), and the March of Dimes recommend that alcohol not be used during pregnancy because no safe threshold has been identified. Reduced-alcohol wines and beers contain small amounts of alcohol and also are contraindicated. Despite the multiple warnings of fetal injury caused by alcohol, some women continue to drink in pregnancy and they should be offered assistance. However, for those women who are fearful of the alcohol they consumed early in pregnancy, possibly before realizing they were pregnant, reassurance is advised.

Allergens

Restriction of the maternal diet during pregnancy and lactation is not advised as a strategy to lower the risk of infant food allergies and may be counterproductive (Renz et al, 2018). Maternal dietary proteins found in amniotic fluid and cord blood have been hypothesized to support the development of tolerance but the issue is still being debated (Jeurink et al, 2018). The mother should avoid her own allergens during pregnancy and lactation but should eat a variety of other foods, including the father's allergenic foods. Regarding peanuts, studies have shown the child has a slightly increased risk of developing peanut sensitization if a mother eats peanuts more than twice a week, but avoidance by the mother appears to be associated with even higher risk (Fleischer et al, 2013). The mother is encouraged to breastfeed exclusively for the first few months. Foods should be added to the infant's diet carefully while still receiving breastmilk, but delaying introduction of solid foods past

6 months provides no benefit. Use of probiotics by the mother or child may be beneficial, but type, timing, and dose are unknown. The roles of maternal fish oil consumption and vitamin D deficiency are also being studied but current data are conflicting and no definite dietary guidance can be given (Garcia-Larsen et al, 2018).

Artificial Sweeteners

Research on the safety of artificial sweeteners is limited, but the FDA has deemed the following safe for use in moderation, including during pregnancy and lactation: saccharin, acesulfame-K, sucralose, aspartame, neotame, advantame, steviol glycosides from stevia leaves, and extracts from monk fruit.

Food additives, including artificial sweeteners, are tested for short- and long-term toxicity; reproductive effects, including teratogenicity; and any adverse effects on an animal's reproductive organs or systems, any birth defects, and genetic toxicity (Rulis and Levitt, 2009). From that data, a safety factor is applied; usually 1/100th of the dose in which any problems have been seen. The resulting value is the acceptable daily intake (ADI), defined as the estimated amount of a food additive that someone can safely consume on average every day over a lifetime without any appreciable health risk. Monk fruit is too new for an ADI to have been determined. Current intakes of the other sweeteners listed here, except for stevia, are well below these ADI levels (Shankar et al, 2013; see Chapter 29).

Saccharin (Sweet'N Low, Sweet Twin, Sugar Twin, Necta Sweet) crosses the placenta (Cohen-Addad et al, 1986) and may accumulate in the fetus and in breastmilk, but adverse effects on the fetus and infant have not been documented (Pope et al, 2014). It has been delisted as a human carcinogen (Kroger et al, 2006; Shankar et al, 2013).

Acesulfame-K (Sunett, Sweet One) consumption by pregnant women is classified as safe, even without long-term studies during human pregnancy. It often is used in conjunction with other artificial sweeteners. It is said to not be metabolized in humans (Kroger et al, 2006). However, in mice it can appear in the amniotic fluid and breastmilk after an oral infusion (Zhang et al, 2011) and animal models have shown it can cross the placenta and increase the preference for sweets as adults (Pope et al, 2014).

Sucralose (Splenda, Nevella), a carbohydrate derived from sucrose, appears to pass through the GI tract relatively unchanged, is not bio-reactive, and does not bioaccumulate (Magnuson et al, 2017). There is no evidence of harm when used during pregnancy and lactation (Pope et al, 2014). It has not been found to be teratogenic in animal studies.

Aspartame (Equal, NutraSweet, Natra Taste) is metabolized to phenylalanine, aspartic acid, and methanol in the GI tract. Studies have shown no significant effect on fertility, conception rates, embryo toxicity, fetotoxicity, or teratogenesis at the levels tested in animals (London, 1988). Its use during pregnancy and lactation has not been

found to increase risk of brain tumors in children (Shankar et al, 2013). The aspartic acid does not cross the placenta in monkeys, and the methanol content is less than that of many fruit juices (Kroger et al, 2006; London, 1988; Pope et al, 2014). Although it is not absolutely contraindicated for women with PKU or for women breast-feeding an infant with PKU, it must be counted as a phenylalanine source. High circulating concentrations of phenylalanine are known to damage the fetal brain (see Chapter 42). Neotame (Newtame) is also a source of phenylalanine and aspartic acid but, because it is much sweeter, the amounts consumed are negligible and do not have to be counted (Kroger et al, 2006). Advantame is also a source of phenylalanine but at such low concentrations that it also does not need to be counted (FDA, 2014). There are no human reproductive studies on advantame, but it is sweeter than neotame, so very small amounts would likely be consumed.

Both stevia and monk fruit are plant-derived sweeteners considered generally recognized as safe (GRAS) in their purified forms. Stevia (Pure Via, Truvia, SweetLeaf) has not been found to affect fetal development, at least with short-term use. *Stevia rebaudiana* traditionally has been used by the indigenous populations of Paraguay for fertility control (Ulbricht et al, 2010). Animal studies have suggested that steviol glycosides may have adverse effects on the male reproductive system, but there are no confirming studies in humans (Kroger et al, 2006; Ulbricht et al, 2010). Caution is advised when used by pregnant or lactating women, or for use longer than 2 years, because of insufficient evidence of safety (Ulbricht et al, 2010; Pope et al, 2014). There is little information on the excretion of Rebaudioside A (the refined preparation of the active ingredient, now considered GRAS) and the other plant components, including steviol glycosides, into breastmilk, so caution is advised when nursing a newborn or a preterm infant. The ADI for stevia is the equivalent of only 9 sweetener packets/day for someone weighing 60 kg. For the extracts of *Siraitia grosvenorii*, known as Swingle fruit, Luo Han Guo, or monk fruit, there is no information available for pregnancy or lactation.

Sugar alcohols (polyols) and polydextrose, a type of dietary fiber, are both likely safe for use during pregnancy. Other sweeteners are available internationally, including thaumatin (*Thaumatococcus daniellii*), derived from the Katemfe fruit. The effect on pregnancy is unknown but is not expected to be of concern (Pope et al, 2014).

Artificial sweeteners often are found in foods with low nutrient content. Intakes may have to be limited so as not to displace the more valuable, nutrient-dense foods. Although average intakes are well below the ADI, an assessment of the diet is warranted to identify those women who may be ingesting multiple sources of artificial sweeteners. If intakes are high, alternatives should be offered.

Bisphenol-A, Phthalates, and Other Environmental Toxins

Bisphenol-A (BPA), an endocrine disruptor, is associated with recurrent miscarriages and may affect thyroid function in humans, especially in the fetus. Its function at the cellular level is still being investigated but there is evidence in mice that it acts similar to diethylstilbestrol (DES) (ACOG, 2013b). Phthalates are associated with shortened gestational length and developmental disruptions. BPA and phthalates, along with 20 other chemicals, are associated with increased risk of weight gain, insulin resistance, and type 2 diabetes later in life after developmental exposure (Barouki et al, 2012). See Table 14.2 for more examples.

There are calls to limit the use of BPA, phthalates, and other environmental toxins. Although recommendations can be made to avoid specific plastics and canned foods (BPA is used as a lining material), most people also have high exposure through air, dust, and personal care products (Sathyanarayana et al, 2013), and changing behavior does not necessarily reduce risk. In addition, having a plastic labeled

“BPA free” does not ensure safety. Most plastics under stress (exposure to boiling water, ultraviolet rays in sunlight, or microwaving) release estrogenic chemicals that may be of more concern than those plastics containing BPA (Yang et al, 2011).

Although it is known that exposure to environmental toxins can have long-term effects, it is unknown whether or how the effects vary by gender or life stage. It is also unknown how the placenta mediates exposure to toxins (ACOG, 2013b; Bloomfield, 2011). The effects may be nonlinear (i.e., low doses can be more harmful than high doses) (Barouki et al, 2012). There are also potential effects on gene expression. ACOG is calling for better research on the reproductive effects of environmental toxins and societal change regarding exposure to these toxins (ACOG, 2013b).

Much of the effect of these chemicals may be during organogenesis, so reducing preconceptional exposure is likely to be most productive. Raising concerns with a mother later in pregnancy without actually being able to change outcomes would not be helpful.

Caffeine and Energy Drinks

Caffeine crosses the placenta and increases maternal catecholamines, but it appears that intakes of less than 200 mg/day are not associated with increased risk of miscarriages, low birthweight, or preterm birth (Practice Committee, 2017). It does not decrease uterine blood flow or oxygenation. However, although there is no clear evidence of harm, the evidence also does not follow the expected dose-response curve, so the effect cannot be determined definitively. The half-life of caffeine increases during pregnancy (8.3 hours longer on average, but can be up to 16 hours longer) so the effect on the fetal brain is potentially increased (Temple et al, 2017). Smoking doubles the clearance rate but alcohol consumption decreases it.

Caffeinated beverages are not considered to be of high nutritional quality, and moderation is encouraged. See Appendix 25 for caffeine food sources. Energy drinks and energy shots are not recommended during pregnancy. They may contain very high caffeine levels (> 500 mg) and also can be highly sweetened (Temple et al, 2017). In addition, these drinks often have high levels of added nutrients and herbal products that have not been evaluated for safety during pregnancy (Procter and Campbell, 2014).

Lead and Cadmium

Contaminants in food are the exception rather than the rule in the United States, but they do occur. In high concentrations, they can pass across the placenta to the fetus (Fig. 14.7). Heavy metals are of particular concern.

Lead contamination is associated with increased risk of miscarriage, gestational hypertension, IUGR, preterm delivery, and impaired neurobehavioral development. It easily crosses the placenta by passive diffusion (Caserta et al, 2013).

In addition to old paint chips, poorly glazed dishware (often imported) and leaded crystal decanters may contain high amounts of lead. Pregnant women should avoid using dolomite as a calcium supplement because the seashells or sea coral often contain heavy metals, including lead, as a result of dumping industrial wastes in the oceans. Imported candies from many areas, including Mexico, China, and India, have also been found to contain lead (Handley et al, 2017). Spices and herbs, notably ground turmeric, have been found to be adulterated with lead chromate (Cowell et al, 2017). Lead can also be found in imported cosmetics, ceremonial powders, and medications, including kohl, henna, sindoor, ayurvedic medicines, and Mexican digestive medicines (Lin et al, 2010). It has also been found in maca root powder (*Lepidium meyenii*), often taken as a fertility enhancer (Johnson-Arbor et al, 2018).

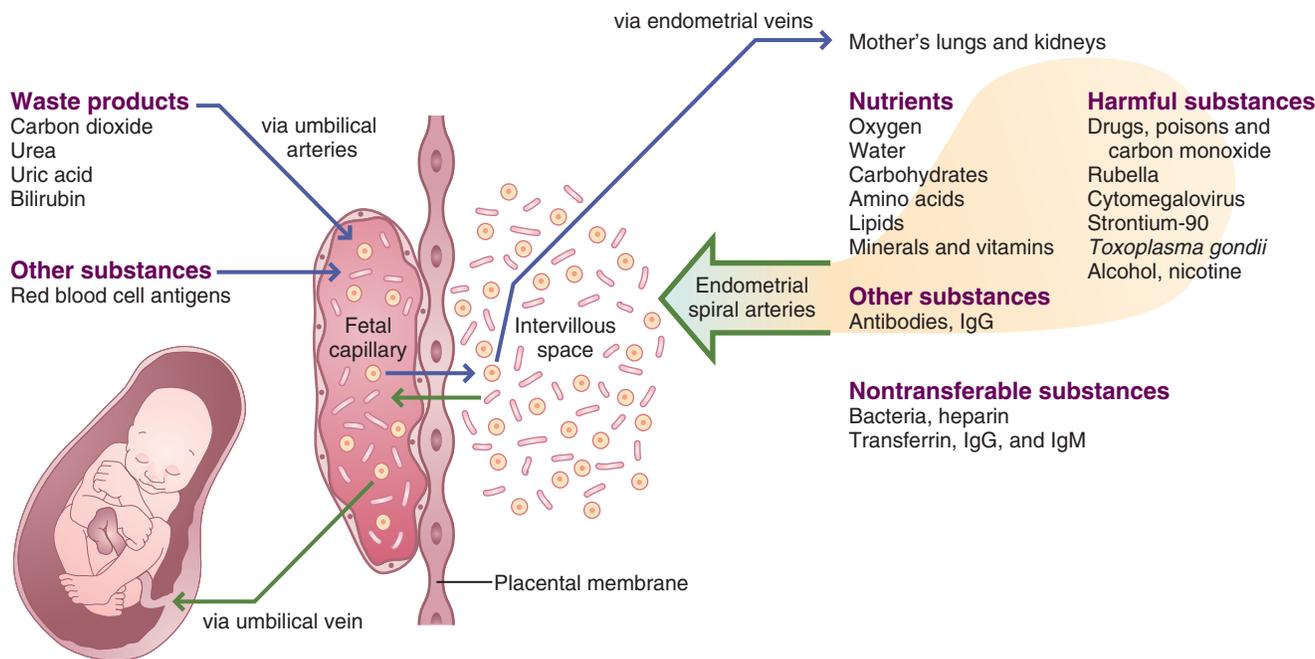

Fig. 14.7 Transfer of substances across the placental membrane. *Ig*, Immunoglobulin.

Cadmium exposure is associated with poor fetal growth (Caserta et al, 2013). It accumulates in the placenta rather than in the fetus, affecting zinc transport to the fetus and altering both the production of placental hormones and trophoblast cell migration. One source of cadmium and other heavy metals may be seaweeds grown in contaminated waters (Desideri et al, 2016).

Other potential contaminants, or sources of contamination, may be important as well, so local issues should be investigated and appropriate guidance given.

Listeria monocytogenes

Listeria monocytogenes affects 1600 Americans each year, killing 260 of them, making it the third leading cause of death resulting from food poisoning (CDC, 2018d). Pregnant women are 10 times more likely than other healthy adults to become infected with *Listeria* spp. and rates among U.S. Hispanic women are 24 times that of the general population, but the reasons for the increased susceptibility are unclear. Although the incidence of listeriosis declined 42% between 1996 and 2012 because of better food safety measures, it has plateaued since then and a better understanding of the effect of different strains, doses, genetic susceptibility, and other unknown factors is needed (Wadhwa Desai and Smith, 2017).

In studies of women who developed listeriosis during pregnancy, 10% to 20% suffered a miscarriage, 11% had a stillbirth, and 50% of them had a preterm delivery (Adams Waldorf and McAdams, 2013). *Listeria* can also cause neonatal meningitis, sepsis, and pneumonia. It may only cause flu-like symptoms in the mother and can mimic a urinary tract infection, but many women have no symptoms and the lack of maternal symptoms is not a reliable marker for fetal risk. Fetal transmission is not inevitable. Infections are much more likely during the third trimester (96%) than in the first (3%), but the consequences are more serious with the earlier infections. With better surveillance and more food recalls, there is now more of an awareness of an exposure, but there is little guidance on how to prevent

the devastating effects if the mother is asymptomatic (Wadhwa Desai and Smith, 2017).

Listeria is a soilborne bacteria and infection results from eating contaminated foods of animal origin or raw produce. Because it can also be airborne, can tolerate high salt environments, and grows in moist environments at refrigeration temperatures, raw milk, smoked seafood, frankfurters, pâté, soft cheeses (especially if made with unpasteurized milk), and uncooked meats are likely sources. Most cases of listeriosis are associated with sporadic contamination rather than epidemics (CDC, 2018d). Because of improvements in processing, the risk of contamination in packaged cold cuts is now one fifth that of retail-sliced meats (Batz et al, 2011). Recommendations to reduce risk include using only pasteurized food products and heating precooked meat products to steaming (Box 14.6).

Mercury and Polychlorinated Biphenyls (PCBs)

Methylmercury contamination is known to affect fetal neural development disproportionately. It crosses the placenta and blood-brain barrier and accumulates in the fetus. Cord blood levels are 2 to 3 times that of maternal levels (Schofield, 2017).

Traces of methylmercury are found in most fish, but concentrations are highest in those fish that are large and predatory. Although advisories are specific to local conditions, the U.S. EPA and FDA currently recommend that all women of childbearing age avoid the consumption of those fish that surpass 1 ppm methylmercury. The methylmercury accumulates in the lean tissue, so cooking methods do not affect the mercury content of the fish (see *Focus On: Childhood Methylmercury Exposure and Toxicity* in Chapter 16).

Not everyone has found long-term problems with methylmercury consumption (Van Wijngaarden et al, 2013). Research shows that selenium may mitigate the harmful effects of mercury by a variety of potential mechanisms. However, the role of selenium in mercury poisoning is multifaceted and bidirectional, with complex interactions depending on the form of mercury, the form of selenium, the

BOX 14.6 *Listeria* Guidelines

Follow the general safety guidelines in **Box 14.5**, including the following:

- Avoid cross contamination with the fluid from hot dog packages.
- Keep raw meats separated from vegetables, cooked foods, and ready-to-eat foods.
- Wash fruits and vegetables thoroughly.
- Eat perishable and ready-to-eat foods (dairy, meat, poultry, seafood, produce) as soon as possible. Check for “use by” dates once/week and throw out food that has passed. Follow recommended storage times for foods.
- Wipe up spills immediately. Clean the refrigerator regularly with hot water and mild liquid detergent, rinse.

Choose lower risk foods.

- Avoid unpasteurized milk or any foods made from raw milks.
- Make sure soft cheeses (feta, Brie, Camembert, blue-veined, or Mexican style “queso blanco,” “queso fresco,” or Panela) are made with pasteurized milk.
- Do not eat hot dogs, luncheon meats, or deli meats unless reheated to steaming (165° F). Meats may be chilled afterward. As an alternative, cooked meats or canned meats (salmon, chicken, tuna) may be used for sandwiches.
- Do not eat refrigerated pâtés or meat spreads. Canned or shelf-stable versions may be eaten.
- Do not eat ham salad, chicken salad, or seafood salad made at the store. Instead, make them at home following general food safety guidelines.
- Do not eat refrigerated smoked seafood unless it is in a cooked dish (165° F). This includes smoked salmon, trout, whitefish, cod, tuna, and mackerel. They are often labeled “nova-style,” “lox,” “kippered,” “smoked,” or “jerky.” They are found in the refrigerated section or sold at the deli counter. Canned or shelf-stable versions may be eaten.

Adapted from Cox JT, Phelan ST: Food safety in pregnancy, part 1: putting risks into perspective, *Contemporary Ob/Gyn* 54:44, 2009a; United States Department of Health and Human Services (USDHHS): *Food Safety for Pregnant Women* (website): https://www.foodsafety.gov/risk/pregnant/index.html#_Food_Poisoning_During_1, 2018.

organ, and the dose (Spiller, 2018). The selenium and mercury contents of fish and shellfish are now being characterized worldwide (Burger and Gochfeld, 2013). Although some have promoted a selenium:mercury ratio as a better way to characterize risk, that may be premature. Selenium appears to protect against mercury toxicity only up to a limit, and excess selenium also can be highly toxic.

Fish also can be a source of polychlorinated biphenyls (PCBs), and prenatal exposure has been associated with child neurologic deficits (Cox and Phelan, 2009b). Although no longer produced, PCBs still remain in the water systems. Although PCBs can be absorbed through the skin and lungs, they primarily enter the body from ingestion of contaminated fatty fish. Farmed and wild ocean fish can contain PCBs, but fresh water fish from the Great Lakes are often of more concern. PCBs readily pass through the placenta and breastmilk. Pregnant and nursing women should avoid eating fish from water known to be highly contaminated with PCBs. Fish from other areas should be cooked to minimize the ingestion of the fat and the skin should not be eaten.

Regarding wild versus farmed salmon, there is controversy. Farmed Atlantic salmon is higher in contaminants (PCBs, dioxins, polybrominated diphenyl ethers or PBDEs, and some pesticides) than wild Pacific salmon, but it also contains higher levels of omega-3s than wild Pacific salmon. Although no data are specific to

BOX 14.7 Fish Safety Guidelines

- Do not eat shark, tilefish from the Gulf of Mexico (also called golden or white snapper, golden bass), king mackerel, marlin, orange roughy, bigeye tuna, or swordfish.
- Albacore (“white”) canned tuna should be limited to 4 oz/week. See Chapter 16 for other fish that should also be limited.
- Other cooked fish and seafood may be eaten, up to 12 oz/week. See *Focus On: Omega-3 Fatty Acids in Pregnancy and Lactation* for recommended choices.
- Avoid refrigerated seafood products unless cooked before eating (165° F).
- Avoid raw or undercooked fish and seafood, including sushi and shellfish. All fish and shellfish should be cooked to 145° F.
- Observe local advisories regarding mercury and other contaminants. For access to your state’s or territory’s advisories, see: <https://fishadvisoryonline.epa.gov/general.aspx>.

Adapted from Cox JT, Phelan ST: Food safety in pregnancy, part 2: what can I eat, doctor? *Contemporary Ob/Gyn* 54:24, 2009b; United States Department of Health and Human Services (USDHHS): *Food Safety for Pregnant Women* (website): https://www.foodsafety.gov/risk/pregnant/index.html#_Food_Poisoning_During_1, 2018; Food and Drug Administration (FDA): *Advice about Eating Fish: What Pregnant Women & Parents Should Know*, November 2017. <https://www.fda.gov/Food/ResourcesForYou/Consumers/ucm393070.htm>.

pregnancy, researchers conclude that the benefit (lives saved from coronary disease) from North and South American farmed sources outweighs the risk (lives lost to cancer) and is on par with the wild sources (Cox and Phelan, 2009b).

The federal guidelines regarding the consumption of commercially available fish have increased the number of fishes that should be avoided (see Chapter 16). Local fresh waters and therefore fish may also be contaminated. Questions regarding methylmercury, PCBs, and other contaminants should be directed to state natural resource departments. In addition, many fish have different local names and both availability and acceptability vary widely, so the guidance many need to be adapted to local conditions.

Most fish and seafood are low in methylmercury, and a few are particularly high in DHA (see *Focus On: Omega-3 Fatty Acids in Pregnancy and Lactation*), so consumption should be promoted. Fish may carry pathogens as well and all fish and seafood should be well cooked (Box 14.7).

Other Foodborne Pathogens and Probiotics

Brucella spp., *Salmonella* spp., and *Campylobacter jejuni* are also of particular concern for pregnant women (Procter and Campbell, 2014). Prompt diagnosis of brucellosis and maternal antibiotic treatment can save the life of the fetus. Transmission of *Brucella* spp. through breastmilk also has been reported. Cases of fetal sepsis and multiorgan failure, leading to death, have been reported with nontyphoidal *Salmonella*. *Salmonella typhi*, the bacteria that cause typhoid fever, and *Campylobacter jejuni* can cross the placenta and infect the fetus, causing miscarriage, stillbirth, or preterm labor (Dean and Kendall, 2012). In addition, other food contaminants, including *E. coli*, can affect anyone, including pregnant women. If exposed, women should be treated carefully, avoiding dehydration. To limit exposure, food recalls should be observed and careful food choices should be made. Federal guidance is available (see Chapter 8).

For a discussion of the issues regarding the microbiome, see *Clinical Insight: The Microbiome During Pregnancy and Lactation*.

CLINICAL INSIGHT

The Microbiome During Pregnancy and Lactation

The importance of the microbiome is now more appreciated, including during pregnancy. While it is now generally thought that the presence of bacteria is not necessarily a pathogenic condition, there is not yet complete consensus on that point (Manuck, 2017; Zhou and Xiao, 2018).

The microbiome of both males and females appears to play a role in conception, including the seminal fluid microbiome (Younes et al, 2018). The vaginal microbiome is known to be important in reproduction and appears to affect assisted reproductive technology (ART) results, but research is still preliminary (García-Velasco et al, 2017). It varies over time and between women, but whether, and how, the diet affects it is still unknown. The vaginal microbiome colonizes the newborn during delivery, potentially affecting immune function and neurodevelopment.

It is now known that the placenta, amniotic fluid, and fetus are not sterile and that microbes move from the maternal to the fetal environment. How that transfer occurs is not completely clear but is hypothesized to be through the blood (Prince et al, 2015), possibly through increased permeability of gingival vascular bed in gingivitis (Younes et al, 2018). Also unclear is whether the transfer can also go from the fetus to the mother (Pelzer et al, 2017). The microbiome of the placenta appears to be unique, is established early, and is more similar to the maternal oral cavity than to her gut, vaginal, or skin microbiome (Prince et al, 2015). Historically, the concern has been that transfer of bacteria to amniotic fluid could cause inflammation and therefore preterm delivery. Particular concern is raised for those women with immune suppression or dysfunction, as well as those with abnormalities in the gastrointestinal mucosal barrier. However, assuming the presence of bacteria is a normal phenomenon, questions are now being investigated regarding how these bacteria vary, what impact they have, and how they can be modified to help maternal and offspring health.

It is now known that the microbiome varies between women. It gets less diverse over the course of pregnancy and the microbiome among women with gestational diabetes mellitus (GDM) is even less diverse (Wickens et al, 2017). The consequences of the variability are not yet clear but it is known that the microbiome midpregnancy differs among women who go on to deliver preterm (Manuck, 2017) and it is speculated that *Lactobacillus* may provide an antibacterial defense over the intraamniotic infections associated with preterm birth. The microbiome may affect perinatal depression and anxiety (Rackers et al, 2018). The dietary components affecting mood, anxiety, and stress response are not completely clear but it appears a high fat diet affects the microbiome composition. In maternal obesity, an altered microbiome is associated with altered short-chain fatty acid production and gene expression, as well as poor glucose control, but whether interventions can help restrain weight gain, reduce GDM frequency, or improve insulin sensitivity is unclear (Zhou and Xiao, 2018). There is no consistent evidence that interventions affect preterm birth risk or other infant or maternal outcomes, including SGA, LGA, or premature rupture of membranes (PROM) (Jarde et al, 2018). There is some

evidence that maternal supplementation with particular strains and doses may be helpful in controlling gestational weight gain, frequency of GDM, glycemic control, modulating inflammatory markers, and reducing the risk of preeclampsia, as well as preventing the development of airway inflammation in offspring (in mice) (Rodríguez-González et al, 2018). Also being investigated are the effects of the microbiome on the fetus' developing immune system and metabolic functioning. However, in the case of atopic disorders, it is not clear if maternal supplementation during pregnancy only, without lactation or infant supplementation, will lower the risk of infant eczema (Wickens et al, 2018; Garcia-Larsen et al, 2018). It is thought that the microbial colonization of the uterus, placenta, and amniotic fluid may prime the fetus to become tolerant to bacteria after birth and therefore affect the infant microbiome and long-term health (Younes et al, 2018).

Improving maternal dysbiosis may help infant health and probiotics appear to be safe when used by healthy people. Attempts to modify the maternal microbiome through the use of prebiotics and probiotics are being investigated for potential benefit during pregnancy. However, there is no evidence yet of a direct beneficial effect of probiotics on reproductive health outcomes (García-Velasco et al, 2017). The results of interventions are often inconsistent and, although most studies have been done on women with normal weight, it is unclear about the impact of prepregnant body mass index (BMI) on the microbiome or the ability to change it. The optimal combination of bacteria (most often tested are *Lactobacillus* spp. and/or *Bifidobacterium* spp.), strains, dosing, timing and duration of exposure, and routes of administration, as well as the age, baseline nutritional status of the mother, and the interaction with stress are all critical and not yet clear, nor is the relative impact of probiotic supplements compared with the consumption of fermented foods. However, there is evidence that the use of fermented milk products is associated with up to a 40% reduction in the risk of severe preeclampsia, depending on the dose (Griffin, 2015), but even just 30 mL/day appears helpful (Berti et al, 2017). Whether the bacteria must be whole or living is also unclear but there is evidence of effective host priming, even if the bacteria are dead, at least in murine studies (Pelzer et al, 2017). In addition, for many commercial products, there appears to be a lack of correlation between the label and the actual contents of the supplements (Jarde et al, 2018) and, while contamination with pathogens is uncommon, it has been reported (Sohn and Underwood, 2017). Many trials are underway and the clinical and application guidelines are still in development.

During lactation, the milk microbiome may contribute to short- and long-term infant health and also to mammary health. Mammary dysbiosis often leads to acute, subacute, or subclinical mastitis. This condition may be resistant to antibiotics and could lead to undesired early weaning. New research providing selected lactobacilli strains isolated from breastmilk show potential in treating this painful condition so that the continuation of successful breastfeeding is not jeopardized (Fernández et al, 2014).

Toxoplasma gondii

Toxoplasma gondii is a parasite that may cross the placenta, causing miscarriage or fetal death. Survivors have chorioretinitis, hearing loss, and long-term neurologic and neurocognitive deficits, but can also have rashes, hepatosplenomegaly, ascites, fever, periventricular calcifications, ventriculomegaly, and seizures (ACOG, 2015c). Rates of congenital toxoplasmosis in the United States are unknown (it is not a reportable disease) but are estimated at 400 to 4000 cases/year (Cox and Phelan, 2009a). Although present in all countries, the prevalence varies considerably. Highest rates of congenital toxoplasmosis are found in some countries in South America, the Middle East, and Africa (Torgerson and Mastroiacovo, 2013).

Symptoms are often mild, flu-like, and unrecognized, although people with immunosuppression can have chorioretinitis and encephalitis. Clinical toxoplasmosis is rare in the United States, and 90% of pregnant women who are infected have no noticeable symptoms (Cox and Phelan, 2009a). However, even without maternal symptoms, the fetus can become infected. Overall transmission rates appear to be 20% to 50% but vary by trimester, including 10% to 15% in the first trimester, 25% in the second, and over 60% in the third trimester (ACOG, 2015c). Although transmission is lowest in the first trimester, the severity is also highest and as many as 90% of those exposed will eventually develop sequelae, even without clinical signs at birth. The risk of passing the parasite to the fetus is reduced greatly if the mother

has been previously exposed and is already seropositive. Although some countries (including France, Austria, Italy, Portugal, and Uruguay) routinely screen pregnant women (Oz, 2017), this is not standard practice in the United States except for those with HIV or immunosuppression (ACOG, 2015c).

Commonly women are encouraged to not handle used kitty litter when pregnant, because the cat is the definitive host for *Toxoplasma*. However, a cat passes the oocysts for only a few weeks in its lifetime. In addition, these oocysts are infective only after being exposed to the environment for at least a day. If the litter box is changed daily, there is little danger, even if the cat were infected and passing the eggs. Cats should be kept indoors and not fed raw meat.

Because the oocysts can live in the environment for years, water, dust, insects, and garden soil can also be contaminated. Fruits and vegetables must be washed, and contaminated water should not be ingested. Gloves should be used when gardening.

Meats and milks also can be infected with tissue cysts, and it is estimated that up to half the cases of toxoplasmosis occur with handling or eating undercooked or raw infected meats, especially wild game and those meats labeled “free-range” or organic (Jones and Dubey, 2012). Oysters, clams, and mussels can be contaminated through water runoff. Unpasteurized goat, camel, and donkey milk are also known sources (Oz, 2017), as are homemade cured, dried, and smoked meats. The injected salt solution that often is used in pork and chicken will kill tissue cysts, as may freezing the meat for a few days. Cooking will kill the parasite, but minimum temperatures must be achieved (Box 14.8).

BOX 14.8 *Toxoplasma* Guidelines

- Follow the general food safety guidelines from Box 14.5.
- Freeze meats for several days before cooking.
- Wash hands after handling raw meats.
- Cook meats to at least 150° F + 3-minute rest (whole cuts), 160° F (ground meats, wild game), or 165° F (poultry). These temperatures may be higher than the USDA recommends for other pathogens. Do not sample meat until it is cooked. Meats that are smoked, cured in brine, or dried may still be infectious.
- Raw oysters, mussels, and clams should not be eaten.
- Keep children's sandboxes covered when not in use.
- Wear gloves when gardening or handling sand from a sandbox. Wash hands thoroughly afterward.
- Peel or thoroughly wash fruits and vegetables before eating.
- Avoid unpasteurized milk, including goat's milk.
- Do not drink water from the environment unless it is boiled.
- Keep your cats indoors. Do not feed them raw or undercooked meats or unpasteurized milks.
- Clean the litter box daily. If possible, have someone else change the litter box. If not, wear gloves and wash hands with soap and warm water afterward.
- Do not adopt a new cat while pregnant nor handle strays, especially kittens.
- Control rodents and other potential intermediate hosts.
- If butchering wild game or venison, bury the organs so that wild cats cannot eat them and spread the infection.

Guide for Eating during Pregnancy

Recommended Food Intake

The increased nutrient requirements of pregnancy can often be met by following the Daily Food Guide (Table 14.15). The USDA MyPlate Plan can be used interactively online. Although it can be a starting point, it is designed for those women with uncomplicated pregnancies. In addition, unless very nutrient-dense foods are chosen, it is likely to be deficient in iron, vitamin D, vitamin E, choline, potassium, and DHA (Center for Nutrition Policy and Promotion [CNPP], 2018). Box 14.9 provides a summary of nutritional care. Weight gain and fetal growth should be monitored and the plan modified as needed.

Fluids

Drinking 8 to 10 glasses of quality fluid daily, mainly water, is encouraged. The DRI for fluid increases slightly during pregnancy, but a woman's body size as well as climate conditions are important considerations. Adequate hydration improves the overall sense of well-being. Frequent urination is often a complaint from pregnant women. However, optimal hydration reduces risks for urinary tract infections, kidney stones, and constipation. In addition, dehydration can cause uterine irritability. Women often must be reminded to pay attention to their intake of liquids, using urine color after the first morning void as a guide.

Nutrient Supplementation During Pregnancy

Supplementation of a mother's diet during pregnancy may take the form of additional energy, protein, fatty acids, vitamins, or minerals that exceed her routine daily intake. The more compromised the nutritional status of the woman, the greater the benefit for pregnancy outcome with improved diet and nutrient supplementation. Among women in low- and middle-income countries, supplementation of both micronutrients and macronutrients, including balanced protein-energy supplements as well as lipid supplements, can improve fetal growth and birth outcomes (Vaivada et al, 2017), including a reduced risk of preterm births (Heidkamp et al, 2017). It is unclear, however, if supplementation benefits fetal growth if the maternal status is not compromised (da Silva Lopes et al, 2017). In the United States pregnant women at nutritional risk are encouraged to enroll in the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), administered by the USDA. The WIC program serves eligible pregnant women and breastfeeding (until 1 year postpartum) and nonbreastfeeding women (until 6 months postpartum), as well as infants and children (up to age 5). For women, “nutritional risk” criteria may include anemia, poor gestational weight gain, and inadequate diet, as well as a variety of preexisting medical conditions. WIC provides targeted supplemental foods, nutrition education, and breastfeeding support as well as health care referrals. Outcome studies show improved birth weights and higher mean gestational ages in infants born to WIC participants.

The goal for nutritional supplementation is to consume the necessary nutrients as food, taking advantage of the likely beneficial synergistic effects and including phytonutrients or other bioactive compounds whose effects are not yet fully appreciated. However, judicious use of dietary supplements (as a multivitamin-multimineral) is needed with undernourished women, including those with a history of bariatric surgery, teenage mothers, women with substance abuse, women with a short interval between pregnancies, women with a history of delivering an infant with LBW, and those pregnant with multiple fetuses. Preconceptional supplementation is recommended for folic acid and may be warranted for other nutrients as well. Current research is examining which micronutrients are most critical to include in the multivitamin-multimineral supplements (da Silva Lopes et al, 2017).

TABLE 14.15 Daily Food Guide: Recommended Servings for a Woman Pregnant with a Singleton or Lactating

Food Group	PREGNANT WOMAN (NORMAL WEIGHT, 30 MINUTES EXERCISE/WEEK)			LACTATING WOMAN (NO FORMULA SUPPLEMENTATION)		Serving Sizes (1)
	First Trimester	Second Trimester	Third Trimester	Early Lactation (0-6 mos)	Later Lactation (6+ mos)	
Total daily calories	1800	2200	2400	2130	2200	
Meat and beans, oz	5	6	6.5	7	6	1 oz = 1 oz meat, poultry, or fish, 1 egg, ¼ c beans, ½ oz nuts, ¼ c tofu
Milk products, cups	3	3	3	3-4	3	1 c = 1 c milk or yogurt, 1.5 oz hard cheese, 2 c cottage cheese
Breads, grains, oz – half should be whole grains	6	7	8	8	9	1 oz = 1 slice bread, ½ c cooked starch, 1 c RTE cereal
Fruits and Vegetables (cups)	4	5	5	6	6	1 c = 1 c raw or cooked fruit or vegetable, ½ c dried fruit, 2 c leafy vegetables
<i>Vitamin C rich</i>	1	1	1	1	1	
<i>Beta-carotene rich</i>	1	1	1	1	1	
<i>Folate rich</i>	1	1	1	1	1	
<i>Others</i>	1	2	2	3	3	
Fats and oils, tsp	6	7	8	8	8	Included are those foods naturally high in fats, including olives, avocados, and nuts
Extras, calories	290	360	410	330	400	High fat or sugar foods or higher amounts of foods from the other groups
Beverages	10 c water/day (watch urine color)			8-12 glasses water or other beverage (drink to satisfy thirst)		8 oz.

BOX 14.9 Summary of Nutritional Care During Pregnancy

1. A variety of foods, focusing on nutrient-dense food choices
2. Energy intake to allow for appropriate weight gain
3. Protein intake to meet nutritional needs, approximately an additional 25 g/day; additional 50 g/day/fetus if pregnant with more than one fetus. This often requires 20% of energy intake from protein
4. DHA from fatty fish (low in methylmercury) twice a week
5. Mineral and vitamin intakes to meet the recommended daily allowances. Folic acid supplementation is often required; iron supplementation may be necessary
6. Sodium intake that is not excessive but not less than 2300 mg/day. Iodized salt is recommended
7. Sufficient fluid intake to produce dilute urine, usually at least 2 L/day
8. Alcohol omitted
9. Omission of toxins and nonnutritive substances from food, water, and environment as much as possible

Many pregnant women have limited knowledge regarding the nutrients in the dietary supplements they have been advised to purchase. Dietary supplements are not regulated as drugs in the United States (Binns et al, 2018). There is no standard definition of what a dietary supplement labeled “prenatal vitamin” must contain and the contents

vary widely. Having it be available by prescription does not imply that the supplement is better, nor safer, nor that it contains higher levels of any particular nutrient (Saldanha et al, 2017). In fact, a recent study found those prenatal supplements available over-the-counter actually contain more nutrients than many of the supplements available only by prescription. It is important to read the label on prenatal supplements because some are much more complete than others, and some include ingredients in addition to the vitamins and minerals. Women often need advice on local, suitable choices. Look for those that contain the United States Pharmacopeia (USP), Consumer Labs, or National Sanitation Foundation (NSF) seals of approval for quality (not safety or effectiveness) (see Chapter 11). A balanced prenatal supplement should contain 400 to 800 mcg of folic acid and also should contain iron unless contraindicated. Caution is advised with the use of the prenatal gummies because they seldom contain iron. Copper is recommended if the supplement also contains zinc or iron (Uriu-Adams et al, 2010). The supplement should contain 150 mcg of iodine in the form of potassium iodide, not kelp or seaweed (Leung et al, 2013). Although some contain DHA, at least as much benefit can come from including high DHA fish regularly in the diet (see *Focus On: Omega-3 Fatty Acids in Pregnancy and Lactation*).

Those supplements containing nutrient levels much higher than the DRI are not recommended because of known teratogenic effects (e.g., preformed vitamin A), as well as potential epigenetic effects. Some contain many additional ingredients, including herbal preparations,

many of which have not been evaluated for safety during pregnancy and may be contraindicated, especially during the first trimester.

As a reminder, prenatal multivitamins-multiminerals may be more critical when a woman's nutritional status is at risk. For others, they may be used as insurance but should not be used as a substitute for eating well. Whether prenatal multivitamin-multimineral supplements are necessary for women living in affluent societies is debated, but their use is common. For women living in low- and middle-income conditions, prenatal supplementation has been associated with better birth outcomes (Vaivada et al, 2017).

Nutrition Education

Nutrition intervention, including medical nutrition therapy (MNT), has been effective in improving the maternal diet, reducing the risk of anemia in late pregnancy, and improving gestational weight gain, thus lowering the risk of preterm birth and improving infant head circumference size and birth weight (Blondin and LoGiudice, 2018). For low-income recipients at risk for low gain and therefore poor fetal growth and preterm delivery, results are enhanced if education is combined with balanced energy and protein supplementation and/or micronutrient supplements. Among women who are overweight and obese, dietary and lifestyle advice results in a significant reduction in the relative risk of delivering an LGA infant, with no increase in the risk of delivering an SGA baby, even if there is no effect on maternal weight gain (Dodd et al, 2015).

ACOG recommends that any woman who is overweight or obese be offered nutrition assessment and counseling, both during the preconception period and the prenatal visits (ACOG, 2014; ACOG, 2015d) and this should continue postpartum to minimize postpartum weight retention. Regarding the effectiveness of MNT on curbing excessive maternal weight gain, results are mixed but interventions can be effective (Elliott-Sale et al, 2018) and studies are ongoing. The intensity of the intervention needs to be balanced with compliance limitations, and addressing barriers must be individualized (Dodd et al, 2015). It appears that diet interventions are more effective than those focusing on physical activity or both (Walker et al, 2018). However, while exercise programs alone do not appear to affect maternal weight gain or birthweight, they do improve maternal fitness (Seneviratne et al, 2015) and may provide other long-term benefits. It is unclear whether a particular exercise dose is critical and it is also unclear if the effect of exercise varies by maternal prepregnant BMI (McDonald et al, 2016).

All women should be given appropriate guidance on the weight gain, as well as nutrient intakes, that are expected, as recommended by the WHO (WHO, 2016b). Although energy needs increase slightly, the mother is not "eating for two" because of the hormonal and metabolic changes that occur during pregnancy, including lowering of maternal nutrient stores (Wakimoto et al, 2015). Helping a mother find acceptable concentrated sources of nutrients and minimizing the intake of high-calorie, low-nutrient foods is likely to reassure the woman who starts the pregnancy overweight or obese and/or is gaining excessively. Just routine weighing is not effective in reducing gestational weight gain, at least among women with obesity (Haby et al, 2018). However, it is certainly helpful when combined with other interventions (Goldstein et al, 2016) and mothers often want guidance.

Although repeated individual face-to-face contact with personalized advice is often done, it isn't always effective. Group meetings are sometimes helpful because of the expanded support that they provide, but in some instances women gain even more weight when participating in group education. While literature may be useful and sufficient for some, for many people just receiving printed materials is likely to not be beneficial. Although eHealth (electronic) and mHealth (mobile) interventions have potential, they have not been shown to be effective. Overall,

there is no one best intervention with optimal duration, intensity, or setting. Interventions should be adapted to local conditions and individualized. Even low levels of intensity and frequency can be helpful in giving a client small "nudges" (Walker et al, 2018).

MNT is known to be helpful during pregnancy. However, to be most effective, dietitians and nutritionists must consider all current issues. A pregnant woman may have poor weight gain and also low iron levels. Foods that address both issues at the same time should be used. She may have low calcium intake but also have GDM, thus modifying how she is counseled. She may have cultural practices that could affect her nutritional status. For example, a woman who is consistently veiled when outside of her house may be at particular risk of low vitamin D levels because of the lack of sun exposure on her skin. She may have preexisting medical conditions that must be managed, including carrying parasitic infections common in her home country. She may develop issues during pregnancy (e.g., anemia, gallstones, or GDM) but also may have medical issues that are not directly related to the pregnancy (e.g., cancer or a Crohn's disease flare-up). She may experience trauma from a motor vehicle accident or physical abuse that could require an ICU admission. She may be willing to walk more but be afraid to do so near her home or after dark. All nutritional issues must be balanced, often with little research data to give firm guidance. One should give the best advice known but be open to changes as the evidence becomes available.

In addition, cultural aspects of counseling also must be kept in mind (see Chapter 10). The beliefs and customs of the home culture of both parents are important in predicting health behaviors and should be addressed, ideally preconceptionally. Acculturation of both is important, but the direction of influence can't always be predicted. For example, non-Hispanic white mothers are more likely to smoke than non-Hispanic black or Hispanic women. However, rates of smoking are higher among immigrants with higher levels of acculturation. A father's beliefs and acculturation are also important, influencing maternal health behaviors (Cheng et al, 2018). For many health behaviors, nativity appears to be more important than ethnicity.

A woman's perceived risk of abnormal weight gain may differ from the U.S. norm. Childrearing, including pregnancy and lactation, usually has strong cultural components, and it is advisable to understand the beliefs and customs of the population groups being served. Although each individual does not necessarily follow, or may not even be aware of, all the beliefs held in the culture, they may influence a person's response to nutritional suggestions. For example, a woman coming from a culture that believes that cleft lip and palate are caused by seeing an eclipse may rely on the safety pin over her abdomen to protect her and may therefore be less concerned about taking her folic acid supplements. If a woman, or a family member, is fearful that eating crabs during pregnancy will cause a miscarriage, that belief should be respected and other sources of protein can be chosen (Milman et al, 2016). A Vietnamese woman who is fearful of drinking cold orange juice immediately postpartum because of the negative effect it will have on the skin years later may be willing to warm the juice, put sugar in it, or eat kiwis for vitamin C instead. A woman from Mexico who believes that you must comply with a craving or something will be missing from the baby, will be afraid to not eat the dirt she is craving. However, she may be willing to smell the wet dirt and eat a burned tortilla, thus complying with the craving but ingesting something that is not likely to be contaminated. She may believe that "vitamins make you hungry" and so will stop taking her prenatal supplements if she feels, or has been told, she is gaining too much weight.

Families often need to be reassured that low-fat and nonfat milks contain the same levels of protein, calcium, and vitamin D as the whole milk (i.e., they are not watered down milk and therefore dangerous for pregnancy). Immigrants from countries where tap water is not potable

need to be reassured that it is treated in the United States and is safe to drink, and that bottled water is not only more expensive but also often does not contain fluoride. On the other hand, an immigrant may be fearful of the prenatal care in the United States when she is not routinely screened for *Toxoplasma gondii*, as is the standard of care at home.

Cultural differences are not apparent just with immigrants. Women who follow a well-balanced vegetarian diet can certainly have a successful pregnancy, assuming food availability is not limited. However, these women may need nutritional guidance regarding protein, iron, zinc, calcium, omega-3 fatty acids, and vitamin B₁₂, especially as trying to eat the required volume of food becomes the limiting factor later in the pregnancy (see Chapter 10). Followers of Jehovah's Witness, because they choose not to receive blood transfusions, may need both earlier and more consistent advice on the consumption of high-iron foods to help keep their iron levels as optimal as possible, lowering their risk of severe complications even if blood loss at delivery is high. Those who practice different dietary patterns during holidays, including fasting, may need guidance on how to minimize the impact of that change on the developing fetus. Someone working nights may need ideas on how to distribute her meals to optimize glucose control.

Pregnant women are adult learners and relevant, simple, concrete messages are most effective, especially if they are memorable and motivational (Girard and Olude, 2012). Having mothers set their own goals is helpful (Haby et al, 2018). Blaming parents for their choices is not helpful and care should be taken when discussing the epigenetic consequences of actions or inactions. All people should be counseled with sensitivity, reinforcing those practices that are particularly helpful and modifying only those practices that may be harmful. One must investigate atypical dietary patterns and food sources to best fit the customs of the patient. Cultural differences should not be ignored or rejected outright. If there are some that must be modified now, it is best to explain why, how, and for how long. Otherwise, the guidance of grandmothers and cultural history will likely prevail.

Pregnancy is a time of great impact. Although historically the goal had just been a full-term, full-size newborn, now the focus has expanded to include ensuring someone biologically predisposed to be healthy from birth to old age (ACOG, 2013b). It is often a time when a mother is very receptive to doing her best for her child. Eating more fruits and vegetables, lean meats, low-fat milks, and whole grains while minimizing excess fat, sugar, and salt intakes will likely improve maternal health and birth outcomes in the short term. Animal research is showing high maternal intakes of fats and sugars during pregnancy and lactation results in altered development of the central reward system in offspring, leading to excessive intakes of these foods postnatally (Mennella, 2014). In addition, research has demonstrated that flavors familiar to the infant, from exposure through the amniotic fluid and breastmilk, are more likely to be accepted by that child when first offered, thus increasing the chance of consumption. Although this may be important nutritionally, exposure to a variety of flavors early in life when the developing brain has heightened sensitivity to environmental influences also appears to facilitate acceptance of novel foods later. Eating better during pregnancy helps develop better food habits for the mother and the rest of her family that, hopefully, will carry on past the current pregnancy, improving the entire family's health. In addition, she is likely to be having positive epigenetic effects and improving the health of future generations, as well as lowering health care costs (Simeoni et al, 2018).

POSTPARTUM PERIOD = PRECONCEPTUAL PERIOD

Reproductive health concerns do not end at delivery and the postpartum period can be considered the "fourth trimester." In addition, for

many women, the postpartum period can be considered a preconceptional period.

Excess postpartum weight retention is associated with increased risk of GDM and hypertension during a subsequent pregnancy, even in normal- and underweight women who gain appropriately in that subsequent pregnancy. Nutrition and exercise counseling should continue postpartum, with the goal of returning the mother to her prepregnant weight within 6 to 12 months and achieving healthy BMI before attempting another pregnancy. However, because less than half of postpartum women achieve their prepregnant weight by 1 year, and over a quarter of women keep at least 10 pounds, all women who are overweight or obese should be offered nutrition counseling for at least 12 to 18 months after delivery (Stang and Huffman, 2016). Intensive dietary intervention, along with objective targets for exercise such as the use of heart rate monitors or pedometers, appear most effective (Nascimento et al, 2014).

Appropriately treating or resolving medical issues such as GDM before a subsequent pregnancy will help ensure a healthy outcome for both mother and baby. Adequate stress management will minimize the adverse effects of stress hormones on offspring neurodevelopment (Huberty et al, 2017).

Nutrient stores also need to be replenished, and short interpregnancy intervals (less than 12 to 18 months) are associated with increased risk of miscarriage, preterm delivery, IUGR or LBW, stillbirth, and early neonatal death (Wu et al, 2012a), as well as maternal morbidity and mortality (Huberty et al, 2017). The nutritional demands of breastfeeding also must be considered, and for those in areas with limited resources, it may take at least 1 year to recover. The WHO recommends women delay conception at least 24 months after a live birth to reduce the risk of adverse maternal, perinatal, and neonatal outcomes, but the applicability of these recommendations to women in the United States is questioned and is being studied (Ahrens et al, 2018). Maternal depletion is theorized to operate through changes in protein and energy balance, but maternal weight is not a predictor of micronutrient status. Even in high-income countries, LBW risk increases if the interpregnancy interval is less than 6 months, and a significant proportion of low-income women in the United States are still iron deficient 2 years after delivery (Bodnar et al, 2002). Other nutrients also may be depleted for an extended period, including folate, vitamin A, and DHA, negatively affecting the subsequent pregnancy (Conde-Agudelo et al, 2012). An antioxidant-rich preconceptional diet may lower oxidative stress and improve pregnancy outcomes. Inflammation is also thought to play a role in increased risk with short interconceptional periods (Wendt et al, 2012), and those women who have no nonpregnant, nonlactating time may be at particular risk. Women who have interpregnancy food supplementation have babies with higher birthweights and lengths and maternal hemoglobin values are higher (Wakimoto et al, 2015).

It is theorized that preconceptional nutrition is as critical as nutrition during pregnancy and for many nutrients, likely more critical because of their role in placental formation and organogenesis (see Preconception and Fertility).

LACTATION

Exclusive breastfeeding is unequivocally the preferred method of infant feeding for the first 6 months of life. Many professional health organizations have endorsed this recommendation, including the Academy of Nutrition and Dietetics, the AAP, ACOG, the American Academy of Family Practitioners, Healthy People 2020, the WIC program, the U.S. Surgeon General, and the U.S. Breastfeeding Committee. These organizations recommend breastfeeding throughout the first year and beyond, as long as mutually desired by mother and child; the WHO encourages

breastfeeding throughout the second year of life. Breastfeeding offers protection from GI and other infections and serves as a critical source of energy and nutrients during illness, reducing mortality among malnourished children. The development of strong immune and digestive systems in breastfed babies is thought to be due to the development of beneficial bacteria in the baby's gut, providing a healthy gut microbial population.

Mothers should be encouraged to breastfeed for as long as possible, even if it is not the full year. Nutrition from breastmilk and the protection from illness it provides are unmatched by any other substitute. In 2016 the Lancet Breastfeeding Series was released stating that, if optimal duration of a minimum of 12 months was achieved, global health care savings would be \$300 billion dollars per year. Additionally, 820,000 lives per year would be saved, and 20,000 deaths from breast and ovarian cancers could be avoided (Victora et al, 2016). Women should be supported in their decision to breastfeed for any length of time, whether it is for just 2 weeks, 2 years, or longer. Breastmilk continues to provide nutrition and immunities throughout the time the mother is lactating. Many women face barriers that may prevent them from breastfeeding for as long as they would like, so support from the health care system along with family members and the community is necessary for mothers to reach their goals (Fig. 14.8).

There are many health benefits for mother and child, as shown in Box 14.10. A recent study examined the racial and socioeconomic disparities in infant feeding, noting that higher rates of breastfeeding are seen in families in which the mother is older and married, with a higher education and income. Long-term health outcomes of breastfed infants and their nonbreastfed siblings were compared and researchers noted that many of these children had similar long-term positive outcomes as their breastfed siblings or children in a comparative group. The authors concluded that a supportive breastfeeding environment and not breastfeeding alone contributes to long-term positive health outcomes of children (Colen and Ramey, 2014). Studies also have

Fig. 14.8 A nursing mother and her infant enjoy the close physical and emotional contact that accompanies breastfeeding. (Courtesy Robert Raab.)

BOX 14.10 Benefits of Breastfeeding

For Infant

Decreases Incidence and Severity of Infectious Diseases

- Bacterial meningitis
- Bacteremia
- Diarrhea
- Infant botulism
- Necrotizing enterocolitis
- Otitis media
- Respiratory tract infection
- Septicemia
- Urinary tract infection

Decreases Rates of Other Diseases

- Asthma
- Celiac disease
- Crohn's disease
- Food allergies
- Hodgkin's disease
- Hypercholesterolemia
- Leukemia
- Lymphoma
- Overweight and obesity
- Sudden infant death syndrome
- Types 1 and 2 diabetes

Other Benefits

- Promotes analgesia during painful procedures (heel stick for newborns)
- Promotes enhanced performance on cognitive development tests
- Promotes mother-child bonding
- Promotes ready acceptance of solid foods

For Mother

- Decreases menstrual blood loss
- Decreases postpartum bleeding
- Decreases risk of hormonal (breast and ovarian) cancers
- Promotes earlier return to prepregnancy weight
- Increases child spacing
- Promotes rapid uterine involution
- Decreases need for insulin in mothers with diabetes
- Decreases risk of postmenopausal hip fracture and osteoporosis

For Society

- Reduces health care costs
- Decreases costs to public programs (i.e., WIC)
- Prevents excess lost wages resulting from employee absenteeism for sick children
- Supports greener environment

shown that levels of C-reactive protein (CRP), a key biomarker of inflammation and a predictor of increased cardiovascular and metabolic disease risk in adulthood, are significantly lower among individuals who were breastfed. Decreased concentrations corresponded to the duration of earlier breastfeeding. Researchers conclude that the longer the duration of breastfeeding, the less inflammation and lower risk for heart and metabolic diseases later in life (McDade et al, 2014).

In 1991, the WHO and the United Nations Children's Fund adopted the Baby-Friendly Hospital Initiative (BFHI), a global effort to increase the incidence and duration of breastfeeding. To become "baby-friendly," a hospital must demonstrate to an outside review board that it implements the "Ten Steps to Successful Breastfeeding," (Ten Steps) a guideline for mother-baby management in the hospital (Box 14.11). In the United States the nongovernmental agency that oversees the designation process is Baby-Friendly USA. In 2018 the WHO released their revised Implementation Guidance for the BFHI (WHO, 2018a). The original Ten Steps have been further refined to meet the current evidence and have been categorized into four focus areas: (1) critical management procedures to support breastfeeding, (2) key clinical practices to support breastfeeding, (3) coordination, and (4) quality-improvement processes. Baby-Friendly USA will be making changes to the U.S. Guidelines in Criteria to be in alignment with WHO recommendations. In a recent systematic review, the Agency for Healthcare Research and Quality (AHRQ) found that the BFHI is associated with improved rates of breastfeeding initiation and duration (Feltner et al, 2018).

The *Surgeon General's Call to Action to Support Breastfeeding* 2011 report states that breastfeeding should be promoted to all women in the United States and supported by clinicians, employers, communities, researchers, and government leaders. All are encouraged to commit to enabling mothers to meet their personal goals for breastfeeding. However, too many mothers are still not able to reach these goals. Improvement of support systems is needed for mothers to overcome challenges and barriers so often in the way of successful breastfeeding. Excess health risks associated with not breastfeeding can be found in Box 14.12.

BOX 14.11 Baby-Friendly Hospital Initiative: Ten Steps to Successful Breastfeeding

1. Have a written breastfeeding policy that is routinely communicated to all health care staff.
2. Train all health care staff in the skills necessary to implement this policy.
3. Inform all pregnant women about the benefits and management of breastfeeding.
4. Help the mother initiate breastfeeding within 1 hour of birth.
5. Show mothers how to breastfeed and how to maintain lactation, even if they are separated from their infants.
6. Give newborn infants no food or drink other than breastmilk unless medically indicated.
7. Practice rooming-in; allow mothers and infants to remain together 24 hours a day.
8. Encourage breastfeeding on demand.
9. Give no artificial teats or pacifiers (also called dummies or soothers) to breastfeeding infants.
10. Foster the establishment of breastfeeding support groups and refer mothers to them on discharge from the hospital or clinic.

BOX 14.12 Excess Health Risks Associated with Not Breastfeeding

Outcome	Excess Risk* (%)	Comparison Groups
Among full-term infants		
Acute ear infections (otitis media)	100	EFF vs. EBF for 3 or 6 months
Eczema (atopic dermatitis)	47	EBF <3 months vs. EBF ≥3 months
Diarrhea and vomiting (gastrointestinal infection)	178	Never BF vs. ever BF
Hospitalization for lower respiratory tract diseases in the first year	257	Never BF vs. EBF ≥4 months
Asthma, with family history	67	BF, 3 months vs. ≥3 months
Asthma, no family history	35	BF, 3 months vs. ≥3 months
Childhood obesity	32	Never BF vs. ever BF
Type 2 diabetes mellitus	64	Never BF vs. ever BF
Acute lymphocytic leukemia	23	Never BF vs. 6 months
Acute myelogenous leukemia	18	Never BF vs. 6 months
Sudden infant death syndrome	56	Never BF vs. ever BF
Among preterm infants		
Necrotizing enterocolitis	138	Never BF vs. ever BF
Among mothers		
Breast cancer	4	Never BF vs. ever BF (per year of breastfeeding)
Ovarian cancer	27	Never BF vs. ever BF

*The excess risk is approximated by using the odds ratios reported in the referenced studies.

EFF, Exclusive formula feeding.

EBF, Exclusive breastfeeding.

BF, Breastfeeding.

Washington, DC, 2011, Office of the Surgeon General.

Contraindications

Contraindications to breastfeeding are rare, but a few conditions warrant at least a temporary interruption from either direct feeding from the breast or from feeding breastmilk. Breastfeeding is contraindicated for infants with classic galactosemia, and for mothers who have active untreated tuberculosis, are positive for human T-cell lymphotropic virus type 1 or 2, have brucellosis, use drugs of abuse (without medical supervision), have HIV (in the United States) (USDHHS, 2018a), or who take certain medications (i.e., antimetabolites and chemotherapeutic agents). Exclusive breastfeeding in HIV positive mothers on antiretroviral therapy is highly recommended throughout the world (WHO, 2016a). A mother should not breastfeed with active herpes simplex lesions on her breast; however, expressed milk can be used without concern. If a mother develops varicella 5 days before through 2 days after delivery, she should be separated from her infant but can provide her expressed milk to the infant. Mothers who have influenza should be encouraged to continue to breastfeed (CDC, 2018b). Mothers acutely infected with H1N1 influenza should separate themselves from their infants while febrile, but again, can provide their expressed milk for feedings (AAP, 2012). The use of most radioactive isotopes requires

temporary cessation of breastfeeding, ranging from 6 hours to up to 1 month (Hale, 2019). Women undergoing procedures using these types of medications should consult with their health care provider to determine the specific drug used so that adequate time is allowed for clearance, but no more time than is necessary so that breastfeeding can be resumed. Clearance time varies between drugs; expressing and discarding breastmilk can help preserve milk production if extended cessation is necessary.

The CDC advises women in the United States who have HIV to refrain from breastfeeding to avoid postnatal transmission to their infants through their breastmilk. Because sanitary conditions for safe use of infant formula are available in the United States, experts believe the morbidity risk can be kept to a minimum. However, in developing countries where sanitary conditions are not as prevalent, and the rate of mortality in the infant from infectious diseases and malnutrition are high, the health risks of not breastfeeding must be considered. In addition, in areas where HIV is prevalent, exclusively breastfeeding for the first 3 months has been shown to reduce the risk of infants acquiring HIV compared with infants who receive a mixed diet of human milk and other foods, including infant formula. Six months of exclusive breastfeeding while the mother receives antiretroviral therapy has been shown to significantly reduce the postnatal acquisition of HIV (AAP, 2012).

Nutritional Requirements of Lactation

Despite the fact that breastfeeding increases the need for energy and some nutrients, human milk is made from maternal nutrient stores, so well-nourished mothers need not worry that the quality of their breastmilk will suffer from an imperfect diet. Breastmilk remains perfect for the infant even in cases of hardship and famine. Only in rare cases when mothers experience long-term, severe nutritional deficiency is their breastmilk affected. An excuse to not choose breastfeeding based on the fact that a woman enjoys drinking coffee or tea, or an occasional alcoholic beverage, is unwarranted.

Unless a vitamin-mineral deficiency is identified, or the mother has a restricted diet or an issue with malabsorption, dietary supplements are usually not necessary. A diet including a variety of whole foods, adequate in calories, should provide the woman with all the nutrients she needs. Despite this fact, many clinicians recommend the continued use of a prenatal vitamin/mineral supplement for the duration of lactation, especially if the mother remains iron deficient after birth.

Increased prolactin receptors in the breast and therefore higher maternal prolactin levels develop with early suckling stimulation and milk removal, a process enhanced with increased frequency of breastfeeding in the early neonatal period. The maternal response to her infant's hunger cues will stimulate her milk supply, averaging about 8 to 12 breastfeeds over 24 hours in the first 2 to 3 weeks. Encouraging the mother to focus on recognizing hunger cues versus watching the clock is highly recommended. The belief that more milk is made with increased fluid consumption is misguided because the body will excrete excessive fluid to maintain electrolyte balance. This actually may result in a decrease of milk production. Concern for the mother's hydration and her ability to produce an adequate milk supply is only valid during extreme conditions such as severe drought or famine. Insufficient milk supply can be as much of a problem in well-nourished women as in poorly nourished women; cross-cultural studies show it to be unrelated to maternal nutrition status. Poor maternal nutrition may affect the quantity, but not quality, of mothers' milk (Lawrence and Lawrence, 2016). Although a mother's milk maintains its quality even when nutrient intake is suboptimal, the woman feels the effects of eating poorly, possibly affecting her immune system, and feels tired with less energy. A nutritious dietary intake helps her cope with the everyday demands of caring for a new infant.

Milk composition varies according to the mother's diet. For example, the fatty acid composition of a mother's milk reflects her dietary intake. In addition, milk concentrations of selenium, iodine, and some of the B vitamins reflect the maternal diet. Breastmilk of *extremely malnourished* mothers has been shown to have lower levels of various nutrients, reflecting the foods she has available to eat. One must remember that milk composition varies widely in the concentration of macronutrients within and between individual mothers. Several factors, including length of pregnancy, mother's diet, stage of lactation, duration of feeding, and the time of day the feeding takes place, can affect the composition of human milk. Protein levels tend to fall in the early postpartum period, whereas the fat component of the milk initially may decrease and eventually increase in concentration over time. During an individual feeding, fat content typically increases significantly and can result in a much higher caloric content in the milk toward the end of the feeding (Khan et al, 2013). Fat content also may be higher when the interval between breastfeedings is closer together. When the infant "cluster feeds," the milk available in the breast is higher in fat content. When more time is allowed between feedings, the breasts fill with milk with higher water content. At the next feeding, the infant may not be able to consume all the milk available and ends up taking mainly low-fat milk.

Energy

Milk production is 80% efficient: production of 100 mL of milk (approximately 75 kcal) requires an 85-kcal expenditure (Lawrence and Lawrence, 2016). During the first 6 months of lactation, average milk production is 750 mL/day (about 24 oz), with a range of 550 to more than 1200 mL/day. Because production is a function of the frequency, duration, and intensity of infant suckling, infants who feed well are likely to stimulate the production of larger volumes of milk.

The DRI for energy during lactation is 330 kcal greater during the first 6 months of lactation and 400 kcal greater during the second 6 months of lactation over that for a nonpregnant woman. However, considering milk production usually drops to an average of 600 mL/day (approximately 20 oz/day) after other foods are introduced into the infant's diet, ingested calorie levels may have to be adjusted for the individual woman who wishes to avoid weight gain. A mother is able to draw approximately 100 to 150 kcal/day from pregnancy fat stores.

Healthy breastfeeding women can lose as much as 1 pound per week and still supply adequate milk to maintain their infants' growth. The combination of diet and exercise together, or diet alone can help women to lose weight after childbirth (Amorim Adegbeye and Linne, 2013). In a study of 68 adolescent mothers and 64 adult mothers, postpartum weight loss in both groups was significantly greater in those who were exclusively breastfeeding (EBF) compared with those who did not EBF. Moreover, the infants of the mothers continued to grow according to the 2006 WHO growth standards despite their mothers' weight loss (Sámano et al, 2013). However, milk production has been shown to decrease in mothers whose intakes are suboptimal (less than 1500 to 1800 calories/day) (West and Marasco, 2009). Mothers are advised to wait until breastfeeding is well established (approximately 2 months) before consciously trying to lose weight so that an adequate milk supply can be established. Appropriate fluid intake (such as drinking for thirst) and adequate rest also are recommended. A slow weight loss of no more than about 5 pounds per month supports more permanent weight loss as well as allows for adequate energy and nutrition for new motherhood.

Protein

The DRI suggests an additional 25 g of protein a day for lactation, or 71 g of protein a day, based on an RDA of 1.1 gm/kg/day of a woman's

body weight. Clinical judgment is necessary with protein recommendations because 71 g/day may be too low for a woman with a larger body size and too high for the woman with a smaller body. Women with surgical delivery and women who enter pregnancy with poor nutritional status may need additional protein. The average protein requirement for lactation is estimated from milk composition data and the mean daily volume of 750 mL, assuming 70% efficiency in the conversion of dietary protein to milk protein.

Breastmilk has a whey:casein ratio of 90:10 early in lactation, which changes to 80:20 as an average, and to 60:40 as the baby gets older. It is speculated that this ratio makes breastmilk more digestible. In contrast, the whey:casein ratio of cow's milk protein is 18:82. Cow's milk-based infant formula varies among commercial manufacturers, ranging from 18:82 whey:casein, to 52:48 whey:casein, and even up to 100% whey (see Chapter 15).

Carbohydrates

The RDA for carbohydrate is designed to provide enough calories in the diet for adequate volumes of milk and to maintain an adequate energy level during lactation. This may have to be adjusted depending on activity of the mother and the amount of breastfeeding. The woman with poor gestational weight gain may require more carbohydrates. Women who had gestational diabetes during pregnancy should continue on the MNT diet they were on during pregnancy for optimal management of blood sugar if recommended to do so by their medical provider. A modified carbohydrate diet is often implemented to meet the dietary needs in this condition.

The principal carbohydrate in human milk is lactose; however, there is no evidence that maternal intake of carbohydrates affects the level of lactose in her milk.

Lipids

Dietary fat choices by the mother can increase or decrease specific fatty acids in her milk, but not the total amount of fat in the milk. Severe restriction of energy intake results in mobilization of body fat, and the milk produced has a fatty acid composition resembling that of the mother's body fat.

There is no DRI for total lipids during lactation because it depends on the amount of energy required by the mother to maintain milk production. The recommended amounts of specific omega-6 and omega-3 LCPUFAs during lactation vary little from pregnancy; they are crucial for fetal and infant brain development. One to two servings of fish per week meet this need (herring, canned light tuna, salmon). Mothers should avoid eating predatory fish to prevent excessive levels of dietary mercury (pike, marlin, mackerel, albacore tuna, and swordfish) (AAP, 2012; see also Chapter 16). Intake of trans fats should be kept to a minimum by the nursing mother so that the potential for their appearance in her breastmilk is reduced. See *Focus On: Omega-3 Fatty Acids in Pregnancy and Lactation* for more information about including DHA in the maternal diet.

Human milk contains 10 to 20 mg/dL of cholesterol, resulting in an approximate consumption of 100 mg/day, which has been determined to be essential to the diet of the infant. The amount of cholesterol in milk does not reflect the mother's diet and decreases over time as lactation progresses.

Vitamins and Minerals

Vitamin D. The vitamin D content of breastmilk is related to maternal vitamin D intake as well as environmental conditions. Numerous case reports document marginal or significant vitamin D deficiency in infants of lactating women who are veiled, who are dark skinned, who have a BMI of more than 30, who use sunscreens heavily,

or who live in latitudes with decreased sun exposure. Women with lactose intolerance who do not drink vitamin D–fortified milk or take a vitamin supplement may be at higher risk for vitamin D deficiency. Hypocalcemic rickets, including cases of dilated cardiomyopathy, have been reported in the United States in breastfed, dark-skinned infants (Brown et al, 2009).

Because of reports of clinical rickets, the AAP recommends that all infants receive 400 IU (10 mcg) of vitamin D as a daily supplement starting at birth, allowing the infant to easily achieve vitamin D sufficiency. For formula-fed infants, they may cease supplementation once the infant is consuming 1 liter of formula per day. Canada recommends 800 IU/day for adults living north of 45° N latitude, but the mother may need much higher doses (100 mcg or 4000 IU/day) to achieve normal 25(OH)D concentrations and vitamin D adequacy in her exclusively breastfed infant. Because the antirachitic activity of human milk is low (5–80 IU/L), the lactating mother requires a significant amount of vitamin D daily from food or UV exposure. Maternal circulation allows transfer of the parent compound, Vitamin D3 itself, and not circulating 25(OH)D, into human milk. Although maternal baseline circulating 25(OH)D level may be adequate, it cannot be assumed that the vitamin D activity of the mother's milk is adequate for the infant. Because of the binding affinity to vitamin D binding protein, the circulating half-life of 25(OH)D is 3 to 4 weeks, while that of vitamin D3 is just 12 to 24 hours; the reduced affinity of vitamin D3 allows the unbound vitamin D3 to diffuse across cell membranes from blood into the milk. In order for levels for vitamin D to be sustained in both the maternal circulation as well as the milk supply, a daily dose of vitamin D is required. Recent studies have shown that a daily maternal intake of 6400 IU of vitamin D is safe and allows a mother to produce milk that will provide adequate amounts of vitamin D to her exclusively breastfed nursing, without additional supplementation directly to the infant (Hollis et al, 2015).

Calcium. Although breastfeeding mothers should be encouraged to meet their DRI for calcium from their diet, the calcium content of breastmilk is not related to maternal intake, and there is no convincing evidence that maternal change in bone mineral density is influenced by calcium intake across a broad range of intakes up to 1600 mg/day. A recent study evaluated calcium intakes of 33 Gambian lactating women during two different lactational time periods. The study found that even with suboptimal intakes, the bone mineral mobilization during lactation was recovered after lactation. They concluded that successive periods of long lactation are not associated with progressive skeletal depletion (Sawo et al, 2013).

Iodine. Adequate breastmilk iodine levels are particularly important for proper neurodevelopment in nursing infants, and required intakes are nearly double nonpregnant values. Iodine concentrations in breastmilk are considered to be adequate to meet infants' iodine nutritional needs in areas where food sources are adequate. However, mothers living in iodine-deficient areas, especially if also consuming goitrogens or exposed to perchlorate contamination, may produce milk with iodine concentrations insufficient to meet the needs of the infant. As mentioned earlier, hyper- and hypo-thyroidism can affect breastmilk production, and so mothers should choose food sources of iodine, such as iodized salt, dairy foods, seafood, and breads made with iodide. Recent recommendations from the AAP state that lactating women should ensure a daily intake of 290 mcg of iodide, which generally requires supplementation of 150 mcg/day.

Zinc. The requirements for zinc during lactation are greater than those during pregnancy. Breastmilk provides the only dietary source of zinc for exclusively breastfed infants, and it remains a potentially important source of zinc for children beyond infancy who continue to breastfeed. In the process of normal lactation, the zinc content of breastmilk

drops dramatically during the first few months from 2 to 3 mg/day to 1 mg/day by the third month after birth. Zinc supplementation has not been found to affect concentrations in the breastmilk of women in developed countries but may increase the zinc content of the milk of women in developing countries with suboptimal zinc status (Sazawal et al, 2013).

Vitamin B₁₂ and the Vegan Mother. For lactating mothers who follow a strict vegan diet without any animal products, a vitamin B₁₂ supplement is strongly recommended. The milk of a vegan mother can be severely deficient in vitamin B₁₂, leading to a deficiency in her infant which, if not treated, can lead to growth failure and permanent damage to the nervous system. Nursing mothers who follow a strict vegetarian diet should have their infant's B₁₂ levels monitored. Lactating mothers who have undergone gastric bypass surgery are also at greater risk for B₁₂ deficiency (see Appendix 31).

Sodium. Sodium intake during lactation should be controlled with the inclusion of a diet composed of foods high in nutritional value, which are naturally lower in sodium. Although there is no specific recommendation or restriction for sodium in the diet of breastfeeding mothers, a relationship has been established between the sodium intake of mothers and breastfeeding success. A recent study examined whether maternal salt preference may facilitate breastfeeding. The investigators found that mothers with a preference for a low salt intake had higher rates of successful breastfeeding beyond day 7 compared with mothers with high salt preference. Mothers with high salt preference had the shortest exclusive breastfeeding duration up to postnatal day 25 (Verd et al, 2010). Future studies are warranted to determine exactly what effect maternal sodium intake has on the success of breastfeeding.

Fluids

A nursing mother may feel a need to drink simply because of increased fluid output when breastfeeding her infant. She should drink to thirst but not feel she must force fluids, which is not beneficial and may cause discomfort. The beverage of choice is water; however, water is the main component of many beverages and can be used as such in the body.

Caffeine. Caffeine is acceptable in moderate amounts (less than 300 mg daily, see Appendix 25) and does not present a problem for the healthy full-term infant. If the mother is nursing a preterm infant, however, the baby may be particularly sensitive to large intakes of caffeine. In this case the mother is advised to observe her infant closely for signs of overstimulation, such as being unusually fussy or not being able to settle easily. If so, the mother should adjust her caffeine intake accordingly. It may take a few days after reducing caffeine intake for mother to notice a difference in the baby's symptoms. There is no evidence that caffeine affects milk supply, although if a baby is overstimulated, he may not nurse well, which could lead to dysfunctional breastfeeding and eventually a lowered maternal milk supply.

Alcohol. No safe amount of alcohol has been established for the nursing mother, but recommendations include limiting intake to 0.5 g alcohol/kg maternal body weight (AAP, 2012). For a 60-kg mother, this equals approximately 2 oz liquor, 8 oz wine, or two beers per day. Peak alcohol levels occur in about ½ to 1 hour after drinking, although this varies among women depending on mother's body composition. There is no need for a mother to express and discard her milk after taking 1 to 2 drinks, thinking this will speed the elimination of alcohol from the milk, unless it is for her own comfort. As blood alcohol decreases, so does alcohol concentration in the milk. Mothers should be discriminatory about any alcohol intake when nursing a premature, young, or sick baby because this baby would be affected much more than the older, more mature baby. In addition, mothers should consider their ability to care for their children when under the influence of alcohol. If occasional alcohol intake occurs, moderation is advised at all times for breastfeeding mothers.

Box 14.13 Summary of Nutritional Care During Lactation

1. A variety of foods, focusing on nutrient-dense food choices.
2. Energy intake to allow for maintaining health and well-being; calorie level no less than 1800 kcal/day. Intentional weight loss not advised before breastfeeding is well established (approximately 2 months).
3. Protein intake to meet nutritional needs, approximately an additional 25 g/day from base level prepregnancy. This often requires 20% of energy intake from protein.
4. DHA from fatty fish (low in methylmercury) twice a week.
5. Mineral and vitamin intakes to meet the recommended daily allowances (usually met from a variety of foods in the diet). Supplements as directed from health care provider.
6. Drink to thirst; have beverages readily available during nursing and when expressing breastmilk.
7. If desired, alcoholic beverages can be consumed on occasion, in moderation. Not recommended with preterm, very young, or sick infants.
8. Omission of toxins and nonnutritive substances from food, water, and environment as much as possible.

See Table 14.15 and Box 14.13 for summaries of nutritional care during lactation.

Prenatal Breastfeeding Education

The advantages of breastfeeding should be presented throughout the childbearing years. During pregnancy, counseling on the risks of formula feeding and the process of lactation should be provided to women so that they can make an informed decision about how they will feed their baby and so that they understand how to achieve successful breastfeeding. As optimal maternity care practices become the norm in hospitals and birth centers, women should be educated on these practices in advance of delivery. Prenatal breastfeeding education is recommended strongly for women and their partners. The emotional support provided by the mother's partner contributes heavily to the success of the breastfeeding experience.

During this time the mother should identify a support person to call upon after breastfeeding begins. Because initiation and establishment of breastfeeding can seem intense and full of challenges for new mothers, it is wise for her to know who to turn to when questions or concerns arise. A knowledgeable family member or health professional, doula, peer counselor, or childbirth educator can provide the encouragement so often needed for a mother in the early postpartum period. Prenatal breastfeeding counseling with regular follow-up after delivery has been shown to have a positive effect on early initiation and sustained exclusive breastfeeding, especially among primiparous mothers, with group counseling having even more beneficial impact than individual counseling (WHO, 2017). When more complicated problems are identified, an International Board Certified Lactation Consultant (IBCLC) can intervene, which may mean the difference between early weaning and a successful breastfeeding experience.

Physiology and Management of Lactation

Mammary gland growth during menarche and pregnancy prepares the woman for lactation. Hormonal changes in pregnancy markedly increase breast, areola, and nipple size as well as significantly increase ducts and alveoli and influence mammary growth. Late in pregnancy the lobules of the alveolar system are maximally developed, and small amounts of colostrum may be released for several weeks before term and

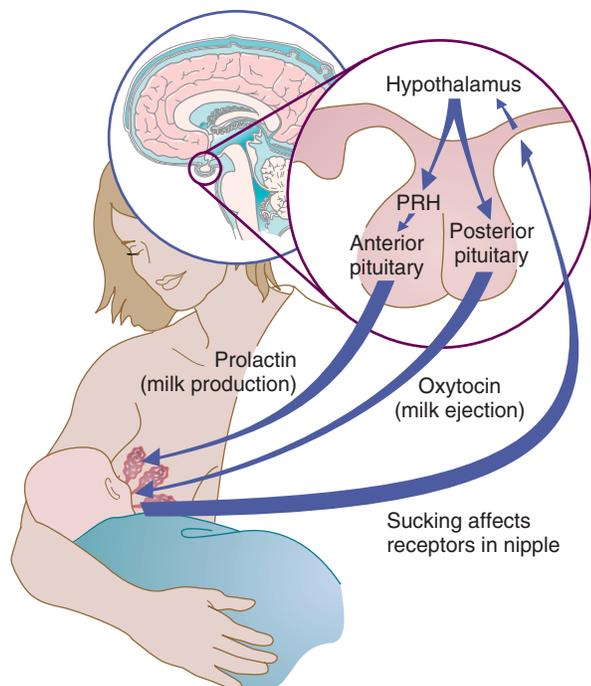

Fig. 14.9 Physiology of milk production and the let-down reflex. PRH, Pituitary-releasing hormone.

for a few days after delivery. After birth there is a rapid drop in circulating levels of estrogen and progesterone accompanied by a rapid increase in prolactin secretion, setting the stage for a copious milk supply.

The usual stimulus for milk production and secretion is suckling. Subcutaneous nerves of the areola send a message via the spinal cord to the hypothalamus, which in turn transmits a message to the pituitary gland, where the anterior and posterior areas are stimulated. Prolactin from the anterior pituitary stimulates alveolar cell milk production, as shown in Fig. 14.9. Women who have diabetes, who are obese, who experience stress during delivery, or who have retained placental fragments in the uterus are at risk for delayed milk production (i.e., when signs of lactogenesis are absent 72 hours after birth).

Oxytocin from the posterior pituitary stimulates the myoepithelial cells of the mammary gland to contract, causing movement of milk through the ducts and lactiferous sinuses, a process referred to as **let-down**. “Let-down” is highly sensitive. Oxytocin may be released by visual, tactile, olfactory, and auditory stimuli; and even by thinking about the infant. Oxytocin secretion also can be inhibited by pain, emotional and physical stress, fatigue, and anxiety.

Stages of Milk and Variations in Composition

Human milk varies in nutritional composition throughout the maternal lactational period and seems to be more sensitive to maternal factors such as body composition, diet, and parity during later lactation than during the first few months (Lawrence and Lawrence, 2016). This fluid is constantly changing to meet the needs of the growing infant; nutrient composition changes throughout the duration of lactation, but also over the course of a day, and even during a feeding.

The delivery of the placenta after the birth of a baby triggers **lactogenesis I**, or the beginning of milk production. **Colostrum** is the thick, yellowish secretion that is the first feeding for the infant. It is higher in protein and lower in fat and carbohydrate, including lactose, than mature milk. It facilitates the passage of meconium (first stool of neonate), is high in antioxidants, and is lower in water-soluble vitamins than

mature milk. Colostrum is also higher in fat-soluble vitamins, protein, sodium, potassium, chloride, zinc, and immunoglobulins than mature milk. Colostrum provides approximately 20 kcal/oz and is a rich source of antibodies. It is considered the baby’s first immunization.

Transitional milk begins to be produced approximately 2 to 5 days after delivery until around 10 to 14 days postpartum. During this stage of **lactogenesis II**, white, creamy milk is produced in much greater quantities than colostrum, and breasts become larger and firmer. This is the time when mothers feel their milk “come in.” It is important for mothers to breastfeed often during this stage (8 to 12 times/day) to avoid engorgement and allow proper emptying of the breast by the infant. This also ensures adequate fluid and nutrition for the baby during this time. This period is an extremely important time to bring in a full milk supply, which can be established by the infant only with unrestricted access to breastfeeding.

Mature milk is the final stage of milk production and usually begins to appear near the end of the second week after childbirth. **Foremilk**, the first milk released during a breastfeed, is high in water content to meet the baby’s hydration needs. It is low in calories but high in water-soluble vitamins and protein. This milk is thinner, sometimes with a bluish color, and resembles skim milk when first released from the breast.

As the baby nurses during a breastfeed, the milk becomes creamier, indicating a higher fat content. This milk, high in fat-soluble vitamins and other nutrients, is called **hindmilk**. It provides satiety and the calories to ensure growth in the baby. It is important for the mother to allow the infant to empty the first breast at each feeding to obtain this hindmilk, before offering the other breast. This way, the baby is assured of obtaining the complete nutrition available from the mother’s milk. Hindmilk is released as the breast is emptied and signals to the baby that a feeding is over. This mechanism helps the infant to learn when to end a feeding and may contribute to the prevention of overeating and subsequently becoming overweight later in life. The longer the mother goes between feedings, the more foremilk will be stored in the breast; however, when feedings are closer together, the baby receives more hindmilk in each feeding. Babies need a balanced diet, with sufficient amounts of foremilk and hindmilk for proper growth and development.

As the mother progresses during the lactational stage of motherhood, her breasts return to her prepregnancy size and may appear somewhat softer and smaller than earlier. This does not indicate a lower milk supply, but only her body’s adjustment to established breastfeeding. A woman continues to produce nutritious mature milk, as well as enjoy the emotional and immunologic benefits, for as long as she breastfeeds. Exclusive breastfeeding is recommended for the first 6 months, followed by continued breastfeeding as complementary foods are introduced, with continuation of breastfeeding for 1 year or longer, as mutually desired by mother and child (AAP, 2012).

As mentioned previously, breastmilk is a dynamic fluid, changing throughout the lactational period of the mother. Breastmilk continues to provide an infant with needed amounts of essential nutrients well beyond the first year of life, especially protein, fat, and most vitamins. Breastfed infants tend to gain less weight and usually are leaner than are formula-fed infants in the second half of infancy, which does not seem to be the result of nutritional deficits, but rather infant self-regulation of energy intake. The nutrients most likely to be limiting in the diets of breastfed infants after 6 months of exclusive breastfeeding are minerals such as iron, zinc, and calcium. These nutrients are readily available through an age-appropriate diet consisting of meats, whole grains, dairy foods, fruits, and vegetables.

During growth spurts, or times of rapid infant development—typically around 2 weeks, again at 4 to 6 weeks, and anytime between

3 and 6 months—babies may increase their desire to nurse to meet caloric needs. If allowed to do so, this triggers an increase in the mother's prolactin level, and after a few days, she will begin to make more milk. If supplements are introduced at these times to satisfy the infant's hunger, the mother will not have the advantage of increased stimulation from the infant's suckling and will not be able to keep up her supply to meet the baby's nutritional needs. Many mothers do not understand this concept of “supply and demand” and unintentionally may sabotage their breastfeeding relationship.

Initiation of Breastfeeding

Breastfeeding is a learned skill for mother and her infant. All babies should be put skin-to-skin immediately after birth and remain in direct skin-to-skin contact until the first feed is accomplished or as long as the mother desires (WHO, 2017; WHO, 2018a). Within 48 to 96 hours after birth the breasts become fuller and firmer as the milk volumes increase. Skin-to-skin contact in the first hour improves breastfeeding exclusivity and duration and helps to regulate temperature, blood sugar, and blood pressure of the infant. This practice is recommended regardless of desired feeding method.

Exclusively breastfed babies do not need additional water because 87% of breastmilk is water. However, cases of hypernatremic dehydration in babies caused by suboptimal breastfeeding do occur. Most cases are due to lack of support for mothers who feel intimidated and overwhelmed at delivery, lack breastfeeding education, and are unaware of the consequences of dehydration. Extreme heat or hot weather also may increase the need for more frequent breastfeeding to avoid dehydration. The consequence of hypernatremic dehydration can be permanent brain damage or death. Therefore it is vital that an experienced health care professional evaluate the breastfeeding within 2 to 4 days after birth; problems identified can be addressed and a plan of care can be implemented (WHO, 2018a).

During the first days and weeks of breastfeeding, mothers should feed on demand or “on cue.” Watching and listening to the infant guides a mother to know when to offer a feeding. When a mother responds to her infant's hunger cues, nursing “on demand,” she provides the quantity the baby needs, as long as supplements are avoided, and pacifiers are not used to “mask” the baby's hunger. A newborn's stomach is very small and holds only about a teaspoon or two of fluid at a time, matching the small amount of colostrum available from the mother. The colostrum is very easily absorbed, and that is why the infant will give frequent hunger cues to the mother. As a newborn's stomach enlarges over the next few days and weeks, so does the mother's milk supply as long as no supplement has interfered with this process of supply and demand. Extra bottle feedings can stretch the infant's stomach so that the supply the mother has available can no longer satisfy the baby. This situation may cause a mother to feel that she does not have enough milk and has failed at breastfeeding, and possibly unnecessarily cause her to wean. It is common to breastfeed 8 to 12 times a day while the breastmilk is increasing and an adequate supply is being established. After breastfeeding has been fully established in the first few weeks, lactating women may begin to feel the strong tingling sensation in the breasts caused by oxytocin release, signaling the let-down reflex. (See earlier explanation.) This sensation automatically causes a sudden release of milk from the breasts. If this occurs when the mother is not available for her baby, firm pressure on the breasts stops milk from flowing.

As breastfeeding continues, mothers begin to settle into a pattern of feeding that is comfortable and relaxed. Although each mother-baby couplet is different, most babies become more efficient at the breast and are able to take in more milk at a feeding time, as much as several ounces in just a few minutes. This allows the feedings to become less frequent

and take less time. When breastfeeding is total nourishment for the baby, some feeds may be short just to satisfy a baby's thirst, and others may last 20 to 30 minutes if the baby is very hungry. This is no cause for worry, as long as the mother continues to respond to the infant's cues. Parents should be educated about this process so that they do not get discouraged or think that the intense feeding schedule that is common in the early weeks will last for the entire breastfeeding experience.

Practice, patience, and perseverance are necessary for successful breastfeeding, along with a strong support system for the mother, including family, friends, health care personnel, her workplace, and the community around her (see Box 14.11). With learned hand expression or the help of an effective breast pump, the mother is able to express and store her milk for later use when she is away from her infant. Pump rentals or purchase may be covered by insurance or available through the WIC program. See Box 14.14 for a summary of tips for success in breastfeeding.

Breastfeeding by Women with Diabetes. Women who have insulin-dependent diabetes may experience “lactation hypoglycemia” as they increase their breastfeeding sessions. Plasma glucose levels in the lactating diabetic mother are lower because of maternal stores being used for milk production. The daily maternal insulin requirement is

Box 14.14 Tips for Breastfeeding Success

During your pregnancy:

- Enroll in the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) program, if eligible.
- Attend a breastfeeding class.
- Ask your medical provider about breastfeeding.
- Read about breastfeeding.
- Get 1 to 2 good nursing bras.
- Find a supportive person that can help you.

In the hospital:

- Let doctors and nurses know that you plan to breastfeed.
- Request that your baby be put skin-to-skin immediately after birth.
- Breastfeed during the first hour after birth.
- Keep baby in room with you 24 hours/day.
- Avoid using bottles or pacifiers.
- Ask for an International Board Certified Lactation Consultant (IBCLC) to help with correct latch.
- Breastfeed whenever your baby shows hunger cues (8 or more times in 24 hours).
- If doctor orders supplementation, use expressed breastmilk first. Request donor milk if unable to provide mother's own milk.
- If you and your baby are separated because of illness, hand express and ask for a breast pump.
- Ask about breastfeeding support services available in your community.

During the first 2 to 3 weeks at home:

- Avoid bottles or a pacifier.
- Breastfeed whenever your baby shows hunger cues, at least 8 times a day.
- Make sure baby latches onto the breast correctly.
- Continue skin-to-skin care whenever possible.
- Watch for 6 to 8 wet and 2 to 3 messy diapers daily by end of first week.
- For questions or concerns, call the WIC Lactation Specialist or an IBCLC.
- See baby's doctor within 1-2 days for a weight check if discharged from the birthing facility before 48 hours of age. Those discharged after 48 hours of age should be seen within 2-3 days of discharge.
- If enrolled in WIC, see nutritionist to obtain nutritious foods for yourself.
- Participate in mother-to-mother support groups.

usually lower in these women, and frequent glucose monitoring must be emphasized to ensure safety for the mother and baby. Because newborns of mothers with diabetes frequently are admitted to the NICU for closer observation, more support should be offered to these mothers to ensure breastfeeding success.

Breastfeeding Preterm and Sick Infants. Breastmilk for a preterm infant is not only beneficial but also absolutely necessary to ensure protection from infection and other illnesses (see Chapter 41). A mother may be overwhelmed when her baby is delivered before the due date or is admitted to the NICU for any reason. If the baby is not strong enough for effective breastfeeding, professional help should be used so that the mother can begin milk expression, and her milk can be available for the infant's nutrition.

A mother may find that she is totally dependent on the breast pump for several days, weeks, or even months. During this time, it is important for the mother (and father) to employ skin-to-skin care of their baby to allow appropriate stimulation of prolactin production in the mother for her milk supply to be maintained. This connection with her newborn also assists in the bonding process so important in the development of a healthy, loving relationship, which is challenged by the unfortunate situation in which the mother and her family find themselves. The mother will continue to need support and encouragement throughout the baby's hospitalization, and even more so when discharge gets closer. The total transfer of care to the parents can be an even bigger challenge, and they will need much guidance and follow-up to ensure breastfeeding is successful.

In the case of adoption, a devastating prognosis, or infant death, the mother can prepare herself for a gradual decrease in her milk supply to allow for her physical health. Any milk she has in storage can be donated to a human milk bank (see *Focus On: What Is a Human Milk Bank?* in Chapter 41). This will give her comfort in knowing that the milk she produced and saved for her own baby will not be wasted but be used for another infant who may need it. Again, much support and guidance from knowledgeable professionals is necessary during these trying times.

Breastfeeding Multiples. Breastfeeding twins, triplets, or more is certainly challenging, but possible. A mother who plans to breastfeed multiples will most likely need assistance, especially in the early days. If the babies are healthy and brought home soon after birth, she can begin breastfeeding them right away and establish her milk supply with the help of at least two babies instead of one. This means a greater milk supply will be available if she responds to their hunger cues, just like with a singleton. She will be busier, no doubt, and feeding multiples during the first few weeks will be intense, to say the least. If the mother is determined to establish a good breastmilk supply early on and has the household help she needs, she can be successful. If, however, the infants are sick and must remain hospitalized for a while, she needs to use an effective breast pump to bring in her milk supply and should make her expressed breastmilk available for the babies' nutrition. A lactation consult with an IBCLC is strongly recommended in such cases.

See [Table 14.16](#) for a summary of common problems that breastfeeding mothers may encounter, with ways to prevent or remedy these situations.

TABLE 14.16 Management of Breastfeeding Difficulties

Problem	Approaches
Inverted nipples	Breast shells with appropriate backing may be used during the last trimester of pregnancy. Before feeding the infant, roll the nipple gently between the fingers until erect. May use breast pump for 1-2 minutes before latching baby to bring nipple out.
Breast engorgement	Massage breasts prior to and during feeding, soften breasts/nipple by expressing a small amount of milk or use reverse pressure softening technique; allow baby to nurse frequently and/or express with hand or pump after feeding to relieve engorgement. Use cool compresses to ease pain after breastfeeding. Raw cabbage leaves placed on breasts for a few minutes every few hours may help to reduce swelling. Approved oral antiinflammatory medication may be used for pain.
Poor latch	Ensure proper positioning at breast; encourage baby to take a "mouth-full" of breast into his mouth; use nipple shield as last resort (use only with professional guidance).
Baby's mouth not open wide enough	Before feeding, depress the infant's lower jaw with one finger as the nipple is guided into the mouth. Elicit wide-open mouth from baby by tickling upper lip with nipple and hand expressing drops of milk from the nipple.
Sore nipples	Assess if pain is acute or chronic. Strive for proper latch (possible temporary use of nipple shields with professional guidance); limited evidence for interventions for initial nipple pain but will likely do no harm: hand express milk and allow to air dry, approved nipple ointment, breast shells with appropriate backing if extremely sensitive, hydrogel pads, approved pain meds. Check for ankyloglossia, fungal infection, or improperly fitting pump flange.
Baby sucks poorly	Stimulate sucking motions by pressing upward under the baby's chin. Use breast massage to express milk in baby's mouth and stimulate suck/swallow. Rule out infant/maternal physical or medical issues.
Baby demonstrates rooting but does not grasp the nipple; eventually cries in frustration	Interrupt the feeding, comfort the infant; the mother should take time to relax before trying again. Place baby in a comfortable position facing the breast. Express a few drops of milk on the nipple to entice the baby to latch.
Baby falls asleep while nursing	Mother may be able to awaken the infant by holding baby upright using skin-to-skin (when possible), rubbing baby's back, talking to baby, or providing similar quiet stimuli; another effort at feeding can then be made. If the baby falls asleep again, the feeding should be postponed. Use breast massage to encourage milk to flow more rapidly and stimulate infant to suck/swallow.
Plugged ducts	Firm fingertip massage in area of plug. Moist heat compresses before/during feedings on affected area. Therapeutic breast massage, frequent emptying of breast. Point baby's tongue in direction of plugged duct. Lecithin supplement may help to prevent recurrence. Refer to medical provider if not resolved within 72 hours.

TABLE 14.16 Management of Breastfeeding Difficulties—cont'd

Problem	Approaches
Mastitis	Signs of infection: breast is red and tender. Possible maternal fever, malaise. Maternal antibiotics may be indicated; call physician. Continue to breastfeed as comfort allows; frequent emptying of breasts with breastfeeding or expression. Breastmilk is safe for baby. Maternal rest recommended.
Thrush	Controversial diagnosis, inconclusive literature. Treatment usually includes mother and baby to prevent cross-infection/reinfection. Wash hands meticulously; sterilize items in contact with mother's breasts or baby's mouth or diaper area. Keep nipples dry. Approved nipple ointment for mother and oral medication (antifungal) for infant indicated—call physician. Breastmilk is safe for baby. Continue to treat at least 1 week after symptoms are gone to prevent return of infection. Some natural remedies may help: vinegar rinses on nipples and baby's diaper area, garlic supplements, probiotics/acidophilus, Echinacea, grapefruit seed extract—consult physician or lactation consultant.
Raynaud's Nipple vasospasms	Ensure proper latch to prevent worsening of symptoms. Keep nipples warm. May apply dry heat immediately after nursing. Use approved pain medication as needed; consider calcium channel blocker. Avoid caffeine, nicotine, and other vasoconstrictive drugs.
Perceived low milk supply	Offer breast frequently to allow infant to stimulate milk supply as desired; practice skin-to-skin care to stimulate prolactin production; express milk after/between feedings; avoid pacifiers and bottle supplementation unless advised by health care professional. Good nutrition, rest, and stress management is also advised. Watch for signs of adequate infant output (frequent wet diapers; appropriate bowel movements). Monitor baby's weight for reassurance of adequate maternal milk supply/infant intake.
True low milk supply	Ensure infant is latched correctly for maximum comfort and effectiveness; offer both breasts at every feeding—switch sides a few times during a feeding session for extra stimulation; avoid pacifiers and bottles; increase breast emptying by nursing or expression (length and frequency)—8-12 times/day; use pump for a few minutes after a breastfeed; when pumping, continue for 5 minutes after milk stops flowing to elicit additional let down; include pumping session between 1 and 5 A.M. when milk production is highest; use high-quality electric double pump (consider renting hospital grade pump); massage breast while pumping; always use correct flange size; use skin-to-skin care at each nursing session; rest/adequate nutrition/hydration; manage stress. Consider galactagogues (natural herbs or medication)—only with medical supervision (see Table 14.17). Supplementation may be necessary (human milk preferred, possibly using supplementer at breast, cup, syringe, dropper).

Consult with physician and IBCLC (International Board Certified Lactation Consultant) for expert advice.

Galactagogues

Low milk supply is a common concern among breastfeeding mothers. Whether real or perceived, mothers throughout the ages have turned to herbal remedies and medications to assist them in increasing their milk supply. Because milk supply is determined mainly by emptying the breasts regularly and effectively, this should be the first action taken to promote milk production. However, sometimes because of the effects of maternal or infant illness and hospitalization, or separation because of work or school, a mother may find that despite her efforts, her milk supply is faltering. Galactagogues also have been used in cases of adoption or relactation (reestablishing a milk supply after weaning). Galactagogues, or milk production stimulants, can be classified as medications, herbals, or foods—each with its own results. Herbals must be used with caution as many contain chemical substances that may be dangerous to the infant. A lactation consultant, registered dietitian nutritionist, or herbalist who is knowledgeable about their use in breastfeeding mothers should be consulted before using them. Standard recommended doses should not be exceeded (Hale, 2019).

Table 14.17 provides a list of common galactagogues along with possible side effects and contraindications. Medications used to increase a mother's milk supply must be prescribed by the mother's health care provider. Lactating women should tell the baby's health care provider if anything is taken to increase milk supply. Although traditional use of galactagogues suggests safety and possible efficacy, the mechanisms of action for most herbals have not been proven (Brodrigg, 2018). Despite some traditional beliefs, beer and other alcoholic beverages do not increase milk supply and should not be used for this purpose.

Sustaining Maternal Milk Supply and Preservation of Successful Breastfeeding

Insufficient milk supply is rarely a problem for the well-fed, well-rested, and unstressed mother who stays in close contact with her baby. Sucking stimulates the flow of milk; thus feeding on demand should supply ample amounts of milk to the infant. Skin-to-skin care also can benefit the mother and baby by stimulating prolactin production in the mother while keeping the baby comforted and familiar with the mother. In the early days, indications of sufficient milk supply are that the baby continues to gain weight and length steadily, has at least six to eight wet diapers daily, and has frequent stools. Refer to Table 14.16 for tips on increasing milk supply.

Occasionally, however, breastfeeding complications can interfere with success. Fig. 14.10 illustrates potential problems in the mother or the infant that should be investigated if the mother feels that her milk supply is dropping or the baby is showing signs of slow growth. The cause of the problem must be identified and corrected to preserve the breastfeeding relationship and maintain the infant's growth and development. Professional assistance is available to identify and correct any complications that may interfere with successful breastfeeding. An IBCLC can be found at birth hospitals or centers, pediatric hospitals, maternal-child clinics, physicians' offices, and private practices.

Sometimes the infant may show intolerance (i.e., fussiness, loose stools) to something the mother has ingested. The mother is advised to temporarily eliminate suspected irritants until a later time when the baby is older and the GI tract more mature. Many times, food sensitivity is outgrown after a few weeks or months. Any food may be the culprit,

TABLE 14.17 Common Galactogogues

Class of Galactogogue	Specific Substance	Comments
Prescription Medications	Domperidone (<i>Motilium</i>)	Raises prolactin and proven useful as a galactogogue; few CNS effects such as depression. Associated with increase in cardiac arrhythmias (QTc prolongation).
	Metoclopramide (<i>Reglan/Maxeran/Maxolon</i>)	Raises prolactin and proven useful as a galactogogue; side effects may include headache, diarrhea, sedation, gastric upset, nausea, extrapyramidal symptoms, severe depression.
Herbals	Fenugreek (<i>Trigonella foenum graecum</i>)	Strong reputation as an effective galactogogue, but undocumented. Side effects include maple syrup odor in urine and sweat (mother and baby); may cause diarrhea, hypoglycemia, dyspnea. Not to be taken during pregnancy.
	Milk Thistle (<i>Silybum marianum/Silymarin</i>)	Reputation as a galactogogue, but undocumented. Side effects include occasional mild GI side effects, increased clearance of metronidazole.
	Cooking herbs: anise, basil, blackseed, caraway, coriander, dill, fennel seeds, moringa leaf Nonfood herbs: alfalfa, blessed thistle, nettle, goat's rue, red clover, shatavari	Historical and cultural uses as galactogogues; effectiveness undocumented. Assumed to be safe with recommended dosages (varies with specific herbs), although strengths of herbal product ingredients may vary depending on particular plant used and how processed; caution is advised for use during pregnancy. Some companies make special blends for breastfeeding mothers.
Foods/beverages	Grains, nuts, seeds: oats (not instant), barley, brown rice, beans, sesame, almonds Fruits/Vegetables: dark green leafy vegetables, apricots, dates, figs, cooked green papaya Soups made from Torbangun or Malunggay leaves	Historical and cultural uses as galactogogues; effectiveness undocumented.

Adapted from Marasco L: Inside track: increasing your milk supply with galactogogues, *J Hum Lact* 24:455, 2008; Hale TW: *Medications and mother's milk*, ed 18, Amarillo, Tex, 2019, Hale Publishing; Academy of Breastfeeding Medicine Protocol Committee (ABM): ABM Clinical Protocol #9: Use of Galactogogues in initiating or augmenting the rate of maternal milk secretion, *Breastfeeding Med* 13:307, 2018.

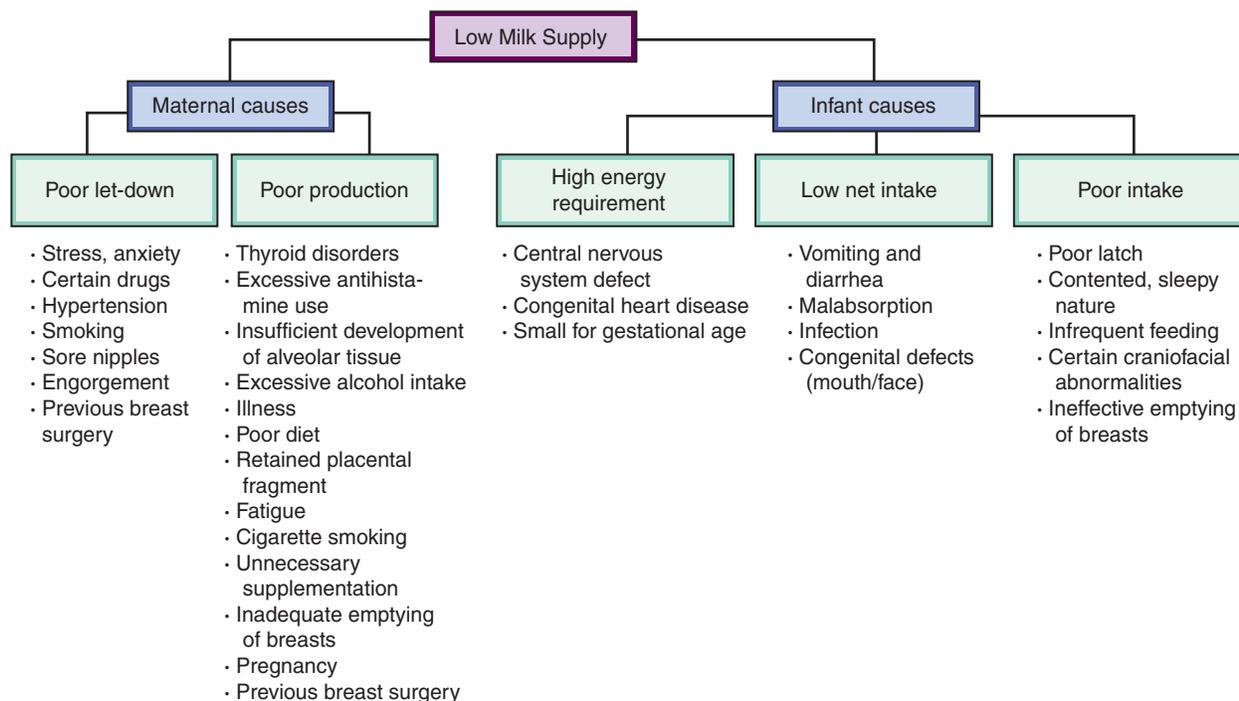

Fig. 14.10 Diagnostic flow chart for inadequate maternal milk supply.

including cow's milk protein (casein fraction), cruciferous vegetables, carbonated drinks, or even spicy foods. When suspicious foods are removed from the mother's diet, it is important to assess the nutritional quality of her diet and supplement appropriately.

Concerns During Lactation

Transfer of Drugs and Toxins into Human Milk

Almost all drugs taken by the mother appear in her milk to some degree. The amount that usually transfers is small, and only rarely does the amount transferred into the mother's milk result in clinically relevant doses in the infant. Many factors influence how medications transfer into human milk: milk/plasma ratio, molecular weight of the drug, and the protein binding and lipid solubility of the drug. Once a drug has been ingested by the infant through the mother's milk, it must travel through the baby's GI tract before absorption. There are many processes here that may disallow the drug from being metabolized in the infant's system. Caution is recommended especially for mothers who are nursing premature or ill infants as they are at a higher risk of the effects of even small amounts of medications that may come through maternal milk (Hale, 2019).

Many mothers have discontinued breastfeeding because of their need for a medication, when in fact there was a good chance that the drug could have been taken without risk to the baby. It is likely that medications penetrate colostrum more than mature milk, although even during this time, the amounts the baby is exposed to are very low. When the medication increases in the mother's plasma, it also increases in her milk. When the medication level falls in the mother's plasma, equilibrium is sought in the mother's milk, which drives the medication back into her plasma for elimination (Hale, 2019).

Centrally active drugs (anticonvulsants, antidepressants, antipsychotics) frequently penetrate milk in elevated levels based merely on their physiochemistry. When sedation, depression, or other central nervous system (CNS) effects are experienced by the mother when taking the medication, it is likely to penetrate the milk and cause similar effects in the infant. These drugs must be used with caution, and the mother should always discuss the risk-benefits of breastfeeding and her need for such medications with her health care provider.

Maternal Substance Abuse. According to the AAP, maternal substance abuse is not a categorical contraindication to breastfeeding. If a mother is well nourished and negative for HIV, even if narcotic-dependent, she should be encouraged to breastfeed as long as she is supervised in a methadone maintenance program (AAP, 2012; Academy of Breastfeeding Medicine Protocol Committee [ABM], 2015). Breastfeeding still provides many immunologic, nutritional, and bonding advantages over artificial feeding. Very little methadone is transferred into breastmilk; however, studies are mixed reporting how breastfeeding should be managed in the mother-infant dyad to lessen the risk for neonatal abstinence syndrome (Isemann et al, 2011). Growth parameters in the child should be monitored to ensure adequate development, but breastfeeding should continue to be encouraged as long as these measures are within the normal range. The long-term effect of methadone exposure beyond the neonatal period is relatively unknown. Studies have shown samples of blood and breastmilk up to 1 year show low concentrations of methadone, justifying the recommendation that mothers continue to breastfeed (Hudak et al, 2012). If a mother decides to discontinue breastfeeding, weaning slowly over 3 to 4 weeks helps to protect the infant from withdrawal symptoms.

The AAP and ACOG have provided information regarding the transfer of drugs and other chemicals into human milk (AAP, 2013). Websites that can provide more information are listed at the end of the chapter.

Environmental Toxins. There is concern about environmental toxins entering the milk of a lactating mother; however, at this time there are no established "safe" levels to aid in clinical interpretation. Despite any pollutants that may be found in human milk, the benefits of breastfeeding far outweigh the risks posed by any contaminants that may be found there. Nonetheless, mothers should take care not to allow any unnecessary exposure to pesticides and other harsh chemicals, as well as limit intake of animal fat, which can contain higher amounts of environmental contaminants. This helps safeguard against unwanted substances in human milk.

In the past, mothers were told not to lose too much weight too fast after pregnancy because it was thought that a rapid weight loss could possibly accelerate the release of toxins stored in a woman's body fat. However, this has not been proven to be true. Nonetheless, slow, steady weight loss during the postpartum period is recommended to allow a healthy return to prepregnancy weight with greater likelihood of keeping the weight off.

Overweight or Obesity

Overweight or obese lactating women can restrict their energy intake (once the milk supply is well-established) by 500 kcal per day by decreasing consumption of foods high in fat and simple sugars, but they must increase their intake of foods high in calcium, vitamin D, vitamin A, vitamin C, and omega-3 fats to provide key nutrients for their milk supply. The lactational period can be used as a time to allow natural slow weight loss in these mothers by taking advantage of the caloric demands of breastfeeding. The nutritional status of lactating women who have previously undergone bariatric surgery requires close attention because suboptimal levels of iron, vitamin A, vitamin D, vitamin K, folate, and calcium have been reported (see Chapter 20).

Women with higher prepregnant BMI values also warrant extra lactation support to prevent early weaning and to reach their breastfeeding goals. Research has shown that although intentions of the obese woman to breastfeed may be strong, there can be many psychosocial determinants that may influence her commitment and ability to initiate or continue nursing her infant. Obese women also have shown to have delayed lactogenesis II, the sudden increase in volume a few days after delivery, which could be a risk factor in not establishing a milk supply. Although obese women experience lower rates of successful breastfeeding, the association between maternal obesity and breastfeeding outcomes has not been explained fully (Hauff et al, 2014).

Exercise and Breastfeeding

The breastfeeding mother should be encouraged to resume an exercise routine a few weeks after delivery and after lactation is well established. Aerobic exercise at 60% to 70% of maximum heart rate has no adverse effect on lactation; infants gain weight at the same rate, and the mother's cardiovascular fitness improves (Lovelady, 2011). Exercise also improves plasma lipids and insulin response in lactating women.

Mothers may be reluctant to exercise because of concerns of how this affects their breastmilk and consequently the growth of their infants. Moderate aerobic exercise (45 minutes/day, 5 days/week) has not been shown to affect milk volume or its composition. Mothers who incorporate diet and exercise into their routines in an effort to lose weight during the postpartum period also have been studied and have shown no ill effects on the growth of their infants (Lovelady, 2011).

Breast Augmentation

Breast augmentation, a procedure in which an implant is inserted into the breast to enlarge it, is a common elective breast procedure. Periareolar and transareolar incisions can cause lactation insufficiency. These mothers should be encouraged to breastfeed, and their infants

monitored for appropriate weight gain. Other means of augmentation, in which implants are placed between breast tissue and the chest wall, usually have no effect on the woman's ability to produce a full milk supply.

Reduction Mammoplasty

Reduction mammoplasty often is recommended for women with extremely large breasts who suffer from back, shoulder, or neck pain or poor body image. In lactating women who have had this surgery there are wide variations in milk production, from little to full production, depending on the amount of tissue removed and the type of surgical incision. These mothers also should be encouraged to breastfeed and be given anticipatory guidance and support; their infants should be monitored closely for appropriate weight gain.

Postpartum Depression

Postpartum depression (PPD) may be one of the most underdiagnosed obstetric complications in the United States. PPD leads to numerous negative consequences affecting the mother and child, including increased costs of medical care, inappropriate medical care, child abuse and neglect, discontinuation of breastfeeding, and family dysfunction. All this adversely affects early brain development in the infant (Earls, 2010), which could possibly lead to future problems.

Although effective treatment is available, fewer than half of mothers with this condition are recognized or seek help. PPD has been found to be lower in breastfeeding mothers (Xu et al, 2014). Because breastfeeding triggers the release of the hormone oxytocin, many women report feeling calm and relaxed while they are nursing. When breastfeeding is successful and things are going well, with maintenance of a good milk supply without complications, and the baby is gaining appropriate weight, the breastfeeding relationship can ward off feelings of loneliness, emptiness, or failure—common feelings in PPD. A higher circulating oxytocin level sustains a sense of calm and allows a mother to cope with the everyday stresses of new motherhood. Conversely, when things are not going well, when complications of breastfeeding and new motherhood become overwhelming, many new mothers experience signs of the “blues,” which can escalate into full PPD. The “baby blues,” affecting 70% to 80% of all new mothers (APO, 2015), is short lived, does not impair functioning, and can be treated with reassurance and emotional support. PPD, however, is characterized by a major depressive episode within 1 month after delivery and is experienced in 10% to 15% of women after giving birth. Symptoms are restlessness, anxiety, fatigue, and a sense of worthlessness. Some new mothers worry they will hurt themselves or their babies. Unlike the “baby blues,” PPD does not go away quickly. A mother with diagnosed PPD usually requires a more intensive approach to treatment (USDHHS, 2018b).

Diet quality and overall nutritional status may affect the risk of PPD (Procter and Campbell, 2014). Many dietary components are being investigated regarding their role in minimizing PPD, including omega-3 fatty acids, folate, vitamins B₂, B₆, B₁₂, D, calcium, iron, and selenium. However, there is little evidence of benefit from supplementation. Mawson and Wang recently proposed that high levels of vitamin A compounds may be in part responsible for maternal PPD, and that breastfeeding offers protection against PPD by maintaining endogenous retinoids below a threshold concentration. Women accumulate retinoids in the liver and the breast during pregnancy in preparation of providing vitamin A to their infants. Because prolonged lactation reduces maternal stores of retinoids, this also provides a natural means of reducing potentially toxic concentrations in the mother (Mawson and Wang, 2013).

When early signs of PPD are present, and a mother stops breastfeeding, even more severe depression can affect the mother. Oxytocin

levels fall abruptly, and a mother's feelings of failure may become even more pronounced. It is critical for families to be aware and for health care providers to screen for early symptoms of PPD not only to prevent more serious symptoms of the disease but also to protect and preserve the breastfeeding relationship. Maternal-child health care providers must prepare mothers and families for expected breastfeeding challenges, advocate for a supportive environment in birthing hospitals, and promote breastfeeding as the cultural norm in the community so that the breastfeeding relationship is successfully established early in the postpartum period (Olson et al, 2014).

PPD can affect milk production, let-down, and the ability to maintain an adequate milk supply for the baby. The elevated levels of cortisol present in PPD may delay lactogenesis II. When the blues turns into a more serious form of PPD, the establishment of a healthy bond between mother and child may be affected, jeopardizing the breastfeeding relationship and potentially leading to early weaning (Wu et al, 2012b).

Medical treatment for PPD while breastfeeding includes medications such as Zoloft, Paxil, and Prozac. These should be taken immediately after a feeding to allow the maximum time for drug clearance from milk before the next feeding. Also, the mother can express and discard her milk collected when peak serum levels of the drug are present. Monoamine oxidase (MAO) inhibitors are contraindicated for treatment of PPD if the mother is breastfeeding (Hale, 2019).

Birth Control and Breastfeeding

Many women begin to think about birth control shortly after delivery and while they are breastfeeding a new baby. The mother must consider the effects of the birth control method on her nursing, as well as how it may affect her milk supply.

The Lactation Amenorrhea Method (LAM) does not involve any device or medication and is completely safe for breastfeeding mothers. LAM is an important modern contraceptive method that, when practiced correctly, has a 98% effectiveness rate 6 months postpartum (Fabic and Choi, 2013). It must be emphasized that the method is effective ONLY when three conditions are met: (1) the infant is less than 6 months old, (2) the mother is amenorrheic, and (3) the mother is fully breastfeeding (baby not receiving anything other than milk at the breast, meeting all sucking needs at the breast without a pacifier). Mothers must be very attentive to the inclusion of all these factors if they are dependent on this method to prevent pregnancy. As soon as one of these parameters is absent, the mother is advised that she should employ an additional form of birth control if pregnancy is still not desirable.

Birth control methods using a combination of progestin and estrogen come in several different forms: combination birth control pill, monthly injections, patch, and the vaginal ring. Although progestin and estrogen are approved by the AAP for use in breastfeeding mothers, it is possible that estrogen-containing contraceptives may affect a mother's milk supply and therefore a progestin-only medication (minipill) may be a better choice, at least until 6 months postpartum. A longer lasting form of progestin-only birth control is the Depo-Provera (“depo”) shot that lasts at least 12 weeks but may be effective even up to a year.

A progestin-only intrauterine device (IUD) such as Mirena may have fewer side effects on a mother's milk supply. This product delivers hormones directly to the lining of the uterus, leading to only a slight increase in serum progesterone levels, less than with the minipill. The birth control implant (Norplant, Implanon) is another choice for women who wish to choose progestin-only means of birth control. The implant can last up to 5 years. Women are warned they may want to consider the pill form before using a longer-lasting form of birth control in case they are susceptible to a drop in milk supply even with

progestin-only pills. This allows them to stop the pills and choose another birth control method (i.e., LAM or barrier) so that they do not have to wait for the effects of the progestin to wear off. No effect on infant growth has been noted with these medications, but for those who may be concerned about the unknown, barrier methods of birth control, an IUD without hormones (ParaGard), or LAM, ensure that no drug is secreted in breastmilk.

One other form of birth control pill, meant to be used as a last resort (breastfeeding or not), is the so-called “morning-after pill.” These are also available in a combination of estrogen and progestin (Preven, Ovral), or the progestin-only form (Plan B, Plan B One-Step). Mothers should consult with their health care providers or lactation consultants if a drop in milk supply is noticed. This may be just a short-lived, temporary condition, but close follow-up can ensure that this is the case. The AAP has approved this medication for use during breastfeeding, although it should be used only in rare circumstances.

Breastfeeding during Pregnancy

Mothers may discover they are pregnant while they are still nursing a young baby or child. If the pregnancy is normal and healthy, it is considered safe to continue to breastfeed throughout the pregnancy. A mother need not worry that her milk will be any less nutritious for her nursling. She may be concerned that the act of breastfeeding will interfere with her pregnancy, but that is not a valid concern unless she experiences a difficult pregnancy and is at risk for early labor.

Increased fatigue and nausea early in pregnancy may be challenging for the expectant mother; however, if breastfeeding continues, rest and a concerted effort to maintain good nutritional intake is a must. Sore nipples are also common early in pregnancy and may be the first sign to the mother that she is pregnant. She may need to employ methods of dealing with nipple tenderness (i.e., distraction, pain management techniques) to get through this period of time if breastfeeding is to continue. Because the quantity of the milk may decrease and the taste of the milk may change early during pregnancy, the nursling may reject breastfeeding altogether and self-wean. A mother may need to provide encouragement to the baby to continue to breastfeed, especially if the baby is very young and still dependent on breast milk to fulfill the majority of nutritional needs.

Tandem Nursing

Tandem nursing is when the mother breastfeeds siblings who are not twins. As soon as the placenta is delivered, the mother will begin to produce colostrum once again. The mother should ensure that the new baby always has priority to this because it provides the protection the newborn needs. Sometimes mothers find that the nursing toddler is a help to her by preventing or relieving engorgement. In fact, with the stronger suck and intake of the toddler, the mother may begin to overproduce for the newborn. If she develops a strong let-down reflex releasing a large quantity of milk when the newborn first latches, it may cause coughing and choking. In this case the mother may want to express a small amount of milk before latching her newborn, or simply allow the toddler to nurse for a few minutes first.

Concerns of hygiene are unwarranted when a mother is nursing two siblings. The small bumps on the areola called **Montgomery glands** produce a natural oil that cleans, lubricates, and protects the nipple during pregnancy and breastfeeding. This oil contains an enzyme that kills bacteria so that both children are protected. In addition, more immunities will be passed on through the breastmilk itself. If, however, the mother or one child develops thrush, she is advised to limit each child to one breast temporarily.

An older baby who has weaned prior to the birth of a new sibling may express interest in breastfeeding again. Handling this situation is

a delicate one and calls for special attention to the older child, whether or not the mother decides to offer the breast again.

Weaning

Weaning begins at the first introduction of anything other than mother’s milk. As a breastmilk substitute or solid foods begin to be offered to the baby, the weaning process has begun. Although breastfed babies tend to accept a variety of solid foods well, because of the fact that they already have been introduced to different flavors of food through their mother’s milk, this does not mean that the infant is ready to stop breastfeeding. Breastmilk is recommended for the infant throughout at least the first year of life as stated previously, and even through the second year of life by some authorities (WHO, 2018b). A mother may choose to allow **baby-led weaning**, which simply means she will offer breastfeeding for as long as the baby is interested. If a baby seems to be losing interest in breastfeeding while still very young (i.e., younger than 12 months), the mother can try various methods of encouraging the baby to continue to breastfeed, such as ensuring a good position at the breast, and cutting out any bottles or foods so that more nutrition will be offered through breastfeeding. An older baby may be distracted easily during nursing sessions; a quiet, darkened room may help to keep the baby focused on nursing and get back on track with breastfeeding regularly. Human milk remains a nutritious fluid for as long as it is produced by the mother; however, the breastfeeding relationship changes as the baby gets older. Babies may show a lack of desire to breastfeed at different ages, depending on many factors. As the child grows, breastfeeding becomes less of a nutritional need but more of a need for the psychological bond with their mother. Older infants may be happy to nurse three to four times a day, and toddlers may show interest only every now and then.

Some mothers may choose **mother-led weaning**, which is when the mother encourages the baby to stop breastfeeding. She may begin to offer other foods or beverages when the baby wants to nurse or try to distract the baby in other ways. If this method is used, the mother should ensure that the baby’s emotional needs are met because this could be a trying time for mother and child. The decision is up to the mother, and her decision should be supported, although if at all possible, she should be encouraged to provide her milk throughout the first year for her health and the health of her baby.

Return to Work or School

A mother’s return to work or school can be a major challenge for continued successful breastfeeding; however, it is possible and encouraged. If a nursing mother returns to work or school, it is best to wait until breastfeeding is going well and a good milk supply has been established. Babies placed in child care experience a higher chance of becoming ill when exposed to other children; however, breastmilk offers protection against germs the child is likely to be exposed to in these environments.

An exclusive diet of human milk continues to provide optimal nutrition through the baby’s first 6 months. After that time, when appropriate solid foods are introduced into the baby’s diet, mother’s milk is the milk of choice at least through the baby’s first year and beyond. The mother also experiences rewards if she is able to continue to breastfeed after her return to work or school. This helps to maintain an emotional connection with her baby because she will be reminded physically throughout the day of the need to express milk from her breasts. She also can continue to preserve the breastfeeding relationship with her baby when at home. Because of the advance in quality of breast pumps on the market today, mothers are able to express milk and maintain their supply effectively and comfortably. See [Table 14.18](#) for breastmilk home storage guidelines.

TABLE 14.18 Home Storage of Human Milk

Type of Breastmilk	Locations and Temperatures		
	Countertop – Room Temperature (≤ 77° F or 25° C)	Refrigerator (40° F or 4° C)	Freezer (≤ 0° F or –18° C)
Freshly Expressed or Pumped	Up to 4 hours	Up to 4 days	Within 6 months is best, up to 12 months is acceptable
Thawed, Previously Frozen	1–2 hours	Up to 1 day (24 hours)	Never refreeze human milk
Leftover from a Feeding (<i>baby did not finish the bottle</i>)	Use within 2 hours after baby's last feeding or discard		

Adapted from CDC: *Proper Storage and Preparation of Breast Milk* (website): https://www.cdc.gov/breastfeeding/recommendations/handling_breastmilk.htm, 2018.

Many mothers are able to obtain breast pumps using their health insurance or through the WIC program. Federal and state laws also offer protection for the lactating worker so that she is ensured a private, clean space (other than a restroom) to express her milk while away from her baby. Mothers should talk to school personnel or their work supervisor before their maternity leave so that a plan is in place upon her return, and so that all parties involved will have an under-

standing of what to expect. Mothers should be made aware of federal and state provisions available to them based on employment category. A woman who expresses her milk regularly throughout the day with an effective pump can maintain a full milk supply for as long as she desires while at work or school full time. A mother facing this situation can find more help with this by discussing any questions or challenges with a lactation professional.

CLINICAL CASE STUDY 1

Carol is a 34-year-old woman who was pregnant recently for the first time, but the baby had anencephaly and died at birth. She has a sister who has spina bifida and an older brother who had a stroke when he was 14. Carol has now been tested and found to have a genetic defect known as a 677C>T polymorphism in the methylenetetrahydrofolate reductase (MTHFR) gene.

Of course, she and her husband were devastated with the loss of their first child, but they also very much want to be parents. She has gone to genetic counseling but is also coming to you to find out what she can do to lower the chances that this happens again. She is worried about using the traditional prenatal vitamin-mineral supplement because she has been cautioned that she is unable to metabolize folic acid from diet and supplements.

Nutrition Diagnostic Statement

- Altered nutrient (folic acid) metabolism related to a genetic alteration as evidenced by positive results for C>T in the MTHFR gene and family history of spina bifida and stroke.

Nutrition Care Questions

- What advice would you give Carol about any special dietary changes?
- Carol knows that there is a special prenatal vitamin-mineral supplement available but does not know how to obtain it. How will you help Carol find this supplement?
- What are the risks for a successful pregnancy outcome if Carol cannot find this special prenatal supplement?
- What other concerns do you have regarding her pregnancy?

CLINICAL CASE STUDY 2

Cecilia is 3 months postpartum after a normal labor and full-term delivery. She tells you that she is exclusively breastfeeding her baby about eight times a day but is very tired and is not getting much sleep because her baby always seems fussy between feedings—day and night. She has been determined to lose her “baby weight” and for the past 6 weeks, she has been restricting her caloric intake to around 1200 calories/day, including approximately six diet drinks every day. She reports that the pediatrician told her that the baby’s weight gain has slowed over the past month and she would like her to begin supplementing the baby with formula. She is hesitant to do this because her goal is to continue breastfeeding exclusively until the baby is 6 months old, and then possibly continue until at least the baby’s first birthday.

Nutrition Diagnostic Statement

- Difficulty breastfeeding related to poor maternal dietary intake as evidenced by mother’s report of inappropriate diet and baby’s poor weight gain

Nutrition Care Questions

- What would you tell Cecilia regarding her concern about losing her “baby weight”?
- What would you tell her to do to improve her dietary intake?
- How would you address her baby’s fussiness and inadequate weight gain?
- What advice would you give her to preserve her breastfeeding and achieve her breastfeeding goals?

pincer grasp

renal solute load

secretory immunoglobulin A (sIgA)

whey proteins

During the first 2 years of life, which are characterized by rapid physical and social growth and development, many changes occur that affect feeding and nutrient intake. The adequacy of infants' nutrient intakes affects their interaction with their environment. Healthy, well-nourished infants have the energy to respond to and learn from the stimuli in their environment and to interact with their parents and caregivers in a manner that encourages bonding and attachment.

PHYSIOLOGIC DEVELOPMENT

The length of gestation, the mother's prepregnancy weight, and the mother's weight gain during gestation determine an infant's birth weight. After birth, the growth of an infant is influenced by genetics and nourishment. Most infants who are genetically determined to be larger reach their **growth channel**, a curve of weight and length or height gain throughout the period of growth, at between 3 and 6 months of age. However, many infants born at or below the tenth percentile for length may not reach their genetically appropriate growth channel until 1 year of age; this is called **catch-up growth**. Infants who are larger at birth and who are genetically determined to be smaller grow at their fetal rate for several months and often do not reach their growth channel until 13 months of age. This phenomenon during the first year of life is called **lag-down growth**.

Growth in infancy is monitored with the routine collection and monitoring of anthropometric data, including weight, length, head circumference, and weight-for-length for age. These are plotted on the appropriate World Health Organization (WHO) growth chart shown in Appendix 3. The WHO growth charts are used for the

first 2 years of life and consist of a series of percentile curves that show the distribution of body measurements in infants and children in optimal growth conditions. When the anthropometric data are plotted on the growth charts, the percentiles rank the infant by showing what percentage of the reference population the infant would equal or exceed. For example, a 7-month-old infant girl who has a weight-for-age at the 75th percentile weighs the same or more than 75% of the reference population for 7-month-old girls and weighs less than 25% of the same population. It is important to monitor growth trends over time and not focus on one measurement.

Infants may lose approximately 7% of their body weight during the first few days of life, but their birth weight usually is regained by the seventh to tenth day. Weight loss of more than 10% in the newborn period indicates need for further assessment regarding adequacy of feeding. Growth thereafter proceeds at a rapid but decelerating rate. Infants usually double their birth weight by 4 to 6 months of age and triple it by the age of 1 year. The amount of weight gained by the infant during the second year approximates the birth weight. Infants increase their length by 50% during the first year of life and double it by 4 years. Total body fat increases rapidly during the first 9 months, after which the rate of fat gain tapers off throughout the rest of childhood. Total body water decreases throughout infancy from 70% at birth to 60% at 1 year. The decrease is almost all in extracellular water, which declines from 42% at birth to 32% at 1 year of age.

The stomach capacity of infants increases from a range of 10 to 20 mL at birth to 200 mL by 1 year, enabling infants to consume more food at a given time and at less frequent intervals as they grow older. During the first weeks of life, gastric acidity decreases and for the first few months remains lower than that of older infants and adults. The rate of emptying is relatively slow, depending on the size and composition of the meal. Because peristalsis and sphincter function along the digestive tract continue to mature during infancy, newborns often

Sections of this chapter were written by Cristine M. Trahms, MS, RDN, CD, FADA.

experience regurgitation (Singendonk et al, 2014). Reducing the volume at each feeding or keeping the infant upright immediately after a feeding can help reduce the risk of regurgitation.

Fat absorption varies in the neonate. Human milk fat is well absorbed, but butterfat is poorly absorbed, with fecal excretions of 20% to 48%. The fat combinations in commercially prepared infant formula are well absorbed. The infant's lingual and gastric lipases hydrolyze short- and medium-chain fatty acids in the stomach. Gastric lipase also hydrolyzes long-chain fatty acids and is important in initiating the digestion of triglycerides in the stomach. Most long-chain triglycerides pass unhydrolyzed into the small intestine, where they are broken down by pancreatic lipase. The bile salt-stimulated lipase present in human milk is stimulated by the infant's bile salts and hydrolyzes the triglycerides in the small intestine into free fatty acids and glycerol. Bile salts, which are effective emulsifiers when combined with monoglycerides, fatty acids, and lecithin, aid in the intestinal digestion of fat.

The activities of the enzymes responsible for the digestion of disaccharides—maltase, isomaltase, and sucrase—reach adult levels by 28 to 32 weeks' gestation. Lactase activity (responsible for digesting the disaccharide in milk) reaches adult levels by birth. Pancreatic amylase, which digests starch, continues to remain low during the first 6 months after birth. If the infant consumes starch before this time, increased activity of salivary amylase and digestion in the colon usually compensate.

The neonate has functional but physiologically immature kidneys that increase in size and concentrating capacity in the early weeks of life. The kidneys double in weight by 6 months and triple in weight by 1 year of age. The last renal tubule is estimated to form between the eighth fetal month and the end of the first postnatal month. The glomerular tuft is covered by a much thicker layer of cells throughout neonatal life than at any later time, which may explain why the glomerular filtration rate is lower during the first 9 months of life than it is in later childhood and adulthood. In the neonatal period the ability to form acid, urine, and concentrate solutes is often limited. The renal concentrating capacity at birth may be limited to as little as 700 mOsm/L in some infants. Others have the concentrating capacity of adults (1200 to 1400 mOsm/L). By 6 weeks, most infants can concentrate urine at adult levels. Renal function in a normal newborn infant is rarely a concern; however, difficulties may arise in infants with diarrhea or those who are fed formula that is too concentrated.

NUTRIENT REQUIREMENTS

Nutrient needs of infants reflect rates of growth, energy expended in activity, basal metabolic needs, and the interaction of the nutrients consumed. Balance studies have defined minimum acceptable levels of intakes for a few nutrients, but for most nutrients the suggested intakes have been extrapolated from the intakes of normal, thriving infants consuming human milk. The dietary reference intakes (DRIs) for infants are shown in the inside cover of this book.

Energy

Full-term infants who are breastfed to satiety or who are fed a standard infant formula generally adjust their intake to meet their energy needs when caregivers are sensitive to the infant's hunger and satiety cues. An effective method for determining the adequacy of an infant's energy intake is to monitor carefully gains in weight, length, head circumference, and weight-for-length for age and plot these data on the WHO growth charts shown in Appendix 3. During the first year a catch-up or lag-down period in growth may occur.

If infants begin to experience a decrease in their rate of weight gain, do not gain weight, or lose weight, their energy and nutrient intake should be monitored carefully. If the rate of growth in length decreases or ceases, potential malnutrition, an undetected disease, or both should be investigated thoroughly. If the weight gain proceeds at a much more rapid rate than growth in length, the energy concentration of the formula, the quantity of formula consumed, and the amount and type of semisolid and table foods offered should be evaluated. The activity level of the infant also should be assessed. Infants who are at the highest end of the growth charts for weight-for-length, or who grow rapidly in infancy, tend to be at greater risk for obesity later in life (Druet et al, 2012).

The equations to calculate the estimated energy requirement (EER) for infants 0 to 12 months of age are in Table 15.1. The EER includes the total energy expenditure plus energy needed for growth for healthy infants with normal growth (see Chapter 2).

Protein

Protein is needed for tissue replacement, deposition of lean body mass, and growth. Protein requirements during the rapid growth of infancy are higher per kilogram of weight than those for older children or adults (Table 15.2). Recommendations for protein intake are based on the composition of human milk, and it is assumed that the efficiency of human milk use is 100%.

Infants require a larger percentage of total amino acids as essential amino acids than do adults. Histidine seems to be an essential amino acid for infants, but not for adults, and tyrosine, cystine, and taurine may be essential for premature infants (Pencharz and Ball, 2006; see Chapter 41).

Human milk or infant formula provides the major portion of protein during the first year of life. The amount of protein in human milk is adequate for the first 6 months of life, even though the amount of protein in human milk is considerably less than in infant formula. From 6 months of age the diet should be supplemented with additional sources of high-quality protein, such as yogurt, strained meats, pureed legumes, mashed egg yolk, pureed fish with low mercury content (i.e., salmon, chunk light tuna, pollock, cod, and perch), or cereal

TABLE 15.1 Equations for Calculating Estimated Energy Requirement (EER) for Infants

Age	Calculation
0-3 months	$(89 \times \text{Weight of infant [kg]} - 100) + 175$
4-6 months	$(89 \times \text{Weight of infant [kg]} - 100) + 56$
7-12 months	$(89 \times \text{Weight of infant [kg]} - 100) + 22$

mixed with formula or human milk. A complete list of low mercury seafood can be found on the Food and Drug Administration (FDA) website under “Eating fish: What pregnant women and parents need to know.”

Infants may not receive adequate protein if their formula is excessively diluted for a prolonged period, or if they have multiple food allergies and are placed on a restricted diet without appropriate medical or nutritional supervision (see Chapter 25).

Lipids

Lipids provide a large proportion of infants’ energy intakes in order to meet the energy demands for rapid growth. The current adequate intake is 31 g of fat per day from birth to 6 months and 30 g of fat per day for infants 7 to 12 months. This is based on the average fat intakes from breastmilk for infants from birth to 6 months and the average fat intakes from breastmilk and complementary foods for infants 7 to 12 months. Significantly lower fat intakes (e.g., with skim-milk feedings) may result in an inadequate total energy intake. An infant may try to correct the energy deficit by increasing the volume of milk ingested but usually cannot make up the entire deficit this way.

Human milk contains the essential fatty acids linoleic acid and alpha-linolenic acid, as well as the longer-chain derivatives **arachidonic acid (ARA)** (C20:4 ω -6) and **docosahexaenoic acid (DHA)** (C22:6 ω -3). While ARA content of human milk is mostly consistent and unaffected by the mother’s diet, DHA content does reflect the mother’s intakes and is found in a wide range of concentrations in human milk (Carlson and Colombo, 2016). See Chapter 14 *Focus On: Omega-3 Fatty Acids in Pregnancy and Lactation*. Infant formulas are supplemented with linoleic acid and alpha-linolenic acid, from which ARA and DHA are derived. Except for a few specialty products, standard formulas for term infants in the United States now also are supplemented with ARA and DHA, although there are no regulatory requirements for their inclusion.

Linoleic acid is essential for growth and dermal integrity. The adequate intake for infants has been set based on the average linoleic acid intake from breastmilk, or 4.4 g/day for infants younger than 6 months of age and based on the average intake from breastmilk and complementary foods, or 4.6 g/day for infants 7 months to 1 year of age. The human milk content of linoleic acid varies based on the mother’s diet; its caloric contribution can range from approximately 6% to 10% of breastmilk’s energy content. The Infant Formula Act of 1980 requires that at least 2.7% of infant formula’s total energy be from linoleic acid. Safflower, corn, and soybean oil are good sources of linoleic acid. The current recommendation for alpha-linolenic acid is 0.5 g/day during the first year of life. This is based on the average intakes from breastmilk for infants 0 to 6 months and average intakes from breastmilk and complementary foods for infants 7 to 12 months. Flaxseed, chia seed, canola oil, and soybean oil are good sources of alpha-linolenic acid.

The concentration of DHA in human milk varies, depending on the amount of DHA in the mother’s diet. DHA and ARA are the major omega-3 and omega-6 long-chain polyunsaturated fatty acids (LCPUFAs) of neural tissues, and DHA is the major fatty acid of the photoreceptor membranes of the retina. Studies looking at visual, neurodevelopmental, or growth outcomes in formula-fed term infants on DHA- or ARA-supplemented formula have shown mixed results (Jasani et al, 2017). Studies are finding that the ratio of DHA to ARA added to formula may be critical (Carlson and Colombo, 2016). The American Academy of Pediatrics (AAP) has not taken an official stand on the addition of LCPUFAs to infant formula.

Carbohydrates

Carbohydrates should supply 30% to 60% of the energy intake during infancy. Approximately 40% of the energy in human milk and 40% to 50% of the energy in infant formulas is derived from lactose or other carbohydrates. Although rare, some infants cannot tolerate lactose and require a modified formula in their diet (see Chapters 27 and 42).

The adequate intake for birth to 6 months is 60 g/day. This is based on the average carbohydrate intake from human milk. The adequate intake for 7 months to 12 months is 95 g/day. This is based on the average carbohydrate intake from human milk and complementary foods. Grains (cereal, pasta, rice), starchy vegetables (peas, corn, potatoes), and sugar from fruits provide natural sources of carbohydrates.

Botulism in infancy is caused by the ingestion of *Clostridium botulinum* spores, which germinate and produce toxins in the bowel lumen. Infant botulism has been associated with eating honey that contains the bacterial spores. Light and dark corn syrups also have been reported to contain the spores, although cases of infant botulism have not been linked to corn syrup. The spores are extremely resistant to heat treatment and are not destroyed by current methods of processing. Thus honey and corn syrup should not be fed to infants younger than 1 year of age because they have not yet developed the immunity required to resist botulism spore development.

Water

The water requirement for infants is determined by the amount lost from the skin and lungs and in the feces and urine, in addition to a small amount needed for growth. The recommended total water intake for infants, based on the DRIs, is 0.7 L/day for infants up to 6 months and 0.8 L/day for infants 6 to 12 months of age. Note that total water includes all water contained in food, beverages, and drinking water. Fluid recommendations per kilogram of body weight are shown in Table 15.3.

Because the renal concentrating capacity of young infants may be less than that of older children and adults, they may be vulnerable to developing a water imbalance. Under ordinary conditions, human milk and formula that is properly prepared supply adequate amounts of water. However, when formula is boiled, the water evaporates and the solutes become concentrated; therefore, boiled milk or formula is inappropriate for infants. In very hot and humid environments, infants may require additional water. When losses of water are high (e.g., vomiting and diarrhea), infants should be monitored carefully for fluid and electrolyte imbalances.

Water deficits result in hypernatremic dehydration and its associated neurologic consequences (e.g., seizures, vascular damage). Hypernatremic dehydration has been reported in breastfed infants who lose greater than 10% of their birth weight in the first few days of life (Panagoda et al, 2015). Because of the potential for hypernatremic dehydration, careful monitoring of volume of intake, daily weights,

TABLE 15.3 Maintenance Fluid Requirements of Infants and Children (Holliday-Segar Method)

Body Weight	Fluid Requirement
0-10 kg	100 mL/kg
11-20 kg	1000 mL + 50 mL/kg for each kg above 10 kg
>20 kg	1500 mL + 20 mL/kg for each kg above 20 kg

From Holliday MA, Segar WE. The maintenance need for water in parenteral fluid therapy. *Pediatrics* 19:823-832, 1957.

and hydration status (e.g., number of wet diapers) in all newborns is warranted.

Water intoxication results in hyponatremia, restlessness, nausea, vomiting, diarrhea, and polyuria or oliguria; seizures also can result. This condition may occur when water is provided as a replacement for milk, the formula is excessively diluted, or bottled water is used instead of an electrolyte solution in the treatment of diarrhea.

Minerals

Calcium

Breastfed infants retain approximately two thirds of their calcium intake. The recommended adequate intake (AI), the mean intake, is based on calcium intakes in healthy breastfed infants. The AI for infants 0 to 6 months of age is 200 mg/day; the AI for infants 6 to 12 months of age is 260 mg/day; formulas contain more calcium per volume than human milk to assure similar levels of calcium absorption (see Appendix 39). During the first year of life, human milk or infant formula is the major source of calcium. Cow's milk or milk alternatives are not appropriate substitutes. Calcium-fortified cereal, yogurt, tofu, and cheese are good sources of calcium.

Fluoride

The importance of fluoride in preventing dental caries has been well documented. However, excessive fluoride may cause dental fluorosis, ranging from fine white lines to entirely chalky teeth (see Chapter 24). To prevent fluorosis, the tolerable upper intake level for fluoride has been set at 0.7 mg/day for infants up to 6 months and 0.9 mg/day for infants 6 to 12 months of age. Fluoride concentration of 0.7 ppm (0.7 mg/L) in drinking water has been proposed as being optimal for safety and caries prevention (*Academy of Nutrition and Dietetics [AND], 2012*). Fluoride content of water supplies can be obtained through local public health departments or water utilities. Fluoride containing toothpaste should be used sparingly—just a smear on a toothbrush (*American Academy of Pediatric Dentistry [AAPD], 2014*).

Human milk is very low in fluoride. Infants who exclusively consume infant formula reconstituted with fluoridated water may be at increased risk of developing mild fluorosis (*Centers for Disease Control and Prevention [CDC], 2015*). Using water that is free of or low in fluoride, which are waters labeled “purified,” “demineralized,” “deionized,” “distilled,” or “produced through reverse-osmosis,” may decrease this risk. Other dietary sources of fluoride during infancy include commercially prepared infant cereals and wet pack cereals processed with fluoridated water. Fluoride supplementation is not recommended for infants younger than 6 months of age, and after 6 months of age is recommended only if an infant is at high risk of developing dental caries and drinks insufficiently fluoridated water (*AND, 2012*). After tooth eruption it is recommended that fluoridated water be offered several times per day to breastfed infants, those who receive cow's milk, and those fed formulas made with water that contain less than 0.3 mg of fluoride/L (*AAP, 2014b*).

Iron

Full-term infants are considered to have adequate stores of iron for growth up to a doubling of their birth weight. This occurs at approximately 4 months of age in full-term infants and much earlier in prematurely born infants. Recommended intakes of iron increase according to age, growth rate, and iron stores. At 4 to 6 months of age, infants who are fed only human milk are at risk for developing a negative iron balance and may deplete their reserves by 6 to 9 months. Iron in human milk is highly bioavailable; however, breastfed infants

should receive an additional source of iron by 4 to 6 months of age (*AAP, 2012*). For breastfed term infants, the AAP recommends iron supplementation of 1 mg/kg/day starting at 4 months of age and continuing until appropriate complementary foods have been introduced (*AAP, 2014b*). Complementary foods high in iron include strained meats and iron-fortified infant cereals. In addition, by 6 months of age offering one serving of vitamin C-rich foods per day enhances iron absorption from nonheme sources such as tofu, beans, peas, lentils, and eggs. Formula-fed infants receive adequate iron from formula. Cow's milk is a poor source of iron and should not be given before 12 months of age.

Iron deficiency and iron deficiency anemia are common health concerns for the older infant. Between 6 and 24 months of age, because of rapid growth, iron requirements per kilogram of body weight are higher than at any other period of life. Risk factors associated with a higher prevalence of iron deficiency anemia include low birth weight, low intake of iron-rich complementary foods, high intake of cow's milk, low socioeconomic status, and immigrant status.

Monitoring iron status is important because of the long-term cognitive effects of iron deficiency in infancy. There is consistent association between iron deficiency anemia in infancy and long-lasting poor cognition, developmental deficits, and behavioral performance (*Domellöf et al, 2014*). Thus it is important that this dietary advice reaches high-risk groups to prevent these significant long-term effects (see Appendix 42 and Chapter 31).

Zinc

Zinc is critical for growth and development. The AI is 2.0 mg for infants 0 to 12 months. During the first 6 months of life, human milk or infant formula provides adequate zinc. Although zinc is better absorbed from human milk than from infant formula, the zinc content of human milk decreases during the first 6 months. A dietary source of zinc becomes necessary for breastfed infants at this time. Good sources of zinc with high bioavailability include red meat, eggs, yogurt, and cheese. The presence of phytic acid makes plant sources of zinc (grains, legumes, nut products) less bioavailable. Infants who are zinc deficient can exhibit growth impairment (*Terrin et al, 2015*; see Appendix 47).

Vitamins

Vitamin B₁₂

Milk from lactating mothers who follow a strict vegan diet may be deficient in vitamin B₁₂, especially if the mother followed the regimen for a long time before and during her pregnancy. Vitamin B₁₂ deficiency has also been diagnosed in infants breastfed by mothers with pernicious anemia (*Roumeliotis et al, 2012*; see Chapter 32). During infancy, signs of vitamin B₁₂ deficiency include inadequate growth, reflux or feeding difficulties, hypotonia, developmental regression, and movement disorders (*Fadilah et al, 2017*; see Appendix 31). Good food sources of vitamin B₁₂ include animal products, including fish, meat, poultry, eggs, milk, and milk products. Vitamin B₁₂ is generally not present in plant foods, but some foods are fortified with vitamin B₁₂, such as breakfast cereals, meat substitutes, nondairy milks, and nutritional yeast products.

Vitamin D

The vitamin D content of breastmilk is correlated to the vitamin D status of the mother. Studies have shown that high maternal intakes of vitamin D, supplemented 2000 IU to 6400 IU per day, were associated with higher breastmilk vitamin D concentrations. However, infants of mothers supplemented with 2000 IU per day or more

have similar serum concentrations as infants receiving a vitamin D supplement of 400 IU per day (Munns et al, 2016). The current recommended dietary allowance (RDA) for vitamin D for lactating mothers is 600 IU per day, and the tolerable upper limit is 4000 IU per day. Coupled with the AAP's recommendation to keep all infants under the age of 6 months out of direct sunlight, exclusively and partially breastfed infants are at high risk for vitamin D deficiency (AAP, 2016). For the prevention of rickets and vitamin D deficiency, a minimum vitamin D intake of 400 IU per day shortly after birth is recommended for all infants. All breastfed infants need a vitamin D supplement of 400 IU per day. Formula-fed infants who consume less than 1000 mL of formula per day also need supplementation (Antonucci et al, 2018).

There appears to be a higher risk of rickets among unsupplemented, breastfed infants and children with dark skin. Because a variety of environmental and family lifestyle factors can affect sunlight exposure and absorption of vitamin D, the AAP recommendations to provide supplemental vitamin D are appropriate for all infants. Supplementation up to 800 IU of vitamin D per day may be needed for infants at higher risk, such as premature infants, dark-skinned infants and children, and those who reside in northern latitudes or at higher altitudes (Antonucci et al, 2018; see Appendix 38).

Vitamin K

The vitamin K requirements of the neonate need special attention. Deficiency may arise because newborns do not store vitamin K and their gut bacteria is not developed enough to supply the needed amount. Low vitamin K can happen in any infant, regardless of gender or ethnicity, and results in bleeding or hemorrhagic disease. This condition is more common in breastfed infants than in formula-fed infants because human milk contains only 2.5 mcg/L of vitamin K, whereas cow's milk-based formulas contain approximately 20 times this amount. All infant formulas contain a minimum of 4 mcg of vitamin K per 100 kcal of formula. The AI for infants is 2 mcg/day during the first 6 months and 2.5 mcg/day during the second 6 months of life. This can be supplied by mature breastmilk, although perhaps not during the first week of life. For breastfed infants, vitamin K supplementation is necessary during that time to considerably decrease the risk for hemorrhagic disease. Most hospitals require that infants receive an injection of vitamin K as a prophylactic measure shortly after birth (CDC, 2017).

Supplementation

Vitamin and mineral supplements should be prescribed only after careful evaluation of the infant's intake. Commercially prepared infant formulas are fortified with all necessary vitamins and minerals; therefore formula-fed infants rarely need supplements. Breastfed infants need additional vitamin D supplementation shortly after birth, and iron by 4 to 6 months of age (see *Focus On: Vitamin and Mineral Supplementation Recommendations for Full-Term Infants*). Chapter 41 discusses the feeding of premature or high-risk infants and their special needs. Chapter 11 discusses more about dietary supplementation.

Analysis of dietary intakes of infants in the United States indicate they are generally adequate, but the likelihood of inadequacy increases beyond 1 year of age. Iron is the main nutrient of concern in the older infant, 6 to 12 months of age, with about 1 in 5 older infants below the estimated average requirement (EAR) with a general trend of consuming less iron-fortified cereal as they approach 1 year of age (Bailey et al, 2018). Supplemental iron may be necessary if unable to increase iron intake from food sources.

FOCUS ON

Vitamin and Mineral Supplementation Recommendations for Full-Term Infants

Vitamin D

Supplementation shortly after birth of 400 IU/day for all breastfed infants and infants consuming less than 1000 mL (33 oz) of vitamin D-fortified formula each day

Vitamin K

Supplementation soon after birth to prevent hemorrhagic disease of the newborn

Iron

Breastfed Infants

Supplement with 1 mg/kg/d starting at 4-6 months of age until adequate iron intake is achieved from complementary foods. Only iron-fortified formulas for weaning or supplementing breastmilk.

Formula-Fed Infants

Only iron-fortified formula during the first year of life

Modified from American Academy of Pediatrics Committee on Nutrition: *Pediatric nutrition*, ed 7, Elk Grove Village, Ill, 2014, American Academy of Pediatrics, 2014.

MILK

Human Milk

Human milk is unquestionably the food of choice for the infant. Its composition is designed to provide the necessary energy and nutrients in appropriate amounts. It contains specific and nonspecific immune factors that support and strengthen the immature immune system of the newborn and thus protect the body against infections. Human milk also helps prevent diarrhea and otitis media (AAP, 2012). Allergic reactions to human milk protein are rare. Moreover, the closeness of the mother and infant during breastfeeding facilitates attachment and bonding (see Fig. 14.11 in Chapter 14) and breastmilk provides nutritional benefits (e.g., optimal nourishment in an easily digestible and bioavailable form), decreases infant morbidity, provides maternal health benefits (e.g., lactation amenorrhea, maternal weight loss, some cancer protection), and has economic and environmental benefits (Lessen and Kavanagh, 2015; see Chapter 14).

During the first few days of life, a breastfeeding infant receives **colostrum**, a yellow, transparent fluid that meets the infant's needs during the first week. It contains less fat and carbohydrate, but more protein and greater concentrations of sodium, potassium, and chloride than mature milk. It is also an excellent source of immunologic substances.

Note that breastfeeding may not be appropriate for mothers with certain infections or those who are taking medications that may have untoward effects on the infant. For example, a mother who is infected with human immunodeficiency virus can transmit the infection to the infant, and a mother using psychotropic drugs or other pharmacologic drugs may pass the medication to the infant through her breastmilk (AAP, 2012; see Chapter 14).

The Academy of Nutrition and Dietetics (AND) and the AAP support exclusive breastfeeding (EBF) for the first 6 months of life and then breastfeeding supplemented by complementary foods until at least 12 months (AAP, 2012; Lessen and Kavanagh, 2015). It is important to note the ages of the infants in these recommendations; adding

other foods at too young of an age decreases breastmilk intake and increases early weaning. Healthy Children 2020 objectives support breastfeeding among mothers of newborn infants (see *Focus On: Healthy Children 2020 Objectives: Nourishment of Infants*).

FOCUS ON

Healthy Children 2020 Objectives: Nourishment of Infants

Healthy People 2020 is a comprehensive set of health objectives for the United States to achieve during the second decade of the twenty-first century. Healthy People 2020 identifies a wide range of public health priorities and specific, measurable objectives. The objectives have 42 focus areas, one of which is Maternal, Infant, and Child Health. The objectives related to nourishment of infants are as follows:

GOAL: Improve the health and well-being of women, infants, children, and families.

Objective: Increase the proportion of infants who are breastfed to 81.9% in the early postpartum period, to 60.6% at 6 months, and to 34.1% at 1 year of age. Increase the proportion of infants that are exclusively breastfed to 46.2% through 3 months of age and 25.5% through 6 months of age.

Objective: Reduce the proportion of breastfed newborns who receive formula supplementation within the first 2 days of life to 14.2%.

GOAL: Promote health and reduce chronic disease risk through the consumption of healthful diets and achievement and maintenance of healthy body weights.

Objective: Eliminate very low food security among children.

Objective: Reduce iron deficiency among children ages 1-2 years to less than 14.3%.

GOAL: Prevent and control oral and craniofacial diseases, conditions, and injuries and improve access to preventive services and dental care.

Objective: Reduce the proportion of young children with dental caries in their primary teeth.

The complete text of the Healthy People 2020 Objectives can be found on the Office of Disease Prevention and Health Promotion Website under HealthyPeople.gov.

Composition of Human and Cow's Milk

The composition of human milk is different from that of cow's milk; for this reason, unmodified cow's milk is not recommended for infants until at least 1 year of age. Both provide approximately 20 kcal/oz; however, the nutrient sources of the energy are different. Protein provides about 6% of the energy in human milk and 20% of the energy in cow's milk. Human milk is 60% **whey proteins** (mainly lactalbumins) and 40% casein; by contrast, cow's milk is 20% whey proteins and 80% casein. **Casein** forms a tough, hard-to-digest curd in the infant's stomach, whereas **alpha-lactalbumin** in human milk forms soft, flocculent, easy-to-digest curds. Taurine and cystine are present in higher concentrations in human milk than in cow's milk; these amino acids may be essential for premature infants. Lactose provides 40% of the energy in human milk and only 30% of the energy in cow's milk (Lawrence and Lawrence, 2016).

Lipids provide about 50% of the energy in human and whole cow's milk. Linoleic acid, an essential fatty acid, provides 4% of the energy in human milk and only 1% to 2% in cow's milk. The cholesterol content of human milk is 10 to 20 mg/dL compared with 10 to 15 mg/dL in whole cow's milk. Less fat is absorbed from cow's milk than from human milk; a lipase in human milk is stimulated by bile salts and contributes significantly to the hydrolysis of milk triglycerides (Lawrence and Lawrence, 2016).

All of the water-soluble vitamins in human milk reflect maternal intake. Cow's milk contains adequate quantities of the B-complex vitamins, but little vitamin C. Human milk and supplemented cow's milk provide sufficient vitamin A. Human milk is a richer source of vitamin E than cow's milk.

The quantity of iron in human and cow's milk is small (0.3 mg/L). Approximately 50% of the iron in human milk is absorbed, whereas less than 10% of the iron in cow's milk is absorbed. The bioavailability of zinc in human milk is higher than in cow's milk. Cow's milk contains four times as much calcium, six times as much phosphorus as human milk, and three times the total salt content of human milk (Lawrence and Lawrence, 2016).

The much higher protein and mineral content of cow's milk results in a higher **renal solute load**, or amount of nitrogenous waste and minerals that must be excreted by the kidney. The sodium and potassium concentrations in human milk are about one third those in cow's milk, contributing to the lower renal solute load of human milk. The osmolality of human milk averages 300 mOsm/kg, whereas that of cow's milk is 350 mOsm/kg (Lawrence and Lawrence, 2016).

Antiinfective Factors

Human milk and colostrum contain antibodies and antiinfective factors that are not present in infant formulas. **Secretory immunoglobulin A (sIgA)**, the predominant immunoglobulin in human milk, plays a role in protecting the infant's immature gut from infection by keeping viruses and bacteria from invading the mucosa. Breastfeeding should be maintained until the infant is at least 3 months of age to obtain this benefit (Lawrence and Lawrence, 2016).

The iron-binding protein **lactoferrin** in human milk deprives certain iron-dependent bacteria in the gastrointestinal tract of iron and thus slows their growth. Lysozymes, which are bacteriolytic enzymes found in human milk, destroy the cell membranes of bacteria after the peroxides and ascorbic acid that are also present in human milk have inactivated them. They also have a significant role in the development of intestinal flora (Lawrence and Lawrence, 2016). Human milk enhances the growth of the bacterium *Lactobacillus bifidus*, which produces an acidic gastrointestinal (GI) environment that interferes with the growth of certain pathogenic organisms. Because of these antiinfective factors, the incidence of infections is lower in breastfed infants than in formula-fed infants.

The Microbiome and Probiotics and Prebiotics

Colonization with nonpathogenic microbiota is important for infant health and affects health and disease in later life. This colonization is necessary for normal immune system development. A disturbance in this process may contribute to immune disease such as food allergies, atopic dermatitis, and asthma. The development of gut microbiota in infancy occurs during a critical window. By 3 years of age, the human GI tract has established its normal flora or microbiome, with the majority of this occurring in the first year of life. This ecosystem in early life is influenced by such factors as mode of birth (cesarean vs. vaginal delivery), environment, human milk vs. formula feeding, introduction to solids, and use of antibiotics (Tanaka and Nakayama, 2017). Breastfeeding and introduction of whole foods can greatly assist in establishing a healthy microbiome for life.

Probiotics are microorganisms that, when administered as an oral supplement or as part of food, may confer health benefits to the host by changing the gut microbiome. Studies have looked at the effects of postnatal probiotic supplementation on the prevention of atopic disease such as asthma, eczema, and allergic rhinitis. Results have been mixed, depending on the strain of probiotics used, and whether the mother also was supplemented during pregnancy (Elazab et al, 2013).

Evidence is emerging that supplementing term infants with the probiotic *Lactobacillus reuteri* (*L. reuteri*) may decrease their risk of colic, gastroesophageal reflux, and constipation (Indrio et al, 2014). However, supplementation with *L. reuteri* does not appear to be effective in treating colic. In fact, a well-controlled study found no reduction in crying or fussiness in colicky infants receiving the probiotic. Interestingly the formula-fed infants who were given *L. reuteri* actually fussed more than formula-fed infants given placebo (Sung et al, 2014). The effectiveness of supplemental probiotic use is still under study. Although probiotics have been found generally to be safe, their content may be variable under current FDA regulation (Van den Nieuwboer et al, 2014). Similar caution should be used as when using other nutrition supplements. See Chapter 11.

Prebiotics are nondigestible food ingredients that promote the growth of the gut's bacteria. Human milk contains prebiotics in the form of **oligosaccharides**, which are highly abundant and unique to human milk. The addition of short-chain gluco-oligosaccharides and long-chain fructo-oligosaccharides to infant formula results in gut microflora more similar to those of human milk-fed infants (Oozeer et al, 2013). The AAP has no official stance on the addition of probiotics or prebiotics to infant formula. Some infant formulas in the United States are now supplemented with probiotics or prebiotics.

Formulas

Infants who are not breastfed are fed an infant formula based on cow's milk or a soy product. Many mothers may choose to offer a combination of breastmilk and formula feedings.

Commercial formulas made from heat-treated nonfat milk or a soy product and supplemented with vegetable fats, vitamins, and minerals are formulated to approximate, as closely as possible, the composition of human milk. They provide the necessary nutrients in an easily absorbed form. The manufacture of infant formulas is regulated by the FDA through the Infant Formula Act (FDA, 2015). By law, infant formulas are required to have a nutrient level that is consistent with these guidelines. They were most recently updated in 2015 to add minimum and maximum levels of selenium (Table 15.4). Refer to individual manufacturers' websites to obtain the most accurate information and compare the composition of various infant formulas and feeding products. Organic infant formulas are increasingly available, and they must also meet all standards required for United States Department of Agriculture Organic certification. Homemade infant formulas are not recommended.

Various products are available for infants who cannot tolerate the protein in cow's milk-based formulas. Soy-based infant formulas are recommended for (1) term infants in vegetarian families, (2) term infants with galactosemia or hereditary primary lactase deficiency, and (3) term infants with documented immunoglobulin E-associated allergy to cow's milk who are not also allergic to soy protein. In many cases, an infant may be allergic to both, and soy formula would not be appropriate. Soy-based formulas are not recommended (1) for preterm infants because of the increased risk of osteopenia and aluminum content, (2) for the prevention of colic or allergy, or (3) for infants with cow's milk protein-induced enterocolitis or enteropathy (AAP, 2014b; see Chapter 25).

The protein in soy infant formula is soy protein isolate supplemented with L-methionine, L-carnitine, and taurine. A concern raised about soy formula includes its content of phytates, which may impair the absorption of minerals and trace elements. Exposure to higher levels of phytoestrogens, isoflavones, and aluminum and their potential health consequences have also been areas of discussion. Aluminum from mineral salts is found in soy infant formulas at concentrations of 500 to 2500 ng/mL, levels that exceed aluminum concentrations in human milk of 4 to 65 ng/mL and in cow's milk formula of 15 to

TABLE 15.4 Nutrient Levels in Infant Formulas as Specified by the Infant Formula Act

Specified Nutrient Component	Minimum Level Required (per 100 kcal of Energy)
Protein (g)	1.8
Fat (g)	3.3
Percentage of calories from fat	30
Linoleic acid (mg)	300
Percentage of calories from linoleic acid	2.7
Vitamin A (IU)	250
Vitamin D (IU)	40
Vitamin E (IU)	0.7
Vitamin K (mcg)	4
Thiamin (B ₁) (mcg)	40
Riboflavin (B ₂) (mcg)	60
Pyridoxine (B ₆) (mcg)	35
Vitamin B ₁₂ (mcg)	0.15
Niacin (mcg)	250
Folic acid (mcg)	4
Pantothenic acid (mcg)	300
Biotin (mcg) (nonmilk-based formulas only)	1.5
Vitamin C (Ascorbic acid) (mg)	8
Choline (mg) (nonmilk-based formulas only)	7
Inositol (mg) (nonmilk-based formulas only)	4
Calcium (mg)	60
Phosphorus (mg)	30
Magnesium (mg)	6
Iron (mg)	0.15
Zinc (mg)	0.5
Manganese (mcg)	5
Copper (mg)	60
Iodine (mg)	5
Selenium (mcg)	2
Sodium (mg)	20
Potassium (mg)	80
Chloride (mcg)	55

From Food and Drug Administration: Electronic Code of Federal Regulations: Title 21:107, Infant Formulas, Final Rule (21 CFR 107), *Fed Reg* 50:45108, 1985. Amended *Fed Reg* 80:35841, 2015.

400 mg/mL. This appears to be of no concern except for preterm infants and infants with renal failure. A systematic review with meta-analysis of infants consuming soy formula found that the patterns of growth; bone health; and metabolic, reproductive, endocrine, immune, and neurologic functions were similar to those of infants fed human milk or cow's milk-based formula (Vandenplas et al, 2014).

Infants who cannot tolerate cow's milk-based or soy products can be fed formulas made from a **casein hydrolysate**, which is casein that has been split into smaller components by treatment with acid, alkali, or enzymes. These formulas do not contain lactose. For infants who have severe food protein intolerances and cannot tolerate hydrolysate

formulas, free amino acid–based formulas are available. Hydrolysate and free amino acid–based formulas often contain some medium-chain triglycerides (MCT) as a portion of the fat, which is helpful in certain malabsorptive conditions. Other formulas are available for children with problems such as malabsorption or metabolic disorders (e.g., phenylketonuria) (see Box 25.9 in Chapter 25).

Formulas are also available for older infants and toddlers. However, “older infant” formulas are usually unnecessary unless toddlers are not receiving adequate amounts of infant or table foods.

Whole Cow’s Milk

Some parents may choose to transition their infant from formula to fresh cow’s milk before 1 year of age. However, the AAP Committee on Nutrition has concluded that infants should not be fed whole cow’s milk during the first year of life (AAP, 2014b). Infants who are fed whole cow’s milk have been found to have lower intakes of iron, linoleic acid, and vitamin E, and excessive intakes of sodium, potassium, and protein. Cow’s milk may cause a small amount of GI blood loss. When introduced at 1 year of age, only pasteurized cow’s milk and milk products should be offered (AAP, 2014a).

Low-fat (1% to 2%) and nonfat milk are also inappropriate for infants during the first 12 months of life. The infants may ingest excessive amounts of protein in large volumes of milk in an effort to meet their energy needs, and the decreased amount of essential fatty acids may be insufficient for preventing deficiency (AAP, 2014b). Substitute or imitation milks such as soy, rice, oat, or nut milks are also inappropriate during the first year of life due to their low content of calories, fat, vitamins, and minerals.

Formula Preparation

Commercial infant formulas are available in ready-to-feed forms that require no preparation, as concentrates prepared by mixing with equal parts of water, and in powder form that is designed to be mixed with 2 oz of water per level scoop of powder.

Infant formulas should be prepared in a clean environment. All equipment, including bottles, nipples, mixers, and the top of the can of formula, should be washed thoroughly. Water used for mixing infant formula must be from a safe water source. If there is concern or uncertainty about the safety of tap water, bottled water may be used or cold water may be boiled for 1 minute (no longer), then cooled to room temperature for no more than 30 minutes before it is used. Boiling water will kill bacteria but will not remove toxic chemicals. Well water should be tested for nitrates before giving it to infants under 1 year of age (AAP, 2014b).

Formula may be prepared for up to a 24-hour period and refrigerated. Formula for each feeding should be warmed in a hot water bath. Microwave heating is not recommended because of the risk of burns from formula that is too hot or unevenly heated. Any formula offered and not consumed at that feeding should be discarded and not reused later, because of bacterial contamination from the infant’s mouth.

Bisphenol-A (BPA) is a chemical that was present in many hard plastic bottles, such as baby bottles and reusable cups, and metal food and beverage containers, including canned liquid infant formula. Due to concerns about the potential effects of BPA on the brain, behavior, and prostate gland in fetuses, infants, and young children, BPA has not been used to make bottles, infant feeding cups, or infant formula packaging for the U.S. market since 2013.

FOOD

Infants can meet their nutrition needs from homemade or commercial infant food. Some families choose to offer a combination of both.

BOX 15.1 Directions for Home Preparation of Infant Foods

1. Select fresh, high-quality fruits, vegetables, or meats.
2. Be sure that all utensils, including cutting boards, grinder, knives, and other items, are thoroughly cleaned.
3. Wash hands before preparing the food.
4. Clean, wash, and trim the food in as little water as possible.
5. Cook the foods until tender in as little water as possible. Avoid overcooking, which may destroy heat-sensitive nutrients.
6. Do not add salt or sugar. Do not add honey to food intended for infants younger than 1 year of age.*
7. Add enough water for the food to be easily puréed.
8. Strain or purée the food using an electric blender, a food mill, a baby food grinder, or a kitchen strainer.
9. Pour purée into an ice cube tray and freeze.
10. When the food is frozen hard, remove the cubes and store in freezer bags.
11. When ready to serve, defrost and heat in a serving container the amount of food that will be consumed at a single feeding.

**Clostridium botulinum* spores, which cause botulism, have been reported in honey; young infants do not have the immune capacity to resist this infection.

Families who would like to make their own infant food can do so easily by following the directions in Box 15.1. Home-prepared foods generally are more concentrated in nutrients than commercially prepared foods because less water is used. Salt and sugar should not be added to foods prepared for infants. Dry infant cereals are fortified with **electrolytically reduced iron**, which is iron that has been fractionated into small particles for improved absorption. Four level tablespoons of cereal provide approximately 5 mg of iron, or approximately half the amount the infant requires. Therefore infant cereal is usually the first food added to the infant’s diet. Rice and rice products have been found to contain arsenic, but at levels that are safe to be consumed as part of a varied diet (FDA, 2016).

Most strained (“Stage 1” or “Stage 2”) and junior (“Stage 3”) meats are prepared with water. Strained meats, which have the highest energy density of any of the commercial baby foods, are an excellent source of high-quality protein and heme iron. Vegetable and fruit baby foods provide carbohydrates and vitamins A and C. Vitamin C is added to numerous commercial fruit products. Stage 1 fruits and vegetables are typically single-ingredient, whereas Stage 2 and Stage 3 foods may contain additional ingredients such as grain or dairy.

Baby yogurts are usually full fat and fortified with vitamin D and are good sources of calcium. They are available plain or flavored with pureed fruits or vegetables. Some may have added sweeteners, which most infants do not need in their diet. They often contain thickeners such as pectin, tapioca starch, or flour.

Various commercially prepared foods and organically grown products are available for infants. See *Focus On: Is Organic Produce Healthier?* in Chapter 8 for a discussion of organic foods. These products vary widely in their nutrient value. Foods for infants should be thoughtfully selected to meet their nutritional and developmental needs.

Previously, families were advised to delay introducing potentially allergenic foods such as dairy, peanuts, egg whites, and fish until after the first birthday. Allergy experts now say that for infants with no family history of food allergy, there is no reason to delay introducing these foods, and in fact introducing these foods before the infant’s first birthday may have protective effects against developing food allergies later in life (Fleischer et al, 2013).

FEEDING

Early Feeding Patterns

Because milk from a mother with an adequate diet is designed uniquely to meet the needs of the human infant, breastfeeding for the first 6 months of life is recommended strongly. Most chronic medical conditions do not contraindicate breastfeeding.

A mother should be encouraged to nurse her infant immediately after birth. Those who care for and counsel parents during the first postpartum days should acquaint themselves with ways in which they can be supportive of breastfeeding. Ideally, counseling and preparation for breastfeeding starts in the last few months or weeks of pregnancy (see Chapter 14).

Regardless of whether infants are breastfed or formula fed, they should be held and cuddled during feedings. Once a feeding rhythm has been established, infants become fussy or cry to indicate they are hungry, whereas they often smile and fall asleep when they are satisfied (Table 15.5). Infants, not adults, should establish the feeding schedules. Feeding schedules vary widely among infants, with breastfed infants tending to feed more frequently than formula-fed infants. Initially, most infants feed every 2 to 3 hours; by 2 months of age most feed every 3 to 4 hours. By 6 months of age infants usually are able to consume enough during the day to allow the parent or caregiver to omit night feedings. Infants may feed more frequently during periods of rapid growth.

Development of Feeding Skills

At birth, infants coordinate sucking, swallowing, and breathing, and are prepared to suckle liquids from the breast or bottle but are not able to handle foods with texture. During the first year, typical infants develop head control, the ability to move into and sustain a sitting posture, and the ability to grasp, first with a **palmar grasp** and then with a refined **pincer grasp** (Fig. 15.1, B). They develop mature sucking and rotary chewing abilities and progress from being fed to feeding themselves using their fingers. In the second year, they learn to feed themselves independently with a spoon (Fig. 15.2).

Addition of Semisolid Foods

Developmental readiness and nutrient needs are the criteria that determine appropriate times for the addition of various foods. During the first 4 months of life, the infant attains head and neck control, and oral motor patterns progress from a suck to a suckling to the beginnings of a mature sucking pattern. For the first 6 months of life, breastmilk or infant formula is adequate as the sole source of nutrition. Table 15.6 lists developmental landmarks and their indications for semisolid and table food introduction.

Around 6 months of age, when the mature sucking movement is refined and munching movements (up-and-down chomping motions) begin, the introduction of strained or pureed foods is appropriate. To support developmental progress, pureed food is offered to the infant from a spoon, not combined with formula in a bottle and not directly from a squeezable pouch (see Fig. 15.1, A). The sequence in which these foods are introduced is not important; however, it is important that one single ingredient food (e.g., peaches, not peach yogurt, which has many ingredients) be introduced at a time. Introducing a single new food at a time at 2- to 7-day intervals enables parents to identify any allergic responses or food intolerances. Introducing vegetables before fruits may increase vegetable acceptance. Foods introduced may vary depending on country of origin and culture of the family.

Infants demonstrate their acceptance of new foods by slowly increasing the variety and quantity of solids they accept. Breastfed infants seem to accept greater flavor varieties than do formula-fed infants

TABLE 15.5 Hunger and Satiety Behaviors in Infants

Approximate Age	Hunger Cue	Satiety Cue
Birth through 5 months	Wakes and tosses Sucks on fist Fusses or cries Opens mouth while feeding to show wants more	Falls asleep Turns head away Seals lips together Decreases rate of sucking or stops sucking Purses lips, bites nipple, spits nipple out, or smiles and lets go
4 months through 6 months	Fusses or cries Smiles, coos, gazes at caregiver during feeding Moves head toward spoon Tries to swipe food toward mouth	Distracted or pays more attention to surroundings Turns head away Bites nipple or spits it out Decreases rate of sucking or stops sucking Obstructs mouth with hands
5 months through 9 months	Reaches for food Points to food	Rate of feeding slows down Pushes food away Keeps mouth tightly closed Changes posture Uses hands more actively
8 months through 11 months	Gets excited when food is presented Reaches for food Points to food	Clenches mouth shut Pushes food away Rate of feeding slows down Shakes head to say “no more” Plays with utensils, throws utensils
10 months through 12 months	Expresses desire for specific food with words or sounds	Hands bottle or cup to caregiver Shakes head to say “no more” Sputters with tongue and lips

Modified from U.S. Department of Agriculture: *Infant Nutrition and Feeding: a Guide for Use in the WIC And CSF Programs*, Washington DC, 2009.

(Harris and Coulthard, 2016). Parents who thoughtfully offer a variety of nourishing foods are more likely to provide a well-balanced diet and help their children learn to accept more flavors.

As oral-motor maturation proceeds, an infant’s rotary chewing ability develops, indicating a readiness for more textured foods such as well-cooked mashed vegetables, casseroles, and pasta from the family menu. Learning to grasp—with the palmar grasp, then with an inferior pincer grasp, and finally with the refined pincer grasp—indicates a readiness for finger foods such as oven-dried toast or arrowroot biscuits (see Fig. 15.1, B). Table 15.6 presents recommendations for adding foods to an infant’s diet. Foods with skins or rinds and foods that stick to the roof of the mouth (e.g., hot dogs, grapes, nut butters) may cause choking and should not be offered to young infants.

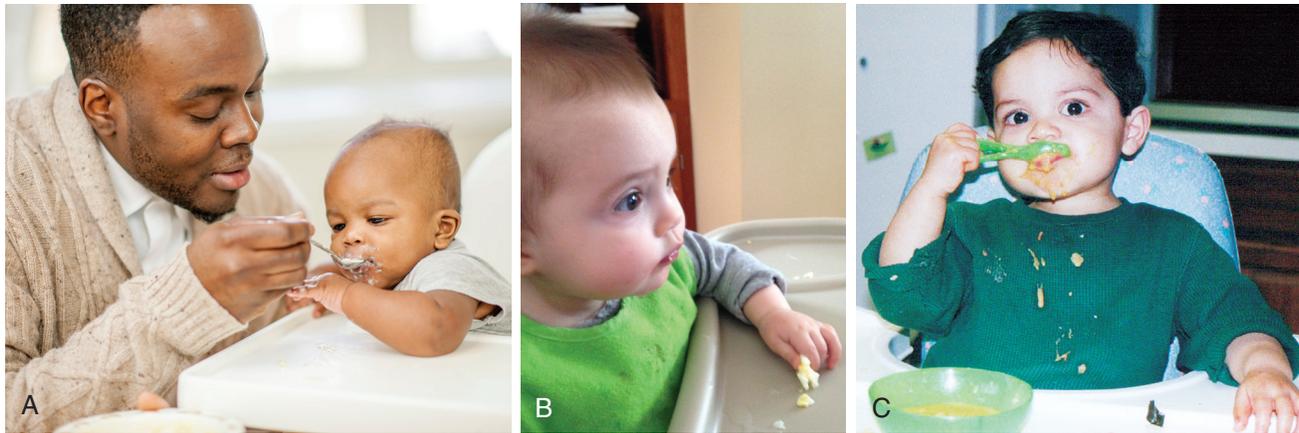

Fig. 15.1 Development of feeding skills in infants and toddlers. **A**, This 6 month old is showing hunger and readiness for the next bite by leaning into the spoon. **B**, This 8-month-old girl is using a refined pincer grasp to pick up her food. **C**, This 19-month-old boy is beginning to use his spoon independently, although he is not yet able to rotate his wrist to keep food on it. (A. From www.istockphoto.com.)

TABLE 15.6 Feeding Behaviors: Developmental Landmarks During the First 2 Years of Life

Developmental Landmarks	Age (MO)	Change Indicated	Examples of Appropriate Foods
Tongue laterally transfers food in the mouth Shows voluntary and independent movements of the tongue and lips Sitting posture can be sustained Shows beginning of chewing movements (up and down movements of the jaw)	6	Introduction of soft, mashed table food	Canned, boneless, skinless fish such as chunk light tuna or salmon (avoid albacore tuna for mercury content); mashed potatoes; well-cooked, mashed vegetables; ground meats in gravy and sauces; mashed beans or pieces of tofu; soft, diced fruit such as bananas, peaches, and pears; yogurt
Reaches for and grasps objects with palmar grasp Brings hand to mouth	6-9	Finger feeding (large pieces of food)	Oven-dried toast, teething biscuits
Approximates lips to rim of the cup	6-9	Introduction of cup for sipping liquids	Water, breastmilk, or infant formula. Juice and cow's milk are not recommended during the first year.
Voluntarily releases food (refined digital [pincer] grasp)	9-12	Finger feeding (small pieces of food)	Bits of cottage cheese, dry cereal, peas, beans, and other bite-size vegetables; small pieces of meat
Shows rotary chewing pattern	9-12	Introduction of food of varied textures from family menu	Well-cooked, chopped meats and casseroles; cooked vegetables and canned fruit (not mashed); toast; potatoes; macaroni, spaghetti; peeled ripe fruit
Understands relationship of container and its contents	9-12	Beginning of self-feeding (though messiness should be expected)	Food that when scooped adheres to the spoon, such as applesauce, cooked cereal, porridge, mashed potatoes, cottage cheese, yogurt
Shows increased movements of the jaw Shows development of ulnar deviation of the wrist	12-18	More skilled at cup and spoon feeding	Chopped fibrous meats, such as roast and steak; raw vegetables and fruit (introduced gradually)
Walks alone	12-18	May seek food and obtain food independently	Mixed textures, food from the family meal; foods of high nutritional value
Names food, expresses preferences; prefers unmixed foods Goes on food jags Appetite appears to decrease	18-24		Balanced food choices, with child permitted to develop food preferences (parents should not be concerned that these preferences will last forever)

Modified from Trahms CM, Pipes P: *Nutrition in infancy and childhood*, ed 6, New York, 1997, McGraw-Hill.

Baby-led weaning is a practice that is becoming popular among parents in industrialized, Western countries, in which parents offer finger foods that infants self-feed as first foods. Some families strictly offer finger foods whereas others choose to offer a combination of finger foods and purees from a spoon. With careful

attention to the infant's developmental readiness and the food's texture and nutrition content, infants fed with baby-led weaning can achieve appropriate growth, meet nutrition needs, and avoid choking (Taylor et al, 2017). See [Box 15.2](#) for more on baby-led weaning.

BOX 15.2 Baby-Led Weaning

Baby-led weaning is a philosophy which promotes infants self-feeding all complementary foods. Infants appropriate for this are able to sit unassisted, have a palmar grasp, and bring food to their mouth, which often happens around 6 months of age.

Special attention should be paid to minimize choking risk, and to ensure the infant meets energy and nutrient needs, specifically iron. Some general guidelines for baby-led weaning include:

- Foods should be mashable between tongue and roof of the mouth or tough enough that they do not break off, such as strips of meat
- Do not offer foods that form a crumb in mouth
- Foods should be as long as infant's fist, at least on one side
- Infants should be sitting upright and always supervised
- Never place an entire food into the infant's mouth. Infants should control how much food they put into their mouth.
- Offer the following foods at each meal:
 - Iron-rich food
 - Energy-rich food
 - Fruit or vegetable
- When an infant is ill, increase breastmilk or formula feeding frequency and offer foods that infant can easily eat.

Although baby-led weaning has been promoted as decreasing risk of childhood overweight because infants learn to self-regulate their intakes better, studies have not supported this claim.

Modified from Taylor RW, Williams SM, Fangupo LJ, et al: Effect of a baby-led approach to complementary feeding on infant growth and overweight: a randomized clinical trial, *JAMA Pediatr* 171:838–846, 2017.

Fig. 15.2 This 2-year-old is skilled at self-feeding because he has the ability to rotate his wrist and elevate his elbow to keep food on the spoon.

During the last quarter of the first year, infants can approximate their lips to the rim of the cup and can drink if the cup is held for them. During the second year they gain the ability to rotate their wrists and elevate their elbows, thus allowing them to hold the cup themselves and manage a spoon (see Fig. 15.1, C). They are very messy eaters at first (Fig. 15.3), but by 2 years of age most typical children skillfully feed themselves (see Fig. 15.2).

Weaning from Breast or Bottle to Cup

The introduction of solids into an infant's diet begins the weaning process in which the infant transitions from a diet of only breastmilk

Fig. 15.3 This 14-month-old girl is learning to self-feed; it's normal to be messy.

or formula to a more varied one. Weaning should proceed gradually and be based on the infant's rate of growth and developmental skills. Weaning foods should be chosen carefully to complement the nutrient needs of the infant, promote appropriate nutrient intake, and maintain growth.

Many infants begin the process of weaning with the introduction of the cup at approximately 6 to 9 months of age and complete the process when they are able to ingest an adequate amount of milk or formula from a cup at 18 to 24 months of age. Parents of infants who are breastfed may choose to transition the infant directly to a cup or have an intermittent transition to a bottle before the cup is introduced.

Early Childhood Caries

Dental caries is the most common chronic disease of childhood (AAP, 2014c). **Early childhood caries (ECC)**, or “baby bottle tooth decay” is a pattern of tooth decay that involves the upper anterior and sometimes lower posterior teeth. ECC is common among infants and children who are allowed to bathe their teeth in sugar (sucrose or lactose) throughout the day and night. If infants are given sugar-sweetened beverages or fruit juice in a bottle during the day or at bedtime after teeth have erupted, the risk of dental caries increases (see Chapter 24).

To promote dental health, infants should be fed and burped and then put to bed without milk or food. Juice should not be introduced into the diet before 12 months of age unless clinically indicated. Juice should be limited to, at most, 4 oz/day for toddlers 1 through 3 years of age and only offered from a cup (Heyman and Abrams, 2017). Parents and caregivers can be taught effective oral health practices for infants, not only by dentists but also by other paraprofessionals (Edelstein, 2017).

Feeding Older Infants

Typically developing children have a natural ability to eat. They eat as much as they need, they grow in the way that is right for them, and they learn to eat the foods their parents eat. As infants transition toward family food, the parent is responsible for what is offered and when and where they eat. The child is responsible for how much and whether to eat the foods that are offered. This is known as the division of responsibility in feeding proposed by the Satter Feeding Dynamics Model. Based on what the child can do, not on how old they are,

parents guide their children through transitions from nipple feeding as a young infant to eventually eating table foods at family meals (Satter, 2000). Table 15.6 highlights appropriate feeding based on developmental landmarks.

As maturation proceeds and the rate of growth slows down, infants' interest in and approach to food changes. Between 9 and 18 months of age most reduce their breastmilk or formula intake. They can become finicky about what and how much they eat.

In the weaning stage infants have to learn many skills, including the ability to chew and swallow solid food and use utensils. They learn to tolerate various textures and flavors of food, eat with their fingers, and then feed themselves with a utensil. Very young children should be encouraged to feed themselves (see *Clinical Insight: A Look at the Food Practices of Infants and Toddlers*).

CLINICAL INSIGHT

A Look at the Food Practices of Infants and Toddlers

The Feeding Infants and Toddlers Study was a national random sample of more than 2500 infants and toddlers from 4 to 24 months of age and their mothers.

- Assuming that a variety of nutritious foods are offered to infants and toddlers, parents and caregivers should encourage self-feeding without concern for compromising energy intake and nutrient adequacy (Carruth et al, 2004b).
- Parents and caregivers should offer a variety of fruits and vegetables daily; sweets, desserts, sweetened beverages, and salty snacks should be offered only occasionally. Because family food choices influence the foods offered to infants, family-based approaches to healthy eating habits should be encouraged (Fox et al, 2004).
- By 24 months of age, 50% of toddlers were described as picky eaters. When offering a new food, caregivers must be willing to provide 8 to 15 repeated exposures to enhance acceptance of that food (Carruth et al, 2004a).
- Infants and toddlers have an innate ability to regulate energy intake. Parents and caregivers should understand the cues of hunger and satiety and recognize that coercive admonitions about eating more or less food can interfere with the infant's or toddler's innate ability to regulate energy intake (Fox et al, 2006).
- On average, infants and toddlers were fed seven times per day, and the percentage of children reported to be eating snacks increased with age. Snack choices for infants and toddlers could be improved by delaying the introduction of and limiting foods that have a low nutrient content and are energy dense (Skinner et al, 2004).

At the beginning of a meal, children are hungry and should be allowed to feed themselves; when they become tired, they can be helped quietly. Emphasis on table manners and the fine points of eating should be delayed until they have the necessary maturity and developmental readiness for such training.

The food should be in a form that is easy to handle and eat. Meat should be cut into bite-size pieces. Potatoes and vegetables should be mashed so that they can be eaten easily with a spoon. Raw fruits and vegetables should be in sizes that can be picked up easily. In addition, the utensils should be small and manageable. Cups should be easy to hold, and dishes should be designed so that they do not tip over easily.

Type of Food

In general, children prefer simple, uncomplicated foods. Food from the family meal can be adapted for the child and served in child-size

portions. Children younger than 6 years of age usually prefer mild-flavored foods. Because a young child's stomach is small, a snack may be required between meals. Children ages 2 to 6 years often prefer raw instead of cooked vegetables and fruits.

Infants should be offered foods that vary in texture and flavor. Infants who are accustomed to many kinds of foods are less likely to limit their variety of food choices later. To add variety to an infant's diet, vegetables and fruits can be added to cereal feedings. In order to ensure a nutritionally adequate diet, it is important to offer a variety of age appropriate foods and textures. Older infants generally reject unfamiliar foods the first time they are offered. When parents continue to offer small portions of these foods without comment, infants become familiar with them and often accept them. It may take 8 to 15 repeated exposures before acceptance of the food (Carruth et al, 2004a). It is important that fruit juice does not replace more nutrient-dense foods. If excessive amounts of juice are consumed, children may fail to thrive.

Serving Size

The size of a serving of food offered to a child is very important. At 1 year of age infants eat one third to one half the amount an adult normally consumes. This proportion increases to one half an adult portion by the time the child reaches 3 years of age and increases to about two thirds by 6 years of age. Young children should not be served a large plateful of food; the size of the plate and the amount should be in proportion to their age. A tablespoon (not a heaping tablespoon) of each food for each year of age is a good guide to follow. Serving less food than parents think or hope will be eaten helps children eat successfully and happily. They will ask for more food if their appetite is not satisfied. As soon as they are able, encourage young children to serve themselves.

Forced Feeding

Children should not be forced to eat; instead, the cause for the unwillingness to eat should be determined. A typical, healthy child eats without coaxing. Children may refuse food because they are too inactive to be hungry or too active and overtired. To avoid overfeeding and underfeeding, parents should be responsive to the cues for hunger and satiety offered by the infant. A child who is fed snacks or given a bottle too close to mealtime (within 90 minutes) is not hungry for the meal and may refuse it.

Parents who support the development of self-feeding skills respond to the infant's need for assistance and offer encouragement for self-feeding; they also allow the infant to initiate and guide feeding interactions without pressure on the infant for neatness in self-feeding or amount of food consumed. If a child refuses to eat, the family meal should be completed without comment, and the plate should be removed. This procedure is usually harder on the parent than on the child. At the next mealtime, the child will be hungry enough to enjoy the food presented.

Eating Environment

Young children should eat their meals at the family table; it gives them an opportunity to learn table manners while enjoying meals with a family group. Sharing the family fare strengthens ties and makes mealtime pleasant. However, if the family meal is delayed, the children should receive their meals at the usual time. When children eat with the family, everyone must be careful not to make unfavorable comments about any food. Children are great imitators of the people they admire; thus, if the father or older siblings make disparaging remarks about squash, for example, young children are likely to do the same.

CLINICAL CASE STUDY

Arvan is a 10-month-old East Indian infant who was born full-term and has been a generally well child. He was referred to see a registered dietitian nutritionist (RDN) due to parents' concerns about his growth and that he "isn't eating enough."

Assessment

Arvan was breastfed from birth until 6 months of age. His mother says her milk supply decreased after returning to work, so she began supplementing with standard infant formula. She says that Arvan would not finish a bottle on his own so had to be force-fed.

Solids were introduced at 6 months of age. Arvan's mother started with ragi (finger millet) mixed with formula. She says that Arvan would eat only a little bit, so again had to be force-fed with a lot of distractions so he would "eat enough."

Arvan's mother says that he is no longer breastfed, and that she and his grandparents have to chase him around the house to get him to finish a bottle of formula. Lately, the distraction feeding has not been working, and Arvan refuses to open his mouth after only taking a few bites of food. She says that parents or grandparents feed him all meals, and that she herself was fed until she was 3 years of age. She says that Arvan often will try to grab the spoon, but the family does not let him feed himself because it creates a mess.

Arvan's mother describes a typical day as the following. She says all meals take close to an hour and involve distractions, coaxing, and sometimes forcing:

7 am: 8 oz. of formula offered, usually finishes all 8 oz.

9 am: Parent or grandparent offers 2 idlis (lentil and rice cake) and ½ large banana. Arvan eats 1 idli and ¼ banana.

11:30 am: 8 oz. of formula offered, finishes about 6 oz.

Nap

1:30 pm: Parent or grandparent offers ½ cup dalia (bulgur) porridge with milk, sugar, ghee (clarified butter), and ground nuts. Arvan eats about 3 tablespoons.

3:30 pm: 8 oz. of formula offered, finishes about 6 oz.

6:00 pm: Parent or grandparent offers ½ cup vegetable khichadi (peas, potatoes, rice, lentils). Arvan eats about ¼ cup.

8:00 pm: 8 oz. of formula offered, finishes about 6 oz.

Diet analysis: 700 kcal, 17 g protein, 500 mg calcium, 300 IU vitamin D, 11 mg iron

Anthropometrics:

Weight (without clothes or diaper): 9.2 kg (~50th percentile)

Length: 77.0 cm (~95th percentile)

Weight-for-length: between 10th and 25th percentiles

Growth history: Arvan's weight was following around the 75th percentile from birth until 6 months of age. At his 9-month well-child visit, his weight percentile had decreased to about the 50th percentile. His length has consistently

followed around the 95th percentile since birth. A very gradual decrease in weight-for-length percentiles from the 25th percentile at birth is noted.

Supplements/medications: None

Laboratories: None

Estimated needs: 740 kcal, 14 g protein, 260 mg calcium, 400 IU vitamin D, 11 mg iron

Nutrition Diagnostic Statements

- Inadequate energy intake related to discordant feeding relationship as evidenced by history of force-feeding, gradual decline in weight-for-length percentile, and intakes below estimated needs.
- Inadequate vitamin D related to food and nutrition knowledge deficit about dietary sources of vitamin D and inadequate food intake as evidenced by vitamin D intake below the AI of 400 IU/d.

Intervention

- Commend Arvan's mother on providing a structured meal schedule and offering nutrition-rich, age-appropriate foods, and encourage her to continue doing so.
- Counsel Arvan's mother about typical infant serving sizes and suggest offering him smaller portions at the beginning of meals. Encourage Arvan to be the one to dictate how much or how little he will eat.
- Explore with Arvan's mother ways to help Arvan develop his self-feeding skills while minimizing mess. Finger foods, drop-mats, remove clothes during meal-times, etc. Point out that Arvan is asserting his desire to feed himself by grabbing the spoon and refusing to be fed by others.
- Educate Arvan's mother about infant hunger and fullness cues and how to respect those cues when spoon-feeding. Suggest that Arvan be given a spoon of his own that he can practice with thick foods such as yogurt or pudding.
- Encourage Arvan's mother to share these recommendations with all family members who feed him.
- Recommend a baby/children's liquid vitamin D supplement that does not exceed 1000 IU/day.

Monitoring/Evaluation

Follow-up in 6 to 8 weeks to monitor the following:

- Weight, length, weight-for-length percentiles, with goal of preventing further decrease in weight-for-length percentile.
- Energy, protein, calcium, vitamin D, iron intakes using 3-day food record or 24-hour recall, with goal of meeting estimated needs and micronutrient DRIs
- Parent/grandparent-child feeding relationship, with goal of diminishing use of distractions, having Arvan's hunger/fullness cues respected, and encouraging self-feeding skills development

Nutrition in Childhood

Beth Ogata, MS, RDN, CD, CSP

Sharon A. Feucht, MA, RDN, CD

KEY TERMS

adiposity rebound
catch-up growth
failure to thrive (FTT)

food jags
growth channels
growth deficiency

pediatric undernutrition
primarily wasted
stunted growth

The period that begins after infancy and lasts until puberty often is referred to as the latent or quiescent period of growth—a contrast to the dramatic changes that occur during infancy and adolescence. Although physical growth may be less remarkable and proceed at a steadier pace than it did during the first year, these preschool and elementary school years are a time of significant growth in the social, cognitive, and emotional areas.

GROWTH AND DEVELOPMENT

Growth Patterns

The rate of growth slows considerably after the first year of life. Increments of change are small compared with those of infancy and adolescence. Weight typically increases an average of 1.6 to 3.9 kg (3½ lb at age 2 years to 8 ½ lb for boys 10 to 11 years) per year with only slight differences between each sex. Girls generally increase their rate of gain between 10 and 11 years, with boys starting between 11 and 12 years of age, signaling the approach of puberty. Height increase increments average 5 to 9 cm (2 to 3½ inches) per year with lower increases in late childhood until the individual growth spurt seen in puberty ([Centers for Disease Control and Prevention \[CDC 2017\]](#)). While growth is generally steady during the preschool and school age years, it can be erratic in individual children, with periods of no growth followed by growth spurts. These patterns usually parallel similar changes in appetite and food intake. For parents, these periods of slower (but normal) growth and decreased appetite can cause anxiety, potentially leading to mealtime struggles.

Body proportions of young children change significantly after the first year. Head growth is minimal, trunk growth slows substantially, and limbs lengthen considerably, all of which create more mature body proportions. Walking and increased physical activity lead to the legs straightening and increased muscle strength in the abdomen and back.

The body composition of preschool and school age children remains relatively constant. Fat gradually decreases during the early childhood years, reaching a minimum between 4 and 6 years of age. Children then experience the **adiposity rebound**, or increase in body fatness in preparation for the pubertal growth spurt. Earlier adiposity rebound (before 5 ½ years of age) has been associated with increased

adult body mass index (BMI) ([Williams and Goulding, 2009](#)). Sex differences in body composition become increasingly apparent: boys have more lean body mass per centimeter of height than girls. Girls have a higher percentage of weight as fat than boys, even in the preschool years, but these differences in lean body mass and fat do not become significant until adolescence.

Assessing Growth

A complete nutrition assessment includes the collection of anthropometric data. This includes length or stature, weight, and weight-for-length or BMI, all of which are plotted on the recommended growth charts (see Appendix 3). Other measurements that are less commonly used but that provide estimates of body composition include mid upper-arm circumference and triceps or subscapular skin folds. Care should be taken to use standardized equipment and techniques for obtaining and plotting growth measurements. Charts designed for birth to 24 months of age are based on length measurements and nude weights, whereas charts used for 2- to 20-year-olds are based on stature (standing height) and weight with light clothing and without shoes (see Chapter 5).

The proportion of weight to length or height is a critical element of growth assessment. This parameter is determined by plotting the weight-for-length on the World Health Organization (WHO) birth to 24-month growth charts, or calculating BMI and plotting it on the 2- to 20-year-old CDC growth charts. Growth measurements obtained at regular intervals provide information about an individual's growth pattern. One-time measurements do not allow for interpretation of growth status. Growth channels are not well established until after 2 years of age. Children generally maintain their heights and weights in the same **growth channels** during the preschool and childhood years, although rates of growth can vary within a selected period.

Growth and medical monitoring, as well as a discussion of developmental expectations, usually occur at annual well child visits with the child's primary care provider. Regular monitoring of growth enables problematic trends to be identified early and intervention initiated so that long-term growth is not compromised. Weight that increases rapidly and crosses growth channels may suggest the development of obesity ([Fig. 16.1](#)). Lack of weight gain over a period of

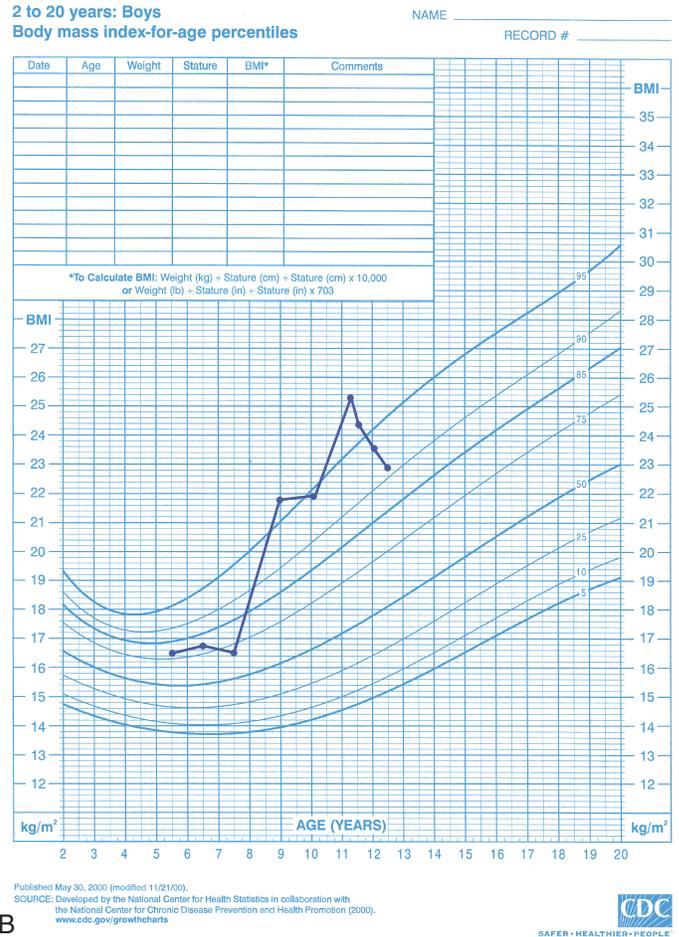

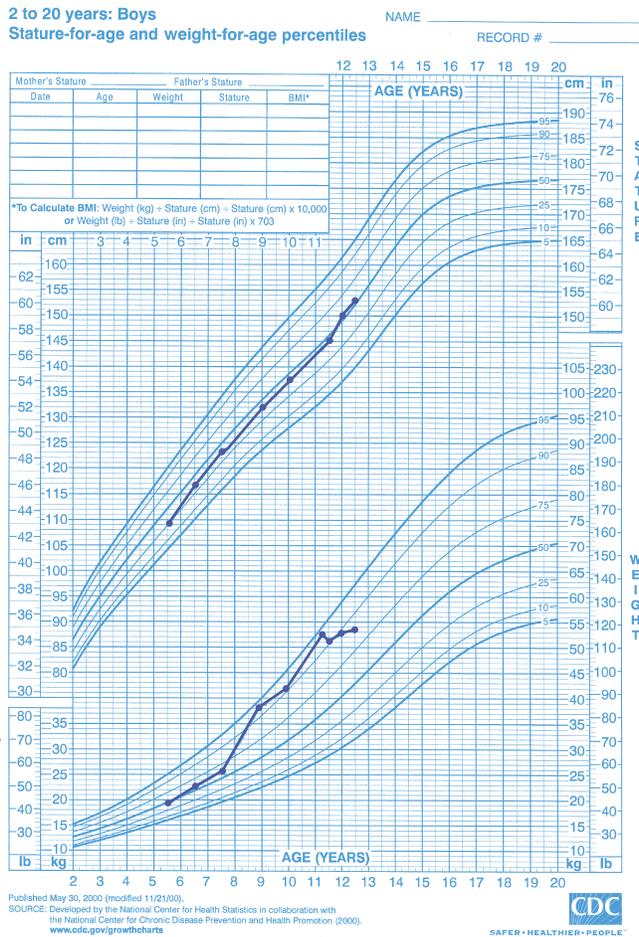

Fig. 16.1 Growth chart (A) and BMI chart (B) for an 8-year-old boy who gained excessive weight after having leg surgery and being immobilized in a body cast for 2 months. The surgery and immobilization were followed by a long period of stress caused by family problems. At the age of 11 years, he became involved in a weight management program. (Source of growth charts only: Centers for Disease Control and Prevention: Growth Charts [website]: <http://www.cdc.gov/growthcharts/>, 2017.)

months or weight loss may be a result of undernutrition, an acute illness, an undiagnosed chronic disease, or significant emotional or family problems (Fig. 16.2). Children evaluated by health care professionals only when they are ill may miss monitoring of growth and development.

Catch-Up Growth

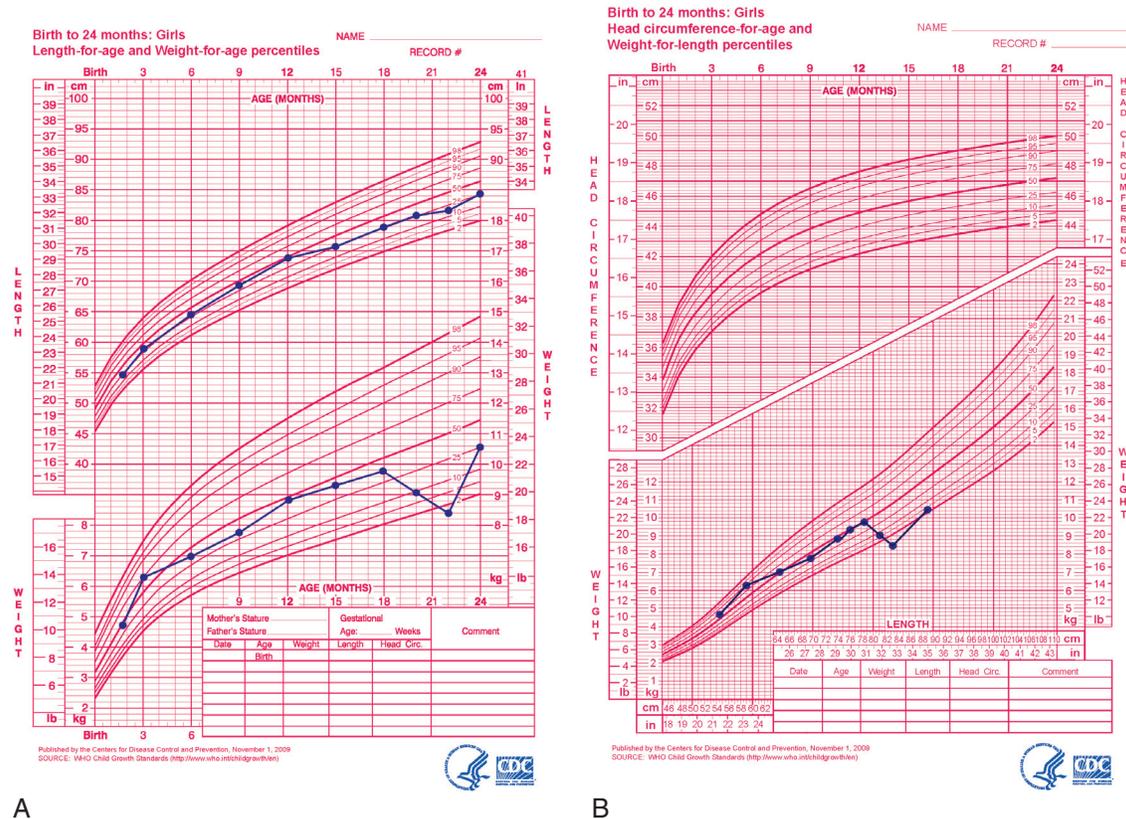

A child who is recovering from an illness or undernutrition and whose growth has slowed or ceased experiences a greater than expected rate of recovery. This recovery is referred to as **catch-up growth**, a period during which the body strives to return to the child's normal growth channel. The degree of growth suppression is influenced by the timing, severity, and duration of the precipitating cause, such as a severe illness or prolonged nutritional deprivation.

Initial studies supported the thesis that malnourished infants who did not experience immediate catch-up growth would have permanent growth restriction. However, studies of malnourished children from developing countries who subsequently received adequate nourishment, as well as reports of children who were malnourished because of chronic disease such as celiac disease or cystic fibrosis, have shown that these children caught up to their normal growth channels after the first year or two of life when their disease was managed.

The nutritional requirements for catch-up growth depend on whether the child has overall **stunted growth** (height and weight are proportionally low) and is chronically malnourished, or is **primarily wasted**, meaning that the weight deficit exceeds the height deficit. With renourishment, expectations for weight gain vary. A chronically malnourished child may not be expected to gain more than 2 to 3 g/kg/day, whereas a child who is primarily wasted may gain as much as 20 g/kg/day.

Nutrient requirements, especially for energy and protein, depend on the rate and stage of catch-up growth. For instance, more protein and energy are needed during the initial period of very rapid weight gain and for those in whom lean tissue is the major component of the weight gain. In addition to energy, other nutrients are important, including vitamin A, iron, and zinc.

Current growth parameters are used to evaluate the child's weight in relation to age and stature and to estimate a "desirable" or goal weight. Formulas are then used to estimate the minimum and maximum energy needed for catch-up growth. After a child who is wasted catches up in weight, dietary management must change to slow the weight gain velocity and avoid excessive gain. The catch-up in linear growth peaks approximately 1 to 3 months after treatment starts, whereas weight gain begins immediately.

A

B

Fig. 16.2 Growth charts for a 2-year-old girl who experienced significant weight loss during a prolonged period of diarrhea and feeding problems. After being diagnosed with celiac disease, she began following a gluten-free diet and entered a period of catch-up growth. (Source of growth charts only: Centers for Disease Control and Prevention: *Growth Charts* [website]: <http://www.cdc.gov/growthcharts/>, 2017.)

NUTRIENT REQUIREMENTS

Because children are growing and developing bones, teeth, muscles, and blood, they need more nutritious food in proportion to their size than do adults. They may be at risk for malnutrition when they have a poor appetite for a long period, eat a limited number of foods, or dilute their diets significantly with nutrient-poor foods.

The dietary reference intakes (DRIs) are based on current knowledge of nutrient intakes needed for optimal health (see inside cover). Most data for preschool and school age children are values interpolated from data on infants and adults. The DRIs are meant to improve the long-term health of the population by reducing the risk of chronic disease and preventing nutrient deficiencies. Thus, when an intake is less than the recommended level, it cannot be assumed that a particular child is inadequately nourished.

Energy

The energy needs of healthy children are determined by basal metabolism, rate of growth, and energy expenditure of activity. Dietary energy must be sufficient to ensure growth and spare protein from being used for energy, while not allowing excess weight gain. The acceptable macronutrient distribution ranges (AMDRs) are 45% to 65% as carbohydrate, 30% to 40% as fat, and 5% to 20% as protein for 1- to 3-year-olds, with carbohydrates the same for 4- to 18-year-olds, 25% to 35% as fat, and 10% to 30% as protein (Institute of Medicine [IOM], 2005).

The DRIs for estimated energy requirement (EER) are average energy requirements based on life-stage groupings for healthy individuals

of normal weight. Toddlers 13 through 35 months are grouped together; for older children the EERs are divided by sex and age (3 to 8 years and 9 to 18 years). The EER includes the total energy expenditure plus energy needed for growth (see Chapter 2). The DRIs are applied to child nutrition programs and other guidelines (Otten et al, 2006). **Box 16.1** provides examples of determining EER for three children. On an individual basis, it can be useful to estimate energy requirements using kilocalories per kilogram of weight or per centimeter of height.

Protein

The need for protein decreases from approximately 1.1 g/kg in early childhood to 0.95 g/kg in late childhood (Table 16.1). Protein intake can range from 5% to 30% of total energy, depending on age. Protein deficiency is uncommon in American children, partly because of the cultural emphasis on high-protein foods. Protein intake less than the estimated average requirement (EAR) or recommended dietary allowance (RDA) is rare among children in the United States (Berryman et al, 2018). Children who are most at risk for inadequate protein intake are those on strict vegan diets, those with multiple food allergies, or those who have limited food selections because of fad diets, severe sensorimotor issues, or inadequate access to food.

Minerals and Vitamins

Minerals and vitamins are necessary for normal growth and development. Insufficient intake can cause impaired growth and result in deficiency diseases. The DRIs are listed inside the cover.

BOX 16.1 Determining Estimated Energy Requirements

(Examples using data from Box 2.1, Chapter 2)

1. For 13- to 35-month-old children:

$$\text{EER (kcal)} = (89 \times \text{wt [kg]}) - 100 + 20$$

An 18-month-old boy has a length of 84 cm and weighs 12.5 kg

$$\text{EER (kcal)} = (89 \times 12.5) - 100 + 20$$

$$\text{EER (kcal)} = 1113 - 100 + 20$$

$$\text{EER (kcal)} = 1033$$

2. For girls 3 through 8 years:

$$\text{EER (kcal)} = 135.3 - [(30.8 \times \text{age in yrs}] + \text{PA} \times [(10 \times \text{wgt in kg}] + [934 \times \text{hgt in m}] + 20$$

A 6½-year-old girl is 112 cm tall, weighs 20.8 kg, and has moderate activity (PA coefficient of 1.31)

$$\text{EER (kcal)} = 135.3 - (30.8 \times 6.5) + 1.31 \times [(10 \times 20.8] + [934 \times 1.12] + 20$$

$$\text{EER (kcal)} = 135.3 - 200.2 + 1.31 \times (208 + 1046.1) + 20$$

$$\text{EER (kcal)} = 135.3 - 200.2 + 1642.9 + 20$$

$$\text{EER (kcal)} = 1598$$

3. For overweight boys 3 through 18 years (weight maintenance):

$$\text{TEE (kcal)} = 114 - [(50.9 \times \text{age in yrs}] + \text{PA} \times [(19.5 \times \text{wgt in kg}] + [1161.4 \times \text{hgt in m}]$$

A 7-year, 4-month-old boy is 128.4 cm tall, weighs 33.9 kg, and has low active activity (PA coefficient of 1.12)

$$\text{TEE (kcal)} = 114 - (50.9 \times 7.25) + 1.12 \times [(19.5 \times 33.9] + [1161.4 \times 1.284]$$

$$\text{TEE (kcal)} = 114 - 39.6 + 1.12 \times (66.1 + 1491.2)$$

$$\text{TEE (kcal)} = 114 - 39.6 + 1744.2$$

$$\text{EER (kcal)} = 1819$$

EER, Estimated energy requirement; PA, physical activity; TEE, total energy expenditure.

TABLE 16.1 Protein Dietary Reference Intakes (DRIs) for Children Through Age 13 Years

Age	Grams/Day*	PROTEIN
		Grams/Kilogram/Day
1-3 yr	13 g/day	1.05 g/kg/day
4-8 yr	19 g/day	0.95 g/kg/day
9-13 yr	34 g/day	0.95 g/kg/day

*Recommended dietary allowance for reference individual (g/day).

Iron

Young children are at risk for iron deficiency and iron deficiency anemia, which can affect development and behavior. National Health and Nutrition Examination Survey (NHANES) data indicate that children with prolonged bottle feeding and those of Mexican American descent are at highest risk for iron deficiency (Hamner et al, 2016; Brotanek et al, 2005; Moshfegh et al, 2005). Recommended intakes must factor in the absorption rate and quantity of iron in foods, especially those of plant origin. The prevalence of iron deficiency among 1- to 5-year-olds in the United State is 7.1%, and the prevalence of iron deficiency anemia is 1.1%, with higher rates among children 1 to 2 years of age (Gupta et al, 2017).

Calcium

Calcium is needed for adequate mineralization and maintenance of growing bone in children. The RDA for calcium for children 1 to 3 years old is 700 mg/day, for children 4 to 8 years it is 1000 mg/day, and for those 9 to 18 years it is 1300 mg per day. Actual need depends on individual absorption rates and dietary factors such as quantities of protein, vitamin D, and phosphorus. Because milk and other dairy products are primary sources of calcium, children who consume limited amounts of these foods are often at risk for poor bone mineralization. Other calcium-fortified foods such as soy, rice, and nut milks and fruit juices are also good sources (see Appendix 39).

Zinc

Zinc is essential for growth; a deficiency results in growth failure, poor appetite, decreased taste acuity, and poor wound healing. Because the best sources of zinc are meat and seafood, some children may regularly have low intakes (see Appendix 47). Diagnosis of zinc deficiency, especially marginal deficiency, may be difficult because laboratory parameters, including plasma, serum erythrocyte, hair, and urine, are of limited value in determining zinc deficiency. There is a positive influence of zinc supplementation on growth and serum zinc concentrations.

Vitamin D

Vitamin D is needed for calcium absorption and deposition of calcium in the bones; other functions within the body, including prevention of chronic diseases such as cancer, cardiovascular disease, and diabetes, are important areas of current investigation. Because this nutrient also is formed from sunlight exposure on the skin, the amount required from dietary sources depends on factors such as geographic location and time spent outside (see Appendix 38).

The DRI for vitamin D for infants is 400 IU (10 mcg) per day and for children is 600 IU (15 mcg) per day. Vitamin D-fortified milk is the primary dietary source of this nutrient, and breakfast cereals and non-dairy milks often are fortified with vitamin D. Dairy products such as cheese and yogurt, however, are not always made from fortified milk. Milks other than cow milk (e.g., goat, soy, almond, or rice) may not be fortified with vitamin D. For young children the current DRI for vitamin D is higher than what may be consumed from a typical diet. Supplementation may be needed after a careful assessment or measurement of vitamin D status. It is becoming more common to measure serum 25(OH) vitamin D in children; however, there is some controversy regarding what constitutes optimal levels (Rovner and O'Brien, 2008).

Vitamin-Mineral Supplements

Thirty-one percent of children under 18 years of age take a multivitamin-mineral supplement (Dwyer et al, 2013). Families with more education, higher incomes, private health insurance, and access to health care were more likely to use supplements. However, these may not be the families who are at greatest risk for having inadequate diets.

Fluoride can help prevent dental caries. If a community's water supply is not fluoridated, fluoride supplements are recommended from 6 months until 16 years of age. However, individual family practices should be assessed, including the child's primary source of fluids (e.g., drinking water, juices, or other beverages) and fluoride sources from child care, school, toothpaste, and mouthwash (see Chapter 25).

The American Academy of Pediatrics (AAP) does not support giving healthy children routine supplements of any vitamins or minerals other than fluoride. However, children at risk for inadequate nutrition who may benefit include those (1) with anorexia, inadequate appetite, or who consume fad diets; (2) with chronic disease (e.g., cystic fibrosis,

inflammatory bowel disease, hepatic disease); (3) from food-insecure families or who suffer parental neglect or abuse; (4) who participate in a dietary program for managing obesity; (5) who consume a vegetarian or vegan diet without adequate calcium intake and/or dairy products and vitamin B₁₂; (6) with faltering growth (failure to thrive); (7) with developmental disabilities.

Children who routinely take a multiple vitamin or a vitamin-mineral supplement usually do not experience negative effects if the supplement contains nutrients in amounts that do not exceed the DRIs, especially the tolerable upper intake level. However, some nutrients can be “missed” by general multiple vitamin supplements. Although many children consume less than the recommended amount of calcium, children’s vitamin-mineral supplements typically do not contain significant amounts of calcium. For example, among children ages 2 to 18 years who took supplements, one-third did not meet recommendations for calcium and vitamin D intakes even with supplements. In addition, supplement use was associated with increased prevalence of excessive intakes of iron, zinc, vitamin A, and folic acid (Bailey et al, 2012). In addition, an analysis of supplements marketed for infants and children indicated that available supplements do not necessarily meet recommendations for intake; for some nutrients, not enough is provided, and for others, the supplements provide excessive amounts (Madden et al, 2014). Children should not take megadoses, particularly of the fat-soluble vitamins and minerals, especially liquid and gummy vitamins, because large amounts

can result in toxicity. Careful evaluation of each pediatric supplement is suggested because many types are available but incomplete. Because many vitamin-mineral supplements look and taste like candy, parents should keep them out of reach of children to avoid excessive intake of nutrients such as iron.

Complementary and integrative nutrition therapies are becoming more common for children, especially for those with special health care needs such as Down syndrome, autism spectrum disorder (ASD), or cystic fibrosis (see Chapters 33 and 43). As part of the nutrition assessment, practitioners should inquire as to the use of these products and therapies, be knowledgeable about their efficacy and safety, and help families determine whether they are beneficial and how to use them (see Chapter 11).

PROVIDING AN ADEQUATE DIET

The development of feeding skills, food habits, and nutrition knowledge parallels the cognitive development that takes place in a series of stages, each laying the groundwork for the next. Table 16.2 outlines the development of feeding skills in terms of Piaget’s theory of child psychology and development.

Intake Patterns

Children’s food patterns have changed over the years. Dietary studies show decreased intakes of sugars and fats in children over age 2,

TABLE 16.2 Feeding, Nutrition, and Piaget’s Theory of Cognitive Development

Developmental Period	Cognitive Characteristics	Relationship to Feeding and Nutrition
Sensorimotor (birth-2 yr)	Neonate progresses from autonomic reflexes to a young child with intentional interaction with the environment and the beginning use of symbols. Food is used primarily to satisfy hunger, as a medium to explore the environment, and to practice fine motor skills.	Progression involves advancing from sucking and rooting reflexes to the acquisition of self-feeding skills.
Preoperational (2-7 yr)	Thought processes become internalized; they are unsystematic and intuitive. Use of symbols increases. Reasoning is based on appearances and happenstance. The child’s approach to classification is functional and unsystematic. The child’s world is viewed egocentrically.	Eating becomes less the center of attention and is secondary to social, language, and cognitive growth. Food is described by color, shape, and quantity, but the child has only a limited ability to classify food into “groups.” Foods tend to be categorized into “like” and “don’t like.” Foods can be identified as “good for you,” but reasons why they are healthy are unknown or mistaken.
Concrete operational (7-11 yr)	The child can focus on several aspects of a situation simultaneously. Cause-and-effect reasoning becomes more rational and systematic. The ability to classify, reclassify, and generalize emerges. A decrease in egocentrism permits the child to take another’s view.	The child begins to realize that nutritious food has a positive effect on growth and health but they have a limited understanding of how or why. Mealtimes take on more of a social significance. The expanding environment increases opportunities for influences on food selection; i.e. peer influence increases.
Formal operational (11 yr and beyond)	Hypothetical and abstract thought expand. The child’s understanding of scientific and theoretical processes deepens.	The concept of nutrients from food functioning at physiologic and biochemical levels can be understood. Conflicts in making food choices may be realized (i.e., knowledge of the nutritious value of foods may conflict with preferences and nonnutritive influences).

although amounts consumed are still higher than recommendations. Whole grain consumption has slightly increased. Children continue to eat the same amounts of fruit, vegetables, dairy and total meat, poultry, and seafood (Bowman et al, 2017).

In comparison to the Dietary Guidelines for Americans, most children do not meet recommendations. Those 2 to 5 years of age do consume adequate fruit, whole grains, and dairy, but all children are still low in vegetable intake (Guenther et al, 2013).

More energy comes from snacks, and portion sizes have increased. In addition, more food is consumed in environments other than the home, often leading to increased energy intake. Foods served to children 6 to 12 years of age at school supply similar amounts of energy and nutrients compared with food eaten at home (Mancino et al, 2010). Foods with low nutrient density (soft drinks, desserts, sweeteners, and salty snacks) often displace nutrient-dense foods.

Like physical growth patterns, food intake patterns are not smooth and consistent. Although subjective, appetites usually follow the rate of growth and nutrient needs. By a child's first birthday, milk consumption begins to decline. In the next year vegetable intake decreases; intakes of cereals, grain products, and sweets increase. Young children often prefer softer protein sources instead of meats that are harder to chew.

Changes in food consumption are reflected in nutrient intakes. The early preschool years show a decrease in calcium, phosphorus, riboflavin, iron, and vitamin A compared with infancy. Intakes of most other key nutrients remain relatively stable. During the early school years, a pattern of consistent and steadily increased intakes of most nutrients is seen until adolescence. In healthy children a wide variability of nutrient intake is seen at any age. Children are most likely to consume inadequate amounts of calcium, vitamin D, fiber, and potassium (Bailey et al, 2010; Kranz et al, 2012). However, clinical signs of malnutrition in American children are rare.

Factors Influencing Food Intake

Numerous influences, some obvious and others subtle, determine the food intake and habits of children. Habits, likes, and dislikes are established in the early years and carried through to adulthood. The major influences on food intake in the developing years include family environment, societal trends, the media, peer pressure, and illness or disease.

Family Environment

For toddlers and preschool children the family is the primary influence in the development of food habits. In young children's immediate environment, parents and older siblings are significant models. Food attitudes of parents, parental behavior, and food practices can be strong predictors of food likes and dislikes and diet complexity in children of primary school age. Similarities between children's and their parents' food preferences are likely to reflect genetic and environmental influences (Savage et al, 2007; Fildes et al, 2014; Larsen et al, 2015).

Contrary to common belief, young children do not have the innate ability to choose a balanced, nutritious diet; they can choose one only when presented with nutritious foods. A positive feeding relationship includes a division of responsibility between parents and children. The parents and other adults are to provide safe, nutritious, developmentally appropriate food as regular meals and snacks. The children decide how much, if any, they eat. This approach is consistent with a responsive parenting approach, allowing the parent and child to recognize hunger and satiety cues and respond appropriately (Black and Aboud, 2011). Ellyn Satter promotes this "division of responsibility" approach to feeding as well (Satter, 2000).

Eating together at family meals is becoming less common, partly because of family schedules, more time eating in front of a screen, and the decreasing amount of time available for planning and preparing family meals. School age children and adolescents who eat more dinners with their families consume more fruits and vegetables, less soda, and fewer fried foods than those who rarely eat dinner with their families (Larson et al, 2007). Family meals have other benefits, including a positive influence on nutrition beliefs and possibly prevention of excessive weight gain. Studies show these effects continue into adulthood (Chan and Sobal, 2011; Watts et al, 2018).

The atmosphere around food and mealtime also influences attitudes toward food and eating. Unrealistic expectations for a child's mealtime manners, arguments, and other emotional stress can have a negative effect. Meals that are rushed create a hectic atmosphere and reinforce the tendency to eat too fast. A positive environment is one in which sufficient time is set aside to eat, occasional spills are tolerated, and conversation that includes all family members is encouraged (Fig. 16.3).

Socioeconomic Influences

Almost one in five American children lives in a family with an income below the poverty line; in 2016 13.3 million children lived in poverty. Single-parent households predominantly headed by women have lower incomes and less money for all expenses, including food, than households headed by men; about half of children in families with a female householder were in poverty (Semega et al, 2017). This phenomenon makes these families increasingly vulnerable to multiple stressors such as marginal health and nutritional status partly because of lack of jobs, child care, adequate housing, and health insurance.

In 2016, 12.3% of U.S. households experienced food insecurity. Among households with children, 16.5% were food insecure, with both children and adults experiencing food insecurity in 8.0% of households with children (Coleman-Jensen et al, 2017). Federal food and nutrition assistance programs (including the Special Supplemental Nutrition Program [SNAP], the Special Supplemental Nutrition Program for Women, Infants and Children [WIC], and the National School Lunch Program) provide benefits to about 59% of food-insecure households (see Chapter 8). The food stamp allotment for families, based on the U.S. Department of Agriculture (USDA) Thrifty Food Plan, does not provide adequate funds to

Fig. 16.3 Eating together gives meals a place of prominence in the home—meals that will not be replaced with fast foods eaten on the run. From www.istockphoto.com.

purchase food based on the government's nutrition guidelines, especially when labor is considered (Davis and You, 2010). Food insecurity also increases the risk for children younger than age 3 years to be iron deficient with anemia. Studies suggest that intermittent hunger in American children is associated with increased developmental risk (see *Focus On: Childhood Hunger and Its Effect on Cognition and Behavior*) (Rose-Jacobs et al, 2008). Even marginal food insecurity, which is often thought not to be an indicator of nutrition risk in adults, is associated with adverse health outcomes in children (Cook et al, 2013).

FOCUS ON

Childhood Hunger and Its Effect on Cognition and Behavior

Food insecurity is associated with anemia, lower nutrient intake, cognitive problems, aggression, and anxiety. Children with food insecurity have poorer general health and higher rates of depression, and for adolescents, suicidal ideation and lower scores on academic tests (Gundersen and Ziliak, 2015; Hobbs and King, 2018). Specific nutrient deficiencies such as iron deficiency anemia can result in a decreased ability to pay attention and poorer problem-solving skills. With federal welfare reform legislation and in economic downturns, an increasing number of children from low-income families are at risk for limited food resources (Stang and Bayerl, 2010).

The U.S. Department of Agriculture (USDA) measures food insecurity through questions administered in a supplement to the Census Bureau's Current Population Survey. Households are divided into the following categories: high food secure (all household members had access at all times to enough food), marginal food secure (some members reported anxiety about food sufficiency or shortage of food, but no indication of changes in diet or food intake), low food secure (at least some household members reported reduced quality, variety, or desirability of diet), and very low food secure (one or more members reported multiple indications of disrupted eating patterns and reduced intake). Data from 2016 indicated that 16.5% of U.S. households with children were food-insecure. In 2016, 6.5 million children in the United States lived in food-insecure households (Coleman-Jensen et al, 2017). Groups at higher risk of food insecurity include households headed by an African American or Hispanic person and those with children (Gundersen and Ziliak, 2015).

A longitudinal study following approximately 21,000 children from kindergarten through third grade found that persistent food insecurity was predictive of impaired academic outcomes, poorer social skills, and a tendency to increased body mass index (BMI) (Ryu and Bartfeld, 2012).

Although these studies have limitations because of other factors that may affect a child's functioning (e.g., stress, family dysfunction, or substance abuse), a correlation exists between children's lack of sufficient food and their behavioral and academic functioning. As future studies provide more evidence of this relationship, it will be clear that social policies must ensure the provision of children's basic needs for optimal growth and development.

Media Messages

Food is marketed to children using a variety of techniques (television, radio and print advertising) and digital messages from a variety of devices. School age children may be exposed to in-school marketing, sponsorship, product placement, and sales promotion. Television advertising and in-school marketing are regulated to some degree. Parents report children younger than 8 years of age spend slightly more

than 2 hours per day watching screens (television, mobile devices, DVDs, video games, and computers) (Rideout, 2017). Children younger than 13 years of age who watch 2 hours of television per day may view 56 to 126 food advertisements; 32% of the ads are for fast food products in the United States. Eighty percent of the food ads focus on foods high in energy or nutrients less desirable using dietary standards (Kelly et al, 2010). In another sample of television advertising to children, more than 40% of commercials were for food, with 80% to 95% for items high in saturated fat, trans fat, sugar, and sodium (Powell et al, 2013).

Screen time can be detrimental to growth and development because it encourages inactivity and passive use of leisure time. In a sample of children 4 to 11 years of age, just over one-third had low levels of active play, while two-thirds of the sample had high screen time; one-fourth of the group had both low activity levels and high screen time (Anderson et al, 2008). Television viewing with its multiple media cues to eat has been suggested as a factor contributing to excessive weight gain in school age children, especially when there is a television in the child's bedroom (Gilbert-Diamond et al, 2014). Increases in hours of television viewing are associated with rising BMIs in boys and girls, with females also affected by watching DVDs/videos and electronic games. For those already at risk with higher BMIs, limits on noneducational viewing may be part of intervention strategies (Falbe et al, 2013). Television viewing has also been inversely associated with fruit and vegetable consumption (American Public Health Association [APHA], 2017).

Preschool children are generally unable to distinguish commercial messages from regular programs; in fact, they often pay more attention to the commercials. As children get older, they gain knowledge about the purpose of commercial advertising and become more critical of its validity but are still susceptible to the messages. Media literacy education programs teach children and adolescents about the intent of advertising and media messages and how to evaluate and interpret their obvious and subtle influences. Comprehensive and consistent regulation approaches plus monitoring the use of the most common persuasive marketing techniques (premium offers, promotional characters, nutrition- and health-related claims, taste and fun appeal) is suggested (Jenkin et al, 2014). Guidance is available for health care providers and families with children through the American Academy of Pediatrics website page, Media and Young Minds (AAP, 2016).

Significant decreases have occurred in beverage and food vending in schools, but both forms of sales still occur. Elementary-age students often are given coupons to encourage their families to purchase food, whereas those in upper grades may be exposed to in-school exclusive beverage contracts and other types of marketing (Terry-McElrath et al, 2014). The USDA has established nutrition standards for snack foods and beverages available for sale in schools but does not address food marketing. Standards that can be enforced are still needed to clarify the nutrition content of all foods and beverages marketed in school settings.

Peer Influence

As children grow, their worlds expand and their social contacts become more important. Peer influence increases with age and affects food attitudes and choices. This may result in a sudden refusal of a food or a request for a currently popular food. Decisions about whether to participate in school meals may be made more on the basis of friends' choices than on the menu. Such behaviors are developmentally typical. Positive behaviors such as a willingness to try new foods can be reinforced. Parents must set limits on undesirable influences but also must be realistic; struggles over food are self-defeating.

FOCUS ON

Childhood Methylmercury Exposure and Toxicity

Mercury toxicity can cause neurologic problems, which can lead to cognitive and motor deficits. Toxicity related to prenatal exposure is documented, and there is evidence that postnatal exposure is dangerous as well (Myers et al, 2009; Oken and Bellinger, 2008). Exposure to mercury can occur through environmental contact and eating contaminated foods. Methylmercury, the most toxic form of mercury, accumulates in fish.

Public health agencies have looked at balancing the benefits of minimizing exposure to this neurotoxin with the risk of limiting intake of docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) as well as a source of high biologic value protein. DHA and EPA are essential omega-3 fatty acids and have received much attention

because of their importance in cognitive and vision development and their cardiovascular benefits (Mahaffey et al, 2008). In addition, fish advisories are available in certain states. The U.S. Environmental Protection Agency's (EPA) reference dose for methylmercury is based on body weight: 0.1 mcg/kg/day. The Food and Drug Administration (FDA) and EPA have made recommendations for fish intake by young children, as well as for women of childbearing age and pregnant and breastfeeding women (FDA, 2017). These recommendations were designed to encourage fish consumption, while limiting exposure to mercury. Current recommendations differ from previous versions by recommending minimum intake of iron. These recommendations are presented in a chart and set of frequently asked questions:

Advice About Eating Fish

What Pregnant Women & Parents Should Know

Fish and other protein-rich foods have nutrients that can help your child's growth and development.

For women of childbearing age (about 16-49 years old), especially pregnant and breastfeeding women, and for parents and caregivers of young children.

- Eat 2 to 3 servings of fish a week from the "Best Choices" list OR 1 serving from the "Good Choices" list.
- Eat a variety of fish.
- Serve 1 to 2 servings of fish a week to children, starting at age 2.
- If you eat fish caught by family or friends, check for fish advisories. If there is no advisory, eat only one serving and no other fish that week.*

Use this chart!

You can use this chart to help you choose which fish to eat, and how often to eat them, based on their mercury levels. The "Best Choices" have the lowest levels of mercury.

What is a serving?

To find out, use the palm of your hand!

For an adult
4 ounces

For children, ages 4 to 7
2 ounces

Best Choices <small>EAT 2 TO 3 SERVINGS A WEEK</small>			OR	Good Choices <small>EAT 1 SERVING A WEEK</small>		
Anchovy	Herring	Scallop		Bluefish	Monkfish	Tilefish (Atlantic Ocean)
Atlantic croaker	Lobster,	Shad		Buffalofish	Rockfish	Tuna, albacore/white tuna, canned and fresh/frozen
Atlantic mackerel	American and spiny	Shrimp		Carp	Sablefish	Tuna, yellowfin
Black sea bass	Mullet	Skate		Chilean sea bass/Patagonian toothfish	Sheepshead	Weakfish/seatrout
Butterfish	Oyster	Smelt		Grouper	Snapper	White croaker/Pacific croaker
Catfish	Pacific chub mackerel	Sole		Hallibut	Spanish mackerel	
Clam	Perch, freshwater and ocean	Squid		Mahi mahi/dolphinfish	Striped bass (ocean)	
Cod	Pickering	Tilapia				
Crab	Plaice	Trout, freshwater				
Crawfish	Pollock	Tuna, canned light (includes skipjack)				
Flounder	Salmon	Whitefish				
Haddock	Sardine	Whiting				
Hake						
Choices to Avoid <small>HIGHEST MERCURY LEVELS</small>						
				King mackerel	Shark	Tilefish (Gulf of Mexico)
				Marlin	Swordfish	Tuna, bigeye
				Orange roughy		

*Some fish caught by family and friends, such as larger carp, catfish, trout and perch, are more likely to have fish advisories due to mercury or other contaminants. State advisories will tell you how often you can safely eat those fish.

Illness or Disease

Children who are ill usually have a decreased appetite and limited food intake. Acute viral or bacterial illnesses are often short-lived but may require an increase in fluids, protein, or other nutrients. Chronic conditions such as asthma, cystic fibrosis, or chronic renal disease may make it difficult to obtain sufficient nutrients for optimal growth. Children with these types of conditions are more likely to have behavior problems relating to food. Children requiring special diets (e.g., those who have

diabetes, food allergies, or phenylketonuria) not only have to adjust to the limits of foods allowed but also have to address issues of independence and peer acceptance as they grow older. Some rebellion against the prescribed diet is typical, especially as children approach puberty.

Feeding Preschool Children

From 1 to 6 years of age children experience vast developmental progress and acquisition of skills. One-year-old children primarily use

Fig. 16.4 Use of alternative eating utensils can increase a preschooler's interest in trying new foods and development of fine motor skills.

fingers to eat and may need assistance with a cup. By 2 years of age, they can hold a cup in one hand and use a spoon well but may prefer to use their hands at times. Six-year-old children have refined skills and are beginning to use a knife for cutting and spreading.

As the growth rate slows after the first year of life, appetite decreases, which often concerns parents. Children have less interest in food and an increased interest in the world around them. They can develop **food jags**, which can be periods when foods that were previously liked are refused, or there are repeated requests to eat the same food meal after meal. This behavior may be attributable to boredom with the usual foods or may be a means of asserting newly discovered independence. Parents may have concerns with their child's seemingly irrational food behavior. Struggles over control of the eating situation are fruitless; no child can be forced to eat. This period is developmental and temporary (Fig. 16.4).

A positive feeding relationship includes a division of responsibility between parents and children. Young children can choose a balanced nutritious diet if presented with nutritious foods. The parents and other adults provide safe, nutritious, developmentally appropriate food as regular meals and snacks; and the children decide how much, if any, they eat (Satter, 2000). Parents maintain control over what foods are offered and have the opportunity to set limits on inappropriate behaviors. Neither rigid control nor a laissez-faire approach is likely to succeed. Parents and other care providers should continue to offer a variety of foods, including the child's favorites, and not make substitutions a routine. Parents' food preferences also influence children's acceptance of foods, as children often model parents' behaviors (Wardle and Cooke, 2008).

With smaller stomach capacities and variable appetites, preschool children should be offered small servings of food four to six times a day at regular and predictable intervals. Snacks are as important as meals in contributing to the total daily nutrient intake. Carefully chosen snacks are those dense in nutrients and least likely to promote dental caries. A general starting point is to offer 1 tablespoon of each

food for every year of age and to serve more food according to the child's appetite. Table 16.3 is a guide for food and portion size.

Senses other than taste play an important part in food acceptance by young children. They tend to avoid food with extreme temperatures, and some foods are rejected because of odor rather than taste. A sense of order in the food presentation often is preferred; many children do not accept foods that touch each other on the plate, and mixed dishes or casseroles with unidentifiable foods are not popular. Broken crackers may go uneaten, or a sandwich may be refused because it is "cut the wrong way."

The physical setting for meals is important. Children's feet should be supported, and chair height should allow a comfortable reach to the table at chest height. Sturdy, child-size tables and chairs are ideal, or a high chair or booster seat should be used. Dishes and cups should be unbreakable and heavy enough to resist tipping. For very young children, a shallow bowl is often better than a plate for scooping. Thick, short-handled spoons and forks allow for an easier grasp. Young children do not eat well if they are tired; this should be considered when meal and play times are scheduled.

Fruit juices and juice drinks are common beverages for young children; they frequently replace water and milk in children's diets. In addition to altering the diet's nutrient content, excessive intake of fruit juice can result in carbohydrate malabsorption and chronic, non-specific diarrhea. This suggests that juices, especially apple and pear, should be avoided when using liquids to treat acute diarrhea. For children with chronic diarrhea, a trial of restricting fruit juices may be warranted before more costly diagnostic tests are done.

When children aged 2 to 11 years consume 100% juice, their diets have significantly higher intakes of energy, carbohydrates, vitamins C and B₆, potassium, riboflavin, magnesium, iron, and folate, and significantly lower intakes of total fat, saturated fatty acids, discretionary fat, and added sugar; this 100% juice intake does not correlate with overweight later (Nicklas et al, 2008). However, excess juice intake (12 to 30 oz/day) by young children may decrease a child's appetite, resulting in decreased food intake and poor growth. The AAP policy statement recommends limiting juice intake: no more than 4 oz per day for 1- to 3-year-olds, 4 to 6 oz per day for 4- to 6-year-olds, and 8 oz per day for 7- to 18-year-olds (Heyman and Abrams, 2017).

Large volumes of sweetened beverages, combined with other dietary and activity factors, may contribute to overweight in a child. High intake of fructose, especially from sucrose and high-fructose corn syrup in processed foods and beverages, may lead to increased plasma triglycerides and insulin resistance. In several studies, low calcium intake and obesity have been correlated with high intake of sugar-sweetened beverages in preschool children (Keller et al, 2009; Lim et al, 2009). Higher milk and lower sweetened-beverage intake is associated with improved nutrient intake, including calcium, potassium, magnesium, and vitamin A (O'Neil et al, 2009). Children should be offered milk, water, and healthy snacks throughout the day instead of sugar-sweetened choices.

Excess sodium is another concern. An increase in sodium or salt intake results in an increase in systolic blood pressure and diastolic blood pressure (Bergman et al, 2010). A reduction in the use of processed foods may be warranted for children with elevated blood pressure. The Dietary Approaches to Stop Hypertension (DASH) diet is useful for all age groups because it increases potassium, magnesium, and calcium in relation to sodium intake (see Appendix 17).

Meal time in group settings is an ideal opportunity for nutrition education programs focused on various learning activities around food (Fig. 16.5). Experiencing new foods, participating in simple food preparation, and planting a garden are activities that develop and enhance positive food habits and attitudes.

TABLE 16.3 Suggested Portion Sizes for Children*

These suggestions are not necessarily appropriate for all children (and may be inappropriate for some children with medical conditions that greatly affect nutrient needs). They are intended to serve as a general framework that can be individualized based on a child's condition and growth pattern.

	1- to 3-Year-Olds	4- to 6-Year-Olds	7- to 12-Year-Olds	Comments
Grain Products	Bread: ½ to 1 slice Rice, pasta, potatoes: ¼ to ½ cup Cooked cereal: ¼ to ½ cup Ready-to-eat cereal: ¼ to ½ cup Tortilla: ½ to 1	Bread: 1 slice Rice, pasta, potatoes: ½ cup Cooked cereal: ½ cup Ready-to-eat cereal: ¾ to 1 cup Tortilla: 1	Bread: 1 slice Rice, pasta, potatoes: ½ cup Cooked cereal: ½ cup Ready-to-eat cereal: 1 cup Tortilla: 1	Include whole grain foods and enriched grain products.
Vegetables	Cooked or pureed: 2-4 tablespoons Raw: few pieces, if child can chew well	Cooked or pureed: 3-4 tablespoons Raw: few pieces	Cooked or pureed: ½ cup Raw: ½ to 1 cup	Include one green leafy or yellow vegetable for vitamin A, such as spinach, carrots, broccoli, or winter squash.
Fruit	Raw (apple, banana, etc.): ½ to 1 small, if child can chew well Canned: 2-4 Tablespoons Juice: 3-4 ounces	Raw (apple, banana, etc.): ½ to 1 small, if child can chew well Canned: 4-8 Tablespoons Juice: 4 ounces	Raw (apple, banana, etc.): 1 small Canned: ¾ cup Juice: 5 ounces	Include one vitamin C-rich fruit, vegetable, or juice, such as citrus juices, an orange, grapefruit sections, strawberries, melon in season, a tomato, or broccoli.

In Trahms CM, Pipes P: *Nutrition in infancy and childhood*, ed 6, St Louis, 1997, WCB/McGraw-Hill and Harris; Harris AB et al: *Nutrition strategies for children with special needs*, 1999, USC University Affiliated Program, Los Angeles.

Fig. 16.5 Children who eat with each other in an appropriate environment often eat more nutritiously and try a wider variety of foods than when eating alone or at home. (Courtesy of Ana Raab.)

Feeding School Age Children

Growth from ages 6 to 12 years is slow but steady, paralleled by a constant increase in food intake. Children are in school a greater part of the day; and they begin to participate in clubs, organized sports, and recreational programs. The influence of peers and significant adults such as teachers, coaches, or sports idols increases. Except for severe

issues, most behavioral problems connected with food have been resolved by this age, and children enjoy eating to alleviate hunger and obtain social satisfaction.

School age children may participate in the school lunch program or bring a lunch from home. The National School Lunch Program (NSLP), established in 1946, is administered by the USDA. Children from low-income families are eligible for free or reduced-price meals. The School Breakfast Program (SBP), begun in 1966, is offered in many schools that participate in the lunch program. The USDA also offers the Afterschool Snacks and Summer Food Service for organized programs, the Fresh Fruit and Vegetable Program in selected schools, the Special Milk program for children not participating in school lunch, and the Child and Adult Food Care Program that reaches children in group or family child care sites (see Chapter 8).

Guidelines for the meals provided by the NSLP, SBP, and other programs are based on the IOM report, *School Meals, Building Blocks for Healthy Eating* and legislated by the 2010 Healthy, Hunger-Free Kids Act (McGuire, 2011). In addition to guidelines to align meal patterns with the Dietary Guidelines and to address other childhood health concerns, the Act makes resources and technical assistance available. Nutrition standards for the NSLP and SBP that follow the IOM recommendations and made significant changes to meal patterns were published in 2012. Some revisions and flexibility in meeting these

standards have been introduced (Food and Nutrition Service, 2012; USDA, 2018).

Efforts have been made to decrease food waste by altering menus to accommodate student preferences, allowing students to decline one or two menu items and offering salad bars. Efforts to increase participation in school lunch require consistent messages that support healthful eating (Hayes et al, 2018).

School wellness policies were required by the school year 2006 to 2007 in institutions participating in school lunch and school breakfast programs. The school, including the administration, teachers, students, and food service personnel, in cooperation with families and the community, are encouraged to work together to support nutrition integrity in the educational setting (Bergman et al, 2010).

Consumption of school meals also is affected by the daily school schedule and the amount of time allotted for children to eat. One study suggested that children should have 25 minutes of seated time to increase dietary intake but also to reduce food waste (Cohen et al, 2016). Recess scheduled before lunch may increase intake of fruits, however more research is needed (Price and Just, 2015; Chapman et al, 2017; Fenton et al, 2015). A Montana “Recess Before Lunch” pilot study documented improvement in the mealtime atmosphere and students’ behavior. Discipline problems on the playground, in the lunchroom, and in the classroom decreased (Montana Office of Public Instruction, 2010).

Children who require a special diet because of certain medical conditions such as diabetes, celiac disease, or documented food allergy are eligible for modified school meals. Children with developmental disabilities are eligible to attend public school from ages 3 to 21 years, and some of them need modified school meals (e.g., meals that are texture modified, or with increased or decreased energy density). To receive modified meals, families must submit written documentation by a medical professional of the diagnosis, meal modification, and rationale. For children receiving special education services, the documentation for meals and feeding can be incorporated as objectives in a child’s individual education plan (IEP) (see Chapter 43).

Studies of lunches packed at home indicate that they usually provide fewer nutrients but less fat than school lunch meals. Favorite foods tend to be packed, so children have less variety. Food choices are limited to those that travel well and require no heating or refrigeration. A typical well-balanced lunch brought from home could include a sandwich with whole-grain bread and a protein-rich filling; fresh vegetables, fruit, or both; low-fat milk; and possibly a cookie, a graham cracker, or another simple dessert. Food safety measures (e.g., keeping perishable foods well chilled) must be observed when packing lunches for school.

Today many school age children are responsible for preparing their own breakfasts. It is not uncommon for children to skip this meal altogether, even children in the primary grades. Children who skip breakfast tend to consume less energy and other nutrients than those who eat breakfast (Wilson et al, 2006). Reviews of the effects of breakfast on cognition and school performance indicate a positive association between breakfast and school performance (Adolphus et al, 2016) (see *Focus On: Breakfast: Does It Affect Learning?*).

Snacks are commonly eaten by school age children, primarily after school and in the evening. As children grow older and have money to spend, they tend to consume more snacks from vending machines, fast-food restaurants, and neighborhood grocery stores. Families should continue to offer wholesome snacks at home and support nutrition education efforts in the school. In most cases, good eating habits established in the first few years help children through this period of decision making and responsibility. Developing and supporting programs and policies that ensure access to

FOCUS ON

Breakfast: Does It Affect Learning?

The educational benefits of school meal programs and especially the role of breakfast in better school performance have been debated and discussed for decades. Overall, breakfast consumption has been associated with better on-task classroom behavior (i.e., attention in class, and engagement in learning activities) regardless of nutritional and/or socioeconomic status. A literature review indicates associations between school performance and breakfast consumption, especially among children who were at nutritional risk (i.e., had wasted and stunted growth) and or were from low socioeconomic backgrounds (Adolphus et al, 2013). School-based breakfast experiments in 9- to 11-year-old and 6- to 8-year-old children found similar positive results with breakfast consumption (i.e., enhanced short-term memory, better spatial memory, and improved processing of complex visual stimuli), but other reports are less supportive (Adolphus et al, 2013). These studies suggest that brain functioning is sensitive to short-term variations in nutrient availability. A short fast may impose greater stress on young children than on adults, resulting in metabolic alterations as various homeostatic mechanisms work to maintain circulating glucose concentrations.

In addition to potential positive effects on academic performance, breakfast contributes significantly to the child’s overall nutrient intake. These studies underscore the potential benefits—not only for low-income and at-risk children but also for all school children—of a breakfast at home or school meal programs that include breakfast. In 2016 14.57 million children participated in school breakfast programs (SBPs) (USDA, 2017). In 2015–2016, an additional 3.7% of students eligible for free and reduced-price school meals ate school breakfasts (Food Research and Action Center [FRAC], 2018).

better-quality food, larger quantities of food, and better living conditions for low-income children help to reduce health disparities where present.

Nutrition Education

As children grow, they acquire knowledge and assimilate concepts. The early years are ideal for providing nutrition information and promoting positive attitudes about all foods. This education can be informal and take place in the home with parents as models and a diet with a wide variety of foods. Food can be used in daily experiences for the toddler and preschooler and to promote the development of language, cognition, and self-help behaviors (e.g., labeling; describing size, shape, and color; sorting; assisting in preparation; and tasting).

More formal nutrition education is provided in preschools, Head Start programs, and public schools. Some programs such as Head Start have federal guidance and standards that incorporate healthy eating and nutrition education for the families involved. Nutrition education in schools is less standard and frequently has minimum or no requirements for inclusion in the curriculum or the training of teachers. Recommendations include policies in schools promoting coordination between nutrition education; access to and promotion of child nutrition programs; and cooperation with families, the community, and health services (Bergman et al, 2010).

Teachers attempting to teach children nutrition concepts and information should take into account the children’s developmental level. The play approach, based on Piaget’s theory of learning, is one method for teaching nutrition and fitness to school age children. Activities and information that focus on real-world relationships with food are most likely to have positive results. Meals, snacks, and food preparation activities provide children opportunities to practice and

reinforce their nutrition knowledge and demonstrate their cognitive understanding. Involving parents in nutrition education projects can produce positive outcomes that are also beneficial in the home. Many written and electronic resources on nutrition education for children exist, including resources through the USDA's Team Nutrition and Choose MyPlate websites.

NUTRITIONAL CONCERNS

Overweight and Obesity

Overweight and obesity among children is a significant public health problem. The prevalence of obesity and overweight increased rapidly in the 1990s and 2000s, and plateaued from 2005 to 2006 and 2013 to 2014 (Hales et al, 2018). Obesity rates in some populations, for example Hispanic and non-Hispanic white children and adolescents, are continuing to increase.

NHANES (2015–2016) reported an obesity (BMI-for-age above the 95th percentile) prevalence of 16.8% in youth ages 2 to 19 years, and extreme obesity (BMI-for-age >120% of the 95th percentile) prevalence of 5.6% (Hales et al, 2018). For children 2 to 5 years of age, the prevalence of obesity decreased from 13.9% in 2003 to 2004 to 9.4% in 2013 to 2014 (Ogden et al, 2018a). Prevalence of obesity is higher among non-Hispanic black and Hispanic youth than among non-Hispanic white and non-Hispanic Asian children and adolescents (Ogden et al, 2018a). The prevalence of obesity varies by income and education level as well; obesity rates are lower in the highest income and education groups than among other groups (Ogden et al, 2018b). The Expert Committee report suggests the following terms to describe risk based on BMI: *obesity* as BMI-for-age at or above the 95th percentile and *overweight* as BMI-for-age between the 85th and 94th percentiles (Barlow and Committee, 2007), and CDC definitions also include a designation for “extreme” or “severe” obesity. Determining whether growing children are obese is difficult. Some excess weight may be gained at either end of the childhood spectrum; the 1-year-old toddler and the prepubescent child may weigh more for developmental and physiologic reasons, but this extra weight is often not permanent. BMI, a useful clinical tool for screening for overweight, has limitations in determining obesity because of variability related to sex, ethnicity, body composition, and maturation stage.

The CDC growth charts allow tracking of BMI from age 2 into adulthood; thus children can be monitored periodically, and intervention provided when the rate of BMI change is excessive. The BMI charts show the adiposity rebound, which normally occurs in children between 4 and 6 years of age (see Appendix 3). Children whose adiposity rebound occurs before 5½ years of age are more likely to weigh more as adults than those whose adiposity rebound occurs after 7 years of age. The timing of the adiposity rebound in childhood and excess fatness in adolescence are two critical factors in the development of obesity, with the latter being the most predictive of adult obesity and related morbidity (Williams and Goulding, 2009).

Although genetic predisposition is an important factor in obesity development, the increases in the prevalence of overweight children cannot be explained by genetics alone. Factors contributing to excess energy intake for the pediatric population include ready access to eating and food establishments, eating tied to sedentary leisure activities, children making more food and eating decisions, larger portion sizes, and decreased physical activity. In addition, American children snack three times a day, with chips, candy, and other low-nutrient foods providing more than 27% of their daily energy intake; this contributes 168 kcal per day (Piernas and Popkin, 2010). Many of the risk factors

for obesity are more prevalent among children from racial/ethnic minorities and families with lower socioeconomic status.

Inactivity plays a major role in obesity development, whether it results from screen time, limited opportunities for physical activity, or safety concerns that prevent children from enjoying free play outdoors. Although increased television viewing and computer and handheld game use have been associated with childhood overweight, a review suggests that the greater risk of overweight is related to television viewing plus a low activity level (Ritchie et al, 2005). The need to use automobiles for short trips limits children's opportunities to walk to local destinations, a phenomenon particularly relevant to children in the suburbs.

Obesity in childhood is not a benign condition, despite the popular belief that overweight children will outgrow their condition. The longer a child has been overweight, the more likely the child is to be overweight or obese during adolescence and adulthood. Consequences of overweight in childhood include psychosocial difficulties such as discrimination, a negative self-image, depression, and decreased socialization. Many overweight children have one or more cardiovascular risk factors such as hyperlipidemia, hypertension, or hyperinsulinemia (Daniels, 2009). An even more dramatic health consequence of overweight is the rapid increase in the incidence of type 2 diabetes in children and adolescents, which has a serious effect on adult health, development of other chronic diseases, and health care costs (see Chapter 30).

The AAP has developed guidelines for overweight screening and assessment for children from age 2 through adolescence (Barlow and Committee, 2007). In addition to growth parameters, other important information includes dietary intake and patterns, previous growth patterns, family history, physical activity, and family interactions. The U.S. Preventive Services Task Force (USPSTF) recommends obesity screening for children and adolescents 6 years and older and referral to comprehensive, intensive behavioral intervention treatment programs, if appropriate (Grossman et al, 2017).

A 2010 paper described a lower prevalence of obesity among children who were exposed to the following routines: regularly eating the evening meal as a family, obtaining adequate night-time sleep, and having limited screen-viewing time (Anderson and Whitaker, 2010). Interventions for obesity in children have had limited effect on the childhood obesity problem, especially for black, Hispanic, and Native American populations. Success is most likely to result from programs that include comprehensive behavioral components such as family involvement, dietary modifications, nutrition information, physical activity, and behavioral strategies (Barlow and Committee, 2007). Incorporating behavioral intervention in obesity treatment improves outcomes and is most effective with a team approach. Depending on the child, goals for weight change may include a decrease in the rate of weight gain, maintenance of weight, or, in severe cases, gradual weight loss (see Chapter 20). An individualized approach should be tailored to each child, with minimum use of restrictive diets or medication, except if there are other significant diseases and no other options.

Intervention strategies require family involvement and support. Incorporating motivational interviewing and stages of change theory into the comprehensive program will likely be more successful (see Chapter 13). Changes to address overweight should include the child's input, with choices and plans that modify the family's food and activity environment, not just the child's. Adequate energy and other nutrients are needed to ensure maintenance of height gain velocity and nutrient stores. The hazards of treating overweight children too aggressively include alternate periods of undereating and overeating, feelings of failure in meeting external expectations, ignoring internal

cues for appetite and satiation, feelings of deprivation and isolation, an increased risk for eating disorders, and a poor or an increasingly poor self-image.

Some children with special health care needs, such as those with Down syndrome, Prader-Willi syndrome, short stature, and limited mobility, are at increased risk for being overweight. Their size, level of activity, and developmental status must be considered when estimating energy intake and providing dietary guidance to their families (see Chapter 43).

Prevention of childhood obesity is an important public health priority in the United States. The IOM has published recommendations that target families, health care professionals, industry, schools, and communities (IOM, 2012). The recommendations include schools (improved nutritional quality of food sold and served, increased physical activity, wellness education), industry (improved nutrition information for consumers, clear media messages), health care professionals (tracking BMI, providing counseling for children and families), and communities and government (better access to healthy foods, improved physical activity opportunities). Schools are a natural environment for obesity prevention, which can include nutrition and health curricula, opportunities for physical education and activity, and appropriate school meals. Efforts have resulted in school nutrition policies that limit the kinds of products sold in vending machines and food and beverages sold for fundraising. Cross-sectional data indicate that policies that limit the sale of competitive foods and beverages (foods sold outside the school meal programs) are associated with changes in consumption and availability of foods. More research is needed to understand long-term health effects of these policies (Chriqui et al, 2014). More research also is needed to develop effective prevention strategies that address the needs of diverse populations.

Families are essential for modeling food choices, healthy eating, and leisure activities for their children. Parents influence children's environment by choosing nutrient-rich foods, having family meals (including breakfast), offering regular snacks, and spending time together in physical activity, all of which can be critical in overweight prevention. Reducing sedentary behaviors can increase energy expenditure and reduce prompts to eat; the AAP recommends limiting screen time to no more than 2 hours per day (AAP, 2016). Parents exerting too much control over their child's food intake or promoting a restrictive diet may cause children to be less able to self-regulate and more likely to overeat when the opportunity is available (Ritchie et al, 2005). Health professionals should support positive parenting within the child's developmental level.

Underweight and Failure to Thrive

Weight loss, lack of weight gain, or **failure to thrive (FTT)** can be caused by an acute or chronic illness, a restricted diet, a poor appetite (resulting from constipation, medication, or other issues), feeding problems, neglect, or a simple lack of food. Some experts prefer the terms **pediatric undernutrition** or **growth deficiency**. Infants and toddlers are most at risk for poor growth, often as a result of prematurity, medical conditions, developmental delays, inadequate parenting, or a combination of these. Dietary practices also can contribute to poor growth, including food restrictions in preschool children stemming from parents' concerns about obesity, atherosclerosis, or other potential health problems.

A careful assessment is critical and must include the social and emotional environment of the child and any physical findings. If neglect is documented to be a contributing factor, health professionals are obligated to report the case to the local child protective services.

Because of the complexity of growth failure, an interdisciplinary team is ideal for assessments and interventions.
